sub(*ere*, *repl***[**, *in* **]**)	Substitute the string *repl* in place of the first instance of the extended regular expression *ERE* in string *in* and return the number of substitutions. An ampersand ('&') appearing in the string *repl* shall be replaced by the string from *in* that matches the ERE. An ampersand preceded with a backslash ('\') shall be interpreted as the literal ampersand character. An occurrence of two consecutive backslashes shall be interpreted as just a single literal backslash character. Any other occurrence of a backslash (for example, preceding any other character) shall be treated as a literal backslash character. Note that if *repl* is a string literal (the lexical token **STRING**; see **Grammar** (on page 2372)), the handling of the ampersand character occurs after any lexical processing, including any lexical backslash escape sequence processing. If *in* is specified and it is not an lvalue (see **Expressions in awk** (on page 2358)), the behavior is undefined. If *in* is omitted, *awk*

shall use the current record ($0) in its place.

substr(*s*, *m***[**, *n* **]**)
Return the at most *n*-character substring of *s* that begins at position *m*, numbering from 1. If *n* is omitted, or if *n* specifies more characters than are left in the string, the length of the substring shall be limited by the length of the string *s*.

tolower(*s*) Return a string based on the string *s*. Each character in *s* that is an uppercase letter specified to have a **tolower** mapping by the *LC_CTYPE* category of the current locale shall be replaced in the returned string by the lowercase letter specified by the mapping. Other characters in *s* shall be unchanged in the returned string.

toupper(*s*) Return a string based on the string *s*. Each character in *s* that is a lowercase letter specified to have a **toupper** mapping by the *LC_CTYPE* category of the current locale is replaced in the returned string by the uppercase letter specified by the mapping. Other characters in *s* are unchanged in the returned string.

All of the preceding functions that take *ERE* as a parameter expect a pattern or a string valued expression that is a regular expression as defined in **Regular Expressions** (on page 2363).

Input/Output and General Functions

The input/output and general functions are:

close(*expression*)
Close the file or pipe opened by a **print** or **printf** statement or a call to **getline** with the same string-valued *expression*. The limit on the number of open *expression* arguments is implementation-defined. If the close was successful, the function shall return zero; otherwise, it shall return non-zero.

expression | **getline [***var***]**
Read a record of input from a stream piped from the output of a command. The stream shall be created if no stream is currently open with the value of *expression* as its command name. The stream created shall be equivalent to one created by a call to the *popen*( ) function with the value of *expression* as the *command* argument and a value of *r* as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value shall read subsequent records from the stream. The stream shall remain open until the **close** function is called with an expression that evaluates to the same string value. At that time, the stream shall be closed as if by a call to the *pclose*( ) function. If *var* is omitted, $0 and **NF** shall be set; otherwise, *var* shall be set and, if appropriate, it shall be considered a numeric string (see **Expressions in awk** (on page 2358)).

The **getline** operator can form ambiguous constructs when there are unparenthesized operators (including concatenate) to the left of the `'|'` (to the beginning of the expression containing **getline**). In the context of the `'$'` operator, `'|'` shall behave as if it had a lower precedence than `'$'`. The result of evaluating other operators is unspecified, and conforming applications shall parenthesize properly all such usages.

getline Set $0 to the next input record from the current input file. This form of **getline** shall set the **NF**, **NR**, and **FNR** variables.

getline *var* Set variable *var* to the next input record from the current input file and, if appropriate, *var* shall be considered a numeric string (see **Expressions in awk** (on page 2358)). This form of **getline** shall set the **FNR** and **NR** variables.

getline [*var***]** < *expression*

Read the next record of input from a named file. The *expression* shall be evaluated to produce a string that is used as a pathname. If the file of that name is not currently open, it shall be opened. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value shall read subsequent records from the file. The file shall remain open until the **close** function is called with an expression that evaluates to the same string value. If *var* is omitted, $0 and **NF** shall be set; otherwise, *var* shall be set and, if appropriate, it shall be considered a numeric string (see **Expressions in awk** (on page 2358)).

The **getline** operator can form ambiguous constructs when there are unparenthesized binary operators (including concatenate) to the right of the '<' (up to the end of the expression containing the **getline**). The result of evaluating such a construct is unspecified, and conforming applications shall parenthesize properly all such usages.

system(*expression*)

Execute the command given by *expression* in a manner equivalent to the *system*() function defined in the System Interfaces volume of IEEE Std 1003.1-200x and return the exit status of the command.

All forms of **getline** shall return 1 for successful input, zero for end-of-file, and −1 for an error.

Where strings are used as the name of a file or pipeline, the application shall ensure that the strings are textually identical. The terminology ‘‘same string value’’ implies that ‘‘equivalent strings’’, even those that differ only by <space>s, represent different files.

User-Defined Functions

The *awk* language also provides user-defined functions. Such functions can be defined as:

```
function name([parameter, ...]) { statements }
```

A function can be referred to anywhere in an *awk* program; in particular, its use can precede its definition. The scope of a function is global.

Function parameters, if present, can be either scalars or arrays; the behavior is undefined if an array name is passed as a parameter that the function uses as a scalar, or if a scalar expression is passed as a parameter that the function uses as an array. Function parameters shall be passed by value if scalar and by reference if array name.

The number of parameters in the function definition need not match the number of parameters in the function call. Excess formal parameters can be used as local variables. If fewer arguments are supplied in a function call than are in the function definition, the extra parameters that are used in the function body as scalars shall evaluate to the uninitialized value until they are otherwise initialized, and the extra parameters that are used in the function body as arrays shall be treated as uninitialized arrays where each element evaluates to the uninitialized value until otherwise initialized.

When invoking a function, no white space can be placed between the function name and the opening parenthesis. Function calls can be nested and recursive calls can be made upon functions. Upon return from any nested or recursive function call, the values of all of the calling function's parameters shall be unchanged, except for array parameters passed by reference. The **return** statement can be used to return a value. If a **return** statement appears outside of a function definition, the behavior is undefined.

In the function definition, <newline>s shall be optional before the opening brace and after the closing brace. Function definitions can appear anywhere in the program where a *pattern-action* pair is allowed.

Grammar

The grammar in this section and the lexical conventions in the following section shall together describe the syntax for *awk* programs. The general conventions for this style of grammar are described in Section 1.10 (on page 2220). A valid program can be represented as the non-terminal symbol *program* in the grammar. This formal syntax shall take precedence over the preceding text syntax description.

                      | GETLINE lvalue
                      ;

    newline_opt       : /* empty */
                      | newline_opt NEWLINE
                      ;
```

This grammar has several ambiguities that shall be resolved as follows:

- Operator precedence and associativity shall be as described in Table 4-1 (on page 2358).
- In case of ambiguity, an **else** shall be associated with the most immediately preceding **if** that would satisfy the grammar.
- In some contexts, a slash (`'/'`) that is used to surround an ERE could also be the division operator. This shall be resolved in such a way that wherever the division operator could appear, a slash is assumed to be the division operator. (There is no unary division operator.)

One convention that might not be obvious from the formal grammar is where <newline>s are acceptable. There are several obvious placements such as terminating a statement, and a backslash can be used to escape <newline>s between any lexical tokens. In addition, <newline>s without backslashes can follow a comma, an open brace, logical AND operator (`"&&"`), logical OR operator (`"||"`), the **do** keyword, the **else** keyword, and the closing parenthesis of an **if**, **for**, or **while** statement. For example:

```
{ print  $1,
         $2 }
```

Lexical Conventions

The lexical conventions for *awk* programs, with respect to the preceding grammar, shall be as follows:

1. Except as noted, *awk* shall recognize the longest possible token or delimiter beginning at a given point.
2. A comment shall consist of any characters beginning with the number sign character and terminated by, but excluding the next occurrence of, a <newline>. Comments shall have no effect, except to delimit lexical tokens.
3. The <newline> shall be recognized as the token **NEWLINE**.
4. A backslash character immediately followed by a <newline> shall have no effect.
5. The token **STRING** shall represent a string constant. A string constant shall begin with the character `'"'`. Within a string constant, a backslash character shall be considered to begin an escape sequence as specified in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). In addition, the escape sequences in Table 4-2 (on page 2364) shall be recognized. A <newline> shall not occur within a string constant. A string constant shall be terminated by the first unescaped occurrence of the character `'"'` after the one that begins the string constant. The value of the string shall be the sequence of all unescaped characters and values of escape sequences between, but not including, the two delimiting `'"'` characters.
6. The token **ERE** represents an extended regular expression constant. An ERE constant shall begin with the slash character. Within an ERE constant, a backslash character shall be considered to begin an escape sequence as specified in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation. In addition, the escape sequences in Table 4-2 (on page 2364) shall be recognized. The application shall ensure that a <newline> does not occur within an ERE constant. An ERE constant shall be terminated by the first unescaped occurrence of the slash character after the one that begins the ERE constant. The extended regular expression represented by the ERE constant shall be the sequence of all unescaped characters and values of escape sequences between, but not including, the two delimiting slash characters.

7. A <blank> shall have no effect, except to delimit lexical tokens or within **STRING** or **ERE** tokens.

8. The token **NUMBER** shall represent a numeric constant. Its form and numeric value shall be equivalent to either of the tokens **floating-constant** or **integer-constant** as specified by the ISO C standard, with the following exceptions:

   a. An integer constant cannot begin with 0x or include the hexadecimal digits `'a'`, `'b'`, `'c'`, `'d'`, `'e'`, `'f'`, `'A'`, `'B'`, `'C'`, `'D'`, `'E'`, or `'F'`.

   b. The value of an integer constant beginning with 0 shall be taken in decimal rather than octal.

   c. An integer constant cannot include a suffix (`'u'`, `'U'`, `'l'`, or `'L'`).

   d. A floating constant cannot include a suffix (`'f'`, `'F'`, `'l'`, or `'L'`).

   If the value is too large or too small to be representable (see Section 1.7.2 (on page 2207)), the behavior is undefined.

9. A sequence of underscores, digits, and alphabetics from the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set), beginning with an underscore or alphabetic, shall be considered a word.

10. The following words are keywords that shall be recognized as individual tokens; the name of the token is the same as the keyword:

    BEGIN
    break
    continue
    delete
    do
    else
    END
    exit
    for
    function
    getline
    if
    in
    next
    print
    printf
    return
    while

11. The following words are names of built-in functions and shall be recognized as the token **BUILTIN_FUNC_NAME**:

    atan2
    close
    cos
    exp
    gsub
    index
    int
    length
    log
    match
    rand
    sin
    split
    sprintf
    sqrt
    srand
    sub
    substr
    system
    tolower
    toupper

    The above-listed keywords and names of built-in functions are considered reserved words.

12. The token **NAME** shall consist of a word that is not a keyword or a name of a built-in function and is not followed immediately (without any delimiters) by the `'('` character.

13. The token **FUNC_NAME** shall consist of a word that is not a keyword or a name of a built-in function, followed immediately (without any delimiters) by the `'('` character. The `'('` character shall not be included as part of the token.

14. The following two-character sequences shall be recognized as the named tokens:

Token Name	Sequence	Token Name	Sequence
ADD_ASSIGN	+=	**NO_MATCH**	!~
SUB_ASSIGN	-=	**EQ**	==
MUL_ASSIGN	*=	**LE**	<=
DIV_ASSIGN	/=	**GE**	>=
MOD_ASSIGN	%=	**NE**	!=
POW_ASSIGN	^=	**INCR**	++
OR	||	**DECR**	--
AND	&&	**APPEND**	>>

15. The following single characters shall be recognized as tokens whose names are the character:

    ```
    <newline> { } ( ) [ ] , ; + – * % ˆ ! > < | ? : ˜ $ =
    ```

There is a lexical ambiguity between the token **ERE** and the tokens `'/'` and **DIV_ASSIGN**. When an input sequence begins with a slash character in any syntactic context where the token `'/'` or **DIV_ASSIGN** could appear as the next token in a valid program, the longer of those two tokens that can be recognized shall be recognized. In any other syntactic context where the token **ERE** could appear as the next token in a valid program, the token **ERE** shall be recognized.

EXIT STATUS

The following exit values shall be returned:

0	All input files were processed successfully.
>0	An error occurred.

The exit status can be altered within the program by using an **exit** expression.

CONSEQUENCES OF ERRORS

If any *file* operand is specified and the named file cannot be accessed, *awk* shall write a diagnostic message to standard error and terminate without any further action.

If the program specified by either the *program* operand or a *progfile* operand is not a valid *awk* program (as specified in the EXTENDED DESCRIPTION section), the behavior is undefined.

APPLICATION USAGE

The **index**, **length**, **match**, and **substr** functions should not be confused with similar functions in the ISO C standard; the *awk* versions deal with characters, while the ISO C standard deals with bytes.

Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

EXAMPLES

The *awk* program specified in the command line is most easily specified within single-quotes (for example, '*program*') for applications using *sh*, because *awk* programs commonly contain characters that are special to the shell, including double-quotes. In the cases where an *awk* program contains single-quote characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

```
awk '/'\''/ { print "quote:", $0 }'
```

prints all lines from the standard input containing a single-quote character, prefixed with *quote*:.

The following are examples of simple *awk* programs:

1. Write to the standard output all input lines for which field 3 is greater than 5:

   ```
   $3 > 5
   ```

2. Write every tenth line:

   ```
   (NR % 10) == 0
   ```

3. Write any line with a substring matching the regular expression:

   ```
   /(G|D)(2[0–9][[:alpha:]]*)/
   ```

4. Print any line with a substring containing a `'G'` or `'D'`, followed by a sequence of digits and characters. This example uses character classes **digit** and **alpha** to match language-independent digit and alphabetic characters respectively:

   ```
   /(G|D)([[:digit:][:alpha:]]*)/
   ```

5. Write any line in which the second field matches the regular expression and the fourth field does not:

   ```
   $2 ~ /xyz/ && $4 !~ /xyz/
   ```

6. Write any line in which the second field contains a backslash:

   ```
   $2 ~ /\\/
   ```

7. Write any line in which the second field contains a backslash. Note that backslash escapes are interpreted twice, once in lexical processing of the string and once in processing the regular expression:

   ```
   $2 ~ "\\\\"
   ```

8. Write the second to the last and the last field in each line. Separate the fields by a colon:

   ```
   {OFS=":";print $(NF-1), $NF}
   ```

9. Write the line number and number of fields in each line. The three strings representing the line number, the colon, and the number of fields are concatenated and that string is written to standard output:

   ```
   {print NR ":" NF}
   ```

10. Write lines longer than 72 characters:

    ```
    length($0) > 72
    ```

11. Write first two fields in opposite order separated by the **OFS**:

    ```
    { print $2, $1 }
    ```

12. Same, with input fields separated by comma or <space>s and <tab>s, or both:

    ```
    BEGIN { FS = ",[ \t]*|[ \t]+" }
          { print $2, $1 }
    ```

13. Add up first column, print sum, and average:

    ```
          {s += $1 }
    END   {print "sum is ", s, " average is", s/NR}
    ```

14. Write fields in reverse order, one per line (many lines out for each line in):

    ```
    { for (i = NF; i > 0; --i) print $i }
    ```

15. Write all lines between occurrences of the strings **start** and **stop**:

    ```
    /start/, /stop/
    ```

16. Write all lines whose first field is different from the previous one:

    ```
    $1 != prev { print; prev = $1 }
    ```

17. Simulate *echo*:

    ```
    BEGIN  {
            for (i = 1; i < ARGC; ++i)
            printf("%s%s", ARGV[i], i==ARGC-1?"\n":" ")
    ```

```
        }
```

18. Write the path prefixes contained in the *PATH* environment variable, one per line:

```
BEGIN  {
        n = split (ENVIRON["PATH"], path, ":")
        for (i = 1; i <= n; ++i)
        print path[i]
}
```

19. If there is a file named **input** containing page headers of the form:

    Page #

    and a file named **program** that contains:

```
/Page/   { $2 = n++; }
         { print }
```

then the command line:

```
awk −f program n=5 input
```

prints the file **input**, filling in page numbers starting at 5.

RATIONALE

The ISO POSIX-2 standard description is based on the new *awk*, ‘‘nawk’’, (see the referenced *The AWK Programming Language*), which introduced a number of new features to the historical *awk*:

1. New keywords: **delete**, **do**, **functin**, **return**
2. New built-in functions: **atan2**, **close**, **cos**, **gsub**, **match**, **rand**, **sin**, **srand**, **sub**, **system**
3. New predefined variables: **FNR**, **ARGC**, **ARGV**, **RSTART**, **RLENGTH**, **SUBSEP**
4. New expression operators: **?**, **:**, **,**, **^**
5. The **FS** variable and the third argument to **split**, now treated as extended regular expressions.
6. The operator precedence, changed to more closely match the C language. Two examples of code that operate differently are:

```
while ( n /= 10 > 1) ...
if (!"wk" ~ /bwk/) ...
```

Several features have been added based on newer implementations of *awk*:

- Multiple instances of −**f** *progfile* are permitted
- The new option −**v** *assignment*
- The new predefined variable **ENVIRON**
- New built-in functions **toupper**, and **tolower**
- More formatting capabilities are added to **printf** to match the ISO C standard

The overall *awk* syntax has always been based on the C language, with a few features from the shell command language and other sources. Because of this, it is not completely compatible with any other language, which has caused confusion for some users. It is not the intent of the standard developers to address such issues. IEEE Std 1003.1-200x has made a few relatively minor changes toward making the language more compatible with the C language as specified by the ISO C standard; most of these changes are based on similar changes in recent implementations, as described above. There remain several C-language conventions that are not in *awk*. One of the notable ones is the comma operator, which is commonly used to specify multiple expressions in the C language **for** statement. Also, there are various places where *awk* is more restrictive than the C language regarding the type of expression that can be used in a given context. These limitations are due to the different features that the *awk* language does provide.

Regular expressions in *awk* have been extended somewhat from historical implementations to make them a pure superset of extended regular expressions, as defined by IEEE Std 1003.1-200x (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4, Extended Regular Expressions). The main extensions are internationalization features and interval expressions. Historical implementations of *awk* have long supported backslash escape sequences as an extension to extended regular expressions, and this extension has been retained despite inconsistency with other utilities. The number of escape sequences recognized in both extended regular expressions and strings has varied (generally increasing with time) among implementations. The set specified by IEEE Std 1003.1-200x includes most sequences known to be supported by popular implementations and by the ISO C standard. One sequence that is not supported is hexadecimal value escapes beginning with `'\x'`. This would allow values expressed in more than 9 bits to be used within *awk* as in the ISO C standard. However, because this syntax has a non-deterministic length, it does not permit the subsequent character to be a hexadecimal digit. This limitation can be dealt with in the C language by the use of lexical string concatenation. In the *awk* language, concatenation could also be a solution for strings, but not for extended regular expressions (either lexical ERE tokens or strings used dynamically as regular expressions). Because of this limitation, the feature has not been added to IEEE Std 1003.1-200x.

When a string variable is used in a context where an extended regular expression normally appears (where the lexical token ERE is used in the grammar) the string does not contain the literal slashes.

Some versions of *awk* allow the form:

```
func name(args, ... ) { statements }
```

This has been deprecated by the authors of the language, who asked that it not be included in IEEE Std 1003.1-200x.

Historical implementations of *awk* produce an error if a **next** statement is executed in a **BEGIN** action, and cause *awk* to terminate if a **next** statement is executed in an **END** action. This behavior has not been documented, and it was not believed that it was necessary to standardize it.

The specification of conversions between string and numeric values is much more detailed than in the documentation of historical implementations or in the referenced *The AWK Programming Language*. Although most of the behavior is designed to be intuitive, the details are necessary to ensure compatible behavior from different implementations. This is especially important in relational expressions since the types of the operands determine whether a string or numeric comparison is performed. From the perspective of an application writer, it is usually sufficient to expect intuitive behavior and to force conversions (by adding zero or concatenating a null string) when the type of an expression does not obviously match what is needed. The intent has been to specify historical practice in almost all cases. The one exception is that, in historical implementations, variables and constants maintain both string and numeric values after their original value is converted by any use. This means that referencing a variable or constant can have unexpected side effects. For example, with historical implementations the following program:

```
{
    a = "+2"
```

```
    b = 2
    if (NR % 2)
        c = a + b
    if (a == b)
        print "numeric comparison"
    else
        print "string comparison"
}
```

would perform a numeric comparison (and output numeric comparison) for each odd-numbered line, but perform a string comparison (and output string comparison) for each even-numbered line. IEEE Std 1003.1-200x ensures that comparisons will be numeric if necessary. With historical implementations, the following program:

```
BEGIN {
    OFMT = "%e"
    print 3.14
    OFMT = "%f"
    print 3.14
}
```

would output `"3.140000e+00"` twice, because in the second **print** statement the constant `"3.14"` would have a string value from the previous conversion. IEEE Std 1003.1-200x requires that the output of the second **print** statement be `"3.140000"`. The behavior of historical implementations was seen as too unintuitive and unpredictable.

It was pointed out that with the rules contained in early drafts, the following script would print nothing:

```
BEGIN {
    y[1.5] = 1
    OFMT = "%e"
    print y[1.5]
}
```

Therefore, a new variable, **CONVFMT**, was introduced. The **OFMT** variable is now restricted to affecting output conversions of numbers to strings and **CONVFMT** is used for internal conversions, such as comparisons or array indexing. The default value is the same as that for **OFMT**, so unless a program changes **CONVFMT** (which no historical program would do), it will receive the historical behavior associated with internal string conversions.

The POSIX *awk* lexical and syntactic conventions are specified more formally than in other sources. Again the intent has been to specify historical practice. One convention that may not be obvious from the formal grammar as in other verbal descriptions is where <newline>s are acceptable. There are several obvious placements such as terminating a statement, and a backslash can be used to escape <newline>s between any lexical tokens. In addition, <newline>s without backslashes can follow a comma, an open brace, a logical AND operator ("&&"), a logical OR operator (`"||"`), the **do** keyword, the **else** keyword, and the closing parenthesis of an **if**, **for**, or **while** statement. For example:

```
{ print $1,
        $2 }
```

The requirement that *awk* add a trailing <newline> to the program argument text is to simplify the grammar, making it match a text file in form. There is no way for an application or test suite to determine whether a literal <newline> is added or whether *awk* simply acts as if it did.

IEEE Std 1003.1-200x requires several changes from historical implementations in order to support internationalization. Probably the most subtle of these is the use of the decimal-point character, defined by the *LC_NUMERIC* category of the locale, in representations of floating-point numbers. This locale-specific character is used in recognizing numeric input, in converting between strings and numeric values, and in formatting output. However, regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing *awk* programs (including assignments in command line arguments). This is essentially the same convention as the one used in the ISO C standard. The difference is that the C language includes the *setlocale*( ) function, which permits an application to modify its locale. Because of this capability, a C application begins executing with its locale set to the C locale, and only executes in the environment-specified locale after an explicit call to *setlocale*( ). However, adding such an elaborate new feature to the *awk* language was seen as inappropriate for IEEE Std 1003.1-200x. It is possible to execute an *awk* program explicitly in any desired locale by setting the environment in the shell.

The undefined behavior resulting from NULs in extended regular expressions allows future extensions for the GNU *gawk* program to process binary data.

The behavior in the case of invalid *awk* programs (including lexical, syntactic, and semantic errors) is undefined because it was considered overly limiting on implementations to specify. In most cases such errors can be expected to produce a diagnostic and a non-zero exit status. However, some implementations may choose to extend the language in ways that make use of certain invalid constructs. Other invalid constructs might be deemed worthy of a warning, but otherwise cause some reasonable behavior. Still other constructs may be very difficult to detect in some implementations. Also, different implementations might detect a given error during an initial parsing of the program (before reading any input files) while others might detect it when executing the program after reading some input. Implementors should be aware that diagnosing errors as early as possible and producing useful diagnostics can ease debugging of applications, and thus make an implementation more usable.

The unspecified behavior from using multi-character **RS** values is to allow possible future extensions based on extended regular expressions used for record separators. Historical implementations take the first character of the string and ignore the others.

Unspecified behavior when *split*(*string*,*array*,<null>) is used is to allow a proposed future extension that would split up a string into an array of individual characters.

In the context of the **getline** function, equally good arguments for different precedences of the **|** and **<** operators can be made. Historical practice has been that:

```
getline < "a" "b"
```

is parsed as:

```
( getline < "a" ) "b"
```

although many would argue that the intent was that the file **ab** should be read. However:

```
getline < "x" + 1
```

parses as:

```
getline < ( "x" + 1 )
```

Similar problems occur with the **|** version of **getline**, particularly in combination with **$**. For example:

```
$"echo hi" | getline
```

(This situation is particularly problematic when used in a **print** statement, where the **|getline** part might be a redirection of the **print**.)

Since in most cases such constructs are not (or at least should not) be used (because they have a natural ambiguity for which there is no conventional parsing), the meaning of these constructs has been made explicitly unspecified. (The effect is that a conforming application that runs into the problem must parenthesize to resolve the ambiguity.) There appeared to be few if any actual uses of such constructs.

Grammars can be written that would cause an error under these circumstances. Where backwards compatibility is not a large consideration, implementors may wish to use such grammars.

Some historical implementations have allowed some built-in functions to be called without an argument list, the result being a default argument list chosen in some ‘‘reasonable’’ way. Use of **length** as a synonym for **length($0)** is the only one of these forms that is thought to be widely known or widely used; this particular form is documented in various places (for example, most historical *awk* reference pages, although not in the referenced *The AWK Programming Language*) as legitimate practice. With this exception, default argument lists have always been undocumented and vaguely defined, and it is not at all clear how (or if) they should be generalized to user-defined functions. They add no useful functionality and preclude possible future extensions that might need to name functions without calling them. Not standardizing them seems the simplest course. The standard developers considered that **length** merited special treatment, however, since it has been documented in the past and sees possibly substantial use in historical programs. Accordingly, this usage has been made legitimate, but Issue 5 removed the obsolescent marking for XSI-conforming implementations and many otherwise conforming applications depend on this feature.

In **sub** and **gsub**, if *repl* is a string literal (the lexical token **STRING**), then two consecutive backslash characters should be used in the string to ensure a single backslash will precede the ampersand when the resultant string is passed to the function. (For example, to specify one literal ampersand in the replacement string, use **gsub**(**ERE**, `"\\&"`).)

Historically the only special character in the *repl* argument of **sub** and **gsub** string functions was the ampersand (`'&'`) character and preceding it with the backslash character was used to turn off its special meaning.

The description in the ISO POSIX-2: 1993 standard introduced behavior such that the backslash character was another special character and it was unspecified whether there were any other special characters. This description introduced several portability problems, some of which are described below, and so it has been replaced with the more historical description. Some of the problems include:

- Historically, to create the replacement string, a script could use **gsub**(**ERE**, `"\\&"`), but with the ISO POSIX-2: 1993 standard wording, it was necessary to use **gsub**(**ERE**, `"\\\\&"`). Backslash characters are doubled here because all string literals are subject to lexical analysis, which would reduce each pair of backslash characters to a single backslash before being passed to **gsub**.
- Since it was unspecified what the special characters were, for portable scripts to guarantee that characters are printed literally, each character had to be preceded with a backslash. (For example, a portable script had to use **gsub**(**ERE**, `"\\h\\i"`) to produce a replacement string of `"hi"`.)

The description for comparisons in the ISO POSIX-2: 1993 standard did not properly describe historical practice because of the way numeric strings are compared as numbers. The current rules cause the following code:

```
if (0 == "000")
    print "strange, but true"
else
    print "not true"
```

to do a numeric comparison, causing the **if** to succeed. It should be intuitively obvious that this is incorrect behavior, and indeed, no historical implementation of *awk* actually behaves this way.

To fix this problem, the definition of *numeric string* was enhanced to include only those values obtained from specific circumstances (mostly external sources) where it is not possible to determine unambiguously whether the value is intended to be a string or a numeric.

Variables that are assigned to a numeric string shall also be treated as a numeric string. (For example, the notion of a numeric string can be propagated across assignments.) In comparisons, all variables having the uninitialized value are to be treated as a numeric operand evaluating to the numeric value zero.

Uninitialized variables include all types of variables including scalars, array elements, and fields. The definition of an uninitialized value in **Variables and Special Variables** (on page 2361) is necessary to describe the value placed on uninitialized variables and on fields that are valid (for example, **< $NF**) but have no characters in them and to describe how these variables are to be used in comparisons. A valid field, such as **$1**, that has no characters in it can be obtained by from an input line of `"\t\t"` when **FS=**`'\t'`. Historically, the comparison (**$1**<10) was done numerically after evaluating **$1** to the value zero.

The phrase ‘‘... also shall have the numeric value of the numeric string’’ was removed from several sections of the ISO POSIX-2:1993 standard because is specifies an unnecessary implementation detail. It is not necessary for IEEE Std 1003.1-200x to specify that these objects be assigned two different values. It is only necessary to specify that these objects may evaluate to two different values depending on context.

The description of numeric string processing is based on the behavior of the *atof*( ) function in the ISO C standard. While it is not a requirement for an implementation to use this function, many historical implementations of *awk* do. In the ISO C standard, floating-point constants use a period as a decimal point character for the language itself, independent of the current locale, but the *atof*( ) function and the associated *strtod*( ) function use the decimal point character of the current locale when converting strings to numeric values. Similarly in *awk*, floating-point constants in an *awk* script use a period independent of the locale, but input strings use the decimal point character of the locale.

FUTURE DIRECTIONS section added.

Issue 6

The *awk* utility is aligned with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements. |

IEEE PASC Interpretation 1003.2 #211 is applied, adding the sentence ‘‘An occurrence of two consecutive backslashes shall be interpreted as just a single literal backslash character.’’ into the description of the **sub** string function.

NAME

basename — return non-directory portion of a pathname

SYNOPSIS

```
basename string [suffix]
```

DESCRIPTION

The *string* operand shall be treated as a pathname, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.266, Pathname. The string *string* shall be converted to the filename corresponding to the last pathname component in *string* and then the suffix string *suffix*, if present, shall be removed. This shall be done by performing actions equivalent to the following steps in order:

1. If *string* is a null string, it is unspecified whether the resulting string is `'.'` or a null string. In either case, skip steps 2 through 6.
2. If *string* is `"//"`, it is implementation-defined whether steps 3 to 6 are skipped or processed.
3. If *string* consists entirely of slash characters, *string* shall be set to a single slash character. In this case, skip steps 4 to 6.
4. If there are any trailing slash characters in *string*, they shall be removed.
5. If there are any slash characters remaining in *string*, the prefix of *string* up to and including the last slash character in *string* shall be removed.
6. If the *suffix* operand is present, is not identical to the characters remaining in *string*, and is identical to a suffix of the characters remaining in *string*, the suffix *suffix* shall be removed from *string*. Otherwise, *string* is not modified by this step. It shall not be considered an error if *suffix* is not found in *string*.

The resulting string shall be written to standard output.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

string	A string.
suffix	A string.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *basename*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *basename* utility shall write a line to the standard output in the following format:

```
"%s\n", <resulting string>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The definition of *pathname* specifies implementation-defined behavior for pathnames starting with two slash characters. Therefore, applications shall not arbitrarily add slashes to the beginning of a pathname unless they can ensure that there are more or less than two or are prepared to deal with the implementation-defined consequences.

EXAMPLES

If the string *string* is a valid pathname:

```
$(basename "string")
```

produces a filename that could be used to open the file named by *string* in the directory returned by:

```
$(dirname "string")
```

If the string *string* is not a valid pathname, the same algorithm is used, but the result need not be a valid filename. The *basename* utility is not expected to make any judgements about the validity of *string* as a pathname; it just follows the specified algorithm to produce a result string.

The following shell script compiles **/usr/src/cmd/cat.c** and moves the output to a file named **cat** in the current directory when invoked with the argument **/usr/src/cmd/cat** or with the argument **/usr/src/cmd/cat.c**:

```
c99 $(dirname "$1")/$(basename "$1" .c).c
mv a.out $(basename "$1" .c)
```

RATIONALE

The behaviors of *basename* and *dirname* have been coordinated so that when *string* is a valid pathname:

`$(basename "string")`

would be a valid filename for the file in the directory:

`$(dirname "string")`

This would not work for the early proposal versions of these utilities due to the way it specified handling of trailing slashes.

Since the definition of *pathname* specifies implementation-defined behavior for pathnames starting with two slash characters, this volume of IEEE Std 1003.1-200x specifies similar implementation-defined behavior for the *basename* and *dirname* utilities.

FUTURE DIRECTIONS

None.

dirname, Section 2.5 (on page 2235)

CHANGE HISTORY

First released in Issue 2.

Issue 6

IEEE PASC Interpretation 1003.2 #164 is applied.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

batch — schedule commands to be executed in a batch queue

SYNOPSIS

UP

```
batch
```

DESCRIPTION

The *batch* utility shall read commands from standard input and schedule them for execution in a batch queue. It shall be the equivalent of the command:

```
at −q b −m now
```

where queue *b* is a special *at* queue, specifically for batch jobs. Batch jobs shall be submitted to the batch queue with no time constraints and shall be run by the system using algorithms, based on unspecified factors, that may vary with each invocation of *batch*.

XSI Users shall be permitted to use *batch* if their name appears in the file **/usr/lib/cron/at.allow**. If that file does not exist, the file **/usr/lib/cron/at.deny** shall be checked to determine whether the user shall be denied access to *batch*. If neither file exists, only a process with the appropriate privileges shall be allowed to submit a job. If only **at.deny** exists and is empty, global usage shall be permitted. The **at.allow** and **at.deny** files shall consist of one user name per line.

OPTIONS

None.

OPERANDS

None.

STDIN

The standard input shall be a text file consisting of commands acceptable to the shell command language described in Chapter 2 (on page 2231).

INPUT FILES

XSI The text files **/usr/lib/cron/at.allow** and **/usr/lib/cron/at.deny** shall contain zero or more user names, one per line, of users who are, respectively, authorized or denied access to the *at* and *batch* utilities.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *batch*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
LC_TIME	Determine the format and contents for date and time strings written by *batch*.

XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
SHELL	Determine the name of a command interpreter to be used to invoke the at-job. If the variable is unset or null, *sh* shall be used. If it is set to a value other than a name for *sh*, the implementation shall do one of the following: use that shell; use *sh*; use the login shell from the user database; any of the preceding accompanied by a warning diagnostic about which was chosen.
TZ	Determine the timezone. The job shall be submitted for execution at the time specified by *timespec* or **−t** *time* relative to the timezone specified by the *TZ* variable. If *timespec* specifies a timezone, it overrides *TZ*. If *timespec* does not specify a timezone and *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When standard input is a terminal, prompts of unspecified format for each line of the user input described in the STDIN section may be written to standard output.

STDERR

The following shall be written to standard error when a job has been successfully submitted:

```
"job %s at %s\n", at_job_id, <date>
```

where *date* shall be equivalent in format to the output of:

```
date +"%a %b %e %T %Y"
```

The date and time written shall be adjusted so that they appear in the timezone of the user (as determined by the *TZ* variable).

Neither this, nor warning messages concerning the selection of the command interpreter, are considered a diagnostic that changes the exit status.

Diagnostic messages, if any, shall be written to standard error.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

The job shall not be scheduled.

APPLICATION USAGE

It may be useful to redirect standard output within the specified commands.

EXAMPLES

1. This sequence can be used at a terminal:

```
batch
sort < file >outfile
EOT
```

2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

```
batch <<! diff file1 file2 2>&1 >outfile | mailx mygroup !
```

RATIONALE

Early proposals described *batch* in a manner totally separated from *at*, even though the historical model treated it almost as a synonym for *at* −**qb**. A number of features were added to list and control batch work separately from those in *at*. Upon further reflection, it was decided that the benefit of this did not merit the change to the historical interface.

The −**m** option was included on the equivalent *at* command because it is historical practice to mail results to the submitter, even if all job-produced output is redirected. As explained in the RATIONALE for *at*, the **now** keyword submits the job for immediate execution (after scheduling delays), despite some historical systems where *at* **now** would have been considered an error.

FUTURE DIRECTIONS

None.

at

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The NAME is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

bc — arbitrary-precision arithmetic language

SYNOPSIS

`bc [−l] [file ...]`

DESCRIPTION

The *bc* utility shall implement an arbitrary precision calculator. It shall take input from any files given, then read from the standard input. If the standard input and standard output to *bc* are attached to a terminal, the invocation of *bc* shall be considered to be *interactive*, causing behavioral constraints described in the following sections.

OPTIONS

The *bc* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−l	(The letter ell.) Define the math functions and initialize *scale* to 20, instead of the default zero; see the EXTENDED DESCRIPTION section.

OPERANDS

The following operand shall be supported:

file	A pathname of a text file containing *bc* program statements. After all *file*s have been read, *bc* shall read the standard input.

STDIN

See the INPUT FILES section.

INPUT FILES

Input files shall be text files containing a sequence of comments, statements, and function definitions that shall be executed as they are read.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *bc*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The output of the *bc* utility shall be controlled by the program read, and consist of zero or more lines containing the value of all executed expressions without assignments. The radix and precision of the output shall be controlled by the values of the **obase** and **scale** variables; see the EXTENDED DESCRIPTION section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

Grammar

The grammar in this section and the lexical conventions in the following section shall together describe the syntax for *bc* programs. The general conventions for this style of grammar are described in Section 1.10 (on page 2220). A valid program can be represented as the non-terminal symbol **program** in the grammar. This formal syntax shall take precedence over the text syntax description.

```
%token    EOF NEWLINE STRING LETTER NUMBER

%token    MUL_OP

                      | Obase
                      ;
```

Lexical Conventions in bc

The lexical conventions for *bc* programs, with respect to the preceding grammar, shall be as follows:

1. Except as noted, *bc* shall recognize the longest possible token or delimiter beginning at a given point.
2. A comment shall consist of any characters beginning with the two adjacent characters `"/*"` and terminated by the next occurrence of the two adjacent characters `"*/"`. Comments shall have no effect except to delimit lexical tokens.
3. The <newline> shall be recognized as the token **NEWLINE**.
4. The token **STRING** shall represent a string constant; it shall consist of any characters beginning with the double-quote character (`’"’`) and terminated by another occurrence of the double-quote character. The value of the string is the sequence of all characters between, but not including, the two double-quote characters. All characters shall be taken literally from the input, and there is no way to specify a string containing a double-quote character. The length of the value of each string shall be limited to {BC_STRING_MAX} bytes.
5. A <blank> shall have no effect except as an ordinary character if it appears within a **STRING** token, or to delimit a lexical token other than **STRING**.

6. The combination of a backslash character immediately followed by a <newline> shall have no effect other than to delimit lexical tokens with the following exceptions:

   - It shall be interpreted as the character sequence `"\<newline>"` in **STRING** tokens.
   - It shall be ignored as part of a multi-line **NUMBER** token.

7. The token **NUMBER** shall represent a numeric constant. It shall be recognized by the following grammar:

```
NUMBER  : integer
        | '.' integer
        | integer '.'
        | integer '.' integer
        ;

integer : digit
        | integer digit
        ;

digit   : 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7
        | 8 | 9 | A | B | C | D | E | F
        ;
```

8. The value of a **NUMBER** token shall be interpreted as a numeral in the base specified by the value of the internal register **ibase** (described below). Each of the **digit** characters shall have the value from 0 to 15 in the order listed here, and the period character shall represent the radix point. The behavior is undefined if digits greater than or equal to the value of **ibase** appear in the token. However, note the exception for single-digit values being assigned to **ibase** and **obase** themselves, in **Operations in bc** (on page 2400).

9. The following keywords shall be recognized as tokens:

   auto **ibase** **length** **return** **while** |
   break **if** **obase** **scale** |
   define **for** **quit** **sqrt** |

10. Any of the following characters occurring anywhere except within a keyword shall be recognized as the token **LETTER**:

    `a b c d e f g h i j k l m n o p q r s t u v w x y z`

11. The following single-character and two-character sequences shall be recognized as the token **ASSIGN_OP**:

    `=    +=    −=    *=    /=    %=    ^=`

12. If an `'='` character, as the beginning of a token, is followed by a `'−'` character with no intervening delimiter, the behavior is undefined.

13. The following single-characters shall be recognized as the token **MUL_OP**:

    `*    /    %`

14. The following single-character and two-character sequences shall be recognized as the token **REL_OP**:

    `==    <=    >=    !=    <    >`

15. The following two-character sequences shall be recognized as the token **INCR_DECR**:

`++ −−`

16. The following single characters shall be recognized as tokens whose names are the character:

    `<newline> ( ) , + − ; [ ] ˆ { }`

17. The token **EOF** is returned when the end of input is reached.

Operations in bc

There are three kinds of identifiers: ordinary identifiers, array identifiers, and function identifiers. All three types consist of single lowercase letters. Array identifiers shall be followed by square brackets (`"[]"`). An array subscript is required except in an argument or auto list. Arrays are singly dimensioned and can contain up to {BC_DIM_MAX} elements. Indexing shall begin at zero so an array is indexed from 0 to {BC_DIM_MAX}−1. Subscripts shall be truncated to integers. The application shall ensure that function identifiers are followed by parentheses, possibly enclosing arguments. The three types of identifiers do not conflict.

The following table summarizes the rules for precedence and associativity of all operators. Operators on the same line shall have the same precedence; rows are in order of decreasing precedence.

Table 4-3 Operators in *bc*

Operator	Associativity
`++, −−`	N/A
`unary −`	N/A
`^`	Right to left
`*, /, %`	Left to right
`+, binary −`	Left to right
`=, +=, −=, *=, /=, %=, ˆ=`	Right to left
`==, <=, >=, !=, <, >`	None

Each expression or named expression has a *scale*, which is the number of decimal digits that shall be maintained as the fractional portion of the expression.

Named expressions are places where values are stored. Named expressions shall be valid on the left side of an assignment. The value of a named expression shall be the value stored in the place named. Simple identifiers and array elements are named expressions; they have an initial value of zero and an initial scale of zero.

The internal registers **scale**, **ibase**, and **obase** are all named expressions. The scale of an expression consisting of the name of one of these registers shall be zero; values assigned to any of these registers are truncated to integers. The **scale** register shall contain a global value used in computing the scale of expressions (as described below). The value of the register **scale** is limited to 0 ≤ **scale** ≤ {BC_SCALE_MAX} and shall have a default value of zero. The **ibase** and **obase** registers are the input and output number radix, respectively. The value of **ibase** shall be limited to:

`2 ≤ ibase ≤ 16`

The value of **obase** shall be limited to:

`2 ≤ obase ≤ {BC_BASE_MAX}`

When either **ibase** or **obase** is assigned a single **digit** value from the list in **Lexical Conventions in bc** (on page 2398), the value shall be assumed in hexadecimal. (For example, **ibase**=A sets to base ten, regardless of the current **ibase** value.) Otherwise, the behavior is undefined when digits greater than or equal to the value of **ibase** appear in the input. Both **ibase** and **obase** shall have initial values of 10.

Internal computations shall be conducted as if in decimal, regardless of the input and output bases, to the specified number of decimal digits. When an exact result is not achieved, (for example, **scale**=0; 3.2 / 1) the result shall be truncated.

For all values of **obase** specified by this volume of IEEE Std 1003.1-200x, *bc* shall output numeric values by performing each of the following steps in order:

1. If the value is less than zero, a hyphen (`'−'`) character shall be output.
2. One of the following is output, depending on the numerical value:
   - If the absolute value of the numerical value is greater than or equal to one, the integer portion of the value shall be output as a series of digits appropriate to **obase** (as described below) most significant digit first. The most significant non-zero digit shall be output next, followed by each successively less significant digit.
   - If the absolute value of the numerical value is less than one but greater than zero and the scale of the numerical value is greater than zero, it is unspecified whether the character 0 is output.
   - If the numerical value is zero, the character 0 shall be output.
3. If the scale of the value is greater than zero and the numeric value is not zero, a period character shall be output, followed by a series of digits appropriate to **obase** (as described below) representing the most significant portion of the fractional part of the value. If *s* represents the scale of the value being output, the number of digits output shall be *s* if **obase** is 10, less than or equal to *s* if **obase** is greater than 10, or greater than or equal to *s* if **obase** is less than 10. For **obase** values other than 10, this should be the number of digits needed to represent a precision of 10^s.

For **obase** values from 2 to 16, valid digits are the first **obase** of the single characters:

```
0  1  2  3  4  5  6  7  8  9  A  B  C  D  E  F
```

which represent the values zero to 15, inclusive, respectively.

For bases greater than 16, each digit shall be written as a separate multi-digit decimal number. Each digit except the most significant fractional digit shall be preceded by a single <space>. For bases from 17 to 100, *bc* shall write two-digit decimal numbers; for bases from 101 to 1 000, three-digit decimal strings, and so on. For example, the decimal number 1 024 in base 25 would be written as:

```
Δ01Δ15Δ24
```

in base 125, as:

```
Δ008Δ024
```

Very large numbers shall be split across lines with 70 characters per line in the POSIX locale; other locales may split at different character boundaries. Lines that are continued shall end with a backslash (`'\'`).

A function call shall consist of a function name followed by parentheses containing a comma-separated list of expressions, which are the function arguments. A whole array passed as an argument shall be specified by the array name followed by empty square brackets. All function arguments shall be passed by value. As a result, changes made to the formal parameters shall have no effect on the actual arguments. If the function terminates by executing a **return** statement, the value of the function shall be the value of the expression in the parentheses of the **return** statement or shall be zero if no expression is provided or if there is no **return** statement.

The result of **sqrt**(*expression*) shall be the square root of the expression. The result shall be truncated in the least significant decimal place. The scale of the result shall be the scale of the expression or the value of **scale**, whichever is larger.

The result of **length**(*expression*) shall be the total number of significant decimal digits in the expression. The scale of the result shall be zero.

The result of **scale**(*expression*) shall be the scale of the expression. The scale of the result shall be zero.

A numeric constant shall be an expression. The scale shall be the number of digits that follow the radix point in the input representing the constant, or zero if no radix point appears.

The sequence (*expression*) shall be an expression with the same value and scale as *expression*. The parentheses can be used to alter the normal precedence.

The semantics of the unary and binary operators are as follows:

–expression
The result shall be the negative of the *expression*. The scale of the result shall be the scale of *expression*.

The unary increment and decrement operators shall not modify the scale of the named expression upon which they operate. The scale of the result shall be the scale of that named expression.

++named-expression
The named expression shall be incremented by one. The result shall be the value of the named expression after incrementing.

– –named-expression
The named expression shall be decremented by one. The result shall be the value of the named expression after decrementing.

named-expression++
The named expression shall be incremented by one. The result shall be the value of the named expression before incrementing.

named-expression– –
The named expression shall be decremented by one. The result shall be the value of the named expression before decrementing.

