Comments from the WG14 committee on WG23 part 3

I introduced the latest version of the document, pointing out in particular the Language Concepts section (why C is like it is – the vulnerabilities are not errors in the standard – but features to be aware of), and the Section 5 ‘top 10’ issues.

There was a lot of discussion on section5:

- [line 1] The need for the cast after malloc was not liked. Would be better to wrap the allocation in a macro, so the target type and the cast type are guaranteed to be compatible
- [line 2] Martin Sebor has written a paper on the problems with Annex K functions (thought there was some support that the guidance to use Annex K was appropriate – provided there is advice on how to use it correctly)
- [line 4] has ‘Remove’ in it (we should have decided what to do with this!)

Overall, there was some support for a top 10 – for programmers not in the safety/security domain – but with the recognition that they are unlikely to be reading this document. The counter argument was that anyone in the safety/security domain ought to be willing to read the whole document and not need a short summary.

The suggestion was either that:

- the table is converted into a ‘top 10 problems’, rather than a ‘top 10 solutions’
- Remove it completely (this was the general consent)

Some specific issues identified were:

6.5.2 The final recommendation to use the volatile qualification on an enumeration type switch selector wasn’t liked as it interferes with static analysis, and that it shouldn’t be necessary, as a compliant compiler shouldn’t optimise the default clause away.

6.8.2 It was pointed out that the advice to use strncpy is not without issues – as it may remove the string terminator (as explained in 6.8.1). There was general concern that advice like ‘use X’ should include how to use X correctly.

6.11 The focus on casting the return from malloc was not liked, as it was argued that this is a false security. As said earlier the preferred approach ought to be to wrap the allocation and type in a macro

```
#define allocate(T, name, N) T *name = (T*)malloc(N)
```

It was also suggested that this isn’t the main issue with allocation – but rather getting the size wrong – again may be fixed with a macro

```
#define allocateArray(T, name, M) T *name = (T*)malloc(sizeof(T) * M)
```

Observation: we don’t say anything about Variable Length Arrays.

I left a general invitation for anyone with comments to mail me