The exponentiation operator, circumflex (`'^'`), shall bind right to left.

expression^expression
The result shall be the first *expression* raised to the power of the second *expression*. If the second expression is not an integer, the behavior is undefined. If *a* is the scale of the left expression and *b* is the absolute value of the right expression, the scale of the result shall be:

```
if b >= 0 min(a * b, max(scale, a)) if b < 0 scale
```

The multiplicative operators (`'*'`, `'/'`, `'%'`) shall bind left to right.

*expression*expression*
The result shall be the product of the two expressions. If *a* and *b* are the scales of the two expressions, then the scale of the result shall be:

```
min(a+b,max(scale,a,b))
```

expression / *expression*
The result shall be the quotient of the two expressions. The scale of the result shall be the value of **scale**.

expression%*expression*
For expressions *a* and *b*, *a*%*b* shall be evaluated equivalent to the steps:

1. Compute *a* / *b* to current scale.
2. Use the result to compute:

```
a - (a / b) * b
```

to scale:

```
max(scale + scale(b), scale(a))
```

The scale of the result shall be:

```
max(scale + scale(b), scale(a))
```

When **scale** is zero, the `'%'` operator is the mathematical remainder operator.

The additive operators (`'+'`, `'-'`) shall bind left to right.

expression+*expression*
The result shall be the sum of the two expressions. The scale of the result shall be the maximum of the scales of the expressions.

expression−*expression*
The result shall be the difference of the two expressions. The scale of the result shall be the maximum of the scales of the expressions.

The assignment operators (`'='`, `"+="`, `"-="`, `"*="`, `"/="`, `"%="`, `"^="`) shall bind right to left.

named-expression=*expression*
This expression shall result in assigning the value of the expression on the right to the named expression on the left. The scale of both the named expression and the result shall be the scale of *expression*.

The compound assignment forms:

```
named-expression <operator>= expression
```

shall be equivalent to:

```
named-expression=named-expression <operator> expression
```

except that the *named-expression* shall be evaluated only once.

Unlike all other operators, the relational operators (`'<'`, `'>'`, `"<="`, `">="`, `"=="`, `"!="`) shall be only valid as the object of an **if**, **while**, or inside a **for** statement.

expression1<*expression2*
The relation shall be true if the value of *expression1* is strictly less than the value of *expression2*.

expression1>*expression2*
The relation shall be true if the value of *expression1* is strictly greater than the value of *expression2*.

expression1<=*expression2*
The relation shall be true if the value of *expression1* is less than or equal to the value of *expression2*.

expression1>=*expression2*
The relation shall be true if the value of *expression1* is greater than or equal to the value of *expression2*.

expression1= =*expression2*
The relation shall be true if the values of *expression1* and *expression2* are equal.

expression1!=*expression2*
The relation shall be true if the values of *expression1* and *expression2* are unequal.

There are only two storage classes in *bc*, global and automatic (local). Only identifiers that are local to a function need be declared with the **auto** command. The arguments to a function shall be local to the function. All other identifiers are assumed to be global and available to all functions. All identifiers, global and local, have initial values of zero. Identifiers declared as auto shall be allocated on entry to the function and released on returning from the function. They therefore do not retain values between function calls. Auto arrays shall be specified by the array name followed by empty square brackets. On entry to a function, the old values of the names that appear as parameters and as automatic variables shall be pushed onto a stack. Until the function returns, reference to these names shall refer only to the new values.

References to any of these names from other functions that are called from this function also refer to the new value until one of those functions uses the same name for a local variable.

When a statement is an expression, unless the main operator is an assignment, execution of the statement shall write the value of the expression followed by a <newline>.

When a statement is a string, execution of the statement shall write the value of the string.

Statements separated by semicolons or <newline>s shall be executed sequentially. In an interactive invocation of *bc*, each time a <newline> is read that satisfies the grammatical production:

```
input_item : semicolon_list NEWLINE
```

the sequential list of statements making up the **semicolon_list** shall be executed immediately and any output produced by that execution shall be written without any delay due to buffering.

In an **if** statement (**if**(*relation*) *statement*), the *statement* shall be executed if the relation is true.

The **while** statement (**while**(*relation*) *statement*) implements a loop in which the *relation* is tested; each time the *relation* is true, the *statement* shall be executed and the *relation* retested. When the *relation* is false, execution shall resume after *statement*.

A **for** statement(**for**(*expression*; *relation*; *expression*) *statement*) shall be the same as:

```
first-expression
while (relation) {
    statement
    last-expression
}
```

The application shall ensure that all three expressions are present.

The **break** statement shall cause termination of a **for** or **while** statement.

The **auto** statement (**auto** *identifier* **[**,*identifier***]** ...) shall cause the values of the identifiers to be pushed down. The identifiers can be ordinary identifiers or array identifiers. Array identifiers shall be specified by following the array name by empty square brackets. The application shall ensure that the **auto** statement is the first statement in a function definition.

A **define** statement:

```
define LETTER ( opt_parameter_list ) {
    opt_auto_define_list
    statement_list
}
```

defines a function named **LETTER**. If a function named **LETTER** was previously defined, the **define** statement shall replace the previous definition. The expression:

```
LETTER ( opt_argument_list )
```

shall invoke the function named **LETTER**. The behavior is undefined if the number of arguments in the invocation does not match the number of parameters in the definition. Functions shall be defined before they are invoked. A function shall be considered to be defined within its own body, so recursive calls are valid. The values of numeric constants within a function shall be interpreted in the base specified by the value of the **ibase** register when the function is invoked.

The **return** statements (**return** and **return**(*expression*)) shall cause termination of a function, popping of its auto variables, and specification of the result of the function. The first form shall be equivalent to **return**(0). The value and scale of the result returned by the function shall be the value and scale of the expression returned.

The **quit** statement (**quit**) shall stop execution of a *bc* program at the point where the statement occurs in the input, even if it occurs in a function definition, or in an **if**, **for**, or **while** statement.

The following functions shall be defined when the **–l** option is specified:

s(*expression*)
Sine of argument in radians.

c(*expression*)
Cosine of argument in radians.

a(*expression*)
Arctangent of argument.

l(*expression*)
Natural logarithm of argument.

e(*expression*)
Exponential function of argument.

j(*expression*, *expression*)
Bessel function of integer order.

The scale of the result returned by these functions shall be the value of the **scale** register at the time the function is invoked. The value of the **scale** register after these functions have completed their execution shall be the same value it had upon invocation. The behavior is undefined if any of these functions is invoked with an argument outside the domain of the mathematical function.

EXIT STATUS

The following exit values shall be returned:

0	All input files were processed successfully.

unspecified An error occurred.

CONSEQUENCES OF ERRORS

If any *file* operand is specified and the named file cannot be accessed, *bc* shall write a diagnostic message to standard error and terminate without any further action.

In an interactive invocation of *bc*, the utility should print an error message and recover following any error in the input. In a non-interactive invocation of *bc*, invalid input causes undefined behavior.

APPLICATION USAGE

Automatic variables in *bc* do not work in exactly the same way as in either C or PL/1.

For historical reasons, the exit status from *bc* cannot be relied upon to indicate that an error has occurred. Returning zero after an error is possible. Therefore, *bc* should be used primarily by interactive users (who can react to error messages) or by application programs that can somehow validate the answers returned as not including error messages.

The *bc* utility always uses the period (`'.'`) character to represent a radix point, regardless of any decimal-point character specified as part of the current locale. In languages like C or *awk*, the period character is used in program source, so it can be portable and unambiguous, while the locale-specific character is used in input and output. Because there is no distinction between source and input in *bc*, this arrangement would not be possible. Using the locale-specific character in *bc*'s input would introduce ambiguities into the language; consider the following example in a locale with a comma as the decimal-point character:

```
define f(a,b) {
    ...
}
...

f(1,2,3)
```

Because of such ambiguities, the period character is used in input. Having input follow different conventions from output would be confusing in either pipeline usage or interactive usage, so the period is also used in output.

EXAMPLES

In the shell, the following assigns an approximation of the first ten digits of 'π' to the variable *x*:

```
x=$(printf "%s\n" 'scale = 10; 104348/33215' | bc)
```

The following *bc* program prints the same approximation of 'π', with a label, to standard output:

```
scale = 10
"pi equals "
104348 / 33215
```

The following defines a function to compute an approximate value of the exponential function (note that such a function is predefined if the **–l** option is specified):

```
scale = 20
define e(x){
    auto a, b, c, i, s
    a = 1
    b = 1
    s = 1
```

```
    for (i = 1; 1 == 1; i++){
        a = a*x
        b = b*i
        c = a/b
        if (c == 0) {
             return(s)
        }
        s = s+c
    }
}
```

The following prints approximate values of the exponential function of the first ten integers:

```
for (i = 1; i <= 10; ++i) {
    e(i)
}
```

RATIONALE

The *bc* utility is implemented historically as a front-end processor for *dc*; *dc* was not selected to be part of this volume of IEEE Std 1003.1-200x because *bc* was thought to have a more intuitive programmatic interface. Current implementations that implement *bc* using *dc* are expected to be compliant.

The exit status for error conditions has been left unspecified for several reasons:

- The *bc* utility is used in both interactive and non-interactive situations. Different exit codes may be appropriate for the two uses.
- It is unclear when a non-zero exit should be given; divide-by-zero, undefined functions, and syntax errors are all possibilities.
- It is not clear what utility the exit status has.
- In the 4.3 BSD, System V, and Ninth Edition implementations, *bc* works in conjunction with *dc*. The *dc* utility is the parent, *bc* is the child. This was done to cleanly terminate *bc* if *dc* aborted.

The decision to have *bc* exit upon encountering an inaccessible input file is based on the belief that *bc file1 file2* is used most often when at least *file1* contains data/function declarations/initializations. Having *bc* continue with prerequisite files missing is probably not useful. There is no implication in the CONSEQUENCES OF ERRORS section that *bc* must check all its files for accessibility before opening any of them.

There was considerable debate on the appropriateness of the language accepted by *bc*. Several reviewers preferred to see either a pure subset of the C language or some changes to make the language more compatible with C. While the *bc* language has some obvious similarities to C, it has never claimed to be compatible with any version of C. An interpreter for a subset of C might be a very worthwhile utility, and it could potentially make *bc* obsolete. However, no such utility is known in historical practice, and it was not within the scope of this volume of IEEE Std 1003.1-200x to define such a language and utility. If and when they are defined, it may be appropriate to include them in a future version of this volume of IEEE Std 1003.1-200x. This left the following alternatives:

1. Exclude any calculator language from this volume of IEEE Std 1003.1-200x.

   The consensus of the standard developers was that a simple programmatic calculator language is very useful for both applications and interactive users. The only arguments for excluding any calculator were that it would become obsolete if and when a C-compatible one emerged, or that the absence would encourage the development of such a C-compatible one. These arguments did not sufficiently address the needs of current application writers.

2. Standardize the historical *dc*, possibly with minor modifications.

   The consensus of the standard developers was that *dc* is a fundamentally less usable language and that that would be far too severe a penalty for avoiding the issue of being similar to but incompatible with C.

3. Standardize the historical *bc*, possibly with minor modifications.

   This was the approach taken. Most of the proponents of changing the language would not have been satisfied until most or all of the incompatibilities with C were resolved. Since most of the changes considered most desirable would break historical applications and require significant modification to historical implementations, almost no modifications were made. The one significant modification that was made was the replacement of the historical *bc* assignment operators `"=+"`, and so on, with the more modern `"+="`, and so on. The older versions are considered to be fundamentally flawed because of the lexical ambiguity in uses like a=−1.

   In order to permit implementations to deal with backwards compatibility as they see fit, the behavior of this one ambiguous construct was made undefined. (At least three implementations have been known to support this change already, so the degree of change involved should not be great.)

The `'%'` operator is the mathematical remainder operator when **scale** is zero. The behavior of this operator for other values of **scale** is from historical implementations of *bc*, and has been maintained for the sake of historical applications despite its non-intuitive nature.

Historical implementations permit setting **ibase** and **obase** to a broader range of values. This includes values less than 2, which were not seen as sufficiently useful to standardize. These implementations do not interpret input properly for values of **ibase** that are greater than 16. This is because numeric constants are recognized syntactically, rather than lexically, as described in this volume of IEEE Std 1003.1-200x. They are built from lexical tokens of single hexadecimal digits and periods. Since <blank>s between tokens are not visible at the syntactic level, it is not possible to recognize the multi-digit ‘‘digits’’ used in the higher bases properly. The ability to recognize input in these bases was not considered useful enough to require modifying these implementations. Note that the recognition of numeric constants at the syntactic level is not a problem with conformance to this volume of IEEE Std 1003.1-200x, as it does not impact the behavior of conforming applications (and correct *bc* programs). Historical implementations also accept input with all of the digits `'0'`−`'9'` and `'A'`−`'F'` regardless of the value of **ibase**; since digits with value greater than or equal to **ibase** are not really appropriate, the behavior when they appear is undefined, except for the common case of:

```
ibase=8;
    /* Process in octal base. */
...
ibase=A
    /* Restore decimal base. */
```

In some historical implementations, if the expression to be written is an uninitialized array element, a leading <space> and/or up to four leading 0 characters may be output before the character zero. This behavior is considered a bug; it is unlikely that any currently conforming application relies on:

```
echo 'b[3]' | bc
```

returning 00000 rather than 0.

Exact calculation of the number of fractional digits to output for a given value in a base other than 10 can be computationally expensive. Historical implementations use a faster approximation, and this is permitted. Note that the requirements apply only to values of **obase** that this volume of IEEE Std 1003.1-200x requires implementations to support (in particular, not to 1, 0, or negative bases, if an implementation supports them as an extension).

Historical implementations of *bc* did not allow array parameters to be passed as the last parameter to a function. New implementations are encouraged to remove this restriction even though it is not required by the grammar.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

Updated to align with the IEEE P1003.2b draft standard, which included resolution of several interpretations of the ISO POSIX-2:1993 standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

bg — run jobs in the background

SYNOPSIS

UP

```
bg [job_id ...]
```

DESCRIPTION

If job control is enabled (see the description of *set* **–m**), the *bg* utility shall resume suspended jobs from the current environment (see Section 2.12 (on page 2263)) by running them as background jobs. If the job specified by *job_id* is already a running background job, the *bg* utility shall have no effect and shall exit successfully.

Using *bg* to place a job into the background shall cause its process ID to become ‘‘known in the current shell execution environment’’, as if it had been started as an asynchronous list; see Section 2.9.3.1 (on page 2252).

OPTIONS

None.

OPERANDS

The following operand shall be supported:

job_id	Specify the job to be resumed as a background job. If no *job_id* operand is given, the most recently suspended job shall be used. The format of *job_id* is described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.203, Job Control Job ID.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *bg*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The output of *bg* shall consist of a line in the format:

```
"[%d] %s\n", <job-number>, <command>
```

where the fields are as follows:

<*job-number*>	A number that can be used to identify the job to the *wait*, *fg*, and *kill* utilities. Using these utilities, the job can be identified by prefixing the job number with `'%'`.
<*command*>	The associated command that was given to the shell.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

If job control is disabled, the *bg* utility shall exit with an error and no job shall be placed in the background.

APPLICATION USAGE

A job is generally suspended by typing the SUSP character (<control>-Z on most systems); see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. At that point, *bg* can put the job into the background. This is most effective when the job is expecting no terminal input and its output has been redirected to non-terminal files. A background job can be forced to stop when it has terminal output by issuing the command:

```
stty tostop
```

A background job can be stopped with the command:

```
kill −s stop job ID
```

The *bg* utility does not work as expected when it is operating in its own utility execution environment because that environment has no suspended jobs. In the following examples:

```
... | xargs bg
(bg)
```

each *bg* operates in a different environment and does not share its parent shell's understanding of jobs. For this reason, *bg* is generally implemented as a shell regular built-in.

EXAMPLES

None.

RATIONALE

The extensions to the shell specified in this volume of IEEE Std 1003.1-200x have mostly been based on features provided by the KornShell. The job control features provided by *bg*, *fg*, and *jobs* are also based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell versions were selected for this volume of IEEE Std 1003.1-200x to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).

The *bg* utility is expected to wrap its output if the output exceeds the number of display columns.

FUTURE DIRECTIONS

None.

SEE ALSO

fg, *kill*, *jobs*, *wait*

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The JC margin marker on the SYNOPSIS is removed since support for Job Control is mandatory in this issue. This is a FIPS requirement.

NAME

c99 — compile standard C programs

SYNOPSIS

CD

```
c99 [−c][−D name[=value]]...[−E][−g][−I directory] ... [−L directory]
    ... [−o outfile][−Ooptlevel][−s][−U name]... operand ...
```

DESCRIPTION

The *c99* utility is an interface to the standard C compilation system; it shall accept source code conforming to the ISO C standard. The system conceptually consists of a compiler and link editor. The files referenced by *operand*s shall be compiled and linked to produce an executable file. (It is unspecified whether the linking occurs entirely within the operation of *c99*; some implementations may produce objects that are not fully resolved until the file is executed.)

If the **−c** option is specified, for all pathname operands of the form *file***.c**, the files:

```
$(basename pathname .c).o
```

shall be created as the result of successful compilation. If the **−c** option is not specified, it is unspecified whether such **.o** files are created or deleted for the *file***.c** operands.

If there are no options that prevent link editing (such as **−c** or **−E**), and all operands compile and link without error, the resulting executable file shall be written according to the **−o** *outfile* option (if present) or to the file **a.out**.

The executable file shall be created as specified in Section 1.7.1.4 (on page 2204), except that the file permission bits shall be set to:

S_IRWXO | S_IRWXG | S_IRWXU

and the bits specified by the *umask* of the process shall be cleared.

OPTIONS

The *c99* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that:

- The **−l** *library* operands have the format of options, but their position within a list of operands affects the order in which libraries are searched.
- The order of specifying the **−I** and **−L** options is significant.
- Conforming applications shall specify each option separately; that is, grouping option letters (for example, **−cO**) need not be recognized by all implementations.

The following options shall be supported:

−c Suppress the link-edit phase of the compilation, and do not remove any object files that are produced.

−g Produce symbolic information in the object or executable files; the nature of this information is unspecified, and may be modified by implementation-defined interactions with other options.

−s Produce object or executable files, or both, from which symbolic and other information not required for proper execution using the *exec* family defined in the System Interfaces volume of IEEE Std 1003.1-200x, has been removed (stripped). If both **−g** and **−s** options are present, the action taken is unspecified.

−o *outfile* Use the pathname *outfile*, instead of the default **a.out**, for the executable file produced. If the **−o** option is present with **−c** or **−E**, the result is unspecified.

–D *name*[=*value*]
Define *name* as if by a C-language **#define** directive. If no =*value* is given, a value of 1 shall be used. The **–D** option has lower precedence than the **–U** option. That is, if *name* is used in both a **–U** and a **–D** option, *name* shall be undefined regardless of the order of the options. Additional implementation-defined *name*s may be provided by the compiler. Implementations shall support at least 2 048 bytes of **–D** definitions and 256 *names*.

–E Copy C-language source files to standard output, expanding all preprocessor directives; no compilation shall be performed. If any operand is not a text file, the effects are unspecified.

–I *directory* Change the algorithm for searching for headers whose names are not absolute pathnames to look in the directory named by the *directory* pathname before looking in the usual places. Thus, headers whose names are enclosed in double-quotes (`" "`) shall be searched for first in the directory of the file with the **#include** line, then in directories named in **–I** options, and last in the usual places. For headers whose names are enclosed in angle brackets (`"< >"`), the header shall be searched for only in directories named in **–I** options and then in the usual places. Directories named in **–I** options shall be searched in the order specified. Implementations shall support at least ten instances of this option in a single *c99* command invocation.

–L *directory* Change the algorithm of searching for the libraries named in the **–l** objects to look in the directory named by the *directory* pathname before looking in the usual places. Directories named in **–L** options shall be searched in the order specified. Implementations shall support at least ten instances of this option in a single *c99* command invocation. If a directory specified by a **–L** option contains files named **libc.a**, **libm.a**, **libl.a**, or **liby.a**, the results are unspecified.

–O *optlevel* Specify the level of code optimization. If the *optlevel* option-argument is the digit `'0'`, all special code optimizations shall be disabled. If it is the digit `'1'`, the nature of the optimization is unspecified. If the **–O** option is omitted, the nature of the system's default optimization is unspecified. It is unspecified whether code generated in the presence of the **–O** 0 option is the same as that generated when **–O** is omitted. Other *optlevel* values may be supported.

–U *name* Remove any initial definition of *name*.

Multiple instances of the **–D**, **–I**, **–U**, and **–L** options can be specified.

OPERANDS

An *operand* is either in the form of a pathname or the form **–l** *library*. The application shall ensure that at least one operand of the pathname form is specified. The following operands shall be supported:

file.**c** A C-language source file to be compiled and optionally linked. The application shall ensure that the operand is of this form if the **–c** option is used.

file.**a** A library of object files typically produced by the *ar* utility, and passed directly to the link editor. Implementations may recognize implementation-defined suffixes other than **.a** as denoting object file libraries.

file.**o** An object file produced by *c99* **–c** and passed directly to the link editor. Implementations may recognize implementation-defined suffixes other than **.o** as denoting object files.

The processing of other files is implementation-defined.

–l library (The letter ell.) Search the library named:

`lib`*`library`*`.a`

A library shall be searched when its name is encountered, so the placement of a **–l** operand is significant. Several standard libraries can be specified in this manner, as described in the EXTENDED DESCRIPTION section. Implementations may recognize implementation-defined suffixes other than **.a** as denoting libraries.

STDIN

Not used.

INPUT FILES

The input file shall be one of the following: a text file containing a C-language source program, an object file in the format produced by *c99* **–c**, or a library of object files, in the format produced by archiving zero or more object files, using *ar*. Implementations may supply additional utilities that produce files in these formats. Additional input file formats are implementation-defined.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *c99*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TMPDIR Provide a pathname that should override the default directory for temporary files, if any. XSI On XSI-conforming systems, provide a pathname that shall override the default directory for temporary files, if any.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If more than one *file* operand ending in **.c** (or possibly other unspecified suffixes) is given, for each such file:

`"%s:\n", <`*`file`*`>`

may be written. These messages, if written, shall precede the processing of each input file; they shall not be written to the standard output if they are written to the standard error, as described in the STDERR section.

If the **–E** option is specified, the standard output shall be a text file that represents the results of the preprocessing stage of the language; it may contain extra information appropriate for subsequent compilation passes.

STDERR

The standard error shall be used only for diagnostic messages. If more than one *file* operand ending in **.c** (or possibly other unspecified suffixes) is given, for each such file:

```
"%s:\n", <file>
```

may be written to allow identification of the diagnostic and warning messages with the appropriate input file. These messages, if written, shall precede the processing of each input file; they shall not be written to the standard error if they are written to the standard output, as described in the STDOUT section.

This utility may produce warning messages about certain conditions that do not warrant returning an error (non-zero) exit value.

OUTPUT FILES

Object files or executable files or both are produced in unspecified formats.

EXTENDED DESCRIPTION

Standard Libraries

The *c99* utility shall recognize the following **–l** operands for standard libraries:

–l c	This operand shall make visible all functions referenced in the System Interfaces volume of IEEE Std 1003.1-200x, with the possible exception of those functions listed as residing in **<aio.h>**, **<arpa/inet.h>**, **<math.h>**, **<mqueue.h>**, **<netdb.h>**, **<netinet/in.h>**, **<pthread.h>**, **<sched.h>**, **<semaphore.h>**, **<spawn.h>**, **<sys/socket.h>**, *pthread_kill*( ), and *pthread_sigmask*( ) in **<signal.h>**, functions marked as extensions other than as part of the MF or MPR extensions in **<sys/mman.h>**, functions marked as ADV in **<fcntl.h>**, and functions marked as CS, CPT, and TMR in **<time.h>**. This operand shall not be required to be present to cause a search of this library.
–l l	This operand shall make visible all functions required by the C-language output of *lex* that are not made available through the **–l c** operand.
–l pthread	This operand shall make visible all functions referenced in **<pthread.h>** and *pthread_kill*( ) and *pthread_sigmask*( ) referenced in **<signal.h>**. An implementation may search this library in the absence of this operand.
–l m	This operand shall make visible all functions referenced in **<math.h>**. An implementation may search this library in the absence of this operand.
–l rt	This operand shall make visible all functions referenced in **<aio.h>**, **<mqueue.h>**, **<sched.h>**, **<semaphore.h>**, and **<spawn.h>**, functions marked as extensions other than as part of the MF or MPR extensions in **<sys/mman.h>**, functions marked as ADV in **<fcntl.h>**, and functions marked as CS, CPT, and TMR in **<time.h>**. An implementation may search this library in the absence of this operand.
–l trace	This operand shall make visible all functions referenced in **<trace.h>**. An implementation may search this library in the absence of this operand.
–l xnet	This operand makes visible all functions referenced in **<arpa/inet.h>**, **<netdb.h>**, **<netinet/in.h>**, and **<sys/socket.h>**. An implementation may search this library in the absence of this operand.
–l y	This operand shall make visible all functions required by the C-language output of *yacc* that are not made available through the **–l c** operand.

In the absence of options that inhibit invocation of the link editor, such as **−c** or **−E**, the *c99* utility shall cause the equivalent of a **−l c** operand to be passed to the link editor as the last **−l** operand, causing it to be searched after all other object files and libraries are loaded.

It is unspecified whether the libraries **libc.a**, **libm.a**, **librt.a**, **libpthread.a**, **libl.a**, **liby.a**, or **libxnet** exist as regular files. The implementation may accept as **−l** operands names of objects that do not exist as regular files.

External Symbols

The C compiler and link editor shall support the significance of external symbols up to a length of at least 31 bytes; the action taken upon encountering symbols exceeding the implementation-defined maximum symbol length is unspecified.

The compiler and link editor shall support a minimum of 511 external symbols per source or object file, and a minimum of 4 095 external symbols in total. A diagnostic message shall be written to the standard output if the implementation-defined limit is exceeded; other actions are unspecified.

Programming Environments

All implementations shall support one of the following programming environments as a default. Implementations may support more than one of the following programming environments. Applications can use *sysconf*( ) or *getconf* to determine which programming environments are supported.

Table 4-4 Programming Environments: Type Sizes

Programming Environment *getconf* **Name**	**Bits in int**	**Bits in long**	**Bits in pointer**	**Bits in off_t**
_POSIX_V6_ILP32_OFF32	32	32	32	32
_POSIX_V6_ILP32_OFFBIG	32	32	32	≥64
_POSIX_V6_LP64_OFF64	32	64	64	64
_POSIX_V6_LPBIG_OFFBIG	≥32	≥64	≥64	≥64

All implementations shall support one or more environments where the widths of the following types are no greater than the width of type **long**:

blksize_t, **cc_t**, **mode_t**, **nfds_t**, **pid_t**, **ptrdiff_t**, **size_t**, **speed_t**, **ssize_t**, **suseconds_t**, **tcflag_t**, **useconds_t**, **wchar_t**, **wint_t**

The executable files created when these environments are selected shall be in a proper format for execution by the *exec* family of functions. Each environment may be one of the ones in Table 4-4, or it may be another environment. The names for the environments that meet this requirement shall be output by a *getconf* command using the _POSIX_V6_WIDTH_RESTRICTED_ENVS argument. If more than one environment meets the requirement, the names of all such environments shall be output on separate lines. Any of these names can then be used in a subsequent *getconf* command to obtain the flags specific to that environment with the following suffixes added as appropriate:

_CFLAGS	To get the C compiler flags.
_LDFLAGS	To get the linker/loader flags.
_LIBS	To get the libraries.

This requirement may be removed in a future version of IEEE Std 1003.1.

When this utility processes a file containing a function called *main*( ), it shall be defined with a return type equivalent to **int**. Using return from *main*( ) shall be equivalent (other than with respect to language scope issues) to calling *exit*( ) with the returned value. Reaching the end of *main*( ) shall be equivalent to calling *exit*(0). The implementation shall not declare a prototype for this function.

Implementations provide configuration strings for C compiler flags, linker/loader flags, and libraries for each supported environment. When an application needs to use a specific programming environment rather than the implementation default programming environment while compiling, the application shall first verify that the implementation supports the desired environment. If the desired programming environment is supported, the application shall then invoke *c99* with the appropriate C compiler flags as the first options for the compile, the appropriate linker/loader flags after any other options but before any operands, and the appropriate libraries at the end of the operands.

Conforming applications shall not attempt to link together object files compiled for different programming models. Applications shall also be aware that binary data placed in shared memory or in files might not be recognized by applications built for other programming models.

Table 4-5 Programming Environments: c99 and cc Arguments

Programming Environment *getconf* **Name**	**Use**	*c99* **and** *cc* **Arguments** *getconf* **Name**
_POSIX_V6_ILP32_OFF32	C Compiler Flags	POSIX_V6_ILP32_OFF32_CFLAGS
	Linker/Loader Flags	POSIX_V6_ILP32_OFF32_LDFLAGS
	Libraries	POSIX_V6_ILP32_OFF32_LIBS
_POSIX_V6_ILP32_OFFBIG	C Compiler Flags	POSIX_V6_ILP32_OFFBIG_CFLAGS
	Linker/Loader Flags	POSIX_V6_ILP32_OFFBIG_LDFLAGS
	Libraries	POSIX_V6_ILP32_OFFBIG_LIBS
_POSIX_V6_LP64_OFF64	C Compiler Flags	POSIX_V6_LP64_OFF64_CFLAGS
	Linker/Loader Flags	POSIX_V6_LP64_OFF64_LDFLAGS
	Libraries	POSIX_V6_LP64_OFF64_LIBS
_POSIX_V6_LPBIG_OFFBIG	C Compiler Flags	POSIX_V6_LPBIG_OFFBIG_CFLAGS
	Linker/Loader Flags	POSIX_V6_LPBIG_OFFBIG_LDFLAGS
	Libraries	POSIX_V6_LPBIG_OFFBIG_LIBS

EXIT STATUS

The following exit values shall be returned:

0	Successful compilation or link edit.
>0	An error occurred.

CONSEQUENCES OF ERRORS

When *c99* encounters a compilation error that causes an object file not to be created, it shall write a diagnostic to standard error and continue to compile other source code operands, but it shall not perform the link phase and return a non-zero exit status. If the link edit is unsuccessful, a diagnostic message shall be written to standard error and *c99* exits with a non-zero status. A conforming application shall rely on the exit status of *c99*, rather than on the existence or mode of the executable file.

APPLICATION USAGE

Since the *c99* utility usually creates files in the current directory during the compilation process, it is typically necessary to run the *c99* utility in a directory in which a file can be created.

On systems providing POSIX Conformance (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 2, Conformance), *c99* is required only with the C-Language Development option; XSI-conformant systems always provide *c99*.

Some historical implementations have created **.o** files when **–c** is not specified and more than one source file is given. Since this area is left unspecified, the application cannot rely on **.o** files being created, but it also must be prepared for any related **.o** files that already exist being deleted at the completion of the link edit.

Some historical implementations have permitted **–L** options to be interspersed with **–l** operands on the command line. For an application to compile consistently on systems that do not behave like this, it is necessary for a conforming application to supply all **–L** options before any of the **–l** options.

There is the possible implication that if a user supplies versions of the standard functions (before they would be encountered by an implicit **–l c** or explicit **–l m**), that those versions would be used in place of the standard versions. There are various reasons this might not be true (functions defined as macros, manipulations for clean name space, and so on), so the existence of files named in the same manner as the standard libraries within the **–L** directories is explicitly stated to produce unspecified behavior.

All of the functions specified in the System Interfaces volume of IEEE Std 1003.1-200x may be made visible by implementations when the Standard C Library is searched. Conforming applications must explicitly request searching the other standard libraries when functions made visible by those libraries are used.

EXAMPLES

1. The following usage example compiles **foo.c** and creates the executable file **foo**:

   ```
   c99 –o foo foo.c
   ```

   The following usage example compiles **foo.c** and creates the object file **foo.o**:

   ```
   c99 –c foo.c
   ```

   The following usage example compiles **foo.c** and creates the executable file **a.out**:

   ```
   c99 foo.c
   ```

   The following usage example compiles **foo.c**, links it with **bar.o**, and creates the executable file **a.out**. It also creates and leaves **foo.o**:

   ```
   c99 foo.c bar.o
   ```

2. The following example shows how an application using threads interfaces can test for support of and use a programming environment supporting 32-bit **int**, **long**, and **pointer** types and an **off_t** type using at least 64 bits:

   ```
   if [ $(getconf _POSIX_V6_ILP32_OFFBIG) != "–1" ]
   then
       c99 $(getconf POSIX_V6_ILP32_OFFBIG_CFLAGS) –D_XOPEN_SOURCE=600 \
           $(getconf POSIX_V6_ILP32_OFFBIG_LDFLAGS) foo.c –o foo \
           $(getconf POSIX_V6_ILP32_OFFBIG_LIBS) –l pthread
   else
       echo ILP32_OFFBIG programming environment not supported
   ```

```
    exit 1
fi
```

3. The following examples clarify the use and interactions of –**L** options and –**l** operands.

   Consider the case in which module **a.c** calls function *f*( ) in library **libQ.a**, and module **b.c** calls function *g*( ) in library **libp.a**. Assume that both libraries reside in **/a/b/c**. The command line to compile and link in the desired way is:

   ```
   c99 –L /a/b/c main.o a.c –l Q b.c –l p
   ```

   In this case the –**l Q** operand need only precede the first –**l p** operand, since both **libQ.a** and **libp.a** reside in the same directory.

   Multiple –**L** operands can be used when library name collisions occur. Building on the previous example, suppose that the user wants to use a new **libp.a**, in **/a/a/a**, but still wants *f*( ) from **/a/b/c/libQ.a**:

   ```
   c99 –L /a/a/a –L /a/b/c main.o a.c –l Q b.c –l p
   ```

   In this example, the linker searches the –**L** options in the order specified, and finds **/a/a/a/libp.a** before **/a/b/c/libp.a** when resolving references for **b.c**. The order of the –**l** operands is still important, however.

4. The following example shows how an application can use a programming environment where the widths of the following types:

   blksize_t, **cc_t**, **mode_t**, **nfds_t**, **pid_t**, **ptrdiff_t**, **size_t**, **speed_t**, **ssize_t**, **suseconds_t**, **tcflag_t**, **useconds_t**, **wchar_t**, **wint_t**

   are no greater than the width of type **long**:

   ```
   # First choose one of the listed environments ...

   # ... if there are no additional constraints, the first one will do:
   CENV=$(getconf _POSIX_V6_WIDTH_RESTRICTED_ENVS | head -n l)

   # ... or, if an environment that supports large files is preferred,
   # look for names that contain "OFF64" or "OFFBIG". (This chooses
   # the last one in the list if none match):
   for CENV in $(getconf _POSIX_V6_WIDTH_RESTRICTED_ENVS)
   do
       case $CENV in
       *OFF64*|*OFFBIG*) break ;;
       esac
   done

   # The chosen environment name can now be used like this:

   c99 $(getconf ${CENV}_CFLAGS) -D _POSIX_C_SOURCE=200xxxL \
   $(getconf ${CENV}_LDFLAGS) foo.c -o foo \
   $(getconf ${CENV} _LIBS)
   ```

RATIONALE

The *c99* utility is based on the *c89* utility originally introduced in the ISO POSIX-2: 1993 standard.

Some of the changes from *c89* include the modification to the contents of the Standard Libraries section to account for new headers and options; for example, <**spawn.h**> added to the –**l rt** operand, and the –**l** trace operand added for the Tracing functions.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Included for alignment with the ISO/IEC 9899:1999 standard.

NAME

cal — print a calendar

SYNOPSIS

XSI
```
cal [[month] year ]
```

DESCRIPTION

The *cal* utility shall write a calendar to standard output using the Julian calendar for dates from January 1, 1 through September 2, 1752 and the Gregorian calendar for dates from September 14, 1752 through December 31, 9999 as though the Gregorian calendar had been adopted on September 14, 1752.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

month	Specify the month to be displayed, represented as a decimal integer from 1 (January) to 12 (December). The default shall be the current month.
year	Specify the year for which the calendar is displayed, represented as a decimal integer from 1 to 9999. The default shall be the current year.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cal*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.
LC_TIME	Determine the format and contents of the calendar.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
TZ	Determine the timezone used to calculate the value of the current month.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used to display the calendar, in an unspecified format.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Note that:

```
cal 83
```

refers to A.D. 83, not 1983.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

A future version of IEEE Std 1003.1-200x may support locale-specific recognition of the date of adoption of the Gregorian calendar. |

SEE ALSO

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The DESCRIPTION is updated to allow for traditional behavior for years before the adoption of the Gregorian calendar.

NAME

cat — concatenate and print files

SYNOPSIS

```
cat [−u][file ...]
```

DESCRIPTION

The *cat* utility shall read files in sequence and shall write their contents to the standard output in the same sequence.

OPTIONS

The *cat* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−u	Write bytes from the input file to the standard output without delay as each is read.

OPERANDS

The following operand shall be supported:

file	A pathname of an input file. If no *file* operands are specified, the standard input shall be used. If a *file* is '−', the *cat* utility shall read from the standard input at that point in the sequence. The *cat* utility shall not close and reopen standard input when it is referenced in this way, but shall accept multiple occurrences of '−' as a *file* operand.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is '−'. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cat*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall contain the sequence of bytes read from the input files. Nothing else shall be written to the standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All input files were output successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The −**u** option has value in prototyping non-blocking reads from FIFOs. The intent is to support the following sequence:

```
mkfifo foo
cat −u foo > /dev/tty13 &
cat −u > foo
```

It is unspecified whether standard output is or is not buffered in the default case. This is sometimes of interest when standard output is associated with a terminal, since buffering may delay the output. The presence of the −**u** option guarantees that unbuffered I/O is available. It is implementation-defined whether the *cat* utility buffers output if the −**u** option is not specified. Traditionally, the −**u** option is implemented using the equivalent of the *setvbuf*() function defined in the System Interfaces volume of IEEE Std 1003.1-200x.

EXAMPLES

The following command:

```
cat myfile
```

writes the contents of the file **myfile** to standard output.

The following command:

```
cat doc1 doc2 > doc.all
```

concatenates the files **doc1** and **doc2** and writes the result to **doc.all**.

Because of the shell language mechanism used to perform output redirection, a command such as this:

```
cat doc doc.end > doc
```

causes the original data in **doc** to be lost.

The command:

```
cat start − middle − end > file
```

when standard input is a terminal, gets two arbitrary pieces of input from the terminal with a single invocation of *cat*. Note, however, that if standard input is a regular file, this would be equivalent to the command:

```
cat start − middle /dev/null end > file
```

because the entire contents of the file would be consumed by *cat* the first time ’−’ was used as a *file* operand and an end-of-file condition would be detected immediately when ’−’ was referenced the second time.

RATIONALE

Historical versions of the *cat* utility include the options −**e**, −**t**, and −**v**, which permit the ends of lines, <tab>s, and invisible characters, respectively, to be rendered visible in the output. The standard developers omitted these options because they provide too fine a degree of control over what is made visible, and similar output can be obtained using a command such as:

```
sed −n −e ’s/$/$/’ −e l pathname
```

The −**s** option was omitted because it corresponds to different functions in BSD and System V-based systems. The BSD −**s** option to squeeze blank lines can be accomplished by the shell script shown in following example:

```
sed −n ’
# Write non-empty lines.
/./   {
      p
      d
      }
# Write a single empty line, then look for more empty lines.
/^$/  p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^$/  {
      N
      s/.//
      b Empty
      }
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
      p
’
```

The System V −**s** option to silence error messages can be accomplished by redirecting the standard error. Note that the BSD documentation for *cat* uses the term ‘‘blank line’’ to mean the same as the POSIX ‘‘empty line’’: a line consisting only of a <newline>.

The BSD −**n** option was omitted because similar functionality can be obtained from the −**n** option of the *pr* utility.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

cd — change the working directory

SYNOPSIS

```
cd [−L] [−P] [directory]

cd −
```

DESCRIPTION

The *cd* utility shall change the working directory of the current shell execution environment (see Section 2.12 (on page 2263)) by executing the following steps in sequence. (In the following steps, the symbol **curpath** represents an intermediate value used to simplify the description of the algorithm used by *cd*. There is no requirement that **curpath** be made visible to the application.)

1. If no *directory* operand is given and the *HOME* environment variable is empty or undefined, the default behavior is implementation-defined and no further steps shall be taken.

2. If no *directory* operand is given and the *HOME* environment variable is set to a non-empty value, the *cd* utility shall behave as if the directory named in the *HOME* environment variable was specified as the *directory* operand.

3. If the *directory* operand begins with a slash character, set **curpath** to the operand and proceed to step 7.

4. If the first component of the *directory* operand is dot or dot-dot, proceed to step 6.

5. Starting with the first pathname in the colon-separated pathnames of *CDPATH* (see the ENVIRONMENT VARIABLES section) if the pathname is non-null, test if the concatenation of that pathname, a slash character, and the *directory* operand names a directory. If the pathname is null, test if the concatenation of dot, a slash character, and the operand names a directory. In either case, if the resulting string names an existing directory, set **curpath** to that string and proceed to step 7. Otherwise, repeat this step with the next pathname in *CDPATH* until all pathnames have been tested.

6. Set **curpath** to the string formed by the concatenation of the value of *PWD* a slash character, and the operand.

7. If the −**P** option is in effect, the *cd* utility shall perform actions equivalent to the *chdir*( ) function, called with **curpath** as the *path* argument. If these actions succeed, the *PWD* environment variable shall be set to an absolute pathname for the current working directory and shall not contain filename components that, in the context of pathname resolution, refer to a file of type symbolic link. If there is insufficient permission on the new directory, or on any parent of that directory, to determine the current working directory, the value of the *PWD* environment variable is unspecified. If the actions equivalent to *chdir*( ) fail for any reason, the *cd* utility shall display an appropriate error message and not alter the *PWD* environment variable. Whether the actions equivalent to *chdir*( ) succeed or fail, no further steps shall be taken.

8. The **curpath** value shall then be converted to canonical form as follows, considering each component from beginning to end, in sequence:

    a. Dot components and any slashes that separate them from the next component shall be deleted.

    b. For each dot-dot component, if there is a preceding component and it is neither root nor dot-dot, the preceding component, all slashes separating the preceding component from dot-dot, dot-dot, and all slashes separating dot-dot from the following component shall be deleted.

c. An implementation may further simplify **curpath** by removing any trailing slash characters that are not also leading slashes, replacing multiple non-leading consecutive slashes with a single slash, and replacing three or or more leading slashes with a single slash. If, as a result of this canonicalization, the **curpath** variable is null, no further steps shall be taken.

9. The *cd* utility shall then perform actions equivalent to the *chdir*( ) function called with **curpath** as the *path* argument. If these actions failed for any reason, the *cd* utility shall display an appropriate error message and no further steps shall be taken. The *PWD* environment variable shall be set to **curpath**.

If, during the execution of the above steps, the *PWD* environment variable is changed, the *OLDPWD* environment variable shall also be changed to the value of the old working directory (that is the current working directory immediately prior to the call to *cd*).

OPTIONS

The *cd* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

–L	Handle the operand dot-dot logically; symbolic link components shall not be resolved before dot-dot components are processed (see steps 5. and 6. in the DESCRIPTION).
–P	Handle the operand dot-dot physically; symbolic link components shall be resolved before dot-dot components are processed (see step 4. in the DESCRIPTION).

If both –**L** and –**P** options are specified, the last of these options shall be used and all others ignored. If neither –**L** nor –**P** is specified, the operand shall be handled dot-dot logically; see the DESCRIPTION.

OPERANDS

The following operands shall be supported:

directory An absolute or relative pathname of the directory that shall become the new working directory. The interpretation of a relative pathname by *cd* depends on the –**L** option and the *CDPATH* and *PWD* environment variables. If *directory* is an empty string, the results are unspecified.

– When a hyphen is used as the operand, this shall be equivalent to the command: |

```
cd "$OLDPWD" && pwd
```

which changes to the previous working directory and then writes its name.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cd*:

CDPATH A colon-separated list of pathnames that refer to directories. The *cd* utility shall use this list in its attempt to change the directory, as described in the DESCRIPTION. An empty string in place of a directory pathname represents the current directory.

	If *CDPATH* is not set, it shall be treated as if it were an empty string.
HOME	The name of the directory, used when no *directory* operand is specified.
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
OLDPWD	A pathname of the previous working directory, used by *cd* –.
PWD	This variable shall be set as specified in the DESCRIPTION. If an application sets or unsets the value of *PWD*, the behavior of *cd* is unspecified.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If a non-empty directory name from *CDPATH* is used, or if *cd* – is used, an absolute pathname of the new working directory shall be written to the standard output as follows:

```
"%s\n", <new directory>
```

Otherwise, there shall be no output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The directory was successfully changed.
>0	An error occurred.

CONSEQUENCES OF ERRORS

The working directory shall remain unchanged.

APPLICATION USAGE

Since *cd* affects the current shell execution environment, it is always provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(cd /tmp)
nohup cd
find . −exec cd {} \;
```

it does not affect the working directory of the caller's environment.

The user must have execute (search) permission in *directory* in order to change to it.

EXAMPLES

None.

RATIONALE

The use of the *CDPATH* was introduced in the System V shell. Its use is analogous to the use of the *PATH* variable in the shell. The BSD C shell used a shell parameter *cdpath* for this purpose.

A common extension when *HOME* is undefined is to get the login directory from the user database for the invoking user. This does not occur on System V implementations.

Some historical shells, such as the KornShell, took special actions when the directory name contained a dot-dot component, selecting the logical parent of the directory, rather than the actual parent directory; that is, it moved up one level toward the `'/'` in the pathname, remembering what the user typed, rather than performing the equivalent of:

```
chdir("..");
```

In such a shell, the following commands would not necessarily produce equivalent output for all directories:

```
cd .. && ls      ls ..
```

This behavior is not permitted by default because it is not consistent with the definition of dot-dot in most historical practice; that is, while this behavior has been optionally available in the KornShell, other shells have historically not supported this functionality. The logical pathname is stored in the *PWD* environment variable when the *cd* utility completes and this value is used to construct the next directory name if *cd* is invoked with the −**L** option.

FUTURE DIRECTIONS

None.

pwd, the System Interfaces volume of IEEE Std 1003.1-200x, *chdir*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The *cd* −, *PWD*, and *OLDPWD* are added.

The −**L** and −**P** options are added to align with the IEEE P1003.2b draft standard. This also includes the introduction of a new description to include the effect of these options.

NAME

cflow — generate a C-language flowgraph (**DEVELOPMENT**)

SYNOPSIS

XSI

```
cflow [−r][−d num][−D name[=def]] ... [−i incl][−I dir] ...
    [−U dir] ... file ...
```

DESCRIPTION

The *cflow* utility shall analyze a collection of object files or assembler, C-language, *lex* or *yacc* source files, and attempt to build a graph, written to standard output, charting the external references.

OPTIONS

The *cflow* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of the **−D**, **−I**, and **−U** options (which are identical to their interpretation by *c99*) is significant.

The following options shall be supported:

−d *num*	Indicate the depth at which the flowgraph is cut off. The application shall ensure that the argument *num* is a decimal integer. By default this is a very large number (typically greater than 32 000). Attempts to set the cut-off depth to a non-positive integer shall be ignored.
−i *incl*	Increase the number of included symbols. The *incl* option-argument is one of the following characters: *x* Include external and static data symbols. The default shall be to include only functions in the flowgraph. _ (Underscore) Include names that begin with an underscore. The default shall be to exclude these functions (and data if **−i x** is used).
−r	Reverse the caller:callee relationship, producing an inverted listing showing the callers of each function. The listing shall also be sorted in lexicographical order by callee.

OPERANDS

The following operand is supported:

file	The pathname of a file for which a graph is to be generated. Filenames suffixed by **.l** shall shall be taken to be *lex* input, **.y** as *yacc* input, **.c** as *c99* input, and **.i** as the output of *c99* **−E**. Such files shall be processed as appropriate, determined by their suffix. Files suffixed in **.s** (conventionally assembler source) may have more limited information extracted from them.

STDIN

Not used.

INPUT FILES

The input files shall be object files or assembler, C-language, *lex* or *yacc* source files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cflow*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2,

	Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the ordering of the output when the **–r** option is used.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The flowgraph written to standard output shall be formatted as follows:

`"%d %s:%s\n", <reference number>, <global>, <definition>`

Each line of output begins with a reference (that is, line) number, followed by indentation of at least one column position per level. This is followed by the name of the global, a colon, and its definition. Normally globals are only functions not defined as an external or beginning with an underscore; see the OPTIONS section for the **–i** inclusion option. For information extracted from C-language source, the definition consists of an abstract type declaration (for example, **char ***) and, delimited by angle brackets, the name of the source file and the line number where the definition was found. Definitions extracted from object files indicate the filename and location counter under which the symbol appeared (for example, *text*).

Once a definition of a name has been written, subsequent references to that name contain only the reference number of the line where the definition can be found. For undefined references, only "<>" shall be written.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Files produced by *lex* and *yacc* cause the reordering of line number declarations, and this can confuse *cflow*. To obtain proper results, the input of *yacc* or *lex* must be directed to *cflow*.

EXAMPLES

Given the following in **file.c**:

```
int i;
int f();
int g();
int h();
int
main()
{
    f();
    g();
    f();
}
int
f()
{
    i = h();
}
```

The command:

```
cflow −i x file.c
```

produces the output:

```
1 main: int(), <file.c 6>
2    f: int(), <file.c 13>
3        h: <>
4        i: int, <file.c 1>
5    g: <>
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

c99, *lex*, *yacc*

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

chgrp — change the file group ownership

SYNOPSIS

```
chgrp –hR group file ...

chgrp –R [–H | –L | –P ] group file ...
```

DESCRIPTION

The *chgrp* utility shall set the group ID of the file named by each *file* operand to the group ID specified by the *group* operand.

For each *file* operand, or, if the **–R** option is used, each file encountered while walking the directory trees specified by the *file* operands, the *chgrp* utility shall perform actions equivalent to the *chown*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

- The *file* operand shall be used as the *path* argument.
- The user ID of the file shall be used as the *owner* argument.
- The specified group ID shall be used as the *group* argument.

Unless *chgrp* is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file shall be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

OPTIONS

The *chgrp* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

–h	If the system supports group IDs for symbolic links, for each *file* operand that names a file of type symbolic link, *chgrp* shall attempt to set the group ID of the symbolic link instead of the file referenced by the symbolic link. If the system does not support group IDs for symbolic links, for each *file* operand that names a file of type symbolic link, *chgrp* shall do nothing more with the current file and shall go on to any remaining files.
–H	If the **–R** option is specified and a symbolic link referencing a file of type directory is specified on the command line, *chgrp* shall change the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.
–L	If the **–R** option is specified and a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, *chgrp* shall change the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.
–P	If the **–R** option is specified and a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *chgrp* shall change the group ID of the symbolic link if the system supports this operation. The *chgrp* utility shall not follow the symbolic link to any other part of the file hierarchy.
–R	Recursively change file group IDs. For each *file* operand that names a directory, *chgrp* shall change the group of the directory and all files in the file hierarchy below it. Unless a **–H**, **–L**, or **–P** option is specified, it is unspecified which of these options will be used as the default.

Specifying more than one of the mutually-exclusive options **–H**, **–L**, and **–P** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operands shall be supported:

group	A group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file named by one of the *file* operands. If a numeric *group* operand exists in the group database as a group name, the group ID number associated with that group name is used as the group ID.
file	A pathname of a file whose group ID is to be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chgrp*:

	LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
	LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
	LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
	LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The utility executed successfully and all requested changes were made.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Only the owner of a file or the user with appropriate privileges may change the owner or group of a file.

Some implementations restrict the use of *chgrp* to a user with appropriate privileges when the *group* specified is not the effective group ID or one of the supplementary group IDs of the calling process. |

EXAMPLES

None.

RATIONALE

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. The standard developers chose to mask these by specifying only 0 and >0 as exit values.

The functionality of *chgrp* is described substantially through references to *chown*( ). In this way, there is no duplication of effort required for describing the interactions of permissions, multiple groups, and so on.

FUTURE DIRECTIONS

None.

SEE ALSO

chmod, *chown*, the System Interfaces volume of IEEE Std 1003.1-200x, *chown*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

New options −**H**, −**L**, and −**P** are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section to ‘‘Default.’’.

NAME

chmod — change the file modes

SYNOPSIS

```
chmod [−R] mode file ...
```

DESCRIPTION

The *chmod* utility shall change any or all of the file mode bits of the file named by each *file* operand in the way specified by the *mode* operand.

It is implementation-defined whether and how the *chmod* utility affects any alternate or additional file access control mechanism (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.4, File Access Permissions) being used for the specified file.

Only a process whose effective user ID matches the user ID of the file, or a process with the appropriate privileges, shall be permitted to change the file mode bits of a file.

OPTIONS

The *chmod* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−R	Recursively change file mode bits. For each *file* operand that names a directory, *chmod* shall change the file mode bits of the directory and all files in the file hierarchy below it.

OPERANDS

The following operands shall be supported:

mode	Represents the change to be made to the file mode bits of each file named by one of the *file* operands; see the EXTENDED DESCRIPTION section.
file	A pathname of a file whose file mode bits shall be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chmod*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The *mode* operand shall be either a *symbolic_mode* expression or a non-negative octal integer. The *symbolic_mode* form is described by the grammar later in this section.

Each **clause** shall specify an operation to be performed on the current file mode bits of each *file*. The operations shall be performed on each *file* in the order in which the **clause**s are specified.

The **who** symbols **u**, **g**, and **o** shall specify the *user*, *group*, and *other* parts of the file mode bits, respectively. A **who** consisting of the symbol **a** shall be equivalent to **ugo**.

The **perm** symbols **r**, **w**, and **x** represent the *read*, *write*, and *execute*/*search* portions of file mode bits, respectively. The **perm** symbol **s** shall represent the *set-user-ID-on-execution* (when **who** contains or implies **u**) and *set-group-ID-on-execution* (when **who** contains or implies **g**) bits.

The **perm** symbol **X** shall represent the execute/search portion of the file mode bits if the file is a directory or if the current (unmodified) file mode bits have at least one of the execute bits (S_IXUSR, S_IXGRP, or S_IXOTH) set. It shall be ignored if the file is not a directory and none of the execute bits are set in the current file mode bits.

The **permcopy** symbols **u**, **g**, and **o** shall represent the current permissions associated with the user, group, and other parts of the file mode bits, respectively. For the remainder of this section, **perm** refers to the non-terminals **perm** and **permcopy** in the grammar.

If multiple **actionlist**s are grouped with a single **wholist** in the grammar, each **actionlist** shall be applied in the order specified with that **wholist**. The *op* symbols shall represent the operation performed, as follows:

\+ If **perm** is not specified, the '+' operation shall not change the file mode bits.

If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be set.

Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be set.

– If **perm** is not specified, the '–' operation shall not change the file mode bits.

If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be cleared.

Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be cleared.

= Clear the file mode bits specified by the **who** value, or, if no **who** value is specified, all of the file mode bits specified in this volume of IEEE Std 1003.1-200x.

If **perm** is not specified, the '=' operation shall make no further modifications to the file mode bits.

If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be set.

Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be set.

When using the symbolic mode form on a regular file, it is implementation-defined whether or not:

- Requests to set the set-user-ID-on-execution or set-group-ID-on-execution bit when all execute bits are currently clear and none are being set are ignored.
- Requests to clear all execute bits also clear the set-user-ID-on-execution and set-group-ID-on-execution bits.
- Requests to clear the set-user-ID-on-execution or set-group-ID-on-execution bits when all execute bits are currently clear are ignored. However, if the command *ls* **–l** *file* writes an *s* in the position indicating that the set-user-ID-on-execution or set-group-ID-on-execution is set, the commands *chmod* **u–s** *file* or *chmod* **g–s** *file*, respectively, shall not be ignored.

When using the symbolic mode form on other file types, it is implementation-defined whether or not requests to set or clear the set-user-ID-on-execution or set-group-ID-on-execution bits are honored.

If the **who** symbol **o** is used in conjunction with the **perm** symbol **s** with no other **who** symbols being specified, the set-user-ID-on-execution and set-group-ID-on-execution bits shall not be modified. It shall not be an error to specify the **who** symbol **o** in conjunction with the **perm** symbol **s**.

For an octal integer *mode* operand, the file mode bits shall be set absolutely.

For each bit set in the octal number, the corresponding file permission bit shown in the following table shall be set; all other file permission bits shall be cleared. For regular files, for each bit set in the octal number corresponding to the set-user-ID-on-execution or the set-group-ID-on-execution, bits shown in the following table shall be set; if these bits are not set in the octal number, they are cleared. For other file types, it is implementation-defined whether or not requests to set or clear the set-user-ID-on-execution or set-group-ID-on-execution bits are honored.

Octal	Mode Bit	Octal	Mode Bit	Octal	Mode Bit	Octal	Mode Bit
4000	S_ISUID	**0400**	S_IRUSR	**0040**	S_IRGRP	**0004**	S_IROTH
2000	S_ISGID	**0200**	S_IWUSR	**0020**	S_IWGRP	**0002**	S_IWOTH
		0100	S_IXUSR	**0010**	S_IXGRP	**0001**	S_IXOTH

When bits are set in the octal number other than those listed in the table above, the behavior is unspecified.

Grammar for chmod

The grammar and lexical conventions in this section describe the syntax for the *symbolic_mode* operand. The general conventions for this style of grammar are described in Section 1.10 (on page 2220). A valid *symbolic_mode* can be represented as the non-terminal symbol *symbolic_mode* in the grammar. This formal syntax shall take precedence over the preceding text syntax description.

The lexical processing is based entirely on single characters. Implementations need not allow blank characters within the single argument being processed.

```
%start    symbolic_mode
%%

symbolic_mode    : section
                 | symbolic_mode ',' clause
                 ;

clause           : actionlist
                 | wholist actionlist
                 ;

wholist          : who
                 | wholist who

```

EXIT STATUS

The following exit values shall be returned:

0	The utility executed successfully and all requested changes were made.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Some implementations of the *chmod* utility change the mode of a directory before the files in the directory when performing a recursive (−**R** option) change; others change the directory mode after the files in the directory. If an application tries to remove read or search permission for a file hierarchy, the removal attempt fails if the directory is changed first; on the other hand, trying to re-enable permissions to a restricted hierarchy fails if directories are changed last. Users should not try to make a hierarchy inaccessible to themselves.

Some implementations of *chmod* never used the process' *umask* when changing modes; systems conformant with this volume of IEEE Std 1003.1-200x do so when **who** is not specified. Note the difference between:

```
chmod a-w file
```

which removes all write permissions, and:

```
chmod -- -w file
```

which removes write permissions that would be allowed if **file** was created with the same *umask*.

Conforming applications should never assume that they know how the set-user-ID and set-group-ID bits on directories are interpreted.

EXAMPLES

Mode	Results
a+=	Equivalent to *a*+,*a*=; clears all file mode bits.
go+−w	Equivalent to *go*+,*go*−*w*; clears group and other write bits.
g=*o*−*w*	Equivalent to *g*=*o*,*g*−*w*; sets group bit to match other bits and then clears group write bit.
g−*r*+*w*	Equivalent to *g*−*r*,*g*+*w*; clears group read bit and sets group write bit.
=*g*	Sets owner bits to match group bits and sets other bits to match group bits.

RATIONALE

The functionality of *chmod* is described substantially through references to concepts defined in the System Interfaces volume of IEEE Std 1003.1-200x. In this way, there is less duplication of effort required for describing the interactions of permissions. However, the behavior of this utility is not described in terms of the *chmod*( ) function from the System Interfaces volume of IEEE Std 1003.1-200x because that specification requires certain side effects upon alternate file access control mechanisms that might not be appropriate, depending on the implementation.

Implementations that support mandatory file and record locking as specified by the 1984 /usr/group standard historically used the combination of set-group-ID bit set and group execute bit clear to indicate mandatory locking. This condition is usually set or cleared with the symbolic mode **perm** symbol **l** instead of the **perm** symbols **s** and **x** so that the mandatory locking mode is not changed without explicit indication that that was what the user intended. Therefore, the details on how the implementation treats these conditions must be defined in the documentation. This volume of IEEE Std 1003.1-200x does not require mandatory locking (nor does the System Interfaces volume of IEEE Std 1003.1-200x), but does allow it as an extension. However, this volume of IEEE Std 1003.1-200x does require that the *ls* and *chmod* utilities work consistently in this area. If *ls* **–l** *file* indicates that the set-group-ID bit is set, *chmod* **g–s** *file* must clear it (assuming appropriate privileges exist to change modes).

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. This problem is avoided here by specifying only 0 and >0 as exit values.

The System Interfaces volume of IEEE Std 1003.1-200x indicates that implementation-defined restrictions may cause the S_ISUID and S_ISGID bits to be ignored. This volume of IEEE Std 1003.1-200x allows the *chmod* utility to choose to modify these bits before calling *chmod*( ) (or some function providing equivalent capabilities) for non-regular files. Among other things, this allows implementations that use the set-user-ID and set-group-ID bits on directories to enable extended features to handle these extensions in an intelligent manner.

The **X perm** symbol was adopted from BSD-based systems because it provides commonly desired functionality when doing recursive (**–R** option) modifications. Similar functionality is not provided by the *find* utility. Historical BSD versions of *chmod*, however, only supported **X** with *op*+; it has been extended in this volume of IEEE Std 1003.1-200x because it is also useful with *op*=. (It has also been added for *op*– even though it duplicates **x**, in this case, because it is intuitive and easier to explain.)

The grammar was extended with the *permcopy* non-terminal to allow historical-practice forms of symbolic modes like **o**=**u** –**g** (that is, set the ‘‘other’’ permissions to the permissions of ‘‘owner’’ minus the permissions of ‘‘group’’).

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Octal modes have been kept and made mandatory despite being marked obsolescent in the previous version of this volume of IEEE Std 1003.1-200x.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section to ‘‘Default.’’.

NAME

chown — change the file ownership

SYNOPSIS

`chown −hR owner[:group] file ...`

`chown −R [−H | −L | −P ] owner[:group] file ...`

DESCRIPTION

The *chown* utility shall set the user ID of the file named by each *file* operand to the user ID specified by the *owner* operand.

For each *file* operand, or, if the **−R** option is used, each file encountered while walking the directory trees specified by the *file* operands, the *chown* utility shall perform actions equivalent to the *chown*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

1. The *file* operand shall be used as the *path* argument.
2. The user ID indicated by the *owner* portion of the first operand shall be used as the *owner* argument.
3. If the *group* portion of the first operand is given, the group ID indicated by it shall be used as the *group* argument; otherwise, the group ID of the file shall be used as the *group* argument.

Unless *chown* is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file shall be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

OPTIONS

The *chown* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

−h If the system supports user IDs for symbolic links, for each *file* operand that names a file of type symbolic link, *chown* shall attempt to set the user ID of the symbolic link. If the system supports group IDs for symbolic links, and a group ID was specified, for each *file* operand that names a file of type symbolic link, *chown* shall attempt to set the group ID of the symbolic link. If the system does not support user or group IDs for symbolic links, for each *file* operand that names a file of type symbolic link, *chown* shall do nothing more with the current file and shall go on to any remaining files.

−H If the **−R** option is specified and a symbolic link referencing a file of type directory is specified on the command line, *chown* shall change the user ID (and group ID, if specified) of the directory referenced by the symbolic link and all files in the file hierarchy below it.

−L If the **−R** option is specified and a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, *chown* shall change the user ID (and group ID, if specified) of the directory referenced by the symbolic link and all files in the file hierarchy below it.

−P If the **−R** option is specified and a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *chown* shall change the owner ID (and group ID, if specified) of the symbolic link if the system supports this operation. The *chown* utility shall not follow the symbolic link to any other part of the file hierarchy.

–R	Recursively change file user and group IDs. For each *file* operand that names a directory, *chown* shall change the user ID (and group ID, if specified) of the directory and all files in the file hierarchy below it. Unless a **–H**, **–L**, or **–P** option is specified, it is unspecified which of these options will be used as the default.

Specifying more than one of the mutually-exclusive options **–H**, **–L**, and **–P** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operands shall be supported:

owner[:*group*]	A user ID and optional group ID to be assigned to *file*. The *owner* portion of this operand shall be a user name from the user database or a numeric user ID. Either specifies a user ID which shall be given to each file named by one of the *file* operands. If a numeric *owner* operand exists in the user database as a user name, the user ID number associated with that user name shall be used as the user ID. Similarly, if the *group* portion of this operand is present, it shall be a group name from the group database or a numeric group ID. Either specifies a group ID which shall be given to each file. If a numeric group operand exists in the group database as a group name, the group ID number associated with that group name shall be used as the group ID.
file	A pathname of a file whose user ID is to be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chown*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The utility executed successfully and all requested changes were made.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Only the owner of a file or the user with appropriate privileges may change the owner or group of a file.

Some implementations restrict the use of *chown* to a user with appropriate privileges.

EXAMPLES

None.

RATIONALE

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. These are masked by specifying only 0 and >0 as exit values.

The functionality of *chown* is described substantially through references to functions in the System Interfaces volume of IEEE Std 1003.1-200x. In this way, there is no duplication of effort required for describing the interactions of permissions, multiple groups, and so on.

The 4.3 BSD method of specifying both owner and group was included in this volume of IEEE Std 1003.1-200x because:

- There are cases where the desired end condition could not be achieved using the *chgrp* and *chown* (that only changed the user ID) utilities. (If the current owner is not a member of the desired group and the desired owner is not a member of the current group, the *chown*( ) function could fail unless both owner and group are changed at the same time.)
- Even if they could be changed independently, in cases where both are being changed, there is a 100% performance penalty caused by being forced to invoke both utilities.

The BSD syntax *user*[.*group*] was changed to *user*[:*group*] in this volume of IEEE Std 1003.1-200x because the period is a valid character in login names (as specified by the Base Definitions volume of IEEE Std 1003.1-200x, login names consist of characters in the portable filename character set). The colon character was chosen as the replacement for the period character because it would never be allowed as a character in a user name or group name on historical implementations.

The −**R** option is considered by some observers as an undesirable departure from the historical UNIX system tools approach; since a tool, *find*, already exists to recurse over directories, there seemed to be no good reason to require other tools to have to duplicate that functionality. However, the –**R** option was deemed an important user convenience, is far more efficient than forking a separate process for each element of the directory hierarchy, and is in widespread historical use.

FUTURE DIRECTIONS

None.

chmod, *chgrp*, the System Interfaces volume of IEEE Std 1003.1-200x, *chown*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

New options –**h**, –**H**, –**L**, and –**P** are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section is changed to ‘‘Default.’’.

NAME

cksum — write file checksums and sizes

SYNOPSIS

```
cksum [file ...]
```

DESCRIPTION

The *cksum* utility shall calculate and write to standard output a cyclic redundancy check (CRC) for each input file, and also write to standard output the number of octets in each file. The CRC used is based on the polynomial used for CRC error checking in the ISO/IEC 8802-3:1996 standard (Ethernet).

The encoding for the CRC checksum is defined by the generating polynomial:

$$G(x)=x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^{8}+x^{7}+x^{5}+x^{4}+x^{2}+x+1$$

Mathematically, the CRC value corresponding to a given file shall be defined by the following procedure:

1. The n bits to be evaluated are considered to be the coefficients of a mod 2 polynomial $M(x)$ of degree $n-1$. These n bits are the bits from the file, with the most significant bit being the most significant bit of the first octet of the file and the last bit being the least significant bit of the last octet, padded with zero bits (if necessary) to achieve an integral number of octets, followed by one or more octets representing the length of the file as a binary value, least significant octet first. The smallest number of octets capable of representing this integer shall be used.

2. $M(x)$ is multiplied by x^{32} (that is, shifted left 32 bits) and divided by $G(x)$ using mod 2 division, producing a remainder $R(x)$ of degree ≤ 31.

3. The coefficients of $R(x)$ are considered to be a 32-bit sequence.

4. The bit sequence is complemented and the result is the CRC.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file	A pathname of a file to be checked. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cksum*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

For each file processed successfully, the *cksum* utility shall write in the following format:

```
"%u %d %s\n", <checksum>, <# of octets>, <pathname>
```

If no *file* operand was specified, the pathname and its leading <space> shall be omitted.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All files were processed successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *cksum* utility is typically used to quickly compare a suspect file against a trusted version of the same, such as to ensure that files transmitted over noisy media arrive intact. However, this comparison cannot be considered cryptographically secure. The chances of a damaged file producing the same CRC as the original are small; deliberate deception is difficult, but probably not impossible.

Although input files to *cksum* can be any type, the results need not be what would be expected on character special device files or on file types not described by the System Interfaces volume of IEEE Std 1003.1-200x. Since this volume of IEEE Std 1003.1-200x does not specify the block size used when doing input, checksums of character special files need not process all of the data in those files.

The algorithm is expressed in terms of a bitstream divided into octets. If a file is transmitted between two systems and undergoes any data transformation (such as changing little-endian byte ordering to big-endian), identical CRC values cannot be expected. Implementations performing such transformations may extend *cksum* to handle such situations.

EXAMPLES

None.

RATIONALE

The following C-language program can be used as a model to describe the algorithm. It assumes that a **char** is one octet. It also assumes that the entire file is available for one pass through the function. This was done for simplicity in demonstrating the algorithm, rather than as an implementation model.

0xa2f33668, 0xbcb4666d, 0xb8757bda, 0xb5365d03, 0xb1f740b4
};

unsigned long memcrc(const unsigned char *b, size_t n)
{
/*  Input arguments:
 *  const char*   b == byte sequence to checksum
 *  size_t        n == length of sequence
 */

    register unsigned   i, c, s = 0;

    for (i = n; i > 0; --i) {
        c = (unsigned)(*b++);
        s = (s << 8) ^ crctab[(s >> 24) ^ c];
    }

    /* Extend with the length of the string. */
    while (n != 0) {
        c = n & 0377;
        n >>= 8;
        s = (s << 8) ^ crctab[(s >> 24) ^ c];
    }

    return ~s;
}
```

The historical practice of writing the number of ‘‘blocks’’ has been changed to writing the number of octets, since the latter is not only more useful, but also since historical implementations have not been consistent in defining what a ‘‘block’’ meant. Octets are used instead of bytes because bytes can differ in size between systems.

The algorithm used was selected to increase the operational robustness of *cksum*. Neither the System V nor BSD *sum* algorithm was selected. Since each of these was different and each was the default behavior on those systems, no realistic compromise was available if either were selected—some set of historical applications would break. Therefore, the name was changed to *cksum*. Although the historical *sum* commands will probably continue to be provided for many years, programs designed for portability across systems should use the new name.

The algorithm selected is based on that used by the ISO / IEC 8802-3: 1996 standard (Ethernet) for the frame check sequence field. The algorithm used does not match the technical definition of a *checksum*; the term is used for historical reasons. The length of the file is included in the CRC calculation because this parallels inclusion of a length field by Ethernet in its CRC, but also because it guards against inadvertent collisions between files that begin with different series of zero octets. The chance that two different files produce identical CRCs is much greater when their lengths are not considered. Keeping the length and the checksum of the file itself separate would yield a slightly more robust algorithm, but historical usage has always been that a single number (the checksum as printed) represents the signature of the file. It was decided that historical usage was the more important consideration.

Early proposals contained modifications to the Ethernet algorithm that involved extracting table values whenever an intermediate result became zero. This was demonstrated to be less robust than the current method and mathematically difficult to describe or justify.

The calculation used is identical to that given in pseudo-code in the referenced Sarwate article. The pseudo-code rendition is:

```
X <– 0; Y <– 0;
for i <– m –1 step –1 until 0 do
    begin
    T <– X(1) ˆ A[i];
    X(1) <– X(0); X(0) <– Y(1); Y(1) <– Y(0); Y(0) <– 0;
    comment: f[T] and f’[T] denote the T-th words in the
        table f and f’ ;
    X <– X ˆ f[T]; Y <– Y ˆ f’[T];
    end
```

The pseudo-code is reproduced exactly as given; however, note that in the case of *cksum*, **A[i]** represents a byte of the file, the words **X** and **Y** are treated as a single 32-bit value, and the tables **f** and **f’** are a single table containing 32-bit values.

The referenced Sarwate article also discusses generating the table.

NAME

cmp — compare two files

SYNOPSIS

`cmp [ −l | −s ] file1 file2`

DESCRIPTION

The *cmp* utility shall compare two files. The *cmp* utility shall write no output if the files are the same. Under default options, if they differ, it shall write to standard output the byte and line number at which the first difference occurred. Bytes and lines shall be numbered beginning with 1.

OPTIONS

The *cmp* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−l	(Lowercase ell.) Write the byte number (decimal) and the differing bytes (octal) for each difference.
−s	Write nothing for differing files; return exit status only.

OPERANDS

The following operands shall be supported:

file1	A pathname of the first file to be compared. If *file1* is `'−'`, the standard input shall be used.
file2	A pathname of the second file to be compared. If *file2* is `'−'`, the standard input shall be used.

If both *file1* and *file2* refer to standard input or refer to the same FIFO special, block special, or character special file, the results are undefined.

STDIN

The standard input shall be used only if the *file1* or *file2* operand refers to standard input. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cmp*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

In the POSIX locale, results of the comparison shall be written to standard output. When no options are used, the format shall be:

```
"%s %s differ: char %d, line %d\n", file1, file2,
    <byte number>, <line number>
```

When the **–l** option is used, the format shall be:

```
"%d %o %o\n", <byte number>, <differing byte>,
    <differing byte>
```

for each byte that differs. The first <*differing byte*> number is from *file1* while the second is from *file2*. In both cases, <*byte number*> shall be relative to the beginning of the file, beginning with 1.

No output shall be written to standard output when the **–s** option is used.

STDERR

The standard error shall be used only for diagnostic messages. If *file1* and *file2* are identical for the entire length of the shorter file, in the POSIX locale the following diagnostic message shall be written, unless the **–s** option is specified:

```
"cmp: EOF on %s%s\n", <name of shorter file>, <additional info>
```

The <*additional info*> field shall either be null or a string that starts with a <blank> and contains no <newline>s. Some implementations report on the number of lines in this case.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The files are identical.
1	The files are different; this includes the case where one file is identical to the first part of the other.
>1	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Although input files to *cmp* can be any type, the results might not be what would be expected on character special device files or on file types not described by the System Interfaces volume of IEEE Std 1003.1-200x. Since this volume of IEEE Std 1003.1-200x does not specify the block size used when doing input, comparisons of character special files need not compare all of the data in those files.

For files which are not text files, line numbers simply reflect the presence of a <newline>, without any implication that the file is organized into lines.

EXAMPLES

None.

RATIONALE

The global language in Section 1.11 (on page 2221) indicates that using two mutually-exclusive options together produces unspecified results. Some System V implementations consider the option usage:

```
cmp -l -s ...
```

to be an error. They also treat:

```
cmp -s -l ...
```

as if no options were specified. Both of these behaviors are considered bugs, but are allowed.

The word **char** in the standard output format comes from historical usage, even though it is actually a byte number. When *cmp* is supported in other locales, implementations are encouraged to use the word *byte* or its equivalent in another language. Users should not interpret this difference to indicate that the functionality of the utility changed between locales.

Some implementations report on the number of lines in the identical-but-shorter file case. This is allowed by the inclusion of the <*additional info*> fields in the output format. The restriction on having a leading <blank> and no <newline>s is to make parsing for the filename easier. It is recognized that some filenames containing white-space characters make parsing difficult anyway, but the restriction does aid programs used on systems where the names are predominantly well behaved.

FUTURE DIRECTIONS

None.

SEE ALSO

comm, *diff*

CHANGE HISTORY

First released in Issue 2.

NAME

comm — select or reject lines common to two files

SYNOPSIS

```
comm [−123] file1 file2
```

DESCRIPTION

The *comm* utility shall read *file1* and *file2*, which should be ordered in the current collating sequence, and produce three text columns as output: lines only in *file1*, lines only in *file2*, and lines in both files.

If the lines in both files are not ordered according to the collating sequence of the current locale, the results are unspecified.

OPTIONS

The *comm* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−1	Suppress the output column of lines unique to *file1*.
−2	Suppress the output column of lines unique to *file2*.
−3	Suppress the output column of lines duplicated in *file1* and *file2*.

OPERANDS

The following operands shall be supported:

file1	A pathname of the first file to be compared. If *file1* is `'−'`, the standard input shall be used.
file2	A pathname of the second file to be compared. If *file2* is `'−'`, the standard input shall be used.

If both *file1* and *file2* refer to standard input or to the same FIFO special, block special, or character special file, the results are undefined.

STDIN

The standard input shall be used only if one of the *file1* or *file2* operands refers to standard input. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *comm*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the collating sequence *comm* expects to have been used when the input files were sorted.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in

arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *comm* utility shall produce output depending on the options selected. If the −**1**, −**2**, and −**3** options are all selected, *comm* shall write nothing to standard output.

If the −**1** option is not selected, lines contained only in *file1* shall be written using the format:

```
"%s\n", <line in file1>
```

If the −**2** option is not selected, lines contained only in *file2* are written using the format:

```
"%s%s\n", <lead>, <line in file2>
```

where the string <*lead*> is as follows:

<tab>	The −**1** option is not selected.
null string	The −**1** option is selected.

If the −**3** option is not selected, lines contained in both files shall be written using the format:

```
"%s%s\n", <lead>, <line in both>
```

where the string <*lead*> is as follows:

<tab><tab>	Neither the −**1** nor the −**2** option is selected.
<tab>	Exactly one of the −**1** and −**2** options is selected.
null string	Both the −**1** and −**2** options are selected.

If the input files were ordered according to the collating sequence of the current locale, the lines written shall be in the collating sequence of the original lines.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All input files were successfully output as specified.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If the input files are not properly presorted, the output of *comm* might not be useful.

EXAMPLES

If a file named **xcu** contains a sorted list of the utilities in this volume of IEEE Std 1003.1-200x, a file named **xpg3** contains a sorted list of the utilities specified in the X/Open Portability Guide, Issue 3, and a file named **svid89** contains a sorted list of the utilities in the System V Interface Definition Third Edition:

```
comm −23 xcu xpg3 | comm −23 − svid89
```

would print a list of utilities in this volume of IEEE Std 1003.1-200x not specified by either of the other documents:

```
comm −12 xcu xpg3 | comm −12 − svid89
```

would print a list of utilities specified by all three documents, and:

```
comm −12 xpg3 svid89 | comm −23 − xcu
```

would print a list of utilities specified by both XPG3 and the SVID, but not specified in this volume of IEEE Std 1003.1-200x.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

command — execute a simple command

SYNOPSIS

`command [−p] command_name [argument ...]`

UP `command [ −v | −V ] command_name`

DESCRIPTION

The *command* utility shall cause the shell to treat the arguments as a simple command, suppressing the shell function lookup that is described in Section 2.9.1.1 (on page 2249), item 1b.

If the *command_name* is the same as the name of one of the special built-in utilities, the special properties in the enumerated list at the beginning of Section 2.14 (on page 2266) shall not occur. In every other respect, if *command_name* is not the name of a function, the effect of *command* (with no options) shall be the same as omitting *command*.

On systems supporting the User Portability Utilities option, the *command* utility also shall provide information concerning how a command name is interpreted by the shell; see **−v** and **−V**.

OPTIONS

The *command* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−p Perform the command search using a default value for *PATH* that is guaranteed to find all of the standard utilities.

−v (On systems supporting the User Portability Utilities option.) Write a string to standard output that indicates the pathname or command that will be used by the shell, in the current shell execution environment (see Section 2.12 (on page 2263)), to invoke *command_name*, but do not invoke *command_name*.

- Utilities, regular built-in utilities, *command_name*s including a slash character, and any implementation-defined functions that are found using the *PATH* variable (as described in Section 2.9.1.1 (on page 2249)), shall be written as absolute pathnames.
- Shell functions, special built-in utilities, regular built-in utilities not associated with a *PATH* search, and shell reserved words shall be written as just their names.
- An alias shall be written as a command line that represents its alias definition.
- Otherwise, no output shall be written and the exit status shall reflect that the name was not found.

−V (On systems supporting the User Portability Utilities option.) Write a string to standard output that indicates how the name given in the *command_name* operand will be interpreted by the shell, in the current shell execution environment (see Section 2.12 (on page 2263)), but do not invoke *command_name*. Although the format of this string is unspecified, it shall indicate in which of the following categories *command_name* falls and shall include the information stated:

- Utilities, regular built-in utilities, and any implementation-defined functions that are found using the *PATH* variable (as described in Section 2.9.1.1 (on page 2249)), shall be identified as such and include the absolute pathname in the string.

- Other shell functions shall be identified as functions.
- Aliases shall be identified as aliases and their definitions included in the string.
- Special built-in utilities shall be identified as special built-in utilities.
- Regular built-in utilities not associated with a *PATH* search shall be identified as regular built-in utilities. (The term ''regular'' need not be used.)
- Shell reserved words shall be identified as reserved words.

OPERANDS

The following operands shall be supported:

argument	One of the strings treated as an argument to *command_name*.
command_name	The name of a utility or a special built-in utility.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *command*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PATH	Determine the search path used during the command search described in Section 2.9.1.1 (on page 2249), except as described under the −**p** option.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the −**v** option is specified, standard output shall be formatted as:

```
"%s\n", <pathname or command>
```

When the −**V** option is specified, standard output shall be formatted as:

```
"%s\n", <unspecified>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

When the −**v** or −**V** options are specified, the following exit values shall be returned:

0 Successful completion.

>0 The *command_name* could not be found or an error occurred.

Otherwise, the following exit values shall be returned:

126 The utility specified by *command_name* was found but could not be invoked.

127 An error occurred in the *command* utility or the utility specified by *command_name* could not be found.

Otherwise, the exit status of *command* shall be that of the simple command specified by the arguments to *command*.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The order for command search allows functions to override regular built-ins and path searches. This utility is necessary to allow functions that have the same name as a utility to call the utility (instead of a recursive call to the function).

The system default path is available using *getconf*; however, since *getconf* may need to have the *PATH* set up before it can be called itself, the following can be used:

```
command −p getconf _CS_PATH
```

There are some advantages to suppressing the special characteristics of special built-ins on occasion. For example:

```
command exec > unwritable-file
```

does not cause a non-interactive script to abort, so that the output status can be checked by the script.

The *command*, *env*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ‘‘failure to find a utility’’ from ‘‘invoked utility exited with an error indication’’. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ‘‘normal error conditions’’ and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

Since the −**v** and −**V** options of *command* produce output in relation to the current shell execution environment, *command* is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(PATH=foo command −v)
 nohup command −v
```

it does not necessarily produce correct results. For example, when called with *nohup* or an *exec* function, in a separate utility execution environment, most implementations are not able to identify aliases, functions, or special built-ins.

Two types of regular built-ins could be encountered on a system and these are described separately by *command*. The description of command search in Section 2.9.1.1 (on page 2249) allows for a standard utility to be implemented as a regular built-in as long as it is found in the appropriate place in a *PATH* search. So, for example, *command* −**v** *true* might yield **/bin/true** or some similar pathname. Other implementation-defined utilities that are not defined by this volume of IEEE Std 1003.1-200x might exist only as built-ins and have no pathname associated with them. These produce output identified as (regular) built-ins. Applications encountering these are not able to count on *exec*ing them, using them with *nohup*, overriding them with a different *PATH*, and so on.

EXAMPLES

1. Make a version of *cd* that always prints out the new working directory exactly once:

```
cd() {
    command cd "$@" >/dev/null
    pwd
}
```

2. Start off a ‘‘secure shell script’’ in which the script avoids being spoofed by its parent:

```
IFS='
'
#    The preceding value should be <space><tab><newline>.
#    Set IFS to its default value.

\unalias −a
#    Unset all possible aliases.
#    Note that unalias is escaped to prevent an alias
#    being used for unalias.

unset −f command
#    Ensure command is not a user function.

PATH="$(command −p getconf _CS_PATH):$PATH"
#    Put on a reliable PATH prefix.

#    ...
```

At this point, given correct permissions on the directories called by *PATH*, the script has the ability to ensure that any utility it calls is the intended one. It is being very cautious because it assumes that implementation extensions may be present that would allow user functions to exist when it is invoked; this capability is not specified by this volume of IEEE Std 1003.1-200x, but it is not prohibited as an extension. For example, the *ENV* variable precedes the invocation of the script with a user start-up script. Such a script could define functions to spoof the application.

RATIONALE

Since *command* is a regular built-in utility it is always found prior to the *PATH* search.

There is nothing in the description of *command* that implies the command line is parsed any differently from that of any other simple command. For example:

```
command a | b ; c
```

is not parsed in any special way that causes `'|'` or `';'` to be treated other than a pipe operator or semicolon or that prevents function lookup on **b** or **c**.

The *command* utility is somewhat similar to the Eighth Edition shell *builtin* command, but since *command* also goes to the file system to search for utilities, the name *builtin* would not be intuitive.

The *command* utility is most likely to be provided as a regular built-in. It is not listed as a special built-in for the following reasons:

- The removal of exportable functions made the special precedence of a special built-in unnecessary.
- A special built-in has special properties (see Section 2.14 (on page 2266)) that were inappropriate for invoking other utilities. For example, two commands such as:

  ```
  date > unwritable-file
  ```

  ```
  command date > unwritable-file
  ```

  would have entirely different results; in a non-interactive script, the former would continue to execute the next command, the latter would abort. Introducing this semantic difference along with suppressing functions was seen to be non-intuitive.

The −**p** option is present because it is useful to be able to ensure a safe path search that finds all the POSIX Shell and Utilities standard utilities. This search might not be identical to the one that occurs through one of the POSIX System Interfaces *exec* functions when *PATH* is unset. At the very least, this feature is required to allow the script to access the correct version of *getconf* so that the value of the default path can be accurately retrieved.

The *command* −**v** and −**V** options were added to satisfy requirements from users that are currently accomplished by three different historical utilities: *type* in the System V shell, *whence* in the KornShell, and *which* in the C shell. Since there is no historical agreement on how and what to accomplish here, the POSIX *command* utility was enhanced and the historical utilities were left unmodified. The C shell *which* merely conducts a path search. The KornShell *whence* is more elaborate—in addition to the categories required by POSIX, it also reports on tracked aliases, exported aliases, and undefined functions.

The output format of −**V** was left mostly unspecified because human users are its only audience. Applications should not be written to care about this information; they can use the output of −**v** to differentiate between various types of commands, but the additional information that may be emitted by the more verbose −**V** is not needed and should not be arbitrarily constrained in its verbosity or localization for application parsing reasons.

CHANGE HISTORY

First released in Issue 4.

NAME

compress — compress data

SYNOPSIS

XSI

```
compress [−fv][−b bits][file ...]

compress [−cfv][−b bits][file]
```

DESCRIPTION

The *compress* utility shall attempt to reduce the size of the named files by using adaptive Lempel-Ziv coding algorithm.

Note: Lempel-Ziv is US Patent 4464650, issued to William Eastman, Abraham Lempel, Jacob Ziv, Martin Cohn on August 7th, 1984, and assigned to Sperry Corporation. |

Lempel-Ziv-Welch compression is covered by US Patent 4558302, issued to Terry A. Welch on December 10th, 1985, and assigned to Sperry Corporation. |

On systems not supporting adaptive Lempel-Ziv coding algorithm, the input files shall not be changed and an error value greater than two shall be returned. Except when the output is to the standard output, each file shall be replaced by one with the extension **.Z**. If the invoking process has appropriate privileges, the ownership, modes, access time, and modification time of the original file are preserved. If appending the **.Z** to the filename would make the name exceed {NAME_MAX} bytes, the command shall fail. If no files are specified, the standard input shall be compressed to the standard output.

OPTIONS

The *compress* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−b *bits* Specify the maximum number of bits to use in a code. For a conforming application, the *bits* argument shall be: |

`9 <= bits <= 14`

The implementation may allow *bits* values of greater than 14. The default is 14, 15, or 16.

−c Cause *compress* to write to the standard output; the input file is not changed, and no **.Z** files are created.

−f Force compression of *file*, even if it does not actually reduce the size of the file, or if the corresponding *file*.**Z** file already exists. If the −**f** option is not given, and the process is not running in the background, the user is prompted as to whether an existing *file*.**Z** file should be overwritten.

−v Write the percentage reduction of each file to standard error.

OPERANDS

The following operand shall be supported:

file A pathname of a file to be compressed.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`.

INPUT FILES

If *file* operands are specified, the input files contain the data to be compressed.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *compress*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If no *file* operands are specified, or if a *file* operand is **'−'**, or if the −**c** option is specified, the standard output contains the compressed output.

STDERR

The standard error shall be used only for diagnostic and prompt messages and the output from −**v**.

OUTPUT FILES

The output files shall contain the compressed output. The format of compressed files is unspecified and interchange of such files between implementations (including access via unspecified file sharing mechanisms) is not required by IEEE Std 1003.1-200x.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
1	An error occurred.
2	One or more files were not compressed because they would have increased in size (and the −**f** option was not specified).
>2	An error occurred.

CONSEQUENCES OF ERRORS

The input file shall remain unmodified.

APPLICATION USAGE

The amount of compression obtained depends on the size of the input, the number of *bits* per code, and the distribution of common substrings. Typically, text such as source code or English is reduced by 50-60%. Compression is generally much better than that achieved by Huffman coding or adaptive Huffman coding (*compact*), and takes less time to compute.

Although *compress* strictly follows the default actions upon receipt of a signal or when an error occurs, some unexpected results may occur. In some implementations it is likely that a partially compressed file is left in place, alongside its uncompressed input file. Since the general operation of *compress* is to delete the uncompressed file only after the **.Z** file has been successfully filled, an application should always carefully check the exit status of *compress* before arbitrarily deleting files that have like-named neighbors with **.Z** suffixes.

The limit of 14 on the *bits* option-argument is to achieve portability to all systems (within the restrictions imposed by the lack of an explicit published file format). Some implementations based on 16-bit architectures cannot support 15 or 16-bit uncompression. |

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

An error case is added for systems not supporting adaptive Lempel-Ziv coding.

NAME

cp — copy files

SYNOPSIS

```
cp [-fip] source_file target_file

cp [-fip] source_file ... target

cp -R [-H | -L | -P][-fip] source_file ... target

OB  cp -r [-H | -L | -P][-fip] source_file ... target
```

DESCRIPTION

The first synopsis form is denoted by two operands, neither of which are existing files of type directory. The *cp* utility shall copy the contents of *source_file* (or, if *source_file* is a file of type symbolic link, the contents of the file referenced by *source_file*) to the destination path named by *target_file*.

The second synopsis form is denoted by two or more operands where the –**R** or –**r** options are not specified and the first synopsis form is not applicable. It shall be an error if any *source_file* is a file of type directory, if *target* does not exist, or if *target* is a file of a type defined by the System Interfaces volume of IEEE Std 1003.1-200x, but is not a file of type directory. The *cp* utility shall copy the contents of each *source_file* (or, if *source_file* is a file of type symbolic link, the contents of the file referenced by *source_file*) to the destination path named by the concatenation of *target*, a slash character, and the last component of *source_file*.

The third and fourth synopsis forms are denoted by two or more operands where the –**R** or –**r** options are specified. The *cp* utility shall copy each file in the file hierarchy rooted in each *source_file* to a destination path named as follows:

- If *target* exists and is a file of type directory, the name of the corresponding destination path for each file in the file hierarchy shall be the concatenation of *target*, a slash character, and the pathname of the file relative to the directory containing *source_file*.
- If *target* does not exist and two operands are specified, the name of the corresponding destination path for *source_file* shall be *target*; the name of the corresponding destination path for all other files in the file hierarchy shall be the concatenation of *target*, a slash character, and the pathname of the file relative to *source_file*.

It shall be an error if *target* does not exist and more than two operands are specified, or if *target* exists and is a file of a type defined by the System Interfaces volume of IEEE Std 1003.1-200x, but is not a file of type directory.

In the following description, the term *dest_file* refers to the file named by the destination path. The term *source_file* refers to the file that is being copied, whether specified as an operand or a file in a file hierarchy rooted in a *source_file* operand. If *source_file* is a file of type symbolic link:

- If neither the –**R** nor –**r** options were specified, *cp* shall take actions based on the type and contents of the file referenced by the symbolic link, and not by the symbolic link itself.
- If the –**R** option was specified:
  - — If none of the options –**H**, –**L**, nor –**P** were specified, it is unspecified which of –**H**, –**L**, or –**P** will be used as a default.
  - — If the –**H** option was specified, *cp* shall take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand.
  - — If the –**L** option was specified, *cp* shall take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand or any symbolic

links encountered during traversal of a file hierarchy.

  - If the −**P** option was specified, *cp* shall copy any symbolic link specified as a *source_file* operand and any symbolic links encountered during traversal of a file hierarchy, and shall not follow any symbolic links.

- If the −**r** option was specified, the behavior is implementation-defined.

For each *source_file*, the following steps shall be taken:

1. If *source_file* references the same file as *dest_file*, *cp* may write a diagnostic message to standard error; it shall do nothing more with *source_file* and shall go on to any remaining files.

2. If *source_file* is of type directory, the following steps shall be taken:

   a. If neither the −**R** or −**r** options were specified, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

   b. If *source_file* was not specified as an operand and *source_file* is dot or dot-dot, *cp* shall do nothing more with *source_file* and go on to any remaining files.

   c. If *dest_file* exists and it is a file type not specified by the System Interfaces volume of IEEE Std 1003.1-200x, the behavior is implementation-defined.

   d. If *dest_file* exists and it is not of type directory, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file* or any files below *source_file* in the file hierarchy, and go on to any remaining files.

   e. If the directory *dest_file* does not exist, it shall be created with file permission bits set to the same value as those of *source_file*, modified by the file creation mask of the user if the −**p** option was not specified, and then bitwise-inclusively OR'ed with S_IRWXU. If *dest_file* cannot be created, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files. It is unspecified if *cp* attempts to copy files in the file hierarchy rooted in *source_file*.

   f. The files in the directory *source_file* shall be copied to the directory *dest_file*, taking the four steps (1 to 4) listed here with the files as *source_file*s.

   g. If *dest_file* was created, its file permission bits shall be changed (if necessary) to be the same as those of *source_file*, modified by the file creation mask of the user if the −**p** option was not specified.

   h. The *cp* utility shall do nothing more with *source_file* and go on to any remaining files.

3. If *source_file* is of type regular file, the following steps shall be taken:

   a. If *dest_file* exists, the following steps shall be taken:

      i. If the −**i** option is in effect, the *cp* utility shall write a prompt to the standard error and read a line from the standard input. If the response is not affirmative, *cp* shall do nothing more with *source_file* and go on to any remaining files.

      ii. A file descriptor for *dest_file* shall be obtained by performing actions equivalent to the *open*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x called using *dest_file* as the *path* argument, and the bitwise-inclusive OR of O_WRONLY and O_TRUNC as the *oflag* argument.

      iii. If the attempt to obtain a file descriptor fails and the −**f** option is in effect, *cp* shall attempt to remove the file by performing actions equivalent to the *unlink*( ) function defined in the System Interfaces volume of

IEEE Std 1003.1-200x called using *dest_file* as the *path* argument. If this attempt succeeds, *cp* shall continue with step 3b.

b. If *dest_file* does not exist, a file descriptor shall be obtained by performing actions equivalent to the *open*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x called using *dest_file* as the *path* argument, and the bitwise-inclusive OR of O_WRONLY and O_CREAT as the *oflag* argument. The file permission bits of *source_file* shall be the *mode* argument.

c. If the attempt to obtain a file descriptor fails, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

d. The contents of *source_file* shall be written to the file descriptor. Any write errors shall cause *cp* to write a diagnostic message to standard error and continue to step 3e.

e. The file descriptor shall be closed.

f. The *cp* utility shall do nothing more with *source_file*. If a write error occurred in step 3d, it is unspecified if *cp* continues with any remaining files. If no write error occurred in step 3d, *cp* shall go on to any remaining files.

4. Otherwise, the following steps shall be taken:

   a. If the **–r** option was specified, the behavior is implementation-defined.

   b. If the **–R** option was specified, the following steps shall be taken:

      i. The *dest_file* shall be created with the same file type as *source_file*.

      ii. If *source_file* is a file of type FIFO, the file permission bits shall be the same as those of *source_file*, modified by the file creation mask of the user if the **–p** option was not specified. Otherwise, the permissions, owner ID, and group ID of *dest_file* are implementation-defined.

      If this creation fails for any reason, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

      iii. If *source_file* is a file of type symbolic link, the pathname contained in *dest_file* shall be the same as the pathname contained in *source_file*.

      If this fails for any reason, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

If the implementation provides additional or alternate access control mechanisms (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.4, File Access Permissions), their effect on copies of files is implementation-defined.

OPTIONS

The *cp* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–f If a file descriptor for a destination file cannot be obtained, as described in step 3.a.ii., attempt to unlink the destination file and proceed.

–H Take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand.

–i Write a prompt to standard error before copying to any existing destination file. If the response from the standard input is affirmative, the copy shall be attempted;

otherwise, it shall not.

–L Take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand or any symbolic links encountered during traversal of a file hierarchy.

–P Take actions on any symbolic link specified as a *source_file* operand or any symbolic link encountered during traversal of a file hierarchy.

–p Duplicate the following characteristics of each source file in the corresponding destination file:

1. The time of last data modification and time of last access. If this duplication fails for any reason, *cp* shall write a diagnostic message to standard error.
2. The user ID and group ID. If this duplication fails for any reason, it is unspecified whether *cp* writes a diagnostic message to standard error.
3. The file permission bits and the S_ISUID and S_ISGID bits. Other, implementation-defined, bits may be duplicated as well. If this duplication fails for any reason, *cp* shall write a diagnostic message to standard error.

If the user ID or the group ID cannot be duplicated, the file permission bits S_ISUID and S_ISGID shall be cleared. If these bits are present in the source file but are not duplicated in the destination file, it is unspecified whether *cp* writes a diagnostic message to standard error.

The order in which the preceding characteristics are duplicated is unspecified. The *dest_file* shall not be deleted if these characteristics cannot be preserved.

–R Copy file hierarchies.

OB **–r** Copy file hierarchies. The treatment of special files is implementation-defined.

Specifying more than one of the mutually-exclusive options **–H**, **–L**, and **–P** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operands shall be supported:

source_file A pathname of a file to be copied.

target_file A pathname of an existing or nonexistent file, used for the output when a single file is copied.

target A pathname of a directory to contain the copied files.

STDIN

The standard input shall be used to read an input line in response to each prompt specified in the STDERR section. Otherwise, the standard input shall not be used.

INPUT FILES

The input files specified as operands may be of any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cp*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.
LC_MESSAGES	Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

A prompt shall be written to standard error under the conditions specified in the DESCRIPTION section. The prompt shall contain the destination pathname, but its format is otherwise unspecified. Otherwise, the standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files may be of any type.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All files were copied successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

If *cp* is prematurely terminated by a signal or error, files or file hierarchies may be only partially copied and files and directories may have incorrect permissions or access and modification times.

APPLICATION USAGE

The difference between −**R** and −**r** is in the treatment by *cp* of file types other than regular and directory. The original −**r** flag, for historic reasons, does not handle special files any differently from regular files, but always reads the file and copies its contents. This has obvious problems in the presence of special file types; for example, character devices, FIFOs, and sockets. The −**R** option is intended to recreate the file hierarchy and the −**r** option supports historical practice. It was anticipated that a future version of this volume of IEEE Std 1003.1-200x would deprecate the −**r** option, and for that reason, there has been no attempt to fix its behavior with respect to FIFOs or other file types where copying the file is clearly wrong. However, some implementations support −**r** with the same abilities as the −**R** defined in this volume of IEEE Std 1003.1-200x. To accommodate them as well as systems that do not, the differences between −**r** and −**R** are implementation-defined. Implementations may make them identical. The −**r** option is now marked obsolescent.

The set-user-ID and set-group-ID bits are explicitly cleared when files are created. This is to prevent users from creating programs that are set-user-ID or set-group-ID to them when copying files or to make set-user-ID or set-group-ID files accessible to new groups of users. For example, if a file is set-user-ID and the copy has a different group ID than the source, a new group of users has execute permission to a set-user-ID program than did previously. In particular, this is a problem for superusers copying users' trees.

EXAMPLES

None.

RATIONALE

The −**i** option exists on BSD systems, giving applications and users a way to avoid accidentally removing files when copying. Although the 4.3 BSD version does not prompt if the standard input is not a terminal, the standard developers decided that use of −**i** is a request for interaction, so when the destination path exists, the utility takes instructions from whatever responds on standard input.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application using the −**i** option relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

The −**p** option is historical practice on BSD systems, duplicating the time of last data modification and time of last access. This volume of IEEE Std 1003.1-200x extends it to preserve the user and group IDs, as well as the file permissions. This requirement has obvious problems in that the directories are almost certainly modified after being copied. This volume of IEEE Std 1003.1-200x requires that the modification times be preserved. The statement that the order in which the characteristics are duplicated is unspecified is to permit implementations to provide the maximum amount of security for the user. Implementations should take into account the obvious security issues involved in setting the owner, group, and mode in the wrong order or creating files with an owner, group, or mode different from the final value.

It is unspecified whether *cp* writes diagnostic messages when the user and group IDs cannot be set due to the widespread practice of users using −**p** to duplicate some portion of the file characteristics, indifferent to the duplication of others. Historic implementations only write diagnostic messages on errors other than [EPERM].

The −**r** option is historical practice on BSD and BSD-derived systems, copying file hierarchies as opposed to single files. This functionality is used heavily in historical applications, and its loss would significantly decrease consensus. The −**R** option was added as a close synonym to the −**r** option, selected for consistency with all other options in this volume of IEEE Std 1003.1-200x that do recursive directory descent.

When a failure occurs during the copying of a file hierarchy, *cp* is required to attempt to copy files that are on the same level in the hierarchy or above the file where the failure occurred. It is unspecified if *cp* shall attempt to copy files below the file where the failure occurred (which cannot succeed in any case).

Permissions, owners, and groups of created special file types have been deliberately left as implementation-defined. This is to allow systems to satisfy special requirements (for example, allowing users to create character special devices, but requiring them to be owned by a certain group). In general, it is strongly suggested that the permissions, owner, and group be the same as if the user had run the historical *mknod*, *ln*, or other utility to create the file. It is also probable that additional privileges are required to create block, character, or other implementation-defined special file types.

Additionally, the −**p** option explicitly requires that all set-user-ID and set-group-ID permissions be discarded if any of the owner or group IDs cannot be set. This is to keep users from unintentionally giving away special privilege when copying programs.

When creating regular files, historical versions of *cp* use the mode of the source file as modified by the file mode creation mask. Other choices would have been to use the mode of the source file unmodified by the creation mask or to use the same mode as would be given to a new file created by the user (plus the execution bits of the source file) and then modify it by the file mode creation mask. In the absence of any strong reason to change historic practice, it was in large part retained.

When creating directories, historical versions of *cp* use the mode of the source directory, plus read, write, and search bits for the owner, as modified by the file mode creation mask. This is done so that *cp* can copy trees where the user has read permission, but the owner does not. A side effect is that if the file creation mask denies the owner permissions, *cp* fails. Also, once the copy is done, historical versions of *cp* set the permissions on the created directory to be the same as the source directory, unmodified by the file creation mask.

This behavior has been modified so that *cp* is always able to create the contents of the directory, regardless of the file creation mask. After the copy is done, the permissions are set to be the same as the source directory, as modified by the file creation mask. This latter change from historical behavior is to prevent users from accidentally creating directories with permissions beyond those they would normally set and for consistency with the behavior of *cp* in creating files.

It is not a requirement that *cp* detect attempts to copy a file to itself; however, implementations are strongly encouraged to do so. Historical implementations have detected the attempt in most cases.

There are two methods of copying subtrees in this volume of IEEE Std 1003.1-200x. The other method is described as part of the *pax* utility (see *pax* (on page 2900)). Both methods are historical practice. The *cp* utility provides a simpler, more intuitive interface, while *pax* offers a finer granularity of control. Each provides additional functionality to the other; in particular, *pax* maintains the hard-link structure of the hierarchy, while *cp* does not. It is the intention of the standard developers that the results be similar (using appropriate option combinations in both utilities). The results are not required to be identical; there seemed insufficient gain to applications to balance the difficulty of implementations having to guarantee that the results would be exactly identical.

The wording allowing *cp* to copy a directory to implementation-defined file types not specified by the System Interfaces volume of IEEE Std 1003.1-200x is provided so that implementations supporting symbolic links are not required to prohibit copying directories to symbolic links. Other extensions to the System Interfaces volume of IEEE Std 1003.1-200x file types may need to use this loophole as well.

FUTURE DIRECTIONS

The –**r** option may be removed; use –**R** instead.

SEE ALSO

mv, *find*, *ln*, *pax*

CHANGE HISTORY

First released in Issue 2.

Issue 6

The –**r** option is marked obsolescent.

The new options –**H**, –**L**, and –**P** are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

IEEE PASC Interpretation 1003.2 #194 is applied, adding a description of the –**P** option.

NAME

crontab — schedule periodic background work

SYNOPSIS

UP
```
crontab [file]

crontab [ −e | −l | −r ]
```

DESCRIPTION

The *crontab* utility shall create, replace, or edit a user's *crontab* entry; a crontab entry is a list of commands and the times at which they shall be executed. The new crontab entry can be input by specifying *file* or input from standard input if no *file* operand is specified, or by using an editor, if **−e** is specified.

Upon execution of a command from a crontab entry, the implementation shall supply a default environment, defining at least the following environment variables:

HOME	A pathname of the user's home directory.
LOGNAME	The user's login name.
PATH	A string representing a search path guaranteed to find all of the standard utilities.
SHELL	A pathname of the command interpreter. When *crontab* is invoked as specified by this volume of IEEE Std 1003.1-200x, the value shall be a pathname for *sh*.

The values of these variables when *crontab* is invoked as specified by this volume of IEEE Std 1003.1-200x shall not affect the default values provided when the scheduled command is run.

If standard output and standard error are not redirected by commands executed from the crontab entry, any generated output or errors shall be mailed, via an implementation-defined method, to the user.

XSI Users shall be permitted to use *crontab* if their names appear in the file **/usr/lib/cron/cron.allow**. If that file does not exist, the file **/usr/lib/cron/cron.deny** shall be checked to determine whether the user shall be denied access to *crontab*. If neither file exists, only a process with appropriate privileges shall be allowed to submit a job. If only **cron.deny** exists and is empty, global usage shall be permitted. The **cron.allow** and **cron.deny** files shall consist of one user name per line.

OPTIONS

The *crontab* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−e	Edit a copy of the invoking user's crontab entry, or create an empty entry to edit if the crontab entry does not exist. When editing is complete, the entry shall be installed as the user's crontab entry.
−l	(The letter ell.) List the invoking user's crontab entry.
−r	Remove the invoking user's crontab entry.

OPERANDS

The following operand shall be supported:

file	The pathname of a file that contains specifications, in the format defined in the INPUT FILES section, for crontab entries.

STDIN

See the INPUT FILES section.

INPUT FILES

In the POSIX locale, the user or application shall ensure that a crontab entry is a text file consisting of lines of six fields each. The fields shall be separated by <blank>s. The first five fields shall be integer patterns that specify the following:

1. Minute [0,59]
2. Hour [0,23]
3. Day of the month [1,31]
4. Month of the year [1,12]
5. Day of the week ([0,6] with 0=Sunday)

Each of these patterns can be either an asterisk (meaning all valid values), an element, or a list of elements separated by commas. An element shall be either a number or two numbers separated by a hyphen (meaning an inclusive range). The specification of days can be made by two fields (day of the month and day of the week). If month, day of month, and day of week are all asterisks, every day shall be matched. If either the month or day of month is specified as an element or list, but the day of week is an asterisk, the month and day of month fields shall specify the days that match. If both month and day of month are specified as asterisk, but day of week is an element or list, then only the specified days of the week match. Finally, if either the month or day of month is specified as an element or list, and the day of week is also specified as an element or list, then any day matching either the month and day of month, or the day of week, shall be matched.

The sixth field of a line in a crontab entry is a string that shall be executed by *sh* at the specified times. A percent sign character in this field shall be translated to a <newline>. Any character preceded by a backslash (including the '%') shall cause that character to be treated literally. Only the first line (up to a '%' or end-of-line) of the command field shall be executed by the command interpreter. The other lines shall be made available to the command as standard input.

Blank lines and those whose first non-<blank> is '#' shall be ignored.

XSI The text files **/usr/lib/cron/cron.allow** and **/usr/lib/cron/cron.deny** shall contain zero or more user names, one per line, of users who are, respectively, authorized or denied access to the service underlying the *crontab* utility.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *crontab*:

EDITOR Determine the editor to be invoked when the **−e** option is specified. The default editor shall be *vi*.

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the **−l** option is specified, the crontab entry shall be written to the standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

The user's crontab entry is not submitted, removed, edited, or listed.

APPLICATION USAGE

The format of the *crontab* entry shown here is guaranteed only for the POSIX locale. Other cultures may be supported with substantially different interfaces, although implementations are encouraged to provide comparable levels of functionality.

The default settings of the *HOME*, *LOGNAME*, *PATH*, and *SHELL* variables that are given to the scheduled job are not affected by the settings of those variables when *crontab* is run; as stated, they are defaults. The text about ''invoked as specified by this volume of IEEE Std 1003.1-200x'' means that the implementation may provide extensions that allow these variables to be affected at runtime, but that the user has to take explicit action in order to access the extension, such as give a new option flag or modify the format of the crontab entry.

A typical user error is to type only *crontab*; this causes the system to wait for the new crontab entry on standard input. If end-of-file is typed (generally <control>-D), the crontab entry is replaced by an empty file. In this case, the user should type the interrupt character, which prevents the crontab entry from being replaced.

EXAMPLES

1. Clean up **core** files every weekday morning at 3:15 am:

```
15 3 * * 1-5 find $HOME −name core 2>/dev/null | xargs rm −f
```

2. Mail a birthday greeting:

```
0 12 14 2 * mailx john%Happy Birthday!%Time for lunch.
```

3. As an example of specifying the two types of days:

```
0 0 1,15 * 1
```

would run a command on the first and fifteenth of each month, as well as on every Monday. To specify days by only one field, the other field should be set to `'*'`; for example:

```
0 0 * * 1
```

would run a command only on Mondays.

RATIONALE

All references to a *cron* daemon and to *cron files* have been omitted. Although historical implementations have used this arrangement, there is no reason to limit future implementations.

This description of *crontab* is designed to support only users with normal privileges. The format of the input is based on the System V *crontab*; however, there is no requirement here that the actual system database used by the *cron* daemon (or a similar mechanism) use this format internally. For example, systems derived from BSD are likely to have an additional field appended that indicates the user identity to be used when the job is submitted.

The −**e** option was adopted from the SVID as a user convenience, although it does not exist in all historical implementations.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

csplit — split files based on context

SYNOPSIS

UP
```
csplit [−ks][−f prefix][−n number] file arg1 ...argn
```

DESCRIPTION

The *csplit* utility shall read the file named by the *file* operand, write all or part of that file into other files as directed by the *arg* operands, and write the sizes of the files.

OPTIONS

The *csplit* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−f *prefix*	Name the created files *prefix***00**, *prefix***01**, . . ., *prefixn*. The default is **xx00** . . . **xx***n*. If the *prefix* argument would create a filename exceeding {NAME_MAX} bytes, an error shall result, *csplit* shall exit with a diagnostic message and no files shall be created.
−k	Leave previously created files intact. By default, *csplit* shall remove created files if an error occurs.
−n *number*	Use *number* decimal digits to form filenames for the file pieces. The default shall be 2.
−s	Suppress the output of file size messages.

OPERANDS

The following operands shall be supported:

file	The pathname of a text file to be split. If *file* is '−', the standard input shall be used.

The operands *arg1* . . . *argn* can be a combination of the following:

/*rexp*/**[***offset***]**	A file shall be created using the content of the lines from the current line up to, but not including, the line that results from the evaluation of the regular expression with *offset*, if any, applied. The regular expression *rexp* shall follow the rules for basic regular expressions described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions. The application shall use the sequence "\/" to specify a slash character within the *rexp*. The optional offset shall be a positive or negative integer value representing a number of lines. A positive integer value can be preceded by '+'. If the selection of lines from an *offset* expression of this type would create a file with zero lines, or one with greater than the number of lines left in the input file, the results are unspecified. After the section is created, the current line shall be set to the line that results from the evaluation of the regular expression with any offset applied. If the current line is the first line in the file and a regular expression operation has not yet been performed, the pattern match of *rexp* shall be applied from the current line to the end of the file. Otherwise, the pattern match of *rexp* shall be applied from the line following the current line to the end of the file.
%*rexp*%**[***offset***]**	Equivalent to /*rexp*/**[***offset***]**, except that no file shall be created for the selected section of the input file. The application shall use the sequence "\%" to specify a

percent-sign character within the *rexp*.

line_no	Create a file from the current line up to (but not including) the line number *line_no*. Lines in the file shall be numbered starting at one. The current line becomes *line_no*.
{*num*}	Repeat operand. This operand can follow any of the operands described previously. If it follows a *rexp* type operand, that operand shall be applied *num* more times. If it follows a *line_no* operand, the file shall be split every *line_no* lines, *num* times, from that point.

An error shall be reported if an operand does not reference a line between the current position and the end of the file.

STDIN

See the INPUT FILES section.

INPUT FILES

The input file shall be a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *csplit*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

If the −**k** option is specified, created files shall be retained. Otherwise, the default action occurs.

STDOUT

Unless the −**s** option is used, the standard output shall consist of one line per file created, with a format as follows:

```
"%d\n", <file size in bytes>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files shall contain portions of the original input file; otherwise, unchanged.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

By default, created files shall be removed if an error occurs. When the −**k** option is specified, created files shall not be removed if an error occurs.

APPLICATION USAGE

None.

EXAMPLES

1. This example creates four files, **cobol00** . . . **cobol03**:

   ```
   csplit −f cobol file ’/procedure division/’ /par5./ /par16./
   ```

   After editing the split files, they can be recombined as follows:

   ```
   cat cobol0[0−3] > file
   ```

   Note that this example overwrites the original file.

2. This example would split the file after the first 99 lines, and every 100 lines thereafter, up to 9 999 lines; this is because lines in the file are numbered from 1 rather than zero, for historical reasons:

   ```
   csplit −k file  100  {99}
   ```

3. Assuming that **prog.c** follows the C-language coding convention of ending routines with a `’}’` at the beginning of the line, this example creates a file containing each separate C routine (up to 21) in **prog.c**:

   ```
   csplit −k prog.c ’%main(%’  ’/ˆ}/+1’ {20}
   ```

RATIONALE

The −**n** option was added to extend the range of filenames that could be handled.

Consideration was given to adding a −**a** flag to use the alphabetic filename generation used by the historical *split* utility, but the functionality added by the −**n** option was deemed to make alphabetic naming unnecessary.

FUTURE DIRECTIONS

None.

SEE ALSO

sed, *split*

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The description of regular expression operands is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

ctags — create a tags file (**DEVELOPMENT**, **FORTRAN**)

SYNOPSIS

UP
```
ctags [−a][−f tagsfile] pathname ...

ctags −x pathname ...
```

DESCRIPTION

The *ctags* utility shall be provided on systems that support the User Portability Utilities option, the Software Development Utilities option, and either or both of the C-Language Development Utilities option and FORTRAN Development Utilities option. On other systems, it is optional.

The *ctags* utility shall write a *tags* file or an index of objects from C-language or FORTRAN source files specified by the *pathname* operands. The tags file shall list the locators of language-specific objects within the source files. A locator consists of a name, pathname, and either a search pattern or a line number that can be used in searching for the object definition. The objects that shall be recognized are specified in the EXTENDED DESCRIPTION section.

OPTIONS

The *ctags* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−a	Append to tags file.
−f *tagsfile*	Write the object locator lists into *tagsfile* instead of the default file named **tags** in the current directory.
−x	Produce a list of object names, the line number, and filename in which each is defined, as well as the text of that line, and write this to the standard output. A **tags** file shall not be created when **−x** is specified.

OPERANDS

The following *pathname* operands are supported:

file.**c**	Files with basenames ending with the **.c** suffix shall be treated as C-language source code. Such files that are not valid input to *c99* produce unspecified results.
file.**h**	Files with basenames ending with the **.h** suffix shall be treated as C-language source code. Such files that are not valid input to *c99* produce unspecified results.
file.**f**	Files with basenames ending with the **.f** suffix shall be treated as FORTRAN-language source code. Such files that are not valid input to *fort77* produce unspecified results.

The handling of other files is implementation-defined.

STDIN

See the INPUT FILES section.

INPUT FILES

The input files shall be text files containing source code in the language indicated by the operand filename suffixes.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ctags*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the order in which output is sorted for the −**x** option. The POSIX locale determines the order in which the tags file is written.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). When processing C-language source code, if the locale is not compatible with the C locale described by the ISO C standard, the results are unspecified.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The list of object name information produced by the −**x** option shall be written to standard output in the following format:

```
"%s %d %s %s", <object-name>, <line-number>, <filename>,
    <text>
```

where <*text*> is the text of line <*line-number*> of file <*filename*>.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

When the −**x** option is not specified, the format of the output file shall be:

```
"%s\t%s\t/%s/\n", <identifier>, <filename>, <pattern>
```

where <*pattern*> is a search pattern that could be used by an editor to find the defining instance of <*identifier*> in <*filename*> (where *defining instance* is indicated by the declarations listed in the EXTENDED DESCRIPTION).

An optional circumflex ('^') can be added as a prefix to <*pattern*>, and an optional dollar sign can be appended to <*pattern*> to indicate that the pattern is anchored to the beginning (end) of a line of text. Any slash or backslash characters in <*pattern*> shall be preceded by a backslash character. The anchoring circumflex, dollar sign, and escaping backslash characters shall not be considered part of the search pattern. All other characters in the search pattern shall be considered literal characters.

An alternative format is:

```
"%s\t%s\t?%s?\n", <identifier>, <filename>, <pattern>
```

which is identical to the first format except that slashes in <*pattern*> shall not be preceded by escaping backslash characters, and question mark characters in <*pattern*> shall be preceded by backslash characters.

A second alternative format is:

```
"%s\t%s\t%d\n", <identifier>, <filename>, <lineno>
```

where <*lineno*> is a decimal line number that could be used by an editor to find <*identifier*> in <*filename*>.

Neither alternative format shall be produced by *ctags* when it is used as described by IEEE Std 1003.1-200x, but the standard utilities that process tags files shall be able to process those formats as well as the first format.

In any of these formats, the file shall be sorted by identifier, based on the collation sequence in the POSIX locale.

EXTENDED DESCRIPTION

If the operand identifies C-language source, the *ctags* utility shall attempt to produce an output line for each of the following objects:

- Function definitions
- Type definitions
- Macros with arguments

It may also produce output for any of the following objects:

- Function prototypes
- Structures
- Unions
- Global variable definitions
- Enumeration types
- Macros without arguments
- **#define** statements
- **#line** statements

Any **#if** and **#ifdef** statements shall produce no output. The tag **main** is treated specially in C programs. The tag formed shall be created by prefixing **M** to the name of the file, with the trailing **.c**, and leading pathname components (if any) removed.

On systems that do not support the C-Language Development Utilities option, *ctags* produces undefined results for C-language source code files. It should write to standard error a message identifying this condition and cause a non-zero exit status to be produced.

If the operand identifies FORTRAN source, the *ctags* utility shall produce an output line for each function definition. It may also produce output for any of the following objects:

- Subroutine definitions
- COMMON statements
- PARAMETER statements

- DATA and BLOCK DATA statements
- Statement numbers

On systems that do not support the FORTRAN Development Utilities option, *ctags* produces unspecified results for FORTRAN source code files. It should write to standard error a message identifying this condition and cause a non-zero exit status to be produced.

It is implementation-defined what other objects (including duplicate identifiers) produce output.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The output with **–x** is meant to be a simple index that can be written out as an off-line readable function index. If the input files to *ctags* (such as **.c** files) were not created using the same locale as that in effect when *ctags* **–x** is run, results might not be as expected.

The description of C-language processing says ‘‘attempts to’’ because the C language can be greatly confused, especially through the use of **#define**s, and this utility would be of no use if the real C preprocessor were run to identify them. The output from *ctags* may be fooled and incorrect for various constructs.

EXAMPLES

None.

RATIONALE

The option list was significantly reduced from that provided by historical implementations. The **–F** option was omitted as redundant, since it is the default. The **–B** option was omitted as being of very limited usefulness. The **–t** option was omitted since the recognition of typedefs is now required for C source files. The **–u** option was omitted because the update function was judged to be not only inefficient, but also rarely needed.

An early proposal included a **–w** option to suppress warning diagnostics. Since the types of such diagnostics could not be described, the option was omitted as being not useful.

The text for *LC_CTYPE* about compatibility with the C locale acknowledges that the ISO C standard imposes requirements on the locale used to process C source. This could easily be a superset of that known as ‘‘the C locale’’ by way of implementation extensions, or one of a few alternative locales for systems supporting different codesets. No statement is made for FORTRAN because the ANSI X3.9-1978 standard (FORTRAN 77) does not (yet) define a similar locale concept. However, a general rule in this volume of IEEE Std 1003.1-200x is that any time that locales do not match (preparing a file for one locale and processing it in another), the results are suspect.

The collation sequence of the tags file is not affected by *LC_COLLATE* because it is typically not used by human readers, but only by programs such as *vi* to locate the tag within the source files. Using the POSIX locale eliminates some of the problems of coordinating locales between the *ctags* file creator and the *vi* file reader.

Historically, the tags file has been used only by *ex* and *vi*. However, the format of the tags file has been published to encourage other programs to use the tags in new ways. The format allows either patrerns or line numbers to find the identifiers because the historical *vi* recognizes either.

The *ctags* utility does not produce the format using line numbers because it is not useful following any source file changes that add or delete lines. The documented search patterns match historical practice. It should be noted that literal leading circumflex or trailing dollar-sign characters in the search pattern will only behave correctly if anchored to the beginning of the line or end of the line by an additional circumflex or dollar-sign character.

Historical implementations also understand the objects used by the languages Pascal and sometimes LISP, and they understand the C source output by *lex* and *yacc*. The *ctags* utility is not required to accommodate these languages, although implementors are encouraged to do so.

The following historical option was not specified, as *vgrind* is not included in this volume of IEEE Std 1003.1-200x:

–**v** If the –**v** flag is given, an index of the form expected by *vgrind* is produced on the standard output. This listing contains the function name, filename, and page number (assuming 64-line pages). Since the output is sorted into lexicographic order, it may be desired to run the output through *sort* –**f**. Sample use:

```
ctags –v files | sort –f > index vgrind –x index
```

The special treatment of the tag **main** makes the use of *ctags* practical in directories with more than one program.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The OUTPUT FILES section is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

IEEE PASC Interpretation 1003.2 #168 is applied, changing ‘‘create’’ to ‘‘write’’ in the DESCRIPTION.

NAME

cut — cut out selected fields of each line of a file

SYNOPSIS

```
cut –b list [–n] [file ...]

cut –c list [file ...]

cut –f list [–d delim][–s][file ...]
```

DESCRIPTION

The *cut* utility shall cut out bytes (–**b** option), characters (–**c** option) or character-delimited fields (–**f** option) from each line in one or more files, concatenate them, and write them to standard output.

OPTIONS

The *cut* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The application shall ensure that the option-argument *list* (see options –**b**, –**c**, and –**f** below) is a comma-separated list or <blank>-separated list of positive numbers and ranges. Ranges can be in three forms. The first is two positive numbers separated by a hyphen (*low*–*high*), which represents all fields from the first number to the second number. The second is a positive number preceded by a hyphen (–*high*), which represents all fields from field number 1 to that number. The third is a positive number followed by a hyphen (*low*–), which represents that number to the last field, inclusive. The elements in *list* can be repeated, can overlap, and can be specified in any order, but the bytes, characters, or fields selected shall be written in the order of the input data. If an element appears in the selection list more than once, it shall be written exactly once.

The following options shall be supported:

–**b** *list* Cut based on a *list* of bytes. Each selected byte shall be output unless the –**n** option is also specified. It shall not be an error to select bytes not present in the input line.

–**c** *list* Cut based on a *list* of characters. Each selected character shall be output. It shall not be an error to select characters not present in the input line.

–**d** *delim* Set the field delimiter to the character *delim*. The default is the <tab>.

–**f** *list* Cut based on a *list* of fields, assumed to be separated in the file by a delimiter character (see –**d**). Each selected field shall be output. Output fields shall be separated by a single occurrence of the field delimiter character. Lines with no field delimiters shall be passed through intact, unless –**s** is specified. It shall not be an error to select fields not present in the input line.

–**n** Do not split characters. When specified with the –**b** option, each element in *list* of the form *low*–*high* (hyphen-separated numbers) shall be modified as follows:

- If the byte selected by *low* is not the first byte of a character, *low* shall be decremented to select the first byte of the character originally selected by *low*. If the byte selected by *high* is not the last byte of a character, *high* shall be decremented to select the last byte of the character prior to the character originally selected by *high*, or zero if there is no prior character. If the resulting range element has *high* equal to zero or *low* greater than *high*, the list element shall be dropped from *list* for that input line without causing an error.

Each element in *list* of the form *low*– shall be treated as above with *high* set to the number of bytes in the current line, not including the terminating <newline>. Each element in *list* of the form −*high* shall be treated as above with *low* set to 1. Each element in *list* of the form *num* (a single number) shall be treated as above with *low* set to *num* and *high* set to *num*.

−s	Suppress lines with no delimiter characters, when used with the **−f** option. Unless specified, lines with no delimiters shall be passed through untouched.

OPERANDS

The following operand shall be supported:

file	A pathname of an input file. If no *file* operands are specified, or if a *file* operand is `'−'`, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files, except that line lengths shall be unlimited.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cut*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *cut* utility output shall be a concatenation of the selected bytes, characters, or fields (one of the following):

```
"%s\n", <concatenation of bytes>

"%s\n", <concatenation of characters>

"%s\n", <concatenation of fields and field delimiters>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All input files were output successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Earlier versions of the *cut* utility worked in an environment where bytes and characters were considered equivalent (modulo <backspace> and <tab> processing in some implementations). In the extended world of multi-byte characters, the new –**b** option has been added. The –**n** option (used with –**b**) allows it to be used to act on bytes rounded to character boundaries. The algorithm specified for –**n** guarantees that:

```
cut –b 1–500 –n file > file1
cut –b 501– –n file > file2
```

ends up with all the characters in **file** appearing exactly once in **file1** or **file2**. (There is, however, a <newline> in both **file1** and **file2** for each <newline> in **file**.)

EXAMPLES

Examples of the option qualifier list:

1,4,7	Select the first, fourth, and seventh bytes, characters, or fields and field delimiters.
1–3,8	Equivalent to 1,2,3,8.
–5,10	Equivalent to 1,2,3,4,5,10.
3–	Equivalent to third to last, inclusive.

The *low*–*high* forms are not always equivalent when used with –**b** and –**n** and multi-byte characters; see the description of –**n**.

The following command:

```
cut –d : –f 1,6 /etc/passwd
```

reads the System V password file (user database) and produces lines of the form:

```
<user ID>:<home directory>
```

Most utilities in this volume of IEEE Std 1003.1-200x work on text files. The *cut* utility can be used to turn files with arbitrary line lengths into a set of text files containing the same data. The *paste* utility can be used to create (or recreate) files with arbitrary line lengths. For example, if **file** contains long lines:

```
cut –b 1–500 –n file > file1
cut –b 501– –n file > file2
```

creates **file1** (a text file) with lines no longer than 500 bytes (plus the <newline>) and **file2** that contains the remainder of the data from **file**. (Note that **file2** is not a text file if there are lines in **file** that are longer than 500 + {LINE_MAX} bytes.) The original file can be recreated from **file1** and **file2** using the command:

```
paste –d "\0" file1 file2 > file
```

RATIONALE

Some historical implementations do not count <backspace>s in determining character counts with the **−c** option. This may be useful for using *cut* for processing *nroff* output. It was deliberately decided not to have the **−c** option treat either <backspace>s or <tab>s in any special fashion. The *fold* utility does treat these characters specially.

Unlike other utilities, some historical implementations of *cut* exit after not finding an input file, rather than continuing to process the remaining *file* operands. This behavior is prohibited by this volume of IEEE Std 1003.1-200x, where only the exit status is affected by this problem.

The behavior of *cut* when provided with either mutually-exclusive options or options that do not work logically together has been deliberately left unspecified in favor of global wording in Section 1.11 (on page 2221).

The OPTIONS section was changed in response to P1003.2-N149. The change represents historical practice on all known systems. The original standard was ambiguous on the nature of the output.

The *list* option-arguments are historically used to select the portions of the line to be written, but do not affect the order of the data. For example:

```
echo abcdefghi | cut −c6,2,4−7,1
```

yields `"abdefg"`.

A proposal to enhance *cut* with the following option:

−o Preserve the selected field order. When this option is specified, each byte, character, or field (or ranges of such) shall be written in the order specified by the *list* option-argument, even if this requires multiple outputs of the same bytes, characters, or fields.

was rejected because this type of enhancement is outside the scope of the IEEE P1003.2b draft standard.

FUTURE DIRECTIONS

None.

SEE ALSO

grep, *paste*, Section 2.5 (on page 2235)

CHANGE HISTORY

First released in Issue 2.

Issue 6

The OPTIONS section is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

cxref — generate a C-language program cross-reference table (**DEVELOPMENT**)

SYNOPSIS

XSI
```
cxref [−cs][−o file][−w num] [−D name[=def]]...[−I dir]...
    [−U name]... file ...
```

DESCRIPTION

The *cxref* utility shall analyze a collection of C-language *file*s and attempt to build a cross-reference table. Information from **#define** lines shall be included in the symbol table. A sorted listing shall be written to standard output of all symbols (auto, static, and global) in each *file* separately, or with the −**c** option, in combination. Each symbol shall contain an asterisk before the declaring reference.

OPTIONS

The *cxref* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of the −**D**, −**I**, and −**U** options (which are identical to their interpretation by *c99*) is significant. The following options shall be supported:

−**c**	Write a combined cross-reference of all input files.
−**s**	Operate silently; do not print input filenames.
−**o** *file*	Direct output to named *file*.
−**w** *num*	Format output no wider than *num* (decimal) columns. This option defaults to 80 if *num* is not specified or is less than 51.
−**D**	Equivalent to *c99*.
−**I**	Equivalent to *c99*.
−**U**	Equivalent to *c99*.

OPERANDS

The following operand shall be supported:

file	A pathname of a C-language source file.

STDIN

Not used.

INPUT FILES

The input files are C-language source files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cxref*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the ordering of the output.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in

arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used for the cross-reference listing, unless the −**o** option is used to select a different output file.

The format of standard output is unspecified, except that the following information shall be included:

- If the −**c** option is not specified, each portion of the listing shall start with the name of the input file on a separate line.
- The name line shall be followed by a sorted list of symbols, each with its associated location pathname, the name of the function in which it appears (if it is not a function name itself), and line number references.
- Each line number may be preceded by an asterisk (`'*'`) flag, meaning that this is the declaring reference. Other single-character flags, with implementation-defined meanings, may be included.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output file named by the −**o** option shall be used instead of standard output.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the SYNOPSIS, [−**U** *dir*] is changed to [−**U** *name*].

Issue 6

The APPLICATION USAGE section is added.

NAME

date — write the date and time

SYNOPSIS

```
date [−u] [+format]
```

XSI
```
date [−u] mmddhhmm[[cc]yy]
```

DESCRIPTION

XSI The *date* utility shall write the date and time to standard output or attempt to set the system date and time. By default, the current date and time shall be written. If an operand beginning with `'+'` is specified, the output format of *date* shall be controlled by the conversion specifications and other text in the operand.

OPTIONS

The *date* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−u Perform operations as if the *TZ* environment variable was set to the string `"UTC0"`, or its equivalent historical value of `"GMT0"`. Otherwise, *date* shall use the timezone indicated by the *TZ* environment variable or the system default if that variable is unset or null.

OPERANDS

The following operands shall be supported:

+format When the format is specified, each conversion specifier shall be replaced in the standard output by its corresponding value. All other characters shall be copied to the output without change. The output always shall be terminated with a <newline>.

Conversion Specifications

`%a`	Locale's abbreviated weekday name.
`%A`	Locale's full weekday name.
`%b`	Locale's abbreviated month name.
`%B`	Locale's full month name.
`%c`	Locale's appropriate date and time representation.
`%C`	Century (a year divided by 100 and truncated to an integer) as a decimal number [00,99].
`%d`	Day of the month as a decimal number [01,31].
`%D`	Date in the format *mm*/*dd*/*yy*.
`%e`	Day of the month as a decimal number [1,31] in a two-digit field with leading space character fill.
`%h`	A synonym for `%b`.
`%H`	Hour (24-hour clock) as a decimal number [00,23].
`%I`	Hour (12-hour clock) as a decimal number [01,12].

`%j`	Day of the year as a decimal number [001,366].
`%m`	Month as a decimal number [01,12].
`%M`	Minute as a decimal number [00,59].
`%n`	A <newline>.
`%p`	Locale's equivalent of either AM or PM.
`%r`	12-hour clock time [01,12] using the AM/PM notation; in the POSIX locale, this shall be equivalent to `%I:%M:%S %p`.
`%S`	Seconds as a decimal number [00,60].
`%t`	A <tab>.
`%T`	24-hour clock time [00,23] in the format *HH*:*MM*:*SS*.
`%u`	Weekday as a decimal number [1,7] (1=Monday).
`%U`	Week of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday shall be considered to be in week 0.
`%V`	Week of the year (Monday as the first day of the week) as a decimal number [01,53]. If the week containing January 1 has four or more days in the new year, then it shall be considered week 1; otherwise, it shall be the last week of the previous year, and the next week shall be week 1.
`%w`	Weekday as a decimal number [0,6] (0=Sunday).
`%W`	Week of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday shall be considered to be in week 0.
`%x`	Locale's appropriate date representation.
`%X`	Locale's appropriate time representation.
`%y`	Year within century [00,99].
`%Y`	Year with century as a decimal number.
`%Z`	Timezone name, or no characters if no timezone is determinable.
`%%`	A percent sign character.

See the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3.5, LC_TIME for the conversion specifier values in the POSIX locale.

Modified Conversion Specifications

Some conversion specifiers can be modified by the `E` and `O` modifier characters to indicate a different format or specification as specified in the *LC_TIME* locale description (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3.5, LC_TIME). If the corresponding keyword (see **era**, **era_year**, **era_d_fmt**, and **alt_digits** in the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3.5, LC_TIME) is not specified or not supported for the current locale, the unmodified conversion specifier value shall be used.

`%Ec`	Locale's alternative appropriate date and time representation.

`%EC`	The name of the base year (period) in the locale's alternative representation.
`%Ex`	Locale's alternative date representation.
`%EX`	Locale's alternative time representation.
`%Ey`	Offset from `%EC` (year only) in the locale's alternative representation.
`%EY`	Full alternative year representation.
`%Od`	Day of month using the locale's alternative numeric symbols.
`%Oe`	Day of month using the locale's alternative numeric symbols.
`%OH`	Hour (24-hour clock) using the locale's alternative numeric symbols.
`%OI`	Hour (12-hour clock) using the locale's alternative numeric symbols.
`%Om`	Month using the locale's alternative numeric symbols.
`%OM`	Minutes using the locale's alternative numeric symbols.
`%OS`	Seconds using the locale's alternative numeric symbols.
`%Ou`	Weekday as a number in the locale's alternative representation (Monday = 1).
`%OU`	Week number of the year (Sunday as the first day of the week) using the locale's alternative numeric symbols.
`%OV`	Week number of the year (Monday as the first day of the week, rules corresponding to `%V`), using the locale's alternative numeric symbols.
`%Ow`	Weekday as a number in the locale's alternative representation (Sunday = 0).
`%OW`	Week number of the year (Monday as the first day of the week) using the locale's alternative numeric symbols.
`%Oy`	Year (offset from `%C`) in alternative representation.

XSI *mmddhhmm***[[***cc***]***yy* **]**

Attempt to set the system date and time from the value given in the operand. This is only possible if the user has appropriate privileges and the system permits the setting of the system date and time. The first *mm* is the month (number); *dd* is the day (number); *hh* is the hour (number, 24-hour system); the second *mm* is the minute (number); *cc* is the century and is the first two digits of the year (this is optional); *yy* is the last two digits of the year and is optional. If century is not specified, then values in the range [69,99] shall refer to years 1969 to 1999 inclusive, and values in the range [00,68] shall refer to years 2000 to 2068 inclusive. The current year is the default if *yy* is omitted.

Note: It is expected that in a future version of IEEE Std 1003.1-200x the default century inferred from a 2-digit year will change. (This would apply to all commands accepting a 2-digit year as input.)

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *date*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_TIME	Determine the format and contents of date and time strings written by *date*.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
TZ	Determine the timezone in which the time and date are written, unless the −**u** option is specified. If the *TZ* variable is unset or null and the −**u** is not specified, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When no formatting operand is specified, the output in the POSIX locale shall be equivalent to specifying:

```
date "+%a %b %e %H:%M:%S %Z %Y"
```

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The date was written successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Conversion specifiers are of unspecified format when not in the POSIX locale. Some of them can contain <newline>s in some locales, so it may be difficult to use the format shown in standard output for parsing the output of *date* in those locales.

The range of values for `%S` extends from 0 to 60 seconds to accommodate the occasional leap second.

Although certain of the conversion specifiers in the POSIX locale (such as the name of the month) are shown with initial capital letters, this need not be the case in other locales. Programs using these fields may need to adjust the capitalization if the output is going to be used at the beginning of a sentence.

The date string formatting capabilities are intended for use in Gregorian-style calendars, possibly with a different starting year (or years). The `%x` and `%c` conversion specifications, however, are intended for local representation; these may be based on a different, non-Gregorian calendar.

The `%C` conversion specification was introduced to allow a fallback for the `%EC` (alternative year format base year); it can be viewed as the base of the current subdivision in the Gregorian calendar. The century number is calculated as the year divided by 100 and truncated to an integer; it should not be confused with the use of ordinal numbers for centuries (for example, ‘‘twenty-first century’’.) Both the `%Ey` and `%y` can then be viewed as the offset from `%EC` and `%C`, respectively.

The `E` and `O` modifiers modify the traditional conversion specifiers, so that they can always be used, even if the implementation (or the current locale) does not support the modifier.

The `E` modifier supports alternative date formats, such as the Japanese Emperor’s Era, as long as these are based on the Gregorian calendar system. Extending the `E` modifiers to other date elements may provide an implementation-defined extension capable of supporting other calendar systems, especially in combination with the `O` modifier.

The `O` modifier supports time and date formats using the locale’s alternative numerical symbols, such as Kanji or Hindi digits or ordinal number representation.

Non-European locales, whether they use Latin digits in computational items or not, often have local forms of the digits for use in date formats. This is not totally unknown even in Europe; a variant of dates uses Roman numerals for the months: the third day of September 1991 would be written as 3.IX.1991. In Japan, Kanji digits are regularly used for dates; in Arabic-speaking countries, Hindi digits are used. The `%d`, `%e`, `%H`, `%I`, `%m`, `%S`, `%U`, `%w`, `%W`, and `%y` conversion specifications always return the date and time field in Latin digits (that is, 0 to 9). The `%O` modifier was introduced to support the use for display purposes of non-Latin digits. In the *LC_TIME* category in *localedef*, the optional **alt_digits** keyword is intended for this purpose. As an example, assume the following (partial) *localedef* source:

```
alt_digits  "";"I";"II";"III";"IV";"V";"VI";"VII";"VIII" \
            "IX";"X";"XI";"XII"
d_fmt       "%e.%Om.%Y"
```

With the above date, the command:

```
date "+%x"
```

would yield 3.IX.1991. With the same **d_fmt**, but without the **alt_digits**, the command would yield 3.9.1991.

EXAMPLES

1. The following are input/output examples of *date* used at arbitrary times in the POSIX locale:

```
$ date
Tue Jun 26 09:58:10 PDT 1990
```

```
$ date "+DATE: %m/%d/%y%nTIME: %H:%M:%S"
DATE: 11/02/91
TIME: 13:36:16
```

```
$ date "+TIME: %r"
TIME: 01:36:32 PM
```

2. Examples for Denmark, where the default date and time format is `%a %d %b %Y %T %Z`:

```
$ LANG=da_DK.iso_8859−1 date
ons 02 okt 1991 15:03:32 CET
```

```
$ LANG=da_DK.iso_8859−1 \
    date "+DATO: %A den %e. %B %Y%nKLOKKEN: %H:%M:%S"
DATO: onsdag den 2. oktober 1991
KLOKKEN: 15:03:56
```

3. Examples for Germany, where the default date and time format is `%a %d.%h.%Y, %T %Z`:

```
$ LANG=De_DE.88591 date
Mi 02.Okt.1991, 15:01:21 MEZ
```

```
$ LANG=De_DE.88591 date "+DATUM: %A, %d. %B %Y%nZEIT: %H:%M:%S"
DATUM: Mittwoch, 02. Oktober 1991
ZEIT: 15:02:02
```

4. Examples for France, where the default date and time format is `%a %d %h %Y %Z %T`:

```
$ LANG=Fr_FR.88591 date
Mer 02 oct 1991 MET 15:03:32
```

```
$ LANG=Fr_FR.88591 date "+JOUR: %A %d %B %Y%nHEURE: %H:%M:%S"
JOUR: Mercredi 02 octobre 1991
HEURE: 15:03:56
```

RATIONALE

Some of the new options for formatting are from the ISO C standard. The **−u** option was introduced to allow portable access to Coordinated Universal Time (UTC). The string `"GMT0"` is allowed as an equivalent *TZ* value to be compatible with all of the systems using the BSD implementation, where this option originated.

The `%e` format conversion specifications (adopted from System V) was added because the ISO C standard conversion specifications did not provide any way to produce the historical default *date* output during the first nine days of any month.

There are two varieties of day and week numbering supported (in addition to any others created with the locale-dependent `%E` and `%O` modifier characters):

- The historical variety in which Sunday is the first day of the week and the weekdays preceding the first Sunday of the year are considered week 0. These are represented by `%w` and `%U`. A variant of this is `%W`, using Monday as the first day of the week, but still referring to week 0. This view of the calendar was retained because so many historical applications depend on it and the ISO C standard *strftime*( ) function, on which many *date* implementations are based, was defined in this way.

- The international standard, based on the ISO 8601:2000 standard where Monday is the first weekday and the algorithm for the first week number is more complex: If the week (Monday to Sunday) containing January 1 has four or more days in the new year, then it is week 1; otherwise, it is week 53 of the previous year, and the next week is week 1. These are represented by the new conversion specifications `%u` and `%V`, added as a result of international comments.

FUTURE DIRECTIONS

None.

SEE ALSO

The System Interfaces volume of IEEE Std 1003.1-200x, *printf*( ), *strftime*( )

CHANGE HISTORY

First released in Issue 2.

Issue 5

Changes are made for Year 2000 alignment.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The setting of system date and time is described, including how to interpret two-digit year values if a century is not given.
- The `%EX` modified conversion specification is added.

The Open Group Corrigendum U048/2 is applied, correcting the examples.

The DESCRIPTION is updated to refer to conversion specifications, instead of field descriptors for consistency with the *LC_TIME* category.

A clarification is made such that the current year is the default if the *yy* argument is omitted when setting the system date and time.

NAME

dd — convert and copy a file

SYNOPSIS

```
dd [operand ...]
```

DESCRIPTION

The *dd* utility shall copy the specified input file to the specified output file with possible conversions using specific input and output block sizes. It shall read the input one block at a time, using the specified input block size; it shall then process the block of data actually returned, which could be smaller than the requested block size. It shall apply any conversions that have been specified and write the resulting data to the output in blocks of the specified output block size. If the **bs**=*expr* operand is specified and no conversions other than **sync**, **noerror**, or **notrunc** are requested, the data returned from each input block shall be written as a separate output block; if the read returns less than a full block and the **sync** conversion is not specified, the resulting output block shall be the same size as the input block. If the **bs**=*expr* operand is not specified, or a conversion other than **sync**, **noerror**, or **notrunc** is requested, the input shall be processed and collected into full-sized output blocks until the end of the input is reached.

The processing order shall be as follows:

1. An input block is read.
2. If the input block is shorter than the specified input block size and the **sync** conversion is specified, null bytes shall be appended to the input data up to the specified size. (If either **block** or **unblock** is also specified, <space>s shall be appended instead of null bytes.) The remaining conversions and output shall include the pad characters as if they had been read from the input.
3. If the **bs**=*expr* operand is specified and no conversion other than **sync** or **noerror** is requested, the resulting data shall be written to the output as a single block, and the remaining steps are omitted.
4. If the **swab** conversion is specified, each pair of input data bytes shall be swapped. If there is an odd number of bytes in the input block, the last byte in the input record shall not be swapped.
5. Any remaining conversions (**block**, **unblock**, **lcase**, and **ucase**) shall be performed. These conversions shall operate on the input data independently of the input blocking; an input or output fixed-length record may span block boundaries.
6. The data resulting from input or conversion or both shall be aggregated into output blocks of the specified size. After the end of input is reached, any remaining output shall be written as a block without padding if **conv**=**sync** is not specified; thus, the final output block may be shorter than the output block size.

OPTIONS

None.

OPERANDS

All of the operands shall be processed before any input is read. The following operands shall be supported:

if=*file* Specify the input pathname; the default is standard input.

of=*file* Specify the output pathname; the default is standard output. If the **seek**=*expr* conversion is not also specified, the output file shall be truncated before the copy begins if an explicit **of**=*file* operand is specified, unless **conv**=**notrunc** is specified. |

If **seek**=*expr* is specified, but **conv**=**notrunc** is not, the effect of the copy shall be to preserve the blocks in the output file over which *dd* seeks, but no other portion of the output file shall be preserved. (If the size of the seek plus the size of the input file is less than the previous size of the output file, the output file shall be shortened by the copy.)

ibs=*expr* Specify the input block size, in bytes, by *expr* (default is 512).

obs=*expr* Specify the output block size, in bytes, by *expr* (default is 512).

bs=*expr* Set both input and output block sizes to *expr* bytes, superseding **ibs**= and **obs**=. If no conversion other than **sync**, **noerror**, and **notrunc** is specified, each input block shall be copied to the output as a single block without aggregating short blocks.

cbs=*expr* Specify the conversion block size for **block** and **unblock** in bytes by *expr* (default is zero). If **cbs**= is omitted or given a value of zero, using **block** or **unblock** produces unspecified results.

XSI The application shall ensure that this operand is also specified if the **conv**= operand is specified with a value of **ascii**, **ebcdic**, or **ibm**. For a **conv**= operand with an **ascii** value, the input is handled as described for the **unblock** value, except that characters are converted to ASCII before any trailing <space>s are deleted. For **conv**= operands with **ebcdic** or **ibm** values, the input is handled as described for the **block** value except that the characters are converted to EBCDIC or IBM EBCDIC, respectively, after any trailing <space>s are added.

skip=*n* Skip *n* input blocks (using the specified input block size) before starting to copy. On seekable files, the implementation shall read the blocks or seek past them; on non-seekable files, the blocks shall be read and the data shall be discarded.

seek=*n* Skip *n* blocks (using the specified output block size) from beginning of the output file before copying. On non-seekable files, existing blocks shall be read and space from the current end-of-file to the specified offset, if any, filled with null bytes; on seekable files, the implementation shall seek to the specified offset or read the blocks as described for non-seekable files.

count=*n* Copy only *n* input blocks.

conv=*value*[,*value* . . .]

Where *value*s are comma-separated symbols from the following list:

XSI **ascii** Convert EBCDIC to ASCII; see Table 4-6 (on page 2506).

XSI **ebcdic** Convert ASCII to EBCDIC; see Table 4-6 (on page 2506).

XSI **ibm** Convert ASCII to a different EBCDIC set; see Table 4-7 (on page 2507).

The **ascii**, **ebcdic**, and **ibm** values are mutually-exclusive.

block Treat the input as a sequence of <newline>-terminated or end-of-file-terminated variable-length records independent of the input block boundaries. Each record shall be converted to a record with a fixed length specified by the conversion block size. Any <newline> shall be removed from the input line; <space>s shall be appended to lines that are shorter than their conversion block size to fill the block. Lines that are longer than the conversion block size shall be truncated to the largest number of characters that fit into that size; the number of truncated lines shall be reported (see the STDERR section).

The **block** and **unblock** values are mutually-exclusive.

unblock	Convert fixed-length records to variable length. Read a number of bytes equal to the conversion block size (or the number of bytes remaining in the input, if less than the conversion block size), delete all trailing <space>s, and append a <newline>.
lcase	Map uppercase characters specified by the *LC_CTYPE* keyword **tolower** to the corresponding lowercase character. Characters for which no mapping is specified shall not be modified by this conversion. The **lcase** and **ucase** symbols are mutually-exclusive.
ucase	Map lowercase characters specified by the *LC_CTYPE* keyword **toupper** to the corresponding uppercase character. Characters for which no mapping is specified shall not be modified by this conversion.
swab	Swap every pair of input bytes.
noerror	Do not stop processing on an input error. When an input error occurs, a diagnostic message shall be written on standard error, followed by the current input and output block counts in the same format as used at completion (see the STDERR section). If the **sync** conversion is specified, the missing input shall be replaced with null bytes and processed normally; otherwise, the input block shall be omitted from the output.
notrunc	Do not truncate the output file. Preserve blocks in the output file not explicitly written by this invocation of the *dd* utility. (See also the preceding **of**=*file* operand.)
sync	Pad every input block to the size of the **ibs**= buffer, appending null bytes. (If either **block** or **unblock** is also specified, append <space>s, rather than null bytes.)

The behavior is unspecified if operands other than **conv**= are specified more than once.

For the **bs**=, **cbs**=, **ibs**=, and **obs**= operands, the application shall supply an expression specifying a size in bytes. The expression, *expr*, can be:

1. A positive decimal number
2. A positive decimal number followed by *k*, specifying multiplication by 1 024
3. A positive decimal number followed by *b*, specifying multiplication by 512
4. Two or more positive decimal numbers (with or without *k* or *b*) separated by *x*, specifying the product of the indicated values

All of the operands are processed before any input is read.

XSI The following two tables display the octal number character values used for the **ascii** and **ebcdic** conversions (first table) and for the **ibm** conversion (second table). In both tables, the ASCII values are the row and column headers and the EBCDIC values are found at their intersections. For example, ASCII 0012 (LF) is the second row, third column, yielding 0045 in EBCDIC. The inverted tables (for EBCDIC to ASCII conversion) are not shown, but are in one-to-one correspondence with these tables. The differences between the two tables are highlighted by small boxes drawn around five entries.

STDIN

If no **if**= operand is specified, the standard input shall be used. See the INPUT FILES section.

INPUT FILES

The input file can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *dd*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the classification of characters as uppercase or lowercase, and the mapping of characters from one case to the other.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

For SIGINT, the *dd* utility shall interrupt its current processing, write status information to standard error, and exit as though terminated by SIGINT. It shall take the standard action for all other signals; see the ASYNCHRONOUS EVENTS section in Section 1.11 (on page 2221).

STDOUT

If no **of**= operand is specified, the standard output shall be used. The nature of the output depends on the operands selected.

STDERR

On completion, *dd* shall write the number of input and output blocks to standard error. In the POSIX locale the following formats shall be used:

```
"%u+%u records in\n", <number of whole input blocks>,
    <number of partial input blocks>
```

```
"%u+%u records out\n", <number of whole output blocks>,
    <number of partial output blocks>
```

A partial input block is one for which *read*( ) returned less than the input block size. A partial output block is one that was written with fewer bytes than specified by the output block size.

In addition, when there is at least one truncated block, the number of truncated blocks shall be written to standard error. In the POSIX locale, the format shall be:

```
"%u truncated %s\n", <number of truncated blocks>, "record" (if
    <number of truncated blocks> is one) "records" (otherwise)
```

Diagnostic messages may also be written to standard error.

OUTPUT FILES

If the **of**= operand is used, the output shall be the same as described in the STDOUT section.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The input file was copied successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

If an input error is detected and the **noerror** conversion has not been specified, any partial output block shall be written to the output file, a diagnostic message shall be written, and the copy operation shall be discontinued. If some other error is detected, a diagnostic message shall be written and the copy operation shall be discontinued.

APPLICATION USAGE

The input and output block size can be specified to take advantage of raw physical I/O.

There are many different versions of the EBCDIC codesets. The ASCII and EBCDIC conversions specified for the *dd* utility perform conversions for the version specified by the tables.

EXAMPLES

The following command:

```
dd if=/dev/rmt0h  of=/dev/rmt1h
```

copies from tape drive 0 to tape drive 1, using a common historical device naming convention.

The following command:

```
dd ibs=10  skip=1
```

strips the first 10 bytes from standard input.

This example reads an EBCDIC tape blocked ten 80-byte EBCDIC card images per block into the ASCII file **x**:

```
dd if=/dev/tape of=x ibs=800 cbs=80 conv=ascii,lcase
```

RATIONALE

The OPTIONS section is listed as ‘‘None’’ because there are no options recognized by historical *dd* utilities. Certainly, many of the operands could have been designed to use the Utility Syntax Guidelines, which would have resulted in the classic hyphenated option letters. In this version of this volume of IEEE Std 1003.1-200x, *dd* retains its curious JCL-like syntax due to the large number of applications that depend on the historical implementation.

A suggested implementation technique for **conv**=**noerror**,**sync** is to zero (or <space>-fill, if **block**ing or **unblock**ing) the input buffer before each read and to write the contents of the input buffer to the output even after an error. In this manner, any data transferred to the input buffer before the error was detected is preserved. Another point is that a failed read on a regular file or a disk generally does not increment the file offset, and *dd* must then seek past the block on which the error occurred; otherwise, the input error occurs repetitively. When the input is a magnetic tape, however, the tape normally has passed the block containing the error when the error is reported, and thus no seek is necessary.

The default **ibs**= and **obs**= sizes are specified as 512 bytes because there are historical (largely portable) scripts that assume these values. If they were left unspecified, unusual results could occur if an implementation chose an odd block size.

Historical implementations of *dd* used *creat*( ) when processing **of**=*file*. This makes the **seek**= operand unusable except on special files. The **conv**=**notrunc** feature was added because more recent BSD-based implementations use *open*( ) (without O_TRUNC) instead of *creat*( ), but they fail to delete output file contents after the data copied.

The *w* multiplier (historically meaning *word*), is used in System V to mean 2 and in 4.2 BSD to mean 4. Since *word* is inherently non-portable, its use is not supported by this volume of IEEE Std 1003.1-200x.

Standard EBCDIC does not have the characters '[' and ']'. The values used in the table are taken from a common print train that does contain them. Other than those characters, the print train values are not filled in, but appear to provide some of the motivation for the historical choice of translations reflected here.

The Standard EBCDIC table provides a 1:1 translation for all 256 bytes.

The IBM EBCDIC table does not provide such a translation. The marked cells in the tables differ in such a way that:

1. EBCDIC 0112 ('¢') and 0152 (broken pipe) do not appear in the table.
2. EBCDIC 0137 ('¬') translates to/from ASCII 0236 ('^'). In the standard table, EBCDIC 0232 (no graphic) is used.
3. EBCDIC 0241 ('˜') translates to/from ASCII 0176 ('˜'). In the standard table, EBCDIC 0137 ('¬') is used.
4. 0255 ('[') and 0275 (']') appear twice, once in the same place as for the standard table and once in place of 0112 ('¢') and 0241 ('˜').

In net result:

EBCDIC 0275 (']') displaced EBCDIC 0241 ('˜') in cell 0345.

That displaced EBCDIC 0137 ('¬') in cell 0176.

That displaced EBCDIC 0232 (no graphic) in cell 0136.

That replaced EBCDIC 0152 (broken pipe) in cell 0313.

EBCDIC 0255 ('[') replaced EBCDIC 0112 ('¢').

This translation, however, reflects historical practice that (ASCII) '˜' and '¬' were often mapped to each other, as were '[' and '¢'; and ']' and (EBCDIC) '˜'.

The **cbs** operand is required if any of the **ascii**, **ebcdic**, or **ibm** operands are specified. For the **ascii** operand, the input is handled as described for the **unblock** operand except that characters are converted to ASCII before the trailing <space>s are deleted. For the **ebcdic** and **ibm** operands, the input is handled as described for the **block** operand except that the characters are converted to EBCDIC or IBM EBCDIC after the trailing <space>s are added.

The **block** and **unblock** keywords are from historical BSD practice.

The consistent use of the word **record** in standard error messages matches most historical practice. An earlier version of System V used **block**, but this has been updated in more recent releases.

Early proposals only allowed two numbers separated by **x** to be used in a product when specifying **bs**=, **cbs**=, **ibs**=, and **obs**= sizes. This was changed to reflect the historical practice of allowing multiple numbers in the product as provided by Version 7 and all releases of System V and BSD.

A change to the *swab* conversion is required to match historical practice and is the result of IEEE PASC Interpretation 1003.2 #03 and #04, submitted for the ISO POSIX-2: 1993 standard.

A change to the handling of SIGINT is required to match historical practice and is the result of IEEE PASC Interpretation 1003.2 #06 submitted for the ISO POSIX-2: 1993 standard.

FUTURE DIRECTIONS

None.

sed, *tr*

CHANGE HISTORY

First released in Issue 2.

Issue 5

The second paragraph of the **cbs**= description is reworded and marked EX.

FUTURE DIRECTIONS section added.

Issue 6

Changes are made to *swab* conversion and SIGINT handling to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ''must'' for application requirements.

IEEE PASC Interpretation 1003.2 #209 is applied, clarifying the interaction between *dd* **of**=*file* and **conv**=**notrunc**.

NAME

delta — make a delta (change) to an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI

```
delta [−nps][−g list][−m mrlist][−r SID][−y[comment]] file...
```

DESCRIPTION

The *delta* utility shall be used to permanently introduce into the named SCCS files changes that were made to the files retrieved by *get* (called the *g-files*, or generated files).

OPTIONS

The *delta* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the **−y** option has an optional option-argument. This optional option-argument shall not be presented as a separate argument.

The following options shall be supported:

−r *SID*	Uniquely identify which delta is to be made to the SCCS file. The use of this option shall be necessary only if two or more outstanding *get* commands for editing (*get* **−e**) on the same SCCS file were done by the same person (login name). The SID value specified with the **−r** option can be either the SID specified on the *get* command line or the SID to be made as reported by the *get* utility; see *get* (on page 2675).
−s	Suppress the report to standard output of the activity associated with each *file*. See the STDOUT section.
−n	Specify retention of the edited *g-file* (normally removed at completion of delta processing).
−g *list*	Specify a *list*, (see *get* (on page 2675) for the definition of *list*) of deltas that shall be ignored when the file is accessed at the change level (SID) created by this delta.
−m *mrlist*	Specify a modification request (MR) number that the application shall supply as the reason for creating the new delta. This shall be used if the SCCS file has the **v** flag set; see *admin* (on page 2328). If **−m** is not used and `'−'` is not specified as a file argument, and the standard input is a terminal, the prompt described in the STDOUT section shall be written to standard output before the standard input is read; if the standard input is not a terminal, no prompt shall be issued. MRs in a list shall be separated by <blank>s or escaped <newline>s. An unescaped <newline> shall terminate the MR list. The escape character is <backslash>. If the **v** flag has a value, it shall be taken to be the name of a program which validates the correctness of the MR numbers. If a non-zero exit status is returned from the MR number validation program, the *delta* utility shall terminate. (It is assumed that the MR numbers were not all valid.)
−y[*comment***]**	Describe the reason for making the delta. The *comment* shall be an arbitrary group of lines that would meet the definition of a text file. Implementations shall support *comment*s from zero to 512 bytes and may support longer values. A null string (specified as either **−y**, **−y" "**, or in response to a prompt for a comment) shall be considered a valid *comment*.

If −**y** is not specified and '−' is not specified as a file argument, and the standard input is a terminal, the prompt described in the STDOUT section shall be written to standard output before the standard input is read; if the standard input is not a terminal, no prompt shall be issued. An unescaped <newline> shall terminate the comment text. The escape character is <backslash>.

The −**y** option shall be required if the *file* operand is specified as '−'.

−**p** Write (to standard output) the SCCS file differences before and after the delta is applied in *diff* format; see *diff* (on page 2520).

OPERANDS

The following operand shall be supported:

file A pathname of an existing SCCS file or a directory. If *file* is a directory, the *delta* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is '−', the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only in the following cases:

- To read an *mrlist* or a *comment* (see the −**m** and −**y** options).
- A *file* operand shall be specified as '−'. In this case, the −**y** option must be used to specify the comment, and if the SCCS file has the **v** flag set, the −**m** option must also be used to specify the MR list.

INPUT FILES

Input files shall be text files whose data is to be included in the SCCS files. If the first character of any line of an input file is <SOH> in the POSIX locale, the results are unspecified. If this file contains more than 99 999 lines, the number of lines recorded in the header for this file shall be 99 999 for this delta.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *delta*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES.*

TZ	Determine the timezone in which the time and date are written in the SCCS file. If the *TZ* variable is unset or NULL, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

If SIGINT is caught, temporary files shall be cleaned up and *delta* shall exit with a non-zero exit code. The standard action shall be taken for all other signals; see Section 1.11 (on page 2221).

STDOUT

The standard output shall be used only for the following messages in the POSIX locale:

- Prompts (see the **–m** and **–y** options) in the following formats:

  `"MRs? "`

  `"comments? "`

  The MR prompt, if written, shall always precede the comments prompt.

- A report of each *file*'s activities (unless the **–s** option is specified) in the following format:

```
"%s\n%d inserted\n%d deleted\n%d unchanged\n", <New SID>,
    <number of lines inserted>, <number of lines deleted>,
    <number of lines unchanged>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

Any SCCS files updated shall be files of an unspecified format.

EXTENDED DESCRIPTION

System Date and Time

When a delta is added to an SCCS file, the system date and time shall be recorded for the new delta. If a *get* is performed using an SCCS file with a date recorded apparently in the future, the behavior is unspecified.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Problems can arise if the system date and time have been modified (for example, put forward and then back again, or unsynchronized clocks across a network) and can also arise when different values of the *TZ* environment variable are used.

Problems of a similar nature can also arise for the operation of the *get* utility, which records the date and time in the file body.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

admin, *diff*, *get*, *prs*, *rmdel*

CHANGE HISTORY

First released in Issue 2.

Issue 5

The output format description in the STDOUT section is corrected.

Issue 6

The APPLICATION USAGE section is added.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The normative text is reworded to emphasize the term ‘‘shall’’ for implementation requirements.

The Open Group Base Resolution bwg2001-007 is applied as follows:

- The use of '−' as a file argument is clarified.
- The use of STDIN is added.
- The ASYNCHRONOUS EVENTS section is updated to remove the implicit requirement that implementations re-signal themselves when catching a normally fatal signal.
- New text is added to the INPUT FILES section warning that the maximum lines recorded in the file is 99 999.

New text is added to the EXTENDED DESCRIPTION and APPLICAION USAGE sections regarding how the system date and time may be taken into account, and the *TZ* environment variable is added to the ENVIRONMENT VARIABLES section as per The Open Group Base Resolution bwg2001-007.

NAME

df — report free disk space

SYNOPSIS

`df [−k][−P|−t][file...]`

DESCRIPTION

The *df* utility shall write the amount of available space and file slots for file systems on which the invoking user has appropriate read access. File systems shall be specified by the *file* operands; when none are specified, information shall be written for all file systems. The format of the default output from *df* is unspecified, but all space figures are reported in 512-byte units, unless the **−k** option is specified. This output shall contain at least the file system names, amount of available space on each of these file systems, and the number of free file slots, or *inodes*, available; when **−t** is specified, the output shall contain the total allocated space as well.

OPTIONS

The *df* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−k	Use 1024-byte units, instead of the default 512-byte units, when writing space figures.
−P	Produce output in the format described in the STDOUT section.
−t	Include total allocated-space figures in the output.

OPERANDS

The following operand shall be supported:

file	A pathname of a file within the hierarchy of the desired file system. If a file other than a FIFO, a regular file, a directory or a special file representing the device containing the file system (for example, **/dev/dsk/0s1**) is specified, the results are unspecified. Otherwise, *df* shall write the amount of free space in the file system containing the specified *file* operand.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *df*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

When both the −**k** and −**P** options are specified, the following header line shall be written (in the POSIX locale):

```
"Filesystem 1024-blocks Used Available Capacity Mounted on\n"
```

When the −**P** option is specified without the −**k** option, the following header line shall be written (in the POSIX locale):

```
"Filesystem 512-blocks Used Available Capacity Mounted on\n"
```

The implementation may adjust the spacing of the header line and the individual data lines so that the information is presented in orderly columns.

The remaining output with −**P** shall consist of one line of information for each specified file system. These lines shall be formatted as follows:

```
"%s %d %d %d %d%% %s\n", <file system name>, <total space>,
    <space used>, <space free>, <percentage used>,
    <file system root>
```

In the following list, all quantities expressed in 512-byte units (1 024-byte when −**k** is specified) shall be rounded up to the next higher unit. The fields are:

<file system name>
The name of the file system, in an implementation-defined format.

<total space> The total size of the file system in 512-byte units. The exact meaning of this figure is implementation-defined, but should include *<space used>*, *<space free>*, plus any space reserved by the system not normally available to a user.

<space used> The total amount of space allocated to existing files in the file system, in 512-byte units.

<space free> The total amount of space available within the file system for the creation of new files by unprivileged users, in 512-byte units. When this figure is less than or equal to zero, it shall not be possible to create any new files on the file system without first deleting others, unless the process has appropriate privileges. The figure written may be less than zero.

<percentage used>
The percentage of the normally available space that is currently allocated to all files on the file system. This shall be calculated using the fraction:

```
<space used>/( <space used>+ <space free>)
```

expressed as a percentage. This percentage may be greater than 100 if *<space free>* is less than zero. The percentage value shall be expressed as a positive integer, with any fractional result causing it to be rounded to the next highest integer.

<file system root>
The directory below which the file system hierarchy appears.

XSI The output format is unspecified when **−t** is used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

On most systems, the ‘‘name of the file system, in an implementation-defined format’’ is the special file on which the file system is mounted.

On large file systems, the calculation specified for percentage used can create huge rounding errors.

EXAMPLES

1. The following example writes portable information about the **/usr** file system:

```
df −P /usr
```

2. Assuming that **/usr/src** is part of the **/usr** file system, the following produces the same output as the previous example:

```
df −P /usr/src
```

RATIONALE

The behavior of *df* with the **−P** option is the default action of the 4.2 BSD *df* utility. The uppercase **−P** was selected to avoid collision with a known industry extension using **−p**.

Historical *df* implementations vary considerably in their default output. It was therefore necessary to describe the default output in a loose manner to accommodate all known historical implementations and to add a portable option (**−P**) to provide information in a portable format.

The use of 512-byte units is historical practice and maintains compatibility with *ls* and other utilities in this volume of IEEE Std 1003.1-200x. This does not mandate that the file system itself be based on 512-byte blocks. The **−k** option was added as a compromise measure. It was agreed by the standard developers that 512 bytes was the best default unit because of its complete historical consistency on System V (*versus* the mixed 512/1 024-byte usage on BSD systems), and that a **−k** option to switch to 1 024-byte units was a good compromise. Users who prefer the more logical 1 024-byte quantity can easily alias *df* to *df* **−k** without breaking many historical scripts relying on the 512-byte units.

It was suggested that *df* and the various related utilities be modified to access a *BLOCKSIZE* environment variable to achieve consistency and user acceptance. Since this is not historical practice on any system, it is left as a possible area for system extensions and will be re-evaluated in a future version if it is widely implemented.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

NAME

diff — compare two files

SYNOPSIS

`diff [−c| −e| −f| −C n][−br] file1 file2`

DESCRIPTION

The *diff* utility shall compare the contents of *file1* and *file2* and write to standard output a list of changes necessary to convert *file1* into *file2*. This list should be minimal. No output shall be produced if the files are identical.

OPTIONS

The *diff* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−b	Cause any amount of white space at the end of a line to be treated as a single <newline> (that is, the white-space characters preceding the <newline> are ignored) and other strings of white-space characters, not including <newline>s, to compare equal.
−c	Produce output in a form that provides three lines of context.
−C n	Produce output in a form that provides *n* lines of context (where *n* shall be interpreted as a positive decimal integer).
−e	Produce output in a form suitable as input for the *ed* utility, which can then be used to convert *file1* into *file2*.
−f	Produce output in an alternative form, similar in format to **−e**, but not intended to be suitable as input for the *ed* utility, and in the opposite order.
−r	Apply *diff* recursively to files and directories of the same name when *file1* and *file2* are both directories.

OPERANDS

The following operands shall be supported:

file1, *file2*	A pathname of a file to be compared. If either the *file1* or *file2* operand is `'−'`, the standard input shall be used in its place.

If both *file1* and *file2* are directories, *diff* shall not compare block special files, character special files, or FIFO special files to any files and shall not compare regular files to directories. Further details are as specified in **Diff Directory Comparison Format** (on page 2521). The behavior of *diff* on other file types is implementation-defined when found in directories.

If only one of *file1* and *file2* is a directory, *diff* shall be applied to the non-directory file and the file contained in the directory file with a filename that is the same as the last component of the non-directory file.

STDIN

The standard input shall be used only if one of the *file1* or *file2* operands references standard input. See the INPUT FILES section.

INPUT FILES

The input files may be of any type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *diff*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
LC_TIME	Determine the locale for affecting the format of file timestamps written with the −**C** and −**c** options.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
TZ	Determine the timezone used for calculating file timestamps written with the −**C** and −**c** options. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Diff Directory Comparison Format

If both *file1* and *file2* are directories, the following output formats shall be used.

In the POSIX locale, each file that is present in only one directory shall be reported using the following format:

```
"Only in %s: %s\n", <directory pathname>, <filename>
```

In the POSIX locale, subdirectories that are common to the two directories may be reported with the following format:

```
"Common subdirectories: %s and %s\n", <directory1 pathname>,
    <directory2 pathname>
```

For each file common to the two directories if the two files are not to be compared, the following format shall be used in the POSIX locale:

```
"File %s is a %s while file %s is a %s\n", <directory1 pathname>,
    <file type of directory1 pathname>, <directory2 pathname>,
    <file type of directory2 pathname>
```

For each file common to the two directories, if the files are compared and are identical, no output shall be written. If the two files differ, the following format is written:

```
"diff %s %s %s\n", <diff_options>, <filename1>, <filename2>
```

where <*diff_options*> are the options as specified on the command line.

All directory pathnames listed in this section shall be relative to the original command line arguments. All other names of files listed in this section shall be filenames (pathname components).

Diff Binary Output Format

In the POSIX locale, if one or both of the files being compared are not text files, an unspecified format shall be used that contains the pathnames of two files being compared and the string `"differ"`.

If both files being compared are text files, depending on the options specified, one of the following formats shall be used to write the differences.

Diff Default Output Format

The default (without **−e**, **−f**, **−c**, or **−C** options) *diff* utility output shall contain lines of these forms:

`"%da%d\n", <num1>, <num2>`

`"%da%d,%d\n", <num1>, <num2>, <num3>`

`"%dd%d\n", <num1>, <num2>`

`"%d,%dd%d\n", <num1>, <num2>, <num3>`

`"%dc%d\n", <num1>, <num2>`

`"%d,%dc%d\n", <num1>, <num2>, <num3>`

`"%dc%d,%d\n", <num1>, <num2>, <num3>`

`"%d,%dc%d,%d\n", <num1>, <num2>, <num3>, <num4>`

These lines resemble *ed* subcommands to convert *file1* into *file2*. The line numbers before the action letters shall pertain to *file1*; those after shall pertain to *file2*. Thus, by exchanging *a* for *d* and reading the line in reverse order, one can also determine how to convert *file2* into *file1*. As in *ed*, identical pairs (where *num1*= *num2*) are abbreviated as a single number.

Following each of these lines, *diff* shall write to standard output all lines affected in the first file using the format:

`"<Δ%s", <line>`

and all lines affected in the second file using the format:

`">Δ%s", <line>`

If there are lines affected in both *file1* and *file2* (as with the **c** subcommand), the changes are separated with a line consisting of three hyphens:

`"−−−\n"`

Diff −e Output Format

With the −**e** option, a script shall be produced that shall, when provided as input to *ed*, along with an appended **w** (write) command, convert *file1* into *file2*. Only the **a** (append), **c** (change), **d** (delete), **i** (insert), and **s** (substitute) commands of *ed* shall be used in this script. Text lines, except those consisting of the single character period (`'.'`), shall be output as they appear in the file.

Diff −f Output Format

With the −**f** option, an alternative format of script shall be produced. It is similar to that produced by −**e**, with the following differences:

1. It is expressed in reverse sequence; the output of −**e** orders changes from the end of the file to the beginning; the −**f** from beginning to end.
2. The command form <*lines*> <*command-letter*> used by −**e** is reversed. For example, 10*c* with −**e** would be *c*10 with −**f**.
3. The form used for ranges of line numbers is <space>-separated, rather than comma-separated.

Diff −c or −C Output Format

With the −**c** or −**C** option, the output format shall consist of affected lines along with surrounding lines of context. The affected lines shall show which ones need to be deleted or changed in *file1*, and those added from *file2*. With the −**c** option, three lines of context, if available, shall be written before and after the affected lines. With the −**C** option, the user can specify how many lines of context are written. The exact format follows.

The name and last modification time of each file shall be output in the following format:

```
"*** %s %s\n", file1, <file1 timestamp>
"--- %s %s\n", file2, <file2 timestamp>
```

Each <*file*> field shall be the pathname of the corresponding file being compared. The pathname written for standard input is unspecified.

In the POSIX locale, each <*timestamp*> field shall be equivalent to the output from the following command:

```
date "+%a %b %e %T %Y"
```

without the trailing <newline>, executed at the time of last modification of the corresponding file (or the current time, if the file is standard input).

Then, the following output formats shall be applied for every set of changes.

First, a line shall be written in the following format:

```
"***************\n"
```

Next, the range of lines in *file1* shall be written in the following format:

```
"*** %d,%d ****\n", <beginning line number>, <ending line number>
```

Next, the affected lines along with lines of context (unaffected lines) shall be written. Unaffected lines shall be written in the following format:

```
"ΔΔ%s", <unaffected_line>
```

Deleted lines shall be written as:

```
"−∆%s", <deleted_line>
```

Changed lines shall be written as:

```
"!∆%s", <changed_line>
```

Next, the range of lines in *file2* shall be written in the following format:

```
"−−− %d,%d −−−−\n", <beginning line number>, <ending line number>
```

Then, lines of context and changed lines shall be written as described in the previous formats. Lines added from *file2* shall be written in the following format:

```
"+∆%s", <added_line>
```

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	No differences were found.
1	Differences were found.
>1	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If lines at the end of a file are changed and other lines are added, *diff* output may show this as a delete and add, as a change, or as a change and add; *diff* is not expected to know which happened and users should not care about the difference in output as long as it clearly shows the differences between the files.

EXAMPLES

If **dir1** is a directory containing a directory named **x**, **dir2** is a directory containing a directory named **x**, **dir1/x** and **dir2/x** both contain files named **date.out**, and **dir2/x** contains a file named **y**, the command:

```
diff −r dir1 dir2
```

could produce output similar to:

```
Common subdirectories: dir1/x and dir2/x
Only in dir2/x: y
diff −r dir1/x/date.out dir2/x/date.out
1c1
< Mon Jul  2 13:12:16 PDT 1990
−−−
> Tue Jun 19 21:41:39 PDT 1990
```

RATIONALE

The **–h** option was omitted because it was insufficiently specified and does not add to applications portability.

Historical implementations employ algorithms that do not always produce a minimum list of differences; the current language about making every effort is the best this volume of IEEE Std 1003.1-200x can do, as there is no metric that could be employed to judge the quality of implementations against any and all file contents. The statement ‘‘This list should be minimal’’ clearly implies that implementations are not expected to provide the following output when comparing two 100-line files that differ in only one character on a single line:

```
1,100c1,100
all 100 lines from file1 preceded with "< "
---
all 100 lines from file2 preceded with "> "
```

The ‘‘Only in’’ messages required when the **–r** option is specified are not used by most historical implementations if the **–e** option is also specified. It is required here because it provides useful information that must be provided to update a target directory hierarchy to match a source hierarchy. The ‘‘Common subdirectories’’ messages are written by System V and 4.3 BSD when the **–r** option is specified. They are allowed here but are not required because they are reporting on something that is the same, not reporting a difference, and are not needed to update a target hierarchy.

The **–c** option, which writes output in a format using lines of context, has been included. The format is useful for a variety of reasons, among them being much improved readability and the ability to understand difference changes when the target file has line numbers that differ from another similar, but slightly different, copy. The *patch* utility is most valuable when working with difference listings using the context format. The BSD version of **–c** takes an optional argument specifying the amount of context. Rather than overloading **–c** and breaking the Utility Syntax Guidelines for *diff*, the standard developers decided to add a separate option for specifying a context diff with a specified amount of context (**–C**). Also, the format for context *diff*s was extended slightly in 4.3 BSD to allow multiple changes that are within context lines from each other to be merged together. The output format contains an additional four asterisks after the range of affected lines in the first filename. This was to provide a flag for old programs (like old versions of *patch*) that only understand the old context format. The version of context described here does not require that multiple changes within context lines be merged, but it does not prohibit it either. The extension is upward-compatible, so any vendors that wish to retain the old version of *diff* can do so by adding the extra four asterisks (that is, utilities that currently use *diff* and understand the new merged format will also understand the old unmerged format, but not *vice versa*).

The substitute command was added as an additional format for the **–e** option. This was added to provide implementations a way to fix the classic ‘‘dot alone on a line’’ bug present in many versions of *diff*. Since many implementations have fixed this bug, the standard developers decided not to standardize broken behavior, but rather to provide the necessary tool for fixing the bug. One way to fix this bug is to output two periods whenever a lone period is needed, then terminate the append command with a period, and then use the substitute command to convert the two periods into one period.

The BSD-derived **–r** option was added to provide a mechanism for using *diff* to compare two file system trees. This behavior is useful, is standard practice on all BSD-derived systems, and is not easily reproducible with the *find* utility.

The requirement that *diff* not compare files in some circumstances, even though they have the same name, is based on the actual output of historical implementations. The message specified here is already in use when a directory is being compared to a non-directory. It is extended here to preclude the problems arising from running into FIFOs and other files that would cause *diff* to hang waiting for input with no indication to the user that *diff* was hung. In most common usage, *diff* **−r** should indicate differences in the file hierarchies, not the difference of contents of devices pointed to by the hierarchies.

Many early implementations of *diff* require seekable files. Since the System Interfaces volume of IEEE Std 1003.1-200x supports named pipes, the standard developers decided that such a restriction was unreasonable. Note also that the allowed filename – almost always refers to a pipe.

No directory search order is specified for *diff*. The historical ordering is, in fact, not optimal, in that it prints out all of the differences at the current level, including the statements about all common subdirectories before recursing into those subdirectories.

The message:

```
"diff %s %s %s\n", <diff_options>, <filename1>, <filename2>
```

does not vary by locale because it is the representation of a command, not an English sentence.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **−f** option is added.

The output format for **−c** or **−C** format is changed to align with changes to the IEEE P1003.2b draft standard resulting from IEEE PASC Interpretation 1003.2 #71.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

dirname — return the directory portion of pathname

SYNOPSIS

```
dirname string
```

DESCRIPTION

The *string* operand shall be treated as a pathname, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.266, Pathname. The string *string* shall be converted to the name of the directory containing the filename corresponding to the last pathname component in *string*, performing actions equivalent to the following steps in order:

1. If *string* is //, skip steps 2 to 5.
2. If *string* consists entirely of slash characters, *string* shall be set to a single slash character. In this case, skip steps 3 to 8.
3. If there are any trailing slash characters in *string*, they shall be removed.
4. If there are no slash characters remaining in *string*, *string* shall be set to a single period character. In this case, skip steps 5 to 8.
5. If there are any trailing non-slash characters in *string*, they shall be removed.
6. If the remaining *string* is //, it is implementation-defined whether steps 7 and 8 are skipped or processed.
7. If there are any trailing slash characters in *string*, they shall be removed.
8. If the remaining *string* is empty, *string* shall be set to a single slash character.

The resulting string shall be written to standard output.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

string	A string.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *dirname*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *dirname* utility shall write a line to the standard output in the following format:

```
"%s\n", <resulting string>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The definition of *pathname* specifies implementation-defined behavior for pathnames starting with two slash characters. Therefore, applications shall not arbitrarily add slashes to the beginning of a pathname unless they can ensure that there are more or less than two or are prepared to deal with the implementation-defined consequences.

EXAMPLES

Command	Results
dirname /	/
dirname //	/ or //
dirname /a/b/	/*a*
dirname //a//b//	//*a*
dirname	Unspecified
dirname a	. ($? = 0)
dirname ""	. ($? = 0)
dirname /a	/
dirname /a/b	/*a*
dirname a/b	*a*

RATIONALE

The *dirname* utility originated in System III. It has evolved through the System V releases to a version that matches the requirements specified in this description in System V Release 3. 4.3 BSD and earlier versions did not include *dirname*.

The behaviors of *basename* and *dirname* in this volume of IEEE Std 1003.1-200x have been coordinated so that when *string* is a valid pathname:

```
$(basename "string")
```

would be a valid filename for the file in the directory:

```
$(dirname "string")
```

This would not work for the versions of these utilities in early proposals due to the way processing of trailing slashes was specified. Consideration was given to leaving processing unspecified if there were trailing slashes, but this cannot be done; the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.266, Pathname allows trailing slashes. The *basename* and *dirname* utilities have to specify consistent handling for all valid pathnames.

FUTURE DIRECTIONS

None.

basename, Section 2.5 (on page 2235)

CHANGE HISTORY

First released in Issue 2.

NAME

du — estimate file space usage

SYNOPSIS

UP

```
du [−a | −s][−kx][−H | −L][file ...]
```

DESCRIPTION

By default, the *du* utility shall write to standard output the size of the file space allocated to, and the size of the file space allocated to each subdirectory of, the file hierarchy rooted in each of the specified files. By default, when a symbolic link is encountered on the command line or in the file hierarchy, *du* shall count the size of the symbolic link (rather than the file referenced by the link), and shall not follow the link to another portion of the file hierarchy. The size of the file space allocated to a file of type directory shall be defined as the sum total of space allocated to all files in the file hierarchy rooted in the directory plus the space allocated to the directory itself.

When *du* cannot *stat*( ) files or *stat*( ) or read directories, it shall report an error condition and the final exit status is affected. Files with multiple links shall be counted and written for only one entry. The directory entry that is selected in the report is unspecified. By default, file sizes shall be written in 512-byte units, rounded up to the next 512-byte unit.

OPTIONS

The *du* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−a	In addition to the default output, report the size of each file not of type directory in the file hierarchy rooted in the specified file. Regardless of the presence of the **−a** option, non-directories given as *file* operands shall always be listed.
−H	If a symbolic link is specified on the command line, *du* shall count the size of the file or file hierarchy referenced by the link.
−k	Write the files sizes in units of 1 024 bytes, rather than the default 512-byte units.
−L	If a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *du* shall count the size of the file or file hierarchy referenced by the link.
−s	Instead of the default output, report only the total sum for each of the specified files.
−x	When evaluating file sizes, evaluate only those files that have the same device as the file specified by the *file* operand.

Specifying more than one of the mutually-exclusive options **−H** and **−L** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operand shall be supported:

file	The pathname of a file whose size is to be written. If no *file* is specified, the current directory shall be used.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *du*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The output from *du* shall consist of the amount of the space allocated to a file and the name of the file, in the following format:

```
"%d %s\n", <size>, <pathname>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The use of 512-byte units is historical practice and maintains compatibility with *ls* and other utilities in this volume of IEEE Std 1003.1-200x. This does not mandate that the file system itself be based on 512-byte blocks. The −**k** option was added as a compromise measure. It was agreed by the standard developers that 512 bytes was the best default unit because of its complete historical consistency on System V (*versus* the mixed 512 / 1 024-byte usage on BSD systems), and that a −**k** option to switch to 1 024-byte units was a good compromise. Users who prefer the 1 024-byte quantity can easily alias *du* to *du* −**k** without breaking the many historical scripts relying on the 512-byte units.

The −**b** option was added to an early proposal to provide a resolution to the situation where System V and BSD systems give figures for file sizes in *blocks*, which is an implementation-defined concept. (In common usage, the block size is 512 bytes for System V and 1 024 bytes for BSD systems.) However, −**b** was later deleted, since the default was eventually decided as 512-byte units.

Historical file systems provided no way to obtain exact figures for the space allocation given to files. There are two known areas of inaccuracies in historical file systems: cases of *indirect blocks* being used by the file system or *sparse* files yielding incorrectly high values. An indirect block is space used by the file system in the storage of the file, but that need not be counted in the space allocated to the file. A *sparse* file is one in which an *lseek*( ) call has been made to a position beyond the end of the file and data has subsequently been written at that point. A file system need not allocate all the intervening zero-filled blocks to such a file. It is up to the implementation to define exactly how accurate its methods are.

The −**a** and −**s** options were mutually-exclusive in the original version of *du*. The POSIX Shell and Utilities description is implied by the language in the SVID where −**s** is described as causing ‘‘only the grand total’’ to be reported. Some systems may produce output for −**sa**, but a Strictly Conforming POSIX Shell and Utilities Application cannot use that combination.

The −**a** and −**s** options were adopted from the SVID except that the System V behavior of not listing non-directories explicitly given as operands, unless the −**a** option is specified, was considered a bug; the BSD-based behavior (report for all operands) is mandated. The default behavior of *du* in the SVID with regard to reporting the failure to read files (it produces no messages) was considered counter-intuitive, and thus it was specified that the POSIX Shell and Utilities default behavior shall be to produce such messages. These messages can be turned off with shell redirection to achieve the System V behavior.

The −**x** option is historical practice on recent BSD systems. It has been adopted by this volume of IEEE Std 1003.1-200x because there was no other historical method of limiting the *du* search to a single file hierarchy. This limitation of the search is necessary to make it possible to obtain file space usage information about a file system on which other file systems are mounted, without having to resort to a lengthy *find* and *awk* script.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

This utility is reinstated, as the LEGACY marking was incorrect in Issue 5.

The obsolescent −**r** option has been removed.

The Open Group Corrigendum U025/3 is applied. The *du* utility had incorrectly been marked LEGACY.

The −**H** and −**L** options for symbolic links are added as described in the IEEE P1003.2b draft standard.

NAME

echo — write arguments to standard output

SYNOPSIS

```
echo [string ...]
```

DESCRIPTION

The *echo* utility writes its arguments to standard output, followed by a <newline>. If there are no arguments, only the <newline> is written.

OPTIONS

The *echo* utility shall not recognize the "−−" argument in the manner specified by Guideline 10 of the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines; "−−" shall be recognized as a string operand.

Implementations shall not support any options.

OPERANDS

The following operands shall be supported:

string A string to be written to standard output. If any operand is −**n**, it shall be treated as a string, not an option. The following character sequences shall be recognized within any of the arguments:

`\a`	Write an <alert>.
`\b`	Write a <backspace>.
`\c`	Suppress the <newline> that otherwise follows the final argument in the output. All characters following the '\c' in the arguments shall be ignored.
`\f`	Write a <form-feed>.
`\n`	Write a <newline>.
`\r`	Write a <carriage-return>.
`\t`	Write a <tab>.
`\v`	Write a <vertical-tab>.
`\\`	Write a backslash character.
`\0`*num*	Write an 8-bit value that is the zero, one, two, or three-digit octal number *num*.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *echo*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *echo* utility arguments shall be separated by single <space>s and a <newline> shall follow the last argument. Output transformations shall occur based on the escape sequences in the input. See the OPERANDS section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

In the ISO/IEC 9945-2:1993 standard, it was not possible to use *echo* portably across all systems that were not XSI-conformant unless both **−n** (as the first argument) and escape sequences were omitted.

The *printf* utility can be used portably to emulate any of the traditional behaviors of the *echo* utility as follows:

- The historic System V *echo* and the current requirements in this volume of IEEE Std 1003.1-200x are equivalent to:

  ```
  printf "%b\n" "$*"
  ```

- The BSD *echo* is equivalent to:

  ```
  if [ "X$1" = "X−n" ]
  then
      shift
      printf "%s" "$*"
  else
      printf "%s\n" "$*"
  fi
  ```

New applications are encouraged to use *printf* instead of *echo*.

EXAMPLES

None.

RATIONALE

The *echo* utility has not been made obsolescent because of its extremely widespread use in historical applications. Conforming applications that wish to do prompting without <newline>s or that could possibly be expecting to echo a −**n**, should use the *printf* utility derived from the Ninth Edition system.

As specified, *echo* writes its arguments in the simplest of ways. The two different historical versions of *echo* vary in fatally incompatible ways.

The BSD *echo* checks the first argument for the string −**n** which causes it to suppress the <newline> that would otherwise follow the final argument in the output.

The System V *echo* does not support any options, but allows escape sequences within its operands, as described in the OPERANDS section.

The *echo* utility does not support Utility Syntax Guideline 10 because historical applications depend on *echo* to echo *all* of its arguments, except for the −**n** option in the BSD version.

FUTURE DIRECTIONS

None.

printf

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the OPTIONS section, the last sentence is changed to indicate that implementations ‘‘do not’’ support any options; in the previous issue this said ‘‘need not’’.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- A set of character sequences is defined as *string* operands.
- *LC_CTYPE* is added to the list of environment variables affecting *echo*.
- In the OPTIONS section, implementations shall not support any options.

NAME

ed — edit text

SYNOPSIS

```
ed [−p string][−s][file]
```

DESCRIPTION

The *ed* utility is a line-oriented text editor that uses two modes: *command mode* and *input mode*. In command mode the input characters shall be interpreted as commands, and in input mode they shall be interpreted as text. See the EXTENDED DESCRIPTION section.

OPTIONS

The *ed* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−p *string*	Use *string* as the prompt string when in command mode. By default, there shall be no prompt string.
−s	Suppress the writing of byte counts by **e**, **E**, **r**, and **w** commands and of the `'!'` prompt after a !*command*.

OPERANDS

The following operand shall be supported:

file	If the *file* argument is given, *ed* shall simulate an **e** command on the file named by the pathname, *file*, before accepting commands from the standard input. If the *file* operand is `'−'`, the results are unspecified.

STDIN

The standard input shall be a text file consisting of commands, as described in the EXTENDED DESCRIPTION section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ed*:

HOME	Determine the pathname of the user's home directory.
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of

diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

The *ed* utility shall take the standard action for all signals (see the ASYNCHRONOUS EVENTS section in Section 1.11 (on page 2221)) with the following exceptions:

SIGINT	The *ed* utility shall interrupt its current activity, write the string `"?\n"` to standard output, and return to command mode (see the EXTENDED DESCRIPTION section).
SIGHUP	If the buffer is not empty and has changed since the last write, the *ed* utility shall attempt to write a copy of the buffer in a file. First, the file named **ed.hup** in the current directory shall be used; if that fails, the file named **ed.hup** in the directory named by the *HOME* environment variable shall be used. In any case, the *ed* utility shall exit without returning to command mode.
SIGQUIT	The *ed* utility shall ignore this event.

STDOUT

Various editing commands and the prompting feature (see −**p**) write to standard output, as described in the EXTENDED DESCRIPTION section.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

The output files shall be text files whose formats are dependent on the editing commands given.

EXTENDED DESCRIPTION

The *ed* utility shall operate on a copy of the file it is editing; changes made to the copy shall have no effect on the file until a **w** (write) command is given. The copy of the text is called the *buffer*.

Commands to *ed* have a simple and regular structure: zero, one, or two *addresses* followed by a single-character *command*, possibly followed by parameters to that command. These addresses specify one or more lines in the buffer. Every command that requires addresses has default addresses, so that the addresses very often can be omitted. If the −**p** option is specified, the prompt string shall be written to standard output before each command is read.

In general, only one command can appear on a line. Certain commands allow text to be input. This text is placed in the appropriate place in the buffer. While *ed* is accepting text, it is said to be in *input mode*. In this mode, no commands shall be recognized; all input is merely collected. Input mode is terminated by entering a line consisting of two characters: a period (`'.'`) followed by a <newline>. This line is not considered part of the input text.

Regular Expressions in ed

The *ed* utility shall support basic regular expressions, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions. Since regular expressions in *ed* are always matched against single lines (excluding the terminating <newline>s), never against any larger section of text, there is no way for a regular expression to match a <newline>.

A null RE shall be equivalent to the last RE encountered.

Regular expressions are used in addresses to specify lines, and in some commands (for example, the **s** substitute command) to specify portions of a line to be substituted.

Addresses in ed

Addressing in *ed* relates to the current line. Generally, the current line is the last line affected by a command. The current line number is the address of the current line. If the edit buffer is not empty, the initial value for the current line shall be the last line in the edit buffer; otherwise, zero.

Addresses shall be constructed as follows:

1. The period character (`'.'`) shall address the current line.
2. The dollar sign character (`'$'`) shall address the last line of the edit buffer.
3. The positive decimal number *n* shall address the *n*th line of the edit buffer.
4. The apostrophe-x character pair (`"'x"`) shall address the line marked with the mark name character *x*, which shall be a lowercase letter from the portable character set. It shall be an error if the character has not been set to mark a line or if the line that was marked is not currently present in the edit buffer.
5. A BRE enclosed by slash characters (`'/'`) shall address the first line found by searching forwards from the line following the current line toward the end of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the BRE. The BRE consisting of a null BRE delimited by a pair of slash characters shall address the next line for which the line excluding the terminating <newline> matches the last BRE encountered. In addition, the second slash can be omitted at the end of a command line. Within the BRE, a backslash-slash pair (`"\/"`) shall represent a literal slash instead of the BRE delimiter. If necessary, the search shall wrap around to the beginning of the buffer and continue up to and including the current line, so that the entire buffer is searched.
6. A BRE enclosed by question-mark characters (`'?'`) shall address the first line found by searching backwards from the line preceding the current line toward the beginning of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the BRE. The BRE consisting of a null BRE delimited by a pair of question-mark characters (`"??"`) shall address the previous line for which the line excluding the terminating <newline> matches the last BRE encountered. In addition, the second question-mark can be omitted at the end of a command line. Within the BRE, a backslash-question-mark pair (`"\?"`) shall represent a literal question mark instead of the BRE delimiter. If necessary, the search shall wrap around to the end of the buffer and continue up to and including the current line, so that the entire buffer is searched.
7. A plus-sign (`'+'`) or hyphen character (`'−'`) followed by a decimal number shall address the current line plus or minus the number. A plus-sign or hyphen character not followed by a decimal number shall address the current line plus or minus 1.

Addresses can be followed by zero or more address offsets, optionally <blank>-separated. Address offsets are constructed as follows:

- A plus-sign or hyphen character followed by a decimal number shall add or subtract, respectively, the indicated number of lines to or from the address. A plus-sign or hyphen character not followed by a decimal number shall add or subtract 1 to or from the address.
- A decimal number shall add the indicated number of lines to the address.

It shall not be an error for an intermediate address value to be less than zero or greater than the last line in the edit buffer. It shall be an error for the final address value to be less than zero or greater than the last line in the edit buffer. It shall be an error if a search for a BRE fails to find a matching line.

Commands accept zero, one, or two addresses. If more than the required number of addresses are provided to a command that requires zero addresses, it shall be an error. Otherwise, if more than the required number of addresses are provided to a command, the addresses specified first shall be evaluated and then discarded until the maximum number of valid addresses remain, for the specified command.

Addresses shall be separated from each other by a comma (`','`) or semicolon character (`';'`). In the case of a semicolon separator, the current line (`'.'`) shall be set to the first address, and only then will the second address be calculated. This feature can be used to determine the starting line for forwards and backwards searches; see rules 5. and 6.

Addresses can be omitted on either side of the comma or semicolon separator, in which case the resulting address pairs shall be as follows:

Specified	Resulting
`,`	`1 , $`
`, addr`	`1 ,a ddr`
`addr ,`	`addr , addr`
`;`	`. ; $`
`; addr`	`. ; addr`
`addr ;`	`addr ; addr`

Any <blank>s included between addresses, address separators, or address offsets shall be ignored.

Commands in ed

In the following list of *ed* commands, the default addresses are shown in parentheses. The number of addresses shown in the default shall be the number expected by the command. The parentheses are not part of the address; they show that the given addresses are the default.

It is generally invalid for more than one command to appear on a line. However, any command (except **e**, **E**, **f**, **q**, **Q**, **r**, **w**, and **!**) can be suffixed by the letter **l**, **n**, or **p**; in which case, except for the **l**, **n**, and **p** commands, the command shall be executed and then the new current line shall be written as described below under the **l**, **n**, and **p** commands. When an **l**, **n**, or **p** suffix is used with an **l**, **n**, or **p** command, the command shall write to standard output as described below, but it is unspecified whether the suffix writes the current line again in the requested format or whether the suffix has no effect. For example, the **pl** command (base **p** command with an **l** suffix) shall either write just the current line or write it twice—once as specified for **p** and once as specified for **l**. Also, the **g**, **G**, **v**, and **V** commands shall take a command as a parameter.

Each address component can be preceded by zero or more <blank>s. The command letter can be preceded by zero or more <blank>s. If a suffix letter (**l**, **n**, or **p**) is given, the application shall ensure that it immediately follows the command.

The **e**, **E**, **f**, **r**, and **w** commands shall take an optional *file* parameter, separated from the command letter by one or more <blank>s.

If changes have been made in the buffer since the last **w** command that wrote the entire buffer, *ed* shall warn the user if an attempt is made to destroy the editor buffer via the **e** or **q** commands. The *ed* utility shall write the string:

```
"?\n"
```

(followed by an explanatory message if *help mode* has been enabled via the **H** command) to standard output and shall continue in command mode with the current line number unchanged. If the **e** or **q** command is repeated with no intervening command, it shall take effect.

If a terminal disconnect is detected:

- If the buffer is not empty and has changed since the last write, the *ed* utility shall attempt to write a copy of the buffer to a file named **ed.hup** in the current directory. If this write fails, *ed* shall attempt to write a copy of the buffer to a filename **ed.hup** in the directory named by the *HOME* environment variable. If both these attempts fail, *ed* shall exit without saving the buffer.
- The *ed* utility shall not write the file to the currently remembered pathname or return to command mode, and shall terminate with a non-zero exit status.

If an end-of-file is detected on standard input:

- If the *ed* utility is in input mode, *ed* shall terminate input mode and return to command mode. It is unspecified if any partially entered lines (that is, input text without a terminating <newline>) are discarded from the input text.
- If the *ed* utility is in command mode, it shall act as if a **q** command had been entered.

If the closing delimiter of an RE or of a replacement string (for example, `'/'`) in a **g**, **G**, **s**, **v**, or **V** command would be the last character before a <newline>, that delimiter can be omitted, in which case the addressed line shall be written. For example, the following pairs of commands are equivalent:

```
s/s1/s2   s/s1/s2/p
g/s1      g/s1/p
?s1       ?s1?
```

If an invalid command is entered, *ed* shall write the string:

```
"?\n"
```

(followed by an explanatory message if *help mode* has been enabled via the **H** command) to standard output and shall continue in command mode with the current line number unchanged.

Append Command

Synopsis:

```
(.)a
<text>
.
```

The **a** command shall read the given text and append it after the addressed line; the current line number shall become the address of the last inserted line or, if there were none, the addressed line. Address 0 shall be valid for this command; it shall cause the appended text to be placed at the beginning of the buffer.

Change Command

Synopsis:

```
(.,.)c
<text>
.
```

The **c** command shall delete the addressed lines, then accept input text that replaces these lines; the current line shall be set to the address of the last line input; or, if there were none, at the line after the last line deleted; if the lines deleted were originally at the end of the buffer, the current line number shall be set to the address of the new last line; if no lines remain in the buffer, the current line number shall be set to zero. Address 0 shall be valid for this command; it shall be interpreted as if address 1 were specified.

Delete Command

Synopsis: `(.,.)d`

The **d** command shall delete the addressed lines from the buffer. The address of the line after the last line deleted shall become the current line number; if the lines deleted were originally at the end of the buffer, the current line number shall be set to the address of the new last line; if no lines remain in the buffer, the current line number shall be set to zero.

Edit Command

Synopsis: `e [file]`

The **e** command shall delete the entire contents of the buffer and then read in the file named by the pathname *file*. The current line number shall be set to the address of the last line of the buffer. If no pathname is given, the currently remembered pathname, if any, shall be used (see the **f** command). The number of bytes read shall be written to standard output, unless the **−s** option was specified, in the following format:

`"%d\n", <number of bytes read>`

The name *file* shall be remembered for possible use as a default pathname in subsequent **e**, **E**, **r**, and **w** commands. If *file* is replaced by `'!'`, the rest of the line shall be taken to be a shell command line whose output is to be read. Such a shell command line shall not be remembered as the current *file*. All marks shall be discarded upon the completion of a successful **e** command. If the buffer has changed since the last time the entire buffer was written, the user shall be warned, as described previously.

Edit Without Checking Command

Synopsis: `E [file]`

The **E** command shall possess all properties and restrictions of the **e** command except that the editor shall not check to see whether any changes have been made to the buffer since the last **w** command.

Filename Command

Synopsis: `f [file]`

If *file* is given, the **f** command shall change the currently remembered pathname to *file*; whether the name is changed or not, it shall then write the (possibly new) currently remembered pathname to the standard output in the following format:

`"%s\n", <pathname>`

The current line number shall be unchanged.

Global Command

Synopsis: `(1,$)g/RE/command list`

In the **g** command, the first step shall be to mark every line for which the line excluding the terminating <newline> matches the given *RE*. Then, going sequentially from the beginning of the file to the end of the file, the given *command list* shall be executed for each marked line, with the current line number set to the address of that line. Any line modified by the *command list* shall be unmarked. When the **g** command completes, the current line number shall have the value assigned by the last command in the *command list*. If there were no matching lines, the current line number shall not be changed. A single command or the first of a list of commands shall appear on the same line as the global command. All lines of a multi-line list except the last line shall be ended with a backslash preceding the terminating <newline>; the **a**, **i**, and **c** commands and associated input are permitted. The `'.'` terminating input mode can be omitted if it would be the last line of the *command list*. An empty *command list* shall be equivalent to the **p** command. The use of the **g**, **G**, **v**, **V**, and **!** commands in the *command list* produces undefined results. Any character other than <space> or <newline> can be used instead of a slash to delimit the *RE*. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash.

Interactive Global Command

Synopsis: `(1,$)G/`*`RE`*`/`

In the **G** command, the first step shall be to mark every line for which the line excluding the terminating <newline> matches the given *RE*. Then, for every such line, that line shall be written, the current line number shall be set to the address of that line, and any one command (other than one of the **a**, **c**, **i**, **g**, **G**, **v**, and **V** commands) shall be read and executed. A <newline> shall act as a null command (causing no action to be taken on the current line); an `'&'` shall cause the re-execution of the most recent non-null command executed within the current invocation of **G**. Note that the commands input as part of the execution of the **G** command can address and affect any lines in the buffer. The final value of the current line number shall be the value set by the last command successfully executed. (Note that the last command successfully executed shall be the **G** command itself if a command fails or the null command is specified.) If there were no matching lines, the current line number shall not be changed. The **G** command can be terminated by a SIGINT signal. Any character other than <space> or <newline> can be used instead of a slash to delimit the *RE* and the replacement. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash.

Help Command

Synopsis: `h`

The **h** command shall write a short message to standard output that explains the reason for the most recent `'?'` notification. The current line number shall be unchanged.

Help-Mode Command

Synopsis: `H`

The **H** command shall cause *ed* to enter a mode in which help messages (see the **h** command) shall be written to standard output for all subsequent `'?'` notifications. The **H** command alternately shall turn this mode on and off; it is initially off. If the help-mode is being turned on, the **H** command also explains the previous `'?'` notification, if there was one. The current line number shall be unchanged.

Insert Command

Synopsis:

```
(.)i
<text>
.
```

The **i** command shall insert the given text before the addressed line; the current line is set to the last inserted line or, if there was none, to the addressed line. This command differs from the **a** command only in the placement of the input text. Address 0 shall be valid for this command; it shall be interpreted as if address 1 were specified.

Join Command

Synopsis: `(.,.+1)j`

The **j** command shall join contiguous lines by removing the appropriate <newline>s. If exactly one address is given, this command shall do nothing. If lines are joined, the current line number shall be set to the address of the joined line; otherwise, the current line number shall be unchanged.

Mark Command

Synopsis: `(.)k`*`x`*

The **k** command shall mark the addressed line with name *x*, which the application shall ensure is a lowercase letter from the portable character set. The address `"'x"` shall then refer to this line; the current line number shall be unchanged.

List Command

Synopsis: `(.,.)l`

The **l** command shall write to standard output the addressed lines in a visually unambiguous form. The characters listed in the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\r'`, `'\t'`, `'\v'`) shall be written as the corresponding escape sequence; the `'\n'` in that table is not applicable. Non-printable characters not in the table shall be written as one three-digit octal number (with a preceding backslash character) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than nine bits, the format used for non-printable characters is implementation-defined.

Long lines shall be folded, with the point of folding indicated by <newline> preceded by a backslash; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line shall be marked with a `'$'`, and `'$'` characters within the text shall be written with a preceding backslash. An **l** command can be appended to any other command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**. The current line number shall be set to the address of the last line written.

Move Command

Synopsis: `(.,.)m`*`address`*

The **m** command shall reposition the addressed lines after the line addressed by *address*. Address 0 shall be valid for *address* and cause the addressed lines to be moved to the beginning of the buffer. It shall be an error if address *address* falls within the range of moved lines. The current line number shall be set to the address of the last line moved.

Number Command

Synopsis: `(.,.)n`

The **n** command shall write to standard output the addressed lines, preceding each line by its line number and a <tab>; the current line number shall be set to the address of the last line written. The **n** command can be appended to any command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**.

Print Command

Synopsis: `(.,.)p`

The **p** command shall write to standard output the addressed lines; the current line number shall be set to the address of the last line written. The **p** command can be appended to any command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**.

Prompt Command

Synopsis: `P`

The **P** command shall cause *ed* to prompt with an asterisk (`'*'`) (or *string*, if −**p** is specified) for all subsequent commands. The **P** command alternatively shall turn this mode on and off; it shall be initially on if the −**p** option is specified; otherwise, off. The current line number shall be unchanged.

Quit Command

Synopsis: `q`

The **q** command shall cause *ed* to exit. If the buffer has changed since the last time the entire buffer was written, the user shall be warned, as described previously.

Quit Without Checking Command

Synopsis: `Q`

The **Q** command shall cause *ed* to exit without checking whether changes have been made in the buffer since the last **w** command.

Read Command

Synopsis: `($)r` **[***file***]**

The **r** command shall read in the file named by the pathname *file* and append it after the addressed line. If no *file* argument is given, the currently remembered pathname, if any, shall be used (see the **e** and **f** commands). The currently remembered pathname shall not be changed unless there is no remembered pathname. Address 0 shall be valid for **r** and shall cause the file to be read at the beginning of the buffer. If the read is successful, and −**s** was not specified, the number of bytes read shall be written to standard output in the following format:

```
"%d\n", <number of bytes read>
```

The current line number shall be set to the address of the last line read in. If *file* is replaced by `'!'`, the rest of the line shall be taken to be a shell command line whose output is to be read. Such a shell command line shall not be remembered as the current pathname.

Substitute Command

Synopsis: `(.,.)s/`*RE*`/`*replacement*`/`*flags*

The **s** command shall search each addressed line for an occurrence of the specified RE and replace either the first or all (non-overlapped) matched strings with the *replacement*; see the following description of the **g** suffix. It is an error if the substitution fails on every addressed line. Any character other than <space> or <newline> can be used instead of a slash to delimit the *RE* and the replacement. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash. The current line shall be set to the address of the last line on which a substitution occurred.

An ampersand (`'&'`) appearing in the *replacement* shall be replaced by the string matching the RE on the current line. The special meaning of `'&'` in this context can be suppressed by preceding it by backslash. As a more general feature, the characters `'\n'`, where *n* is a digit, shall be replaced by the text matched by the corresponding back-reference expression. When the character `'%'` is the only character in the *replacement*, the *replacement* used in the most recent substitute command shall be used as the *replacement* in the current substitute command; if there was no previous substitute command, the use of `'%'` in this manner shall be an error. The `'%'` shall lose its special meaning when it is in a replacement string of more than one character or is preceded by a backslash. For each backslash (`'\'`) encountered in scanning *replacement* from beginning to end, the following character shall lose its special meaning (if any). It is unspecified what special meaning is given to any character other than `'&'`, `'\'`, `'%'`, or digits.

A line can be split by substituting a <newline> into it. The application shall ensure it escapes the <newline> in the *replacement* by preceding it by backslash. Such substitution cannot be done as part of a **g** or **v** *command list*. The current line number shall be set to the address of the last line on which a substitution is performed. If no substitution is performed, the current line number shall be unchanged. If a line is split, a substitution shall be considered to have been performed on each of the new lines for the purpose of determining the new current line number. A substitution shall be considered to have been performed even if the replacement string is identical to the string that it replaces.

The application shall ensure that the value of *flags* is zero or more of:

count	Substitute for the *count*th occurrence only of the *RE* found on each addressed line.
g	Globally substitute for all non-overlapping instances of the *RE* rather than just the first one. If both **g** and *count* are specified, the results are unspecified.
l	Write to standard output the final line in which a substitution was made. The line shall be written in the format specified for the **l** command.
n	Write to standard output the final line in which a substitution was made. The line shall be written in the format specified for the **n** command.
p	Write to standard output the final line in which a substitution was made. The line shall be written in the format specified for the **p** command.

Copy Command

Synopsis: `(.,.)taddress`

The **t** command shall be equivalent to the **m** command, except that a copy of the addressed lines shall be placed after address *address* (which can be 0); the current line number shall be set to the address of the last line added.

Undo Command

Synopsis: `u`

The **u** command shall nullify the effect of the most recent command that modified anything in the buffer, namely the most recent **a**, **c**, **d**, **g**, **i**, **j**, **m**, **r**, **s**, **t**, **u**, **v**, **G**, or **V** command. All changes made to the buffer by a **g**, **G**, **v**, or **V** global command shall be undone as a single change; if no changes were made by the global command (such as with **g**/*RE*/**p**), the **u** command shall have no effect. The current line number shall be set to the value it had immediately before the command being undone started.

Global Non-Matched Command

Synopsis: `(1,$)v/`*`RE`*`/`*`command list`*

This command shall be equivalent to the global command **g** except that the lines that are marked during the first step shall be those for which the line excluding the terminating <newline> does not match the *RE*.

Interactive Global Not-Matched Command

Synopsis: `(1,$)V/`*`RE`*`/`

This command shall be equivalent to the interactive global command **G** except that the lines that are marked during the first step shall be those for which the line excluding the terminating <newline> does not match the *RE*.

Write Command

Synopsis: `(1,$)w [`*`file`*`]`

The **w** command shall write the addressed lines into the file named by the pathname *file*. The command shall create the file, if it does not exist, or shall replace the contents of the existing file. The currently remembered pathname shall not be changed unless there is no remembered pathname. If no pathname is given, the currently remembered pathname, if any, shall be used (see the **e** and **f** commands); the current line number shall be unchanged. If the command is successful, the number of bytes written shall be written to standard output, unless the −**s** option was specified, in the following format:

`"%d\n", <`*`number of bytes written`*`>`

If *file* begins with `'!'`, the rest of the line shall be taken to be a shell command line whose standard input shall be the addressed lines. Such a shell command line shall not be remembered as the current pathname. This usage of the write command with `'!'` shall not be considered as a ‘‘last **w** command that wrote the entire buffer’’, as described previously; thus, this alone shall not prevent the warning to the user if an attempt is made to destroy the editor buffer via the **e** or **q** commands.

Line Number Command

Synopsis: `($)=`

The line number of the addressed line shall be written to standard output in the following format:

`"%d\n", <`*`line number`*`>`

The current line number shall be unchanged by this command.

Shell Escape Command

Synopsis: `!`*`command`*

The remainder of the line after the `'!'` shall be sent to the command interpreter to be interpreted as a shell command line. Within the text of that shell command line, the unescaped character `'%'` shall be replaced with the remembered pathname; if a `'!'` appears as the first character of the command, it shall be replaced with the text of the previous shell command executed via `'!'`. Thus, `"!!"` shall repeat the previous !*command*. If any replacements of `'%'` or `'!'` are performed, the modified line shall be written to the standard output before *command* is executed. The `'!'` command shall write:

`"!\n"`

to standard output upon completion, unless the **–s** option is specified. The current line number shall be unchanged.

Null Command

Synopsis: `(.+1)`

An address alone on a line shall cause the addressed line to be written. A <newline> alone shall be equivalent to `"+1p"`. The current line number shall be set to the address of the written line.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion without any file or command errors.
>0	An error occurred.

CONSEQUENCES OF ERRORS

When an error in the input script is encountered, or when an error is detected that is a consequence of the data (not) present in the file or due to an external condition such as a read or write error:

- If the standard input is a terminal device file, all input shall be flushed, and a new command read.
- If the standard input is a regular file, *ed* shall terminate with a non-zero exit status.

APPLICATION USAGE

Because of the extremely terse nature of the default error messages, the prudent script writer begins the *ed* input commands with an **H** command, so that if any errors do occur at least some clue as to the cause is made available.

In previous versions, an obsolescent – option was described. This is no longer specified. Applications should use the **–s** option. Using – as a *file* operand now produces unspecified results. This allows implementations to continue to support the former required behavior.

EXAMPLES

None.

RATIONALE

The initial description of this utility was adapted from the SVID. It contains some features not found in Version 7 or BSD-derived systems. Some of the differences between the POSIX and BSD *ed* utilities include, but need not be limited to:

- The BSD – option does not suppress the `'!'` prompt after a **!** command.
- BSD does not support the special meanings of the `'%'` and `'!'` characters within a **!** command.
- BSD does not support the *addresses* `';'` and `','`.
- BSD allows the command/suffix pairs **pp**, **ll**, and so on, which are unspecified in this volume of IEEE Std 1003.1-200x.
- BSD does not support the `'!'` character part of the **e**, **r**, or **w** commands.
- A failed **g** command in BSD sets the line number to the last line searched if there are no matches.

- BSD does not default the *command list* to the **p** command.
- BSD does not support the **G**, **h**, **H**, **n**, or **V** commands.
- On BSD, if there is no inserted text, the insert command changes the current line to the referenced line −1; that is, the line before the specified line.
- On BSD, the *join* command with only a single address changes the current line to that address.
- BSD does not support the **P** command; moreover, in BSD it is synonymous with the **p** command.
- BSD does not support the *undo* of the commands **j**, **m**, **r**, **s**, or **t**.
- The Version 7 *ed* command **W**, and the BSD *ed* commands **W**, **wq**, and **z** are not present in this volume of IEEE Std 1003.1-200x.

The −**s** option was added to allow the functionality of the now withdrawn – option in a manner compatible with the Utility Syntax Guidelines.

In early proposals there was a limit, {ED_FILE_MAX}, that described the historical limitations of some *ed* utilities in their handling of large files; some of these have had problems with files larger than 100 000 bytes. It was this limitation that prompted much of the desire to include a *split* command in this volume of IEEE Std 1003.1-200x. Since this limit was removed, this volume of IEEE Std 1003.1-200x requires that implementations document the file size limits imposed by *ed* in the conformance document. The limit {ED_LINE_MAX} was also removed; therefore, the global limit {LINE_MAX} is used for input and output lines.

The manner in which the **l** command writes non-printable characters was changed to avoid the historical backspace-overstrike method. On video display terminals, the overstrike is ambiguous because most terminals simply replace overstruck characters, making the **l** format not useful for its intended purpose of unambiguously understanding the content of the line. The historical backslash escapes were also ambiguous. (The string `"a\0011"` could represent a line containing those six characters or a line containing the three characters `'a'`, a byte with a binary value of 1, and a 1.) In the format required here, a backslash appearing in the line is written as `'\\'` so that the output is truly unambiguous. The method of marking the ends of lines was adopted from the *ex* editor and is required for any line ending in <space>s; the `'$'` is placed on all lines so that a real `'$'` at the end of a line cannot be misinterpreted.

Systems with bytes too large to fit into three octal digits must devise other means of displaying non-printable characters. Consideration was given to requiring that the number of octal digits be large enough to hold a byte, but this seemed to be too confusing for applications on the vast majority of systems where three digits are adequate. It would be theoretically possible for the application to use the *getconf* utility to find out the CHAR_BIT value and deal with such an algorithm; however, there is really no portable way that an application can use the octal values of the bytes across various coded character sets, so the additional specification was not worthwhile.

The description of how a NUL is written was removed. The NUL character cannot be in text files, and this volume of IEEE Std 1003.1-200x should not dictate behavior in the case of undefined, erroneous input.

Unlike some of the other editing utilities, the filenames accepted by the **E**, **e**, **R**, and **r** commands are not patterns.

Early proposals stated that the −**p** option worked only when standard input was associated with a terminal device. This has been changed to conform to historical implementations, thereby allowing applications to interpose themselves between a user and the *ed* utility.

The form of the substitute command that uses the **n** suffix was limited in some historical documentation (where this was described incorrectly as ‘‘backreferencing’’). This limit has been omitted because there is no reason an editor processing lines of {LINE_MAX} length should have this restriction. The command **s/x/X/2047** should be able to substitute the 2 047th occurrence of **x** on a line.

The use of printing commands with printing suffixes (such as **pn**, **lp**, and so on) was made unspecified because BSD-based systems allow this, whereas System V does not.

Some BSD-based systems exit immediately upon receipt of end-of-file if all of the lines in the file have been deleted. Since this volume of IEEE Std 1003.1-200x refers to the **q** command in this instance, such behavior is not allowed.

Some historical implementations returned exit status zero even if command errors had occurred; this is not allowed by this volume of IEEE Std 1003.1-200x.

Some historical implementations contained a bug that allowed a single period to be entered in input mode as <backslash> <period> <newline>. This is not allowed by the *ed* because there is no description of escaping any of the characters in input mode; backslashes are entered into the buffer exactly as typed. The typical method of entering a single period has been to precede it with another character and then use the substitute command to delete that character.

It is difficult under some modes of some versions of historical operating system terminal drivers to distinguish between an end-of-file condition and terminal disconnect. IEEE Std 1003.1-200x does not require implementations to distinguish between the two situations, which permits historical implementations of the *ed* utility on historical platforms to conform. Implementations are encouraged to distinguish between the two, if possible, and take appropriate action on terminal disconnect.

Historically, *ed* accepted a zero address for the **a** and **r** commands in order to insert text at the start of the edit buffer. When the buffer was empty the command **.=** returned zero. IEEE Std 1003.1-200x requires conformance to historical practice.

For consistency with the **a** and **r** commands and better user functionality, the **i** and **c** commands must also accept an address of 0, in which case 0*i* is treated as 1*i* and likewise for the **c** command.

All of the following are valid addresses:

`+++`	Three lines after the current line.
`/pattern/−`	One line before the next occurrence of pattern.
`−2`	Two lines before the current line.
`3 −−−− 2`	Line one (note the intermediate negative address).
`1 2 3`	Line six.

Any number of addresses can be provided to commands taking addresses; for example, `"1,2,3,4,5p"` prints lines 4 and 5, because two is the greatest valid number of addresses accepted by the **print** command. This, in combination with the semicolon delimiter, permits users to create commands based on ordered patterns in the file. For example, the command `"3;/foo/;+2p"` will display the first line after line 3 that contains the pattern *foo*, plus the next two lines. Note that the address `"3;"` must still be evaluated before being discarded, because the search origin for the `"/foo/"` command depends on this.

Historically, *ed* disallowed address chains, as discussed above, consisting solely of comma or semicolon separators; for example, `",,,"` or `";;;"` were considered an error. For consistency of address specification, this restriction is removed. The following table lists some of the address forms now possible:

Address	Addr1	Addr2	Status	Comment
`7,`	`7`	`7`	Historical	
`7,5,`	`5`	`5`	Historical	
`7,5,9`	`5`	`9`	Historical	
`7,9`	`7`	`9`	Historical	
`7,+`	`7`	`8`	Historical	
`,`	`1`	`$`	Historical	
`,7`	`1`	`7`	Extension	
`,,`	`$`	`$`	Extension	
`,;`	`$`	`$`	Extension	
`7;`	`7`	`7`	Historical	
`7;5;`	`5`	`5`	Historical	
`7;5;9`	`5`	`9`	Historical	
`7;5,9`	`5`	`9`	Historical	
`7;$;4`	`$`	`4`	Historical	Valid, but erroneous.
`7;9`	`7`	`9`	Historical	
`7;+`	`7`	`8`	Historical	
`;`	`.`	`$`	Historical	
`;7`	`.`	`7`	Extension	
`;;`	`$`	`$`	Extension	
`;,`	`$`	`$`	Extension	

Historically, values could be added to addresses by including them after one or more <blank>s; for example, `"3 – 5p"` wrote the seventh line of the file, and `"/foo/ 5"` was the same as `"5 /foo/"`. However, only absolute values could be added; for example, `"5 /foo/"` was an error. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, *ed* accepted the `'^'` character as an address, in which case it was identical to the hyphen character. IEEE Std 1003.1-200x does not require or prohibit this behavior.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the OPTIONS section, the meaning of –**s** and – is clarified.

Second FUTURE DIRECTION added.

Issue 6

The obsolescent single-minus form has been removed.

A second APPLICATION USAGE note has been added.

The Open Group Corrigendum U025/2 is applied, correcting the description of the Edit section.

The *ed* utility is updated to align with the IEEE P1003.2b draft standard. This includes addition of the treatment of the SIGQUIT signal, changes to *ed* addressing, changes to processing when end-of-file is detected and when terminal disconnect is detected.

13426 The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

env — set the environment for command invocation

SYNOPSIS

```
env [−i][name=value]... [utility [argument...]]
```

DESCRIPTION

The *env* utility shall obtain the current environment, modify it according to its arguments, then invoke the utility named by the *utility* operand with the modified environment.

Optional arguments shall be passed to *utility*.

If no *utility* operand is specified, the resulting environment shall be written to the standard output, with one *name*=*value* pair per line.

OPTIONS

The *env* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−i	Invoke *utility* with exactly the environment specified by the arguments; the inherited environment shall be ignored completely.

OPERANDS

The following operands shall be supported:

name=*value*	Arguments of the form *name*=*value* shall modify the execution environment, and shall be placed into the inherited environment before the *utility* is invoked.
utility	The name of the utility to be invoked. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2266), the results are undefined.
argument	A string to pass as an argument for the invoked utility.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *env*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the location of the *utility*, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables. If *PATH* is specified as a *name*=*value* operand to *env*, the *value* given shall be used in the search for *utility*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If no *utility* operand is specified, each *name*=*value* pair in the resulting environment shall be written in the form:

```
"%s=%s\n", <name>, <value>
```

If the *utility* operand is specified, the *env* utility shall not write to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If the *utility* utility is invoked, the exit status of *env* shall be the exit status of *utility*; otherwise, the *env* utility shall exit with one of the following values:

0	The *env* utility completed successfully.
1–125	An error occurred in the *env* utility.
126	The utility specified by *utility* was found but could not be invoked.
127	The utility specified by *utility* could not be found.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ‘‘failure to find a utility’’ from ‘‘invoked utility exited with an error indication’’. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ‘‘normal error conditions’’ and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

Historical implementations of the *env* utility use the *execvp*( ) or *execlp*( ) functions defined in the System Interfaces volume of IEEE Std 1003.1-200x to invoke the specified utility; this provides better performance and keeps users from having to escape characters with special meaning to the shell. Therefore, shell functions, special built-ins, and built-ins that are only provided by the shell are not found.

EXAMPLES

The following command:

```
env −i PATH=/mybin mygrep xyz myfile
```

invokes the command *mygrep* with a new *PATH* value as the only entry in its environment. In this case, *PATH* is used to locate *mygrep*, which then must reside in **/mybin**.

RATIONALE

As with all other utilities that invoke other utilities, this volume of IEEE Std 1003.1-200x only specifies what *env* does with standard input, standard output, standard error, input files, and output files. If a utility is executed, it is not constrained by the specification of input and output by *env*.

The **−i** option was added to allow the functionality of the withdrawn − option in a manner compatible with the Utility Syntax Guidelines.

Some have suggested that *env* is redundant since the same effect is achieved by:

```
name=value ... utility [ argument ... ]
```

The example is equivalent to *env* when an environment variable is being added to the environment of the command, but not when the environment is being set to the given value. The *env* utility also writes out the current environment if invoked without arguments. There is sufficient functionality beyond what the example provides to justify inclusion of *env*.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

ex — text editor

SYNOPSIS

UP `ex [−rR][−l][−s | −v][−c command][−t tagstring][−w size][file ...]`

DESCRIPTION

The *ex* utility is a line-oriented text editor. There are two other modes of the editor—open and visual—in which screen-oriented editing is available. This is described more fully by the *ex* **open** and **visual** commands and in *vi*.

This section uses the term *edit buffer* to describe the current working text. No specific implementation is implied by this term. All editing changes are performed on the edit buffer, and no changes to it shall affect any file until an editor command writes the file.

Certain terminals do not have all the capabilities necessary to support the complete *ex* definition, such as the full-screen editing commands (*visual mode* or *open mode*). When these commands cannot be supported on such terminals, this condition shall not produce an error message such as ''not an editor command'' or report a syntax error. The implementation may either accept the commands and produce results on the screen that are the result of an unsuccessful attempt to meet the requirements of this volume of IEEE Std 1003.1-200x or report an error describing the terminal-related deficiency.

OPTIONS

The *ex* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c *command* Specify an initial command to be executed in the first edit buffer loaded from an existing file (see the EXTENDED DESCRIPTION section). Implementations may support more than a single **−c** option. In such implementations, the specified commands shall be executed in the order specified on the command line.

−r Recover the named files (see the EXTENDED DESCRIPTION section). Recovery information for a file shall be saved during an editor or system crash (for example, when the editor is terminated by a signal which the editor can catch), or after the use of an *ex* **preserve** command.

A *crash* in this context is an unexpected failure of the system or utility that requires restarting the failed system or utility. A system crash implies that any utilities running at the time also crash. In the case of an editor or system crash, the number of changes to the edit buffer (since the most recent **preserve** command) that will be recovered is unspecified.

If no *file* operands are given and the **−t** option is not specified, all other options, the *EXINIT* variable, and any **.exrc** files shall be ignored; a list of all recoverable files available to the invoking user shall be written, and the editor shall exit normally without further action.

−R Set **readonly** edit option.

−s Prepare *ex* for batch use by taking the following actions:

- Suppress writing prompts and informational (but not diagnostic) messages.
- Ignore the value of *TERM* and any implementation default terminal type and assume the terminal is a type incapable of supporting open or visual modes;

see the **visual** command and the description of *vi*.

- Suppress the use of the *EXINIT* environment variable and the reading of any **.exrc** file; see the EXTENDED DESCRIPTION section.
- Suppress autoindentation, ignoring the value of the **autoindent** edit option.

–t *tagstring*	Edit the file containing the specified *tagstring*; see *ctags*. The tags feature represented by **–t** *tagstring* and the **tag** command is optional. It shall be provided on any system that also provides a conforming implementation of *ctags*; otherwise, the use of **–t** produces undefined results. On any system, it shall be an error to specify more than a single **–t** option.
–v	Begin in visual mode (see *vi*).
–w *size*	Set the value of the *window* editor option to *size*.

OPERANDS

The following operand shall be supported:

file	A pathname of a file to be edited.

STDIN

The standard input consists of a series of commands and input text, as described in the EXTENDED DESCRIPTION section. The implementation may limit each line of standard input to a length of {LINE_MAX}.

If the standard input is not a terminal device, it shall be as if the **–s** option had been specified.

If a read from the standard input returns an error, or if the editor detects an end-of-file condition from the standard input, it shall be equivalent to a SIGHUP asynchronous event.

INPUT FILES

Input files shall be text files or files that would be text files except for an incomplete last line that is not longer than {LINE_MAX}–1 bytes in length and contains no NUL characters. By default, any incomplete last line shall be treated as if it had a trailing <newline>. The editing of other forms of files may optionally be allowed by *ex* implementations.

The **.exrc** files and source files shall be text files consisting of *ex* commands; see the EXTENDED DESCRIPTION section.

By default, the editor shall read lines from the files to be edited without interpreting any of those lines as any form of editor command.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ex*:

COLUMNS	Override the system-selected horizontal screen size. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.
EXINIT	Determine a list of *ex* commands that are executed on editor start-up. See the EXTENDED DESCRIPTION section for more details of the initialization phase.
HOME	Determine a pathname of a directory that shall be searched for an editor start-up file named **.exrc**; see the EXTENDED DESCRIPTION section.
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, the classification of characters as uppercase or lowercase letters, the case conversion of letters, and the detection of word boundaries.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LINES	Override the system-selected vertical screen size, used as the number of lines in a screenful and the vertical screen size in visual mode. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PATH	Determine the search path for the shell command specified in the *ex* editor commands **!**, **shell**, **read**, and **write**, and the open and visual mode command **!**; see the description of command search and execution in Section 2.9.1.1 (on page 2249).
SHELL	Determine the preferred command line interpreter for use as the default value of the **shell** edit option.
TERM	Determine the name of the terminal type. If this variable is unset or null, an unspecified default terminal type shall be used.

ASYNCHRONOUS EVENTS

The following term is used in this and following sections to specify command and asynchronous event actions:

complete write

A complete write is a write of the entire contents of the edit buffer to a file of a type other than a terminal device, or the saving of the edit buffer caused by the user executing the *ex* **preserve** command. Writing the contents of the edit buffer to a temporary file that will be removed when the editor exits shall not be considered a complete write.

The following actions shall be taken upon receipt of signals:

SIGINT

If the standard input is not a terminal device, *ex* shall not write the file or return to command or text input mode, and shall exit with a non-zero exit status.

Otherwise, if executing an open or visual text input mode command, *ex* in receipt of SIGINT shall behave identically to its receipt of the <ESC> character.

Otherwise:

1. If executing an *ex* text input mode command, all input lines that have been completely entered shall be resolved into the edit buffer, and any partially entered line shall be discarded.

2. If there is a currently executing command, it shall be aborted and a message displayed. Unless otherwise specified by the *ex* or *vi* command descriptions, it is unspecified whether any lines modified by the executing command appear modified, or as they were before being modified by the executing command, in the buffer.

   If the currently executing command was a motion command, its associated command shall be discarded.

3. If in open or visual command mode, the terminal shall be alerted.

4. The editor shall then return to command mode.

SIGCONT	The screen shall be refreshed if in open or visual mode.
SIGHUP	If the edit buffer has been modified since the last complete write, *ex* shall attempt to save the edit buffer so that it can be recovered later using the **–r** option or the *ex* **recover** command. The editor shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.
SIGTERM	Refer to SIGHUP.

The action taken for all other signals is unspecified.

STDOUT

The standard output shall be used only for writing prompts to the user, for informational messages, and for writing lines from the file.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output from *ex* shall be text files.

EXTENDED DESCRIPTION

Only the *ex* mode of the editor is described in this section. See *vi* for additional editing capabilities available in *ex*.

When an error occurs, *ex* shall write a message. If the terminal supports a standout mode (such as inverse video), the message shall be written in standout mode. If the terminal does not support a standout mode, and the edit option **errorbells** is set, an alert action shall precede the error message.

By default, *ex* shall start in command mode, which shall be indicated by a **:** prompt; see the **prompt** command. Text input mode can be entered by the **append**, **insert**, or **change** commands; it can be exited (and command mode re-entered) by typing a period (**'.'**) alone at the beginning of a line.

Initialization in ex and vi

The following symbols are used in this and following sections to specify locations in the edit buffer:

alternate and current path names

Two pathnames, named *current* and *alternate*, are maintained by the editor. Any *ex* commands that take filenames as arguments shall set them as follows:

1. If a *file* argument is specified to the *ex* **edit**, **ex**, or **recover** commands, or if an *ex* **tag** command replaces the contents of the edit buffer.

   a. If the command replaces the contents of the edit buffer, the current pathname shall be set to the *file* argument or the file indicated by the tag, and the alternate pathname shall be set to the previous value of the current pathname.

   b. Otherwise, the alternate pathname shall be set to the *file* argument.

2. If a *file* argument is specified to the *ex* **next** command:

   a. If the command replaces the contents of the edit buffer, the current pathname shall be set to the first *file* argument, and the alternate pathname shall be set to the previous value of the current pathname.

3. If a *file* argument is specified to the *ex* **file** command, the current pathname shall be set to the *file* argument, and the alternate pathname shall be set to the previous value of the current pathname.

4. If a *file* argument is specified to the *ex* **read** and **write** commands (that is, when reading or writing a file, and not to the program named by the **shell** edit option), or a *file* argument is specified to the *ex* **xit** command:

   a. If the current pathname has no value, the current pathname shall be set to the *file* argument.

   b. Otherwise, the alternate pathname shall be set to the *file* argument.

If the alternate pathname is set to the previous value of the current pathname when the current pathname had no previous value, then the alternate pathname shall have no value as a result.

current line
The line of the edit buffer referenced by the cursor. Each command description specifies the current line after the command has been executed, as the *current line value*. When the edit buffer contains no lines, the current line shall be zero; see **Addressing in ex** (on page 2562).

current column
The current display line column occupied by the cursor. (The columns shall be numbered beginning at 1.) Each command description specifies the current column after the command has been executed, as the *current column* value. This column is an *ideal* column that is remembered over the lifetime of the editor. The actual display line column upon which the cursor rests may be different from the current column; see the cursor positioning discussion in **Command Descriptions in vi** (on page 3186).

set to non-<blank>
A description for a current column value, meaning that the current column shall be set to the last display line column on which is displayed any part of the first non-<blank> of the line. If the line has no non-<blank> non- <newline>s, the current column shall be set to the last display line column on which is displayed any part of the last non-<newline> in the line. If the line is empty, the current column shall be set to column position 1.

The length of lines in the edit buffer may be limited to {LINE_MAX} bytes. In open and visual mode, the length of lines in the edit buffer may be limited to the number of characters that will fit in the display. If either limit is exceeded during editing, an error message shall be written. If either limit is exceeded by a line read in from a file, an error message shall be written and the edit session may be terminated.

If the editor stops running due to any reason other than a user command, and the edit buffer has been modified since the last complete write, it shall be equivalent to a SIGHUP asynchronous event. If the system crashes, it shall be equivalent to a SIGHUP asynchronous event.

During initialization (before the first file is copied into the edit buffer or any user commands from the terminal are processed) the following shall occur:

1. If the environment variable *EXINIT* is set, the editor shall execute the *ex* commands contained in that variable.
2. If the *EXINIT* variable is not set, and all of the following are true:
   a. The *HOME* environment variable is not null and not empty.
   b. The file **.exrc** in the directory referred to by the *HOME* environment variable:
      1. Exists
      2. Is owned by the same user ID as the real user ID of the process or the process has appropriate privileges
      3. Is not writeable by anyone other than the owner

   the editor shall execute the *ex* commands contained in that file.
3. If and only if all the following are true:
   a. The current directory is not referred to by the *HOME* environment variable.
   b. A command in the *EXINIT* environment variable or a command in the **.exrc** file in the directory referred to by the *HOME* environment variable sets the editor option **exrc**.
   c. The **.exrc** file in the current directory:
      1. Exists
      2. Is owned by the same user ID as the real user ID of the process, or by one of a set of implementation-defined user IDs
      3. Is not writeable by anyone other than the owner

   the editor shall attempt to execute the *ex* commands contained in that file.

Lines in any **.exrc** file that are blank lines shall be ignored. If any **.exrc** file exists, but is not read for ownership or permission reasons, it shall be an error.

After the *EXINIT* variable and any **.exrc** files are processed, the first file specified by the user shall be edited, as follows:

1. If the user specified the **–t** option, the effect shall be as if the *ex* **tag** command was entered with the specified argument, with the exception that if tag processing does not result in a file to edit, the effect shall be as described in step 3. below.
2. Otherwise, if the user specified any command line *file* arguments, the effect shall be as if the *ex* **edit** command was entered with the first of those arguments as its *file* argument.
3. Otherwise, the effect shall be as if the *ex* **edit** command was entered with a nonexistent filename as its *file* argument. It is unspecified whether this action shall set the current pathname. In an implementation where this action does not set the current pathname, any editor command using the current pathname shall fail until an editor command sets the current pathname.

If the **–r** option was specified, the first time a file in the initial argument list or a file specified by the **–t** option is edited, if recovery information has previously been saved about it, that information shall be recovered and the editor shall behave as if the contents of the edit buffer have already been modified. If there are multiple instances of the file to be recovered, the one most recently saved shall be recovered, and an informational message that there are previous versions of the file that can be recovered shall be written. If no recovery information about a file is available, an informational message to this effect shall be written, and the edit shall proceed as usual.

If the −**c** option was specified, the first time a file that already exists (including a file that might not exist but for which recovery information is available, when the −**r** option is specified) replaces or initializes the contents of the edit buffer, the current line shall be set to the last line of the edit buffer, the current column shall be set to non-<blank>, and the *ex* commands specified with the −**c** option shall be executed. In this case, the current line and current column shall not be set as described for the command associated with the replacement or initialization of the edit buffer contents. However, if the −**t** option or a **tag** command is associated with this action, the −**c** option commands shall be executed and then the movement to the tag shall be performed.

The current argument list shall initially be set to the filenames specified by the user on the command line. If no filenames are specified by the user, the current argument list shall be empty. If the −**t** option was specified, it is unspecified whether any filename resulting from tag processing shall be prepended to the current argument list. In the case where the filename is added as a prefix to the current argument list, the current argument list reference shall be set to that filename. In the case where the filename is not added as a prefix to the current argument list, the current argument list reference shall logically be located before the first of the filenames specified on the command line (for example, a subsequent *ex* **next** command shall edit the first filename from the command line). If the −**t** option was not specified, the current argument list reference shall be to the first of the filenames on the command line.

Addressing in ex

Addressing in *ex* relates to the current line and the current column; the address of a line is its 1-based line number, the address of a column is its 1-based count from the beginning of the line. Generally, the current line is the last line affected by a command. The current line number is the address of the current line. In each command description, the effect of the command on the current line number and the current column is described.

Addresses are constructed as follows:

1. The character '.' (period) shall address the current line.
2. The character '$' shall address the last line of the edit buffer.
3. The positive decimal number *n* shall address the *n*th line of the edit buffer.
4. The address "'x" refers to the line marked with the mark name character 'x', which shall be a lowercase letter from the portable character set or one of the characters '`' or '''. It shall be an error if the line that was marked is not currently present in the edit buffer or the mark has not been set. Lines can be marked with the *ex* **mark** or **k** commands, or the *vi* **m** command.
5. A regular expression (RE) enclosed by slashes ('/') shall address the first line found by searching forwards from the line following the current line toward the end of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the regular expression. As stated in **Regular Expressions in ex** (on page 2592), an address consisting of a null regular expression delimited by slashes "//" shall address the next line for which the line excluding the terminating <newline> matches the last regular expression encountered. In addition, the second slash can be omitted at the end of a command line. If the **wrapscan** edit option is set, the search shall wrap around to the beginning of the edit buffer and continue up to and including the current line, so that the entire edit buffer is searched. Within the regular expression, the sequence "\/" shall represent a literal slash instead of the regular expression delimiter.

6. A regular expression enclosed in question marks (`'?'`) shall address the first line found by searching backwards from the line preceding the current line toward the beginning of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the regular expression. An address consisting of a null regular expression delimited by question marks `"??"` shall address the previous line for which the line excluding the terminating <newline> matches the last regular expression encountered. In addition, the second question mark can be omitted at the end of a command line. If the **wrapscan** edit option is set, the search shall wrap around from the beginning of the edit buffer to the end of the edit buffer and continue up to and including the current line, so that the entire edit buffer is searched. Within the regular expression, the sequence `"\?"` shall represent a literal question mark instead of the RE delimiter.

7. A plus sign (`'+'`) or a minus sign (`'−'`) followed by a decimal number shall address the current line plus or minus the number. A `'+'` or `'−'` not followed by a decimal number shall address the current line plus or minus 1.

Addresses can be followed by zero or more address offsets, optionally <blank>-separated. Address offsets are constructed as follows:

1. A `'+'` or `'−'` immediately followed by a decimal number shall add (subtract) the indicated number of lines to (from) the address. A `'+'` or `'−'` not followed by a decimal number shall add (subtract) 1 to (from) the address.

2. A decimal number shall add the indicated number of lines to the address.

It shall not be an error for an intermediate address value to be less than zero or greater than the last line in the edit buffer. It shall be an error for the final address value to be less than zero or greater than the last line in the edit buffer.

Commands take zero, one, or two addresses; see the descriptions of *1addr* and *2addr* in **Command Descriptions in ex** (on page 2569). If more than the required number of addresses are provided to a command that requires zero addresses, it shall be an error. Otherwise, if more than the required number of addresses are provided to a command, the addresses specified first shall be evaluated and then discarded until the maximum number of valid addresses remain.

Addresses shall be separated from each other by a comma (`','`) or a semicolon (`';'`). If no address is specified before or after a comma or semicolon separator, it shall be as if the address of the current line was specified before or after the separator. In the case of a semicolon separator, the current line (`'.'`) shall be set to the first address, and only then will the next address be calculated. This feature can be used to determine the starting line for forwards and backwards searches (see rules 5. and 6.).

A percent sign (`'%'`) shall be equivalent to entering the two addresses `"1,$"`.

Any delimiting <blank>s between addresses, address separators, or address offsets shall be discarded.

Command Line Parsing in ex

The following symbol is used in this and following sections to describe parsing behavior:

escape If a character is referred to as ‘‘backslash escaped’’ or ‘‘<control>-V escaped,’’ it shall mean that the character acquired or lost a special meaning by virtue of being preceded, respectively, by a backslash or <control>-V character. Unless otherwise specified, the escaping character shall be discarded at that time and shall not be further considered for any purpose.

Command-line parsing shall be done in the following steps. For each step, characters already evaluated shall be ignored; that is, the phrase ‘‘leading character’’ refers to the next character that has not yet been evaluated.

1. Leading colon characters shall be skipped.
2. Leading <blank>s shall be skipped.
3. If the leading character is a double-quote character, the characters up to and including the next non-backslash-escaped <newline> shall be discarded, and any subsequent characters shall be parsed as a separate command.
4. Leading characters that can be interpreted as addresses shall be evaluated; see **Addressing in ex** (on page 2562).
5. Leading <blank>s shall be skipped.
6. If the next character is a vertical-line character or a <newline>:
   a. If the next character is a <newline>:
      1. If *ex* is in open or visual mode, the current line shall be set to the last address specified, if any.
      2. Otherwise, if the last command was terminated by a vertical-line character, no action shall be taken; for example, the command `"||<newline>"` shall execute two implied commands, not three.
      3. Otherwise, step 6.b. shall apply.

   b. Otherwise, the implied command shall be the **print** command. The last **#**, **p**, and **l** flags specified to any *ex* command shall be remembered and shall apply to this implied command. Executing the *ex* **number**, **print**, or **list** command shall set the remembered flags to **#**, nothing, and **l**, respectively, plus any other flags specified for that execution of the **number**, **print**, or **list** command.

      If *ex* is not currently performing a **global** or **v** command, and no address or count is specified, the current line shall be incremented by 1 before the command is executed. If incrementing the current line would result in an address past the last line in the edit buffer, the command shall fail, and the increment shall not happen.

   c. The <newline> or vertical-line character shall be discarded and any subsequent characters shall be parsed as a separate command.
7. The command name shall be comprised of the next character (if the character is not alphabetic), or the next character and any subsequent alphabetic characters (if the character is alphabetic), with the following exceptions:
   a. Commands that consist of any prefix of the characters in the command name **delete**, followed immediately by any of the characters `'l'`, `'p'`, `'+'`, `'-'`, or `'#'` shall be interpreted as a **delete** command, followed by a <blank>, followed by the characters that were not part of the prefix of the **delete** command. The maximum number of characters shall be matched to the command name **delete**; for example, `"del"` shall not be treated as `"de"` followed by the flag **l**.

   b. Commands that consist of the character `'k'`, followed by a character that can be used as the name of a mark, shall be equivalent to the mark command followed by a <blank>, followed by the character that followed the `'k'`.

   c. Commands that consist of the character `'s'`, followed by characters that could be interpreted as valid options to the **s** command, shall be the equivalent of the **s** command, without any pattern or replacement values, followed by a <blank>, followed by the characters after the `'s'`.

8. The command name shall be matched against the possible command names, and a command name that contains a prefix matching the characters specified by the user shall be the executed command. In the case of commands where the characters specified by the user could be ambiguous, the executed command shall be as follows:

a	**append**	**n**	**next**	**t**	**t**
c	**change**	**p**	**print**	**u**	**undo**
ch	**change**	**pr**	**print**	**un**	**undo**
e	**edit**	**r**	**read**	**v**	**v**
m	**move**	**re**	**read**	**w**	**write**
ma	**mark**	**s**	**s**		

Implementation extensions with names causing similar ambiguities shall not be checked for a match until all possible matches for commands specified by IEEE Std 1003.1-200x have been checked.

9. If the command is a **!** command, or if the command is a **read** command followed by zero or more <blank>s and a **!**, or if the command is a **write** command followed by one or more <blank>s and a **!**, the rest of the command shall include all characters up to a non-backslash-escaped <newline>. The <newline> shall be discarded and any subsequent characters shall be parsed as a separate *ex* command.

10. Otherwise, if the command is an **edit**, **ex**, or **next** command, or a **visual** command while in open or visual mode, the next part of the command shall be parsed as follows:

    a. Any `'!'` character immediately following the command shall be skipped and be part of the command.

    b. Any leading <blank>s shall be skipped and be part of the command.

    c. If the next character is a `'+'`, characters up to the first non-backslash-escaped <newline> or non-backslash-escaped <blank> shall be skipped and be part of the command.

    d. The rest of the command shall be determined by the steps specified in paragraph 12.

11. Otherwise, if the command is a **global**, **open**, **s**, or **v** command, the next part of the command shall be parsed as follows:

    a. Any leading <blank>s shall be skipped and be part of the command.

    b. If the next character is not an alphanumeric, double-quote, <newline>, backslash, or vertical-line character:

        1. The next character shall be used as a command delimiter.

        2. If the command is a **global**, **open**, or **v** command, characters up to the first non-backslash-escaped <newline>, or first non-backslash-escaped delimiter character, shall be skipped and be part of the command.

        3. If the command is an **s** command, characters up to the first non-backslash-escaped <newline>, or second non-backslash-escaped delimiter character, shall be skipped and be part of the command.

    c. If the command is a **global** or **v** command, characters up to the first non-backslash-escaped <newline> shall be skipped and be part of the command.

  d. Otherwise, the rest of the command shall be determined by the steps specified in paragraph 12.

12. Otherwise:

  a. If the command was a **map**, **unmap**, **abbreviate**, or **unabbreviate** command, characters up to the first non-<control>-V-escaped <newline>, vertical-line, or double-quote character shall be skipped and be part of the command.

  b. Otherwise, characters up to the first non-backslash-escaped <newline>, vertical-line, or double-quote character shall be skipped and be part of the command.

  c. If the command was an **append**, **change**, or **insert** command, and the step 12.b. ended at a vertical-line character, any subsequent characters, up to the next non-backslash-escaped <newline> shall be used as input text to the command.

  d. If the command was ended by a double-quote character, all subsequent characters, up to the next non-backslash-escaped <newline>, shall be discarded.

  e. The terminating <newline> or vertical-line character shall be discarded and any subsequent characters shall be parsed as a separate *ex* command.

Command arguments shall be parsed as described by the Synopsis and Description of each individual *ex* command. This parsing shall not be <blank>-sensitive, except for the **!** argument, which must follow the command name without intervening <blank>s, and where it would otherwise be ambiguous. For example, *count* and *flag* arguments need not be <blank>-separated because `"d22p"` is not ambiguous, but *file* arguments to the *ex* **next** command must be separated by one or more <blank>s. Any <blank> in command arguments for the **abbreviate**, **unabbreviate**, **map**, and **unmap** commands can be <control>-V-escaped, in which case the <blank> shall not be used as an argument delimiter. Any <blank> in the command argument for any other command can be backslash-escaped, in which case that <blank> shall not be used as an argument delimiter.

Within command arguments for the **abbreviate**, **unabbreviate**, **map**, and **unmap** commands, any character can be <control>-V-escaped. All such escaped characters shall be treated literally and shall have no special meaning. Within command arguments for all other *ex* commands that are not regular expressions or replacement strings, any character that would otherwise have a special meaning can be backslash-escaped. Escaped characters shall be treated literally, without special meaning as shell expansion characters or `'!'`, `'%'`, and `'#'` expansion characters. See **Regular Expressions in ex** (on page 2592) and **Replacement Strings in ex** (on page 2592) for descriptions of command arguments that are regular expressions or replacement strings.

Non-backslash-escaped `'%'` characters appearing in *file* arguments to any *ex* command shall be replaced by the current pathname; unescaped `'#'` characters shall be replaced by the alternate pathname. It shall be an error if `'%'` or `'#'` characters appear unescaped in an argument and their corresponding values are not set.

Non-backslash-escaped `'!'` characters in the arguments to either the *ex* **!** command or the open and visual mode **!** command, or in the arguments to the *ex* **read** command, where the first non-<blank> after the command name is a `'!'` character, or in the arguments to the *ex* **write** command where the command name is followed by one or more <blank>s and the first non-<blank> after the command name is a `'!'` character, shall be replaced with the arguments to the last of those three commands as they appeared after all unescaped `'%'`, `'#'`, and `'!'` characters were replaced. It shall be an error if `'!'` characters appear unescaped in one of these commands and there has been no previous execution of one of these commands.

If an error occurs during the parsing or execution of an *ex* command:

- An informational message to this effect shall be written. Execution of the *ex* command shall stop, and the cursor (for example, the current line and column) shall not be further modified.
- If the *ex* command resulted from a map expansion, all characters from that map expansion shall be discarded, except as otherwise specified by the **map** command.
- Otherwise, if the *ex* command resulted from the processing of an *EXINIT* environment variable, a **.exrc** file, a **:source** command, a **–c** option, or a **+***command* specified to an *ex* **edit**, **ex**, **next**, or **visual** command, no further commands from the source of the commands shall be executed.
- Otherwise, if the *ex* command resulted from the execution of a buffer or a **global** or **v** command, no further commands caused by the execution of the buffer or the **global** or **v** command shall be executed.
- Otherwise, if the *ex* command was not terminated by a <newline>, all characters up to and including the next non-backslash-escaped <newline> shall be discarded.

Input Editing in ex

The following symbols are used in this and following sections to specify command actions.

word	In the POSIX locale, a word consists of a maximal sequence of letters, digits, and underscores, delimited at both ends by characters other than letters, digits, or underscores, or by the beginning or end of a line or the edit buffer.

When accepting input characters from the user, in either *ex* command mode or *ex* text input mode, *ex* shall enable canonical mode input processing, as defined in the System Interfaces volume of IEEE Std 1003.1-200x.

If in *ex* text input mode:

1. If the **number** edit option is set, *ex* shall prompt for input using the line number that would be assigned to the line if it is entered, in the format specified for the *ex* **number** command.
2. If the **autoindent** edit option is set, *ex* shall prompt for input using **autoindent** characters, as described by the **autoindent** edit option. **autoindent** characters shall follow the line number, if any.

If in *ex* command mode:

1. If the **prompt** edit option is set, input shall be prompted for using a single `':'` character; otherwise, there shall be no prompt.

The input characters in the following sections shall have the following effects on the input line.

Scroll

Synopsis: `eof`

See the description of the *stty eof* character in *stty*.

If in *ex* command mode:

> If the *eof* character is the first character entered on the line, the line shall be evaluated as if it contained two characters: a <control>-D and a <newline>.
>
> Otherwise, the *eof* character shall have no special meaning.

If in *ex* text input mode:

If the cursor follows an **autoindent** character, the **autoindent** characters in the line shall be modified so that a part of the next text input character will be displayed on the first column in the line after the previous **shiftwidth** edit option column boundary, and the user shall be prompted again for input for the same line.

Otherwise, if the cursor follows a `'0'`, which follows an **autoindent** character, and the `'0'` was the previous text input character, the `'0'` and all **autoindent** characters in the line shall be discarded, and the user shall be prompted again for input for the same line.

Otherwise, if the cursor follows a `'^'`, which follows an **autoindent** character, and the `'^'` was the previous text input character, the `'^'` and all **autoindent** characters in the line shall be discarded, and the user shall be prompted again for input for the same line. In addition, the **autoindent** level for the next input line shall be derived from the same line from which the **autoindent** level for the current input line was derived.

Otherwise, if there are no **autoindent** or text input characters in the line, the *eof* character shall be discarded.

Otherwise, the *eof* character shall have no special meaning.

<newline>

Synopsis: `<newline>`
`<control>-J`

If in *ex* command mode:

Cause the command line to be parsed; <control>-J shall be mapped to the <newline> for this purpose.

If in *ex* text input mode:

Terminate the current line. If there are no characters other than **autoindent** characters on the line, all characters on the line shall be discarded.

Prompt for text input on a new line after the current line. If the **autoindent** edit option is set, an appropriate number of **autoindent** characters shall be added as a prefix to the line as described by the *ex* **autoindent** edit option.

<backslash>

Synopsis: `<backslash>`

Allow the entry of a subsequent <newline> or <control>-J as a literal character, removing any special meaning that it may have to the editor during text input mode. The backslash character shall be retained and evaluated when the command line is parsed, or retained and included when the input text becomes part of the edit buffer.

<control>-V

Synopsis: `<control>-V`

Allow the entry of any subsequent character as a literal character, removing any special meaning that it may have to the editor during text input mode. The <control>-V character shall be discarded before the command line is parsed or the input text becomes part of the edit buffer.

If the ‘‘literal next’’ functionality is performed by the underlying system, it is implementation-defined whether a character other than <control>-V performs this function.

<control>-W

Synopsis: `<control>-W`

Discard the <control>-W, and the word previous to it in the input line, including any <blank>s following the word and preceding the <control>-W. If the ‘‘word erase’’ functionality is performed by the underlying system, it is implementation-defined whether a character other than <control>-W performs this function.

Command Descriptions in ex

The following symbols are used in this section to represent command modifiers. Some of these modifiers can be omitted, in which case the specified defaults shall be used.

1addr A single line address, given in any of the forms described in **Addressing in ex** (on page 2562); the default shall be the current line (`'.'`), unless otherwise specified.

If the line address is zero, it shall be an error, unless otherwise specified in the following command descriptions.

If the edit buffer is empty, and the address is specified with a command other than **=**, **append**, **insert**, **open**, **put**, **read**, or **visual**, or the address is not zero, it shall be an error.

2addr Two addresses specifying an inclusive range of lines. If no addresses are specified, the default for *2addr* shall be the current line only (`".,."`), unless otherwise specified in the following command descriptions. If one address is specified, *2addr* shall specify that line only, unless otherwise specified in the following command descriptions.

It shall be an error if the first address is greater than the second address.

If the edit buffer is empty, and the two addresses are specified with a command other than the **!**, **write**, **wq**, or **xit** commands, or either address is not zero, it shall be an error.

count A positive decimal number. If *count* is specified, it shall be equivalent to specifying an additional address to the command, unless otherwise specified by the following command descriptions. The additional address shall be equal to the last address specified to the command (either explicitly or by default) plus *count*−1.

If this would result in an address greater than the last line of the edit buffer, it shall be corrected to equal the last line of the edit buffer.

flags One or more of the characters `'+'`, `'−'`, `'#'`, `'p'`, or `'l'` (ell). The flag characters can be <blank>-separated, and in any order or combination. The characters `'#'`, `'p'`, and `'l'` shall cause lines to be written in the format specified by the **print** command with the specified *flags*.

The lines to be written are as follows:

1. All edit buffer lines written during the execution of the *ex* **&**, **~**, **list**, **number**, **open**, **print**, **s**, **visual**, and **z** commands shall be written as specified by *flags*.
2. After the completion of an *ex* command with a flag as an argument, the current line shall be written as specified by *flags*, unless the current line was the last line written by the command.

The characters `'+'` and `'−'` cause the value of the current line after the execution of the *ex* command to be adjusted by the offset address as described in **Addressing**

in ex (on page 2562). This adjustment shall occur before the current line is written as described in 2. above.

The default for *flags* shall be none.

buffer One of a number of named areas for holding text. The named buffers are specified by the alphanumeric characters of the POSIX locale. There shall also be one ‘‘unnamed’’ buffer. When no buffer is specified for editor commands that use a buffer, the unnamed buffer shall be used. Commands that store text into buffers shall store the text as it was before the command took effect, and shall store text occurring earlier in the file before text occurring later in the file, regardless of how the text region was specified. Commands that store text into buffers shall store the text into the unnamed buffer as well as any specified buffer.

In *ex* commands, buffer names are specified as the name by itself. In open or visual mode commands the name is preceded by a double quote (`'"'`) character.

If the specified buffer name is an uppercase character, and the buffer contents are to be modified, the buffer shall be appended to rather than being overwritten. If the buffer is not being modified, specifying the buffer name in lowercase and uppercase shall have identical results.

There shall also be buffers named by the numbers 1 through 9. In open and visual mode, if a region of text including characters from more than a single line is being modified by the *vi* **c** or **d** commands, the motion character associated with the **c** or **d** commands specifies that the buffer text shall be in line mode, or the commands **%**, **‘**, **/**, **?**, **(**, **)**, **N**, **n**, **{**, or **}** are used to define a region of text for the **c** or **d** commands, the contents of buffers 1 through 8 shall be moved into the buffer named by the next numerically greater value, the contents of buffer 9 shall be discarded, and the region of text shall be copied into buffer 1. This shall be in addition to copying the text into a user-specified buffer or unnamed buffer, or both. Numeric buffers can be specified as a source buffer for open and visual mode commands; however, specifying a numeric buffer as the write target of an open or visual mode command shall have unspecified results.

The text of each buffer shall have the characteristic of being in either line or character mode. Appending text to a non-empty buffer shall set the mode to match the characteristic of the text being appended. Appending text to a buffer shall cause the creation of at least one additional line in the buffer. All text stored into buffers by *ex* commands shall be in line mode. The *ex* commands that use buffers as the source of text specify individually how buffers of different modes are handled. Each open or visual mode command that uses buffers for any purpose specifies individually the mode of the text stored into the buffer and how buffers of different modes are handled.

file Command text used to derive a pathname. The default shall be the current pathname, as defined previously, in which case, if no current pathname has yet been established it shall be an error, except where specifically noted in the individual command descriptions that follow. If the command text contains any of the characters `'~'`, `'{'`, `'['`, `'*'`, `'?'`, `'$'`, ``'`'``, `'''`, `'"'`, and `'\'`, it shall be subjected to the process of ‘‘shell expansions’’, as described below; if more than a single pathname results and the command expects only one, it shall be an error.

The process of shell expansions in the editor shall be done as follows. The *ex* utility shall pass two arguments to the program named by the shell edit option; the first shall be **–c**, and the second shall be the string `"echo"` and the command text as a single argument. The standard output and standard error of that command shall replace the command text.

! A character that can be appended to the command name to modify its operation, as detailed in the individual command descriptions. With the exception of the *ex* **read**, **write**, and **!** commands, the '**!**' character shall only act as a modifier if there are no <blank>s between it and the command name.

remembered search direction
The *vi* commands **N** and **n** begin searching in a forwards or backwards direction in the edit buffer based on a remembered search direction, which is initially unset, and is set by the *ex* **global**, **v**, **s**, and **tag** commands, and the *vi* **/** and **?** commands.

Abbreviate

Synopsis: `ab[breviate][lhs rhs]`

If *lhs* and *rhs* are not specified, write the current list of abbreviations and do nothing more.

Implementations may restrict the set of characters accepted in *lhs* or *rh*, except that printable characters and <blank>s shall not be restricted. Additional restrictions shall be implementation-defined.

In both *lhs* and *rhs*, any character may be escaped with a <control>-V, in which case the character shall not be used to delimit *lhs* from *rhs*, and the escaping <control>-V shall be discarded.

In open and visual text input mode, if a non-word or <ESC> character that is not escaped by a <control>-V character is entered after a word character, a check shall be made for a set of characters matching *lhs*, in the text input entered during this command. If it is found, the effect shall be as if *rhs* was entered instead of *lhs*.

The set of characters that are checked is defined as follows:

1. If there are no characters inserted before the word and non-word or <ESC> characters that triggered the check, the set of characters shall consist of the word character.
2. If the character inserted before the word and non-word or <ESC> characters that triggered the check is a word character, the set of characters shall consist of the characters inserted immediately before the triggering characters that are word characters, plus the triggering word character.
3. If the character inserted before the word and non-word or <ESC> characters that triggered the check is not a word character, the set of characters shall consist of the characters that were inserted before the triggering characters that are neither <blank>s nor word characters, plus the triggering word character.

It is unspecified whether the *lhs* argument entered for the *ex* **abbreviate** and **unabbreviate** commands is replaced in this fashion. Regardless of whether or not the replacement occurs, the effect of the command shall be as if the replacement had not occurred.

Current line: Unchanged.

Current column: Unchanged.

Append

Synopsis: `[1addr] a[ppend][!]`

Enter text input mode; the input text shall be placed after the specified line. If line zero is specified, the text shall be placed at the beginning of the edit buffer.

This command shall be affected by the **number** and **autoindent** edit options; following the command name with `'!'` shall cause the **autoindent** edit option setting to be toggled for the duration of this command only.

Current line: Set to the last input line; if no lines were input, set to the specified line, or to the first line of the edit buffer if a line of zero was specified, or zero if the edit buffer is empty.

Current column: Set to non-<blank>.

Arguments

Synopsis: `ar[gs]`

Write the current argument list, with the current argument-list entry, if any, between `'['` and `']'` characters.

Current line: Unchanged.

Current column: Unchanged.

Change

Synopsis: `[2addr] c[hange][!][count]`

Enter *ex* text input mode; the input text shall replace the specified lines. The specified lines shall be copied into the unnamed buffer, which shall become a line mode buffer.

This command shall be affected by the **number** and **autoindent** edit options; following the command name with `'!'` shall cause the **autoindent** edit option setting to be toggled for the duration of this command only.

Current line: Set to the last input line; if no lines were input, set to the line before the first address, or to the first line of the edit buffer if there are no lines preceding the first address, or to zero if the edit buffer is empty.

Current column: Set to non-<blank>.

Change Directory

Synopsis:
```
chd[ir][!][directory]
cd[!][directory]
```

Change the current working directory to *directory*.

If no *directory* argument is specified, and the *HOME* environment variable is set to a non-null and non-empty value, *directory* shall default to the value named in the *HOME* environment variable. If the *HOME* environment variable is empty or is undefined, the default value of *directory* is implementation-defined.

If no `'!'` is appended to the command name, and the edit buffer has been modified since the last complete write, and the current pathname does not begin with a `'/'`, it shall be an error.

Current line: Unchanged.

Current column: Unchanged.

Copy

Synopsis:

```
[2addr] co[py] 1addr [flags]
[2addr] t 1addr [flags]
```

Copy the specified lines after the specified destination line; line zero specifies that the lines shall be placed at the beginning of the edit buffer.

Current line: Set to the last line copied.

Current column: Set to non-<blank>.

Delete

Synopsis:

```
[2addr] d[elete][buffer][count][flags]
```

Delete the specified lines into a buffer (defaulting to the unnamed buffer), which shall become a line-mode buffer.

Flags can immediately follow the command name; see **Command Line Parsing in ex** (on page 2563).

Current line: Set to the line following the deleted lines, or to the last line in the edit buffer if that line is past the end of the edit buffer, or to zero if the edit buffer is empty.

Current column: Set to non-<blank>.

Edit

Synopsis:

```
e[dit][!][+command][file]
ex[!][+command][file]
```

If no '!' is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error.

If *file* is specified, replace the current contents of the edit buffer with the current contents of *file*, and set the current pathname to *file*. If *file* is not specified, replace the current contents of the edit buffer with the current contents of the file named by the current pathname. If for any reason the current contents of the file cannot be accessed, the edit buffer shall be empty.

The **+***command* option shall be <blank>-delimited; <blank>s within **+***command* can be escaped by preceding them with a backslash character. The **+***command* shall be interpreted as an *ex* command immediately after the contents of the edit buffer have been replaced and the current line and column have been set.

If the edit buffer is empty:

Current line: Set to 0.

Current column: Set to 1.

Otherwise, if executed while in *ex* command mode or if the **+***command* argument is specified:

Current line: Set to the last line of the edit buffer.

Current column: Set to non-<blank>.

Otherwise, if *file* is omitted or results in the current pathname:

Current line: Set to the first line of the edit buffer.

Current column: Set to non-<blank>.

Otherwise, if *file* is the same as the last file edited, the line and column shall be set as follows; if the file was previously edited, the line and column may be set as follows:

Current line: Set to the last value held when that file was last edited. If this value is not a valid line in the new edit buffer, set to the first line of the edit buffer.

Current column: If the current line was set to the last value held when the file was last edited, set to the last value held when the file was last edited. Otherwise, or if the last value is not a valid column in the new edit buffer, set to non-<blank>.

Otherwise:

Current line: Set to the first line of the edit buffer.

Current column: Set to non-<blank>.

File

Synopsis: `f[ile][file]`

If a *file* argument is specified, the alternate pathname shall be set to the current pathname, and the current pathname shall be set to *file*.

Write an informational message. If the file has a current pathname, it shall be included in this message; otherwise, the message shall indicate that there is no current pathname. If the edit buffer contains lines, the current line number and the number of lines in the edit buffer shall be included in this message; otherwise, the message shall indicate that the edit buffer is empty. If the edit buffer has been modified since the last complete write, this fact shall be included in this message. If the **readonly** edit option is set, this fact shall be included in this message. The message may contain other unspecified information.

Current line: Unchanged.

Current column: Unchanged.

Global

Synopsis:
```
[2addr] g[lobal] /pattern/ [commands]
[2addr] v /pattern/ [commands]
```

The optional `'!'` character after the **global** command shall be the same as executing the **v** command.

If *pattern* is empty (for example, `"//"`) or not specified, the last regular expression used in the editor command shall be used as the *pattern*. The *pattern* can be delimited by slashes (shown in the Synopsis), as well as any non-alphanumeric or non-<blank> other than backslash, vertical line, double quote, or <newline>.

If no lines are specified, the lines shall default to the entire file.

The **global** and **v** commands are logically two-pass operations. First, mark the lines within the specified lines for which the line excluding the terminating <newline> matches (**global**) or does not match (**v** or **global!**) the specified pattern. Second, execute the *ex* commands given by *commands*, with the current line (`'.'`) set to each marked line. If an error occurs during this process, or the contents of the edit buffer are replaced (for example, by the *ex* **:edit** command) an error message shall be written and no more commands resulting from the execution of this command shall be processed.

Multiple *ex* commands can be specified by entering multiple commands on a single line using a vertical line to delimit them, or one per line, by escaping each <newline> with a backslash.

If no commands are specified:

1. If in *ex* command mode, it shall be as if the **print** command were specified.
2. Otherwise, no command shall be executed.

For the **append**, **change**, and **insert** commands, the input text shall be included as part of the command, and the terminating period can be omitted if the command ends the list of commands. The **open** and **visual** commands can be specified as one of the commands, in which case each marked line shall cause the editor to enter open or visual mode. If open or visual mode is exited using the *vi* **Q** command, the current line shall be set to the next marked line, and open or visual mode reentered, until the list of marked lines is exhausted.

The **global**, **v**, and **undo** commands cannot be used in *commands*. Marked lines may be deleted by commands executed for lines occurring earlier in the file than the marked lines. In this case, no commands shall be executed for the deleted lines.

If the remembered search direction is not set, the **global** and **v** commands shall set it to forward.

The **autoprint** and **autoindent** edit options shall be inhibited for the duration of the **g** or **v** command.

Current line: If no commands executed, set to the last marked line. Otherwise, as specified for the executed *ex* commands.

Current column: If no commands are executed, set to non-<blank>; otherwise, as specified for the individual *ex* commands.

Insert

Synopsis: `[1addr] i[nsert][!]`

Enter *ex* text input mode; the input text shall be placed before the specified line. If the line is zero or 1, the text shall be placed at the beginning of the edit buffer.

This command shall be affected by the **number** and **autoindent** edit options; following the command name with `'!'` shall cause the **autoindent** edit option setting to be toggled for the duration of this command only.

Current line: Set to the last input line; if no lines were input, set to the line before the specified line, or to the first line of the edit buffer if there are no lines preceding the specified line, or zero if the edit buffer is empty.

Current column: Set to non-<blank>.

Join

Synopsis: `[2addr] j[oin][!][count][flags]`

If *count* is specified:

If no address was specified, the **join** command shall behave as if *2addr* were the current line and the current line plus *count* (.,. + *count*).

If one address was specified, the **join** command shall behave as if *2addr* were the specified address and the specified address plus *count* (*addr*,*addr* + *count*).

If two addresses were specified, the **join** command shall behave as if an additional address, equal to the last address plus *count* −1 (*addr1*,*addr2*,*addr2* + *count* −1), was specified.

If this would result in a second address greater than the last line of the edit buffer, it shall be corrected to be equal to the last line of the edit buffer.

If no *count* is specified:

If no address was specified, the **join** command shall behave as if *2addr* were the current line and the next line (.,. +1).

If one address was specified, the **join** command shall behave as if *2addr* were the specified address and the next line (*addr*,*addr* +1).

Join the text from the specified lines together into a single line, which shall replace the specified lines.

If a `'!'` character is appended to the command name, the **join** shall be without modification of any line, independent of the current locale.

Otherwise, in the POSIX locale, set the current line to the first of the specified lines, and then, for each subsequent line, proceed as follows:

1. Discard leading <space>s from the line to be joined.
2. If the line to be joined is now empty, delete it, and skip steps 3 through 5.
3. If the current line ends in a <blank>, or the first character of the line to be joined is a `')'` character, join the lines without further modification.
4. If the last character of the current line is a `'.'`, join the lines with two <space>s between them.
5. Otherwise, join the lines with a single <space> between them.

Current line: Set to the first line specified.

Current column: Set to non-<blank>.

List

Synopsis: **[***2addr***]** l**[**ist**][***count***][***flags***]**

This command shall be equivalent to the *ex* command:

[*2addr***]** p**[**rint**][***count***]** l**[***flags***]**

See **Print** (on page 2580).

Map

Synopsis: `map[!][lhs rhs]`

If *lhs* and *rhs* are not specified:

1. If `'!'` is specified, write the current list of text input mode maps.
2. Otherwise, write the current list of command mode maps.
3. Do nothing more.

Implementations may restrict the set of characters accepted in *lhs* or *rhs*, except that printable characters and <blank>s shall not be restricted. Additional restrictions shall be implementation-defined. In both *lhs* and *rhs*, any character can be escaped with a <control>-V, in which case the character shall not be used to delimit *lhs* from *rhs*, and the escaping <control>-V shall be discarded.

If the character `'!'` is appended to the **map** command name, the mapping shall be effective during open or visual text input mode rather than **open** or **visual** command mode. This allows *lhs* to have two different **map** definitions at the same time: one for command mode and one for text input mode.

For command mode mappings:

> When the *lhs* is entered as any part of a *vi* command in open or visual mode (but not as part of the arguments to the command), the action shall be as if the corresponding *rhs* had been entered.
>
> If any character in the command, other than the first, is escaped using a <control>-V character, that character shall not be part of a match to an *lhs*.
>
> It is unspecified whether implementations shall support **map** commands where the *lhs* is more than a single character in length, where the first character of the *lhs* is printable.
>
> If *lhs* contains more than one character and the first character is `'#'`, followed by a sequence of digits corresponding to a numbered function key, then when this function key is typed it shall be mapped to *rhs*. Characters other than digits following a `'#'` character also represent the function key named by the characters in the *lhs* following the `'#'` and may be mapped to *rhs*. It is unspecified how function keys are named or what function keys are supported.

For text input mode mappings:

> When the *lhs* is entered as any part of text entered in open or visual text input modes, the action shall be as if the corresponding *rhs* had been entered.
>
> If any character in the input text is escaped using a <control>-V character, that character shall not be part of a match to an *lhs*.
>
> It is unspecified whether the *lhs* argument entered for the **map** or **unmap** commands is replaced in this fashion. Regardless of whether or not the replacement occurs, the effect of the command shall be as if the replacement had not occurred.

If only part of the *lhs* is entered, it is unspecified how long the editor will wait for additional, possibly matching characters before treating the already entered characters as not matching the *lhs*.

The *rhs* characters shall themselves be subject to remapping, unless otherwise specified by the **remap** edit option, except that if the characters in *lhs* occur as prefix characters in *rhs*, those characters shall not be remapped.

On block-mode terminals, the mapping need not occur immediately (for example, it may occur after the terminal transmits a group of characters to the system), but it shall achieve the same results as if it occurred immediately.

Current line: Unchanged.

Current column: Unchanged.

Mark

Synopsis:

```
[1addr] ma[rk] character
[1addr] k character
```

Implementations shall support *character* values of a single lowercase letter of the POSIX locale and the characters `'‘'` and `'’'`; support of other characters is implementation-defined.

If executing the *vi* **m** command, set the specified mark to the current line and 1-based numbered character referenced by the current column, if any; otherwise, column position 1.

Otherwise, set the specified mark to the specified line and 1-based numbered first non-<blank> non- <newline> in the line, if any; otherwise, the last non-<newline> in the line, if any; otherwise, column position 1.

The mark shall remain associated with the line until the mark is reset or the line is deleted. If a deleted line is restored by a subsequent **undo** command, any marks previously associated with the line, which have not been reset, shall be restored as well. Any use of a mark not associated with a current line in the edit buffer shall be an error.

The marks **‘** and **’** shall be set as described previously, immediately before the following events occur in the editor:

1. The use of `'$'` as an *ex* address
2. The use of a positive decimal number as an *ex* address
3. The use of a search command as an *ex* address
4. The use of a mark reference as an *ex* address
5. The use of the following open and visual mode commands: <control>-], **%**, **(**, **)**, **[**, **]**, **{**, **}**.
6. The use of the following open and visual mode commands: **’**, **G**, **H**, **L**, **M**, **z** if the current line will change as a result of the command
7. The use of the open and visual mode commands: **/**, **?**, **N**, **‘**, **n** if the current line or column will change as a result of the command
8. The use of the *ex* mode commands: **z**, **undo**, **global**, **v**

For rules 1., 2., 3., and 4., the **‘** and **’** marks shall not be set if the *ex* command is parsed as specified by rule 6.a. in **Command Line Parsing in ex** (on page 2563).

For rules 5., 6., and 7., the **‘** and **’** marks shall not be set if the commands are used as motion commands in open and visual mode.

For rules 1., 2., 3., 4., 5., 6., 7., and 8., the **‘** and **’** marks shall not be set if the command fails.

The **‘** and **’** marks shall be set as described previously, each time the contents of the edit buffer are replaced (including the editing of the initial buffer), if in open or visual mode, or if in **ex** mode and the edit buffer is not empty, before any commands or movements (including commands or movements specified by the −**c** or −**t** options or the **+***command* argument) are executed on the edit buffer. If in open or visual mode, the marks shall be set as if executing the *vi*

m command; otherwise, as if executing the *ex* **mark** command.

When changing from **ex** mode to open or visual mode, if the **‘** and **’** marks are not already set, the **‘** and **’** marks shall be set as described previously.

Current line: Unchanged.

Current column: Unchanged.

Move

Synopsis: `[2addr] m[ove] 1addr [flags]`

Move the specified lines after the specified destination line. A destination of line zero specifies that the lines shall be placed at the beginning of the edit buffer. It shall be an error if the destination line is within the range of lines to be moved.

Current line: Set to the last of the moved lines.

Current column: Set to non-<blank>.

Next

Synopsis: `n[ext][!][+command][file ...]`

If no `'!'` is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the **autowrite** option.

If one or more files is specified:

1. Set the argument list to the specified filenames.
2. Set the current argument list reference to be the first entry in the argument list.
3. Set the current pathname to the first filename specified.

Otherwise:

1. It shall be an error if there are no more filenames in the argument list after the filename currently referenced.
2. Set the current pathname and the current argument list reference to the filename after the filename currently referenced in the argument list.

Replace the contents of the edit buffer with the contents of the file named by the current pathname. If for any reason the contents of the file cannot be accessed, the edit buffer shall be empty.

This command shall be affected by the **autowrite** and **writeany** edit options.

The **+***command* option shall be <blank>-delimited; <blank>s can be escaped by preceding them with a backslash character. The **+***command* shall be interpreted as an *ex* command immediately after the contents of the edit buffer have been replaced and the current line and column have been set.

Current line: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

Number

Synopsis: `[2addr] nu[mber][count][flags]`
`[2addr] #[count][flags]`

These commands shall be equivalent to the *ex* command:

`[2addr] p[rint][count] #[flags]`

See **Print**.

Open

Synopsis: `[1addr] o[pen] /pattern/ [flags]`

This command need not be supported on block-mode terminals or terminals with insufficient capabilities. If standard input, standard output, or standard error are not terminal devices, the results are unspecified.

Enter open mode.

The trailing delimiter can be omitted from pattern at the end of the command line. If pattern is empty (for example, `"//"`) or not specified, the last regular expression used in the editor shall be used as the pattern. The pattern can be delimited by slashes (shown in the Synopsis), as well as any alphanumeric, or non-<blank> other than backslash, vertical line, double quote, or <newline>.

Current line: Set to the specified line.

Current column: Set to non-<blank>.

Preserve

Synopsis: `pre[serve]`

Save the edit buffer in a form that can later be recovered by using the **–r** option or by using the *ex* **recover** command. After the file has been preserved, a mail message shall be sent to the user. This message shall be readable by invoking the *mailx* utility. The message shall contain the name of the file, the time of preservation, and an *ex* command that could be used to recover the file. Additional information may be included in the mail message.

Current line: Unchanged.

Current column: Unchanged.

Print

Synopsis: `[2addr] p[rint][count][flags]`

Write the addressed lines. The behavior is unspecified if the number of columns on the display is less than the number of columns required to write any single character in the lines being written.

Non-printable characters, except for the <tab>, shall be written as implementation-defined multi-character sequences.

If the **#** flag is specified or the **number** edit option is set, each line shall be preceded by its line number in the following format:

`"%6dΔΔ", <line number>`

If the **l** flag is specified or the **list** edit option is set:

1. The characters listed in the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions shall be written as the corresponding escape sequence.
2. Non-printable characters not in the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions shall be written as one three-digit octal number (with a preceding backslash) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than 9 bits, the format used for non-printable characters is implementation-defined.
3. The end of each line shall be marked with a `'$'`, and literal `'$'` characters within the line shall be written with a preceding backslash.

Long lines shall be folded; the length at which folding occurs is unspecified, but should be appropriate for the output terminal, considering the number of columns of the terminal.

If a line is folded, and the **l** flag is not specified and the **list** edit option is not set, it is unspecified whether a multi-column character at the folding position is separated; it shall not be discarded.

Current line: Set to the last written line.

Current column: Unchanged if the current line is unchanged; otherwise, set to non-<blank>.

Put

Synopsis: **[***1addr***]** `pu`**[**`t`**][***buffer***]**

Append text from the specified buffer (by default, the unnamed buffer) to the specified line; line zero specifies that the text shall be placed at the beginning of the edit buffer. Each portion of a line in the buffer shall become a new line in the edit buffer, regardless of the mode of the buffer.

Current line: Set to the last line entered into the edit buffer.

Current column: Set to non-<blank>.

Quit

Synopsis: `q`**[**`uit`**][**`!`**]**

If no `'!'` is appended to the command name:

1. If the edit buffer has been modified since the last complete write, it shall be an error.
2. If there are filenames in the argument list after the filename currently referenced, and the last command was not a **quit**, **wq**, **xit**, or **ZZ** (see **Exit** (on page 3220)) command, it shall be an error.

Otherwise, terminate the editing session.

Read

Synopsis: **[***1addr***]** `r`**[**`ead`**][**`!`**][***file***]**

If `'!'` is not the first non-<blank> to follow the command name, a copy of the specified file shall be appended into the edit buffer after the specified line; line zero specifies that the copy shall be placed at the beginning of the edit buffer. The number of lines and bytes read shall be written. If no *file* is named, the current pathname shall be the default. If there is no current pathname, then *file* shall become the current pathname. If there is no current pathname or *file* operand, it shall be an error. Specifying a *file* that is not of type regular shall have unspecified results.

Otherwise, if *file* is preceded by `'!'`, the rest of the line after the `'!'` shall have `'%'`, `'#'`, and `'!'` characters expanded as described in **Command Line Parsing in ex** (on page 2563).

The *ex* utility shall then pass two arguments to the program named by the *shell* edit option; the first shall be **–c** and the second shall be the expanded arguments to the **read** command as a single argument. The standard input of the program shall be set to the standard input of the *ex* program when it was invoked. The standard error and standard output of the program shall be appended into the edit buffer after the specified line.

Each line in the copied file or program output (as delimited by <newline>s or the end of the file or output if it is not immediately preceded by a <newline>), shall be a separate line in the edit buffer. Any occurrences of <carriage-return> and <newline> pairs in the output shall be treated as single <newline>s.

The special meaning of the `'!'` following the **read** command can be overridden by escaping it with a backslash character.

Current line: If no lines are added to the edit buffer, unchanged. Otherwise, if in open or visual mode, set to the first line entered into the edit buffer. Otherwise, set to the last line entered into the edit buffer.

Current column: Set to non-<blank>.

Recover

Synopsis: `rec[over][!]` *`file`*

If no `'!'` is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error.

If no *file* operand is specified, then the current pathname shall be used. If there is no current pathname or *file* operand, it shall be an error.

If no recovery information has previously been saved about *file*, the **recover** command shall behave identically to the **edit** command, and an informational message to this effect shall be written.

Otherwise, set the current pathname to *file*, and replace the current contents of the edit buffer with the recovered contents of *file*. If there are multiple instances of the file to be recovered, the one most recently saved shall be recovered, and an informational message that there are previous versions of the file that can be recovered shall be written. The editor shall behave as if the contents of the edit buffer have already been modified.

Current file: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

Rewind

Synopsis: `rew[ind][!]`

If no `'!'` is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the **autowrite** option.

If the argument list is empty, it shall be an error.

The current argument list reference and the current pathname shall be set to the first filename in the argument list.

Replace the contents of the edit buffer with the contents of the file named by the current pathname. If for any reason the contents of the file cannot be accessed, the edit buffer shall be empty.

This command shall be affected by the **autowrite** and **writeany** edit options.

Current line: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

Set

Synopsis: `se[t][option[=[value]] ...][nooption ...][option? ...][all]`

When no arguments are specified, write the value of the **term** edit option and those options whose values have been changed from the default settings; when the argument *all* is specified, write all of the option values.

Giving an option name followed by the character `'?'` shall cause the current value of that option to be written. The `'?'` can be separated from the option name by zero or more <blank>s. The `'?'` shall be necessary only for Boolean valued options. Boolean options can be given values by the form **set** *option* to turn them on or **set no***option* to turn them off; string and numeric options can be assigned by the form **set** *option*=*value*. Any <blank>s in strings can be included as is by preceding each <blank> with an escaping backslash. More than one option can be set or listed by a single set command by specifying multiple arguments, each separated from the next by one or more <blank>s.

See **Edit Options in ex** (on page 2593) for details about specific options.

Current line: Unchanged.

Current column: Unchanged.

Shell

Synopsis: `sh[ell]`

Invoke the program named in the **shell** edit option with the single argument **−i** (interactive mode). Editing shall be resumed when the program exits.

Current line: Unchanged.

Current column: Unchanged.

Source

Synopsis: `so[urce] file`

Read and execute *ex* commands from *file*. Lines in the file that are blank lines shall be ignored.

Current line: As specified for the individual *ex* commands.

Current column: As specified for the individual *ex* commands.

Substitute

Synopsis:

```
[2addr] s[ubstitute][/pattern/repl/[options][count][flags]]
[2addr] &[options][count][flags]]
[2addr] ~[options][count][flags]]
```

Replace the first instance of the pattern *pattern* by the string *repl* on each specified line. (See **Regular Expressions in ex** (on page 2592) and **Replacement Strings in ex** (on page 2592).) Any non-alphabetic, non-<blank> delimiter other than `'\\'`, `'|'`, double quote, or <newline> can be used instead of `'/'`. Backslash characters can be used to escape delimiters, backslash characters, and other special characters.

The trailing delimiter can be omitted from *pattern* or from *repl* at the end of the command line. If both *pattern* and *repl* are not specified or are empty (for example, `"//"`), the last **s** command shall be repeated. If only *pattern* is not specified or is empty, the last regular expression used in the editor shall be used as the pattern. If only *repl* is not specified or is empty, the pattern shall be replaced by nothing. If the entire replacement pattern is `'%'`, the last replacement pattern to an **s** command shall be used.

Entering a <carriage-return> in *repl* (which requires an escaping backslash in *ex* mode and an escaping <control>-V in open or *vi* mode) shall split the line at that point, creating a new line in the edit buffer. The <carriage-return> shall be discarded.

If options include the letter `'g'` (**global**), all non-overlapping instances of the pattern in the line shall be replaced.

If options includes the letter `'c'` (**confirm**), then before each substitution the line shall be written; the written line shall reflect all previous substitutions. On the following line, <space>s shall be written beneath the characters from the line that are before the *pattern* to be replaced, and `'^'` characters written beneath the characters included in the *pattern* to be replaced. The *ex* utility shall then wait for a response from the user. An affirmative response shall cause the substitution to be done, while any other input shall not make the substitution. An affirmative response shall consist of a line with the affirmative response (as defined by the current locale) at the beginning of the line. This line shall be subject to editing in the same way as the *ex* command line.

If interrupted (see the ASYNCHRONOUS EVENTS section), any modifications confirmed by the user shall be preserved in the edit buffer after the interrupt.

If the remembered search direction is not set, the **s** command shall set it to forward.

In the second Synopsis, the **&** command shall repeat the previous substitution, as if the **&** command were replaced by:

```
s/pattern/repl/
```

where *pattern* and *repl* are as specified in the previous **s**, **&**, or **~** command.

In the third Synopsis, the **~** command shall repeat the previous substitution, as if the `'~'` were replaced by:

```
s/pattern/repl/
```

where *pattern* shall be the last regular expression specified to the editor, and *repl* shall be from the previous substitution (including **&** and **~**) command.

These commands shall be affected by the *LC_MESSAGES* environment variable.

Current line: Set to the last line in which a substitution occurred, or, unchanged if no substitution occurred.

Current column: Set to non-<blank>.

Suspend

Synopsis:
```
su[spend][!]
st[op][!]
```

Allow control to return to the invoking process; *ex* shall suspend itself as if it had received the SIGTSTP signal. The suspension shall occur only if job control is enabled in the invoking shell (see the description of *set* −**m**).

These commands shall be affected by the **autowrite** and **writeany** edit options.

The current **susp** character (see *stty*) shall be equivalent to the **suspend** command.

Tag

Synopsis:
```
ta[g][!] tagstring
```

The results are unspecified if the format of a tags file is not as specified by the *ctags* utility (see *ctags*) description.

The **tag** command shall search for *tagstring* in the tag files referred to by the **tag** edit option, in the order they are specified, until a reference to *tagstring* is found. Files shall be searched from beginning to end. If no reference is found, it shall be an error and an error message to this effect shall be written. If the reference is not found, or if an error occurs while processing a file referred to in the **tag** edit option, it shall be an error, and an error message shall be written at the first occurrence of such an error.

Otherwise, if the tags file contained a pattern, the pattern shall be treated as a regular expression used in the editor; for example, for the purposes of the **s** command.

If the *tagstring* is in a file with a different name than the current pathname, set the current pathname to the name of that file, and replace the contents of the edit buffer with the contents of that file. In this case, if no `'!'` is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the **autowrite** option.

This command shall be affected by the **autowrite**, **tag**, **taglength**, and **writeany** edit options.

Current line: If the tags file contained a line number, set to that line number. If the line number is larger than the last line in the edit buffer, an error message shall be written and the current line shall be set as specified for the **edit** command.

If the tags file contained a pattern, set to the first occurrence of the pattern in the file. If no matching pattern is found, an error message shall be written and the current line shall be set as specified for the **edit** command.

Current column: If the tags file contained a line-number reference and that line-number was not larger than the last line in the edit buffer, or if the tags file contained a pattern and that pattern was found, set to non-<blank>. Otherwise, set as specified for the **edit** command.

Unabbreviate

Synopsis: `una[bbrev] lhs`

If *lhs* is not an entry in the current list of abbreviations (see **Abbreviate** (on page 2571)), it shall be an error. Otherwise, delete *lhs* from the list of abbreviations.

Current line: Unchanged.

Current column: Unchanged.

Undo

Synopsis: `u[ndo]`

Reverse the changes made by the last command that modified the contents of the edit buffer, including **undo**. For this purpose, the **global**, **v**, **open**, and **visual** commands, and commands resulting from buffer executions and mapped character expansions, are considered single commands.

If no action that can be undone preceded the **undo** command, it shall be an error.

If the **undo** command restores lines that were marked, the mark shall also be restored unless it was reset subsequent to the deletion of the lines.

Current line:

1. If lines are added or changed in the file, set to the first line added or changed.
2. Set to the line before the first line deleted, if it exists.
3. Set to 1 if the edit buffer is not empty.
4. Set to zero.

Current column: Set to non-<blank>.

Unmap

Synopsis: `unm[ap][!] lhs`

If `'!'` is appended to the command name, and if *lhs* is not an entry in the list of text input mode map definitions, it shall be an error. Otherwise, delete *lhs* from the list of text input mode map definitions.

If no `'!'` is appended to the command name, and if *lhs* is not an entry in the list of command mode map definitions, it shall be an error. Otherwise, delete *lhs* from the list of command mode map definitions.

Current line: Unchanged.

Current column: Unchanged.

Version

Synopsis: `ve[rsion]`

Write a message containing version information for the editor. The format of the message is unspecified.

Current line: Unchanged.

Current column: Unchanged.

Visual

Synopsis: `[1addr] vi[sual][type][count][flags]`

If *ex* is currently in open or visual mode, the Synopsis and behavior of the visual command shall be the same as the **edit** command, as specified by **Edit** (on page 2573).

Otherwise, this command need not be supported on block-mode terminals or terminals with insufficient capabilities. If standard input, standard output, or standard error are not terminal devices, the results are unspecified.

If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in **window** (on page 2599)). If the `'^'` type character was also specified, the **window** edit option shall be set before being used by the type character.

Enter visual mode. If *type* is not specified, it shall be as if a *type* of `'+'` was specified. The *type* shall cause the following effects:

`+` Place the beginning of the specified line at the top of the display.

`-` Place the end of the specified line at the bottom of the display.

`.` Place the beginning of the specified line in the middle of the display.

`^` If the specified line is less than or equal to the value of the **window** edit option, set the line to 1; otherwise, decrement the line by the value of the **window** edit option minus 1. Place the beginning of this line as close to the bottom of the displayed lines as possible, while still displaying the value of the **window** edit option number of lines.

Current line: Set to the specified line.

Current column: Set to non-<blank>.

Write

Synopsis:
```
[2addr] w[rite][!][>>][file]
[2addr] w[rite][!][file]
[2addr] wq[!][>>][file]
```

If no lines are specified, the lines shall default to the entire file.

The command **wq** shall be equivalent to a **write** command followed by a **quit** command; **wq!** shall be equivalent to **write!** followed by **quit**. In both cases, if the **write** command fails, the **quit** shall not be attempted.

If the command name is not followed by one or more <blank>s, or *file* is not preceded by a `'!'` character, the **write** shall be to a file.

1. If the **>>** argument is specified, and the file already exists, the lines shall be appended to the file instead of replacing its contents. If the **>>** argument is specified, and the file does not already exist, it is unspecified whether the write shall proceed as if the **>>** argument had not been specified or if the write shall fail.
2. If the **readonly** edit option is set (see **readonly** (on page 2596)), the **write** shall fail.
3. If *file* is specified, and is not the current pathname, and the file exists, the **write** shall fail.
4. If *file* is not specified, the current pathname shall be used. If there is no current pathname, the **write** command shall fail.
5. If the current pathname is used, and the current pathname has been changed by the **file** or **read** commands, and the file exists, the **write** shall fail. If the **write** is successful,

subsequent **write**s shall not fail for this reason (unless the current pathname is changed again).

6. If the whole edit buffer is not being written, and the file to be written exists, the **write** shall fail.

For rules 1., 2., 4., and 5., the **write** can be forced by appending the character `'!'` to the command name.

For rules 2., 4., and 5., the **write** can be forced by setting the **writeany** edit option.

Additional, implementation-defined tests may cause the **write** to fail.

If the edit buffer is empty, a file without any contents shall be written.

An informational message shall be written noting the number of lines and bytes written.

Otherwise, if the command is followed by one or more <blank>s, and the file is preceded by `'!'`, the rest of the line after the `'!'` shall have `'%'`, `'#'`, and `'!'` characters expanded as described in **Command Line Parsing in ex** (on page 2563).

The *ex* utility shall then pass two arguments to the program named by the **shell** edit option; the first shall be **–c** and the second shall be the expanded arguments to the **write** command as a single argument. The specified lines shall be written to the standard input of the command. The standard error and standard output of the program. if any, shall be written as described for the **print** command. If the last character in that output is not a <newline>, a <newline> shall be written at the end of the output.

The special meaning of the `'!'` following the **write** command can be overridden by escaping it with a backslash character.

Current line: Unchanged.

Current column: Unchanged.

Write and Exit

Synopsis: `[2addr] x[it][!][file]`

If the edit buffer has not been modified since the last complete **write**, **xit** shall be equivalent to the **quit** command, or if a `'!'` is appended to the command name, to **quit!**.

Otherwise, **xit** shall be equivalent to the **wq** command, or if a `'!'` is appended to the command name, to **wq!**.

Current line: Unchanged.

Current column: Unchanged.

Yank

Synopsis: `[2addr] ya[nk][buffer][count]`

Copy the specified lines to the specified buffer (by default, the unnamed buffer), which shall become a line-mode buffer.

Current line: Unchanged.

Current column: Unchanged.

Adjust Window

Synopsis: `[1addr] z[!][type ...][count][flags]`

If no line is specified, the current line shall be the default; if *type* is omitted as well, the current line value shall first be incremented by 1. If incrementing the current line would cause it to be greater than the last line in the edit buffer, it shall be an error.

If there are <blank>s between the *type* argument and the preceding **z** command name or optional `'!'` character, it shall be an error.

If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in **window** (on page 2599)). If *count* is omitted, it shall default to 2 times the value of the **scroll** edit option, or if **!** was specified, the number of lines in the display minus 1.

If *type* is omitted, then *count* lines starting with the specified line shall be written. Otherwise, *count* lines starting with the line specified by the *type* argument shall be written.

The *type* argument shall change the lines to be written. The possible values of *type* are as follows:

– The specified line shall be decremented by the following value:

```
(((number of ''−'' characters) x count) −1)
```

If the calculation would result in a number less than 1, it shall be an error. Write lines from the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit buffer has been written.

\+ The specified line shall be incremented by the following value:

```
(((number of ''+'' characters) −1) x count) +1
```

If the calculation would result in a number greater than the last line in the edit buffer, it shall be an error. Write lines from the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit buffer has been written.

=,. If more than a single `'.'` or `'='` is specified, it shall be an error. The following steps shall be taken:

1. If *count* is zero, nothing shall be written.
2. Write as many of the *N* lines before the current line in the edit buffer as exist. If *count* or `'!'` was specified, *N* shall be:

   ```
   (count −1) /2
   ```

   Otherwise, *N* shall be:

   ```
   (count −3) /2
   ```

   If *N* is a number less than 3, no lines shall be written.
3. If `'='` was specified as the type character, write a line consisting of the smaller of the number of columns in the display divided by two, or 40 `'−'` characters.
4. Write the current line.
5. Repeat step 3.
6. Write as many of the *N* lines after the current line in the edit buffer as exist. *N* shall be defined as in step 2. If *N* is a number less than 3, no lines shall be written. current line in the edit buffer as exist. If count is less than 3, no lines shall be written.

^ The specified line shall be decremented by the following value:

`(((number of ''^'' characters) +1) x count) −1`

If the calculation would result in a number less than 1, it shall be an error. Write lines from the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit buffer has been written.

Current line: Set to the last line written, unless the type is **=**, in which case, set to the specified line.

Current column: Set to non-<blank>.

Escape

Synopsis: `!` *command*
[*addr***]**`!` *command*

The contents of the line after the `'!'` shall have `'%'`, `'#'`, and `'!'` characters expanded as described in **Command Line Parsing in ex** (on page 2563). If the expansion causes the text of the line to change, it shall be redisplayed, preceded by a single `'!'` character.

The *ex* utility shall execute the program named by the **shell** edit option. It shall pass two arguments to the program; the first shall be **−c**, and the second shall be the expanded arguments to the **!** command as a single argument.

If no lines are specified, the standard input, standard output, and standard error of the program shall be set to the standard input, standard output, and standard error of the *ex* program when it was invoked. In addition, a warning message shall be written if the edit buffer has been modified since the last complete write, and the **warn** edit option is set.

If lines are specified, they shall be passed to the program as standard input, and the standard output and standard error of the program shall replace those lines in the edit buffer. Each line in the program output (as delimited by <newline>s or the end of the output if it is not immediately preceded by a <newline>), shall be a separate line in the edit buffer. Any occurrences of <carriage-return> and <newline> pairs in the output shall be treated as single <newline>s. The specified lines shall be copied into the unnamed buffer before they are replaced, and the unnamed buffer shall become a line-mode buffer.

If in *ex* mode, a single `'!'` character shall be written when the program completes.

This command shall be affected by the **shell** and **warn** edit options. If no lines are specified, this command shall be affected by the **autowrite** and **writeany** edit options. If lines are specified, this command shall be affected by the **autoprint** edit option.

Current line:

1. If no lines are specified, unchanged.
2. Otherwise, set to the last line read in, if any lines are read in.
3. Otherwise, set to the line before the first line of the lines specified, if that line exists.
4. Otherwise, set to the first line of the edit buffer if the edit buffer is not empty.
5. Otherwise, set to zero.

Current column: If no lines are specified, unchanged. Otherwise, set to non-<blank>.

Shift Left

Synopsis: `[2addr] <[< ...][count][flags]`

Shift the specified lines to the start of the line; the number of column positions to be shifted shall be the number of command characters times the value of the **shiftwidth** edit option. Only leading <blank>s shall be deleted or changed into other <blank>s in shifting; other characters shall not be affected.

Lines to be shifted shall be copied into the unnamed buffer, which shall become a line-mode buffer.

This command shall be affected by the **autoprint** edit option.

Current line: Set to the last line in the lines specified.

Current column: Set to non-<blank>.

Shift Right

Synopsis: `[2addr] >[> ...][count][flags]`

Shift the specified lines away from the start of the line; the number of column positions to be shifted shall be the number of command characters times the value of the **shiftwidth** edit option. The shift shall be accomplished by adding <blank>s as a prefix to the line or changing leading <blank>s into other <blank>s. Empty lines shall not be changed.

Lines to be shifted shall be copied into the unnamed buffer, which shall become a line-mode buffer.

This command shall be affected by the **autoprint** edit option.

Current line: Set to the last line in the lines specified.

Current column: Set to non-<blank>.

<control>-D

Synopsis: `<control>-D`

Write the next *n* lines, where *n* is the minimum of the values of the **scroll** edit option and the number of lines after the current line in the edit buffer. If the current line is the last line of the edit buffer it shall be an error.

Current line: Set to the last line written.

Current column: Set to non-<blank>.

Write Line Number

Synopsis: `[1addr] = [flags]`

If *line* is not specified, it shall default to the last line in the edit buffer. Write the line number of the specified line.

Current line: Unchanged.

Current column: Unchanged.

Execute

Synopsis: `[2addr] @ buffer`
`[2addr] * buffer`

If no buffer is specified or is specified as '@' or '*', the last buffer executed shall be used. If no previous buffer has been executed, it shall be an error.

For each line specified by the addresses, set the current line ('.') to the specified line, and execute the contents of the named *buffer* (as they were at the time the **@** command was executed) as *ex* commands. For each line of a line-mode buffer, and all but the last line of a character-mode buffer, the *ex* command parser shall behave as if the line was terminated by a <newline>.

If an error occurs during this process, or a line specified by the addresses does not exist when the current line would be set to it, or more than a single line was specified by the addresses, and the contents of the edit buffer are replaced (for example, by the *ex* **:edit** command) an error message shall be written, and no more commands resulting from the execution of this command shall be processed.

Current line: As specified for the individual *ex* commands.

Current column: As specified for the individual *ex* commands.

Regular Expressions in ex

The *ex* utility shall support regular expressions that are a superset of the basic regular expressions described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions. A null regular expression ("//") shall be equivalent to the last regular expression encountered.

Regular expressions can be used in addresses to specify lines and, in some commands (for example, the **substitute** command), to specify portions of a line to be substituted.

The following constructs can be used to enhance the basic regular expressions:

\< Match the beginning of a *word*. (See the definition of *word* at the beginning of **Command Descriptions in ex** (on page 2569).)

\> Match the end of a *word*.

~ Match the replacement part of the last **substitute** command. The tilde ('~') character can be escaped in a regular expression to become a normal character with no special meaning. The backslash shall be discarded.

When the editor option **magic** is not set, the only characters with special meanings shall be '^' at the beginning of a pattern, '$' at the end of a pattern, and '\'. The characters '.', '*', '[', and '~' shall be treated as ordinary characters unless preceded by a '\'; when preceded by a '\' they shall regain their special meaning, or in the case of backslash, be handled as a single backslash. Backslashes used to escape other characters shall be discarded.

Replacement Strings in ex

The character '&' ('\&' if the editor option **magic** is not set) in the replacement string shall stand for the text matched by the pattern to be replaced. The character '~' ('\~' if **magic** is not set) shall be replaced by the replacement part of the previous **substitute** command. The sequence '\n', where *n* is an integer, shall be replaced by the text matched by the pattern enclosed in the *n*th set of parentheses '\(' and '\)'.

The strings '\l', '\u', '\L', and '\U' can be used to modify the case of elements in the replacement string (using the '\&' or "\"digit) notation. The string '\l' ('\u') shall cause the character that follows to be converted to lowercase (uppercase). The string `'\L'` (`'\U'`) shall cause all characters subsequent to it to be converted to lowercase (uppercase) as they are inserted by the substitution until the string `'\e'` or `'\E'`, or the end of the replacement string, is encountered.

Otherwise, any character following a backslash shall be treated as that literal character, and the escaping backslash shall be discarded.

An example of case conversion with the **s** command is as follows:

```
:p
The cat sat on the mat.
:s/\<.at\>/\u&/gp
The Cat Sat on the Mat.
:s/S\(.*\)M/S\U\1\eM/p
The Cat SAT ON THE Mat.
```

Edit Options in ex

The *ex* utility has a number of options that modify its behavior. These options have default settings, which can be changed using the **set** command.

Options are Boolean unless otherwise specified.

autoindent, ai

[Default *unset*]

If **autoindent** is set, each line in input mode shall be indented (using first as many <tab>s as possible, as determined by the editor option **tabstop**, and then using <space>s) to align with another line, as follows:

1. If in open or visual mode and the text input is part of a line-oriented command (see the EXTENDED DESCRIPTION in *vi*), align to the first column. Otherwise, if in open or visual mode, indentation for each line shall be set as follows:
   a. If a line was previously inserted as part of this command, it shall be set to the indentation of the last inserted line by default, or as otherwise specified for the <control>-D character in **Input Mode Commands in vi** (on page 3220).
   b. Otherwise, it shall be set to the indentation of the previous current line, if any; otherwise, to the first column.
2. For the *ex* **a**, **i**, and **c** commands, indentation for each line shall be set as follows:
   a. If a line was previously inserted as part of this command, it shall be set to the indentation of the last inserted line by default, or as otherwise specified for the *eof* character in **Scroll** (on page 2567).
   b. Otherwise, if the command is the *ex* **a** command, it shall be set to the line appended after, if any; otherwise to the first column.
   c. Otherwise, if the command is the *ex* **i** command, it shall be set to the line inserted before, if any; otherwise to the first column.
   d. Otherwise, if the command is the *ex* **c** command, it shall be set to the indentation of the line replaced.

autoprint, ap

[Default *set*]

If **autoprint** is set, the current line shall be written after each *ex* command that modifies the contents of the current edit buffer, and after each **tag** command for which the tag search pattern was found or tag line number was valid, unless:

1. The command was executed while in open or visual mode.
2. The command was executed as part of a **global** or **v** command or **@** buffer execution.
3. The command was the form of the **read** command that reads a file into the edit buffer.
4. The command was the **append**, **change**, or **insert** command.
5. The command was not terminated by a <newline>.
6. The current line shall be written by a flag specified to the command; for example, **delete #** shall write the current line as specified for the flag modifier to the **delete** command, and not as specified by the **autoprint** edit option.

autowrite, aw

[Default *unset*]

If **autowrite** is set, and the edit buffer has been modified since it was last completely written to any file, the contents of the edit buffer shall be written as if the *ex* **write** command had been specified without arguments, before each command affected by the **autowrite** edit option is executed. Appending the character '!' to the command name of any of the *ex* commands except '!' shall prevent the write. If the write fails, it shall be an error and the command shall not be executed.

beautify, bf

XSI [Default *unset*]

If **beautify** is set, all non-printable characters, other than <tab>s, <newline>s, and <form-feed>s, shall be discarded from text read in from files.

directory, dir

[Default *implementation-defined*]

The value of this option specifies the directory in which the editor buffer is to be placed. If this directory is not writable by the user, the editor shall quit.

edcompatible, ed

[Default *unset*]

Causes the presence of **g** and **c** suffixes on substitute commands to be remembered, and toggled by repeating the suffixes.

errorbells, eb

[Default *unset*]

If the editor is in *ex* mode, and the terminal does not support a standout mode (such as inverse video), and **errorbells** is set, error messages shall be preceded by alerting the terminal.

exrc

[Default *unset*]

If **exrc** is set, *ex* shall access any **.exrc** file in the current directory, as described in **Initialization in ex and vi** (on page 2559). If **exrc** is not set, *ex* shall ignore any **.exrc** file in the current directory during initialization, unless the current directory is that named by the *HOME* environment variable.

ignorecase, ic

[Default *unset*]

If **ignorecase** is set, characters that have uppercase and lowercase representations shall have those representations considered as equivalent for purposes of regular expression comparison.

The **ignorecase** edit option shall affect all remembered regular expressions; for example, unsetting the **ignorecase** edit option shall cause a subsequent *vi* **n** command to search for the last basic regular expression in a case-sensitive fashion.

list

[Default *unset*]

If **list** is set, edit buffer lines written while in *ex* command mode shall be written as specified for the **print** command with the **l** flag specified. In open or visual mode, each edit buffer line shall be displayed as specified for the *ex* print command with the **l** flag specified. In open or visual text input mode, when the cursor does not rest on any character in the line, it shall rest on the `'$'` marking the end of the line.

magic

[Default *set*]

If **magic** is set, modify the interpretation of characters in regular expressions and substitution replacement strings (see **Regular Expressions in ex** (on page 2592) and **Replacement Strings in ex** (on page 2592)).

mesg

[Default *set*]

If **mesg** is set, the permission for others to use the **write** or **talk** commands to write to the terminal shall be turned on while in open or visual mode. The shell-level command *mesg* **n** shall take precedence over any setting of the *ex* **mesg** option; that is, if **mesg y** was issued before the editor started (or in a shell escape), such as:

```
:!mesg y
```

the **mesg** option in *ex* shall suppress incoming messages, but the **mesg** option shall not enable incoming messages if **mesg n** was issued.

number, nu

[Default *unset*]

If **number** is set, edit buffer lines written while in *ex* command mode shall be written with line numbers, in the format specified by the **print** command with the **#** flag specified. In *ex* text input mode, each line shall be preceded by the line number it will have in the file.

In open or visual mode, each edit buffer line shall be displayed with a preceding line number, in the format specified by the *ex* **print** command with the **#** flag specified. This line number shall not be considered part of the line for the purposes of evaluating the current column; that is, column position 1 shall be the first column position after the format specified by the **print** command.

paragraphs, para

[Default in the POSIX locale `IPLPPPQPP LIpplpipbp`]

The **paragraphs** edit option shall define additional paragraph boundaries for the open and visual mode commands. The **paragraphs** edit option can be set to a character string consisting of zero or more character pairs. It shall be an error to set it to an odd number of characters.

prompt

[Default *set*]

If **prompt** is set, *ex* command mode input shall be prompted for with a colon (`':'`); when unset, no prompt shall be written.

readonly

[Default *see text*]

If **readonly** edit option is set, read-only mode shall be enabled (see **Write** (on page 2587)). The **readonly** edit option shall be initialized to set if either of the following conditions are true:

- The command-line option –R was specified.
- Performing actions equivalent to the *access*( ) function called with the following arguments indicates that the file lacks write permission:
  1. The current pathname is used as the *path* argument.
  2. The constant **W_OK** is used as the *amode* argument.

The **readonly** edit option may be initialized to set for other, implementation-defined reasons. The **readonly** edit option shall not be initialized to unset based on any special privileges of the user or process. The **readonly** edit option shall be reinitialized each time that the contents of the edit buffer are replaced (for example, by an **edit** or **next** command) unless the user has explicitly set it, in which case it shall remain set until the user explicitly unsets it. Once unset, it shall again be reinitialized each time that the contents of the edit buffer are replaced.

redraw

[Default *unset*]

The editor simulates an intelligent terminal on a dumb terminal. (Since this is likely to require a large amount of output to the terminal, it is useful only at high transmission speeds.)

remap

[Default *set*]

If **remap** is set, map translation shall allow for maps defined in terms of other maps; translation shall continue until a final product is obtained. If unset, only a one-step translation shall be done.

report

[Default 5]

The value of this **report** edit option specifies what number of lines being added, copied, deleted, or modified in the edit buffer will cause an informational message to be written to the user. The following conditions shall cause an informational message. The message shall contain the number of lines added, copied, deleted, or modified, but is otherwise unspecified.

- An *ex* or *vi* editor command, other than **open**, **undo**, or **visual**, that modifies at least the value of the **report** edit option number of lines, and which is not part of an *ex* **global** or **v** command, or *ex* or *vi* buffer execution, shall cause an informational message to be written.
- An *ex* **yank** or *vi* **y** or **Y** command, that copies at least the value of the **report** edit option plus 1 number of lines, and which is not part of an *ex* **global** or **v** command, or *ex* or *vi* buffer execution, shall cause an informational message to be written.
- An *ex* **global**, **v**, **open**, **undo**, or **visual** command or *ex* or *vi* buffer execution, that adds or deletes a total of at least the value of the **report** edit option number of lines, and which is not part of an *ex* **global** or **v** command, or *ex* or *vi* buffer execution, shall cause an informational message to be written. (For example, if 3 lines were added and 8 lines deleted during an *ex* **visual** command, 5 would be the number compared against the **report** edit option after the command completed.

scroll, scr

[Default (number of lines in the display −1)/2]

The value of the **scroll** edit option shall determine the number of lines scrolled by the *ex* <control>-D and **z** commands. For the *vi* <control>-D and <control>-U commands, it shall be the initial number of lines to scroll when no previous <control>-D or <control>-U command has been executed.

sections

[Default in the POSIX locale `NHSHH HUnhsh`]

The **sections** edit option shall define additional section boundaries for the open and visual mode commands. The **sections** edit option can be set to a character string consisting of zero or more character pairs; it shall be an error to set it to an odd number of characters.

shell, sh

[Default from the environment variable *SHELL*]

The value of this option shall be a string. The default shall be taken from the *SHELL* environment variable. If the *SHELL* environment variable is null or empty, the *sh* (see *sh*) utility shall be the default.

shiftwidth, sw

[Default 8]

The value of this option shall give the width in columns of an indentation level used during autoindentation and by the shift commands (< and >).

showmatch, sm

[Default *unset*]

The functionality described for the **showmatch** edit option need not be supported on block-mode terminals or terminals with insufficient capabilities.

If **showmatch** is set, in open or visual mode, when a `')'` or `'}'` is typed, if the matching `'('` or `'{'` is currently visible on the display, the matching `'('` or `'{'` shall be flagged moving the cursor to its location for an unspecified amount of time.

showmode

[Default *unset*]

If **showmode** is set, in open or visual mode, the current mode that the editor is in shall be displayed on the last line of the display. Command mode and text input mode shall be differentiated; other unspecified modes and implementation-defined information may be displayed.

slowopen

[Default *unset*]

If **slowopen** is set during open and visual text input modes, the editor shall not update portions of the display other than those display line columns that display the characters entered by the user (see **Input Mode Commands in vi** (on page 3220)).

tabstop, ts

[Default 8]

The value of this edit option shall specify the column boundary used by a <tab> in the display (see **autoprint, ap** (on page 2594) and **Input Mode Commands in vi** (on page 3220)).

taglength, tl

[Default zero]

The value of this edit option shall specify the maximum number of characters that are considered significant in the user-specified tag name and in the tag name from the tags file. If the value is zero, all characters in both tag names shall be significant.

tags

[Default *see text*]

The value of this edit option shall be a string of <blank>-delimited pathnames of files used by the **tag** command. The default value is unspecified.

term

[Default from the environment variable *TERM*]

The value of this edit option shall be a string. The default shall be taken from the *TERM* variable in the environment. If the *TERM* environment variable is empty or null, the default is unspecified. The editor shall use the value of this edit option to determine the type of the display device.

The results are unspecified if the user changes the value of the term edit option after editor initialization.

terse

[Default *unset*]

If **terse** is set, error messages may be less verbose. However, except for this caveat, error messages are unspecified. Furthermore, not all error messages need change for different settings of this option.

warn

[Default *set*]

If **warn** is set, and the contents of the edit buffer have been modified since they were last completely written, the editor shall write a warning message before certain **!** commands (see **Escape** (on page 2590)).

window

[Default *see text*]

A value used in open and visual mode, by the <control>-B and <control>-F commands, and, in visual mode, to specify the number of lines displayed when the screen is repainted.

If the −**w** command-line option is not specified, the default value shall be set to the value of the *LINES* environment variable. If the *LINES* environment variable is empty or null, the default shall be the number of lines in the display minus 1.

Setting the **window** edit option to zero or to a value greater than the number of lines in the display minus 1 (either explicitly or based on the −**w** option or the *LINES* environment variable) shall cause the **window** edit option to be set to the number of lines in the display minus 1.

The baud rate of the terminal line may change the default in an implementation-defined manner.

wrapmargin, wm

[Default 0]

If the value of this edit option is zero, it shall have no effect.

If not in the POSIX locale, the effect of this edit option is implementation-defined.

Otherwise, it shall specify a number of columns from the ending margin of the terminal.

During open and visual text input modes, for each character for which any part of the character is displayed in a column that is less than **wrapmargin** columns from the ending margin of the display line, the editor shall behave as follows:

1. If the character triggering this event is a <blank>, it, and all immediately preceding <blank>s on the current line entered during the execution of the current text input command, shall be discarded, and the editor shall behave as if the user had entered a single <newline> instead. In addition, if the next user-entered character is a <space>, it shall be discarded as well.

2. Otherwise, if there are one or more <blank>s on the current line immediately preceding the last group of inserted non-<blank>s which was entered during the execution of the current text input command, the <blank>s shall be replaced as if the user had entered a single <newline> instead.

If the **autoindent** edit option is set, and the events described in 1. or 2. are performed, any <blank>s at or after the cursor in the current line shall be discarded.

The ending margin shall be determined by the system or overridden by the user, as described for *COLUMNS* in in the ENVIRONMENT VARIABLES section and the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

wrapscan, ws

[Default *set*]

If **wrapscan** is set, searches (the *ex* **/** or **?** addresses, or open and visual mode **/**, **?**, **N**, and **n** commands) shall wrap around the beginning or end of the edit buffer; when unset, searches shall stop at the beginning or end of the edit buffer.

writeany, wa

[Default *unset*]

If **writeany** is set, some of the checks performed when executing the *ex* **write** commands shall be inhibited, as described in editor option **autowrite**.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

When any error is encountered and the standard input is not a terminal device file, *ex* shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

Otherwise, when an unrecoverable error is encountered, it shall be equivalent to a SIGHUP asynchronous event.

Otherwise, when an error is encountered, the editor shall behave as specified in **Command Line Parsing in ex** (on page 2563).

APPLICATION USAGE

If a SIGSEGV signal is received while *ex* is saving a file, the file might not be successfully saved.

The **next** command can accept more than one file, so usage such as:

```
next ‘ls [abc]*‘
```

is valid; it would not be valid for the **edit** or **read** commands, for example, because they expect only one file and unspecified results occur.

EXAMPLES

None.

RATIONALE

The *ex*/*vi* specification is based on the historical practice found in the 4 BSD and System V implementations of *ex* and *vi*. A freely redistributable implementation of *ex*/*vi*, which is tracking IEEE Std 1003.1-200x fairly closely, and demonstrates the intended changes between historical implementations and IEEE Std 1003.1-200x, may be obtained by anonymous FTP from:

```
ftp://ftp.rdg.opengroup/pub/mirrors/nvi
```

A *restricted editor* (both the historical *red* utility and modifications to *ex*) were considered and rejected for inclusion. Neither option provided the level of security that users might expect.

It is recognized that *ex* visual mode and related features would be difficult, if not impossible, to implement satisfactorily on a block-mode terminal, or a terminal without any form of cursor addressing; thus, it is not a mandatory requirement that such features should work on all terminals. It is the intention, however, that an *ex* implementation should provide the full set of capabilities on all terminals capable of supporting them.

Options

The −**c** replacement for +*command* was inspired by the −**e** option of *sed*. Historically, all such commands (see **edit** and **next** as well) were executed from the last line of the edit buffer. This meant, for example, that `"+/pattern"` would fail unless the **wrapscan** option was set. IEEE Std 1003.1-200x requires conformance to historical practice. Historically, some implementations restricted the *ex* commands that could be listed as part of the command line arguments. For consistency, IEEE Std 1003.1-200x does not permit these restrictions.

In historical implementations of the editor, the −**R** option (and the **readonly** edit option) only prevented overwriting of files; appending to files was still permitted, mapping loosely into the *csh* **noclobber** variable. Some implementations, however, have not followed this semantic, and **readonly** does not permit appending either. IEEE Std 1003.1-200x follows the latter practice, believing that it is a more obvious and intuitive meaning of **readonly**.

The −**s** option suppresses all interactive user feedback and is useful for editing scripts in batch jobs. The list of specific effects is historical practice. The terminal type ‘‘incapable of supporting open and visual modes’’ has historically been named ‘‘dumb’’.

The −**t** option was required because the *ctags* utility appears in IEEE Std 1003.1-200x and the option is available in all historical implementations of *ex*.

Historically, the *ex* and *vi* utilities accepted a −**x** option, which did encryption based on the algorithm found in the historical *crypt* utility. The −**x** option for encryption, and the associated *crypt* utility, were omitted because the algorithm used was not specifiable and the export control laws of some nations make it difficult to export cryptographic technology. In addition, it did not historically provide the level of security that users might expect.

Standard Input

An end-of-file condition is not equivalent to an end-of-file character. A common end-of-file character, <control>-D, is historically an *ex* command.

There was no maximum line length in historical implementations of *ex*. Specifically, as it was parsed in chunks, the addresses had a different maximum length than the filenames. Further, the maximum line buffer size was declared as BUFSIZ, which was different lengths on different systems. This version selected the value of {LINE_MAX} to impose a reasonable restriction on portable usage of *ex* and to aid test suite writers in their development of realistic tests that exercise this limit.

Input Files

It was an explicit decision by the standard developers that a <newline> be added to any file lacking one. It was believed that this feature of *ex* and *vi* was relied on by users in order to make text files lacking a trailing <newline> more portable. It is recognized that this will require a user-specified option or extension for implementations that permit *ex* and *vi* to edit files of type other than text if such files are not otherwise identified by the system. It was agreed that the ability to edit files of arbitrary type can be useful, but it was not considered necessary to mandate that an *ex* or *vi* implementation be required to handle files other than text files.

The paragraph in the INPUT FILES section, ‘‘By default, . . .’’, is intended to close a long-standing security problem in *ex* and *vi*, that of the ‘‘modeline’’ or ‘‘modelines’’ edit option. This feature allows any line in the first or last five lines of the file containing the strings `"ex:"` or `"vi:"` (and, apparently, `"ei:"` or `"vx:"`) to be a line containing editor commands, and *ex* interprets all the text up to the next `':'` or <newline> as a command. Consider the consequences, for example, of an unsuspecting user using *ex* or *vi* as the editor when replying to a mail message in which a line such as:

```
ex:! rm −rf :
```

appeared in the signature lines. The standard developers believed strongly that an editor should not by default interpret any lines of a file. Vendors are strongly urged to delete this feature from their implementations of *ex* and *vi*.

Asynchronous Events

The intention of the phrase ‘‘complete write’’ is that the entire edit buffer be written to stable storage. The note regarding temporary files is intended for implementations that use temporary files to back edit buffers unnamed by the user.

Historically, SIGQUIT was ignored by *ex*, but was the equivalent of the **Q** command in visual mode; that is, it exited visual mode and entered *ex* mode. IEEE Std 1003.1-200x permits, but does not require, this behavior. Historically, SIGINT was often used by *vi* users to terminate text input mode (<control>-C is often easier to enter than <ESC>). Some implementations of *vi* alerted the terminal on this event, and some did not. IEEE Std 1003.1-200x requires that SIGINT behave identically to <ESC>, and that the terminal not be alerted.

Historically, suspending the *ex* editor during text input mode was similar to SIGINT, as completed lines were retained, but any partial line discarded, and the editor returned to command mode. IEEE Std 1003.1-200x is silent on this issue; implementations are encouraged to follow historical practice, where possible.

Historically, the *vi* editor did not treat SIGTSTP as an asynchronous event, and it was therefore impossible to suspend the editor in visual text input mode. There are two major reasons for this. The first is that SIGTSTP is a broadcast signal on UNIX systems, and the chain of events where the shell *exec*s an application that then *exec*s *vi* usually caused confusion for the terminal state if SIGTSTP was delivered to the process group in the default manner. The second was that most implementations of the UNIX *curses* package are not reentrant, and the receipt of SIGTSTP at the wrong time will cause them to crash. IEEE Std 1003.1-200x is silent on this issue; implementations are encouraged to treat suspension as an asynchronous event if possible.

Historically, modifications to the edit buffer made before SIGINT interrupted an operation were retained; that is, anywhere from zero to all of the lines to be modified might have been modified by the time the SIGINT arrived. These changes were not discarded by the arrival of SIGINT. IEEE Std 1003.1-200x permits this behavior, noting that the *undo* command is required to be able to undo these partially completed commands.

The action taken for signals other than SIGINT, SIGCONT, SIGHUP, and SIGTERM is unspecified because some implementations attempt to save the edit buffer in a useful state when other signals are received.

Standard Error

For *ex*/*vi*, diagnostic messages are those messages reported as a result of a failed attempt to invoke *ex* or *vi*, such as invalid options or insufficient resources, or an abnormal termination condition. Diagnostic messages should not be confused with the error messages generated by inappropriate or illegal user commands.

Initialization in ex and vi

If an *ex* command (other than **cd**, **chdir**, or **source**) has a filename argument, one or both of the alternate and current pathnames will be set. Informally, they are set as follows:

1. If the *ex* command is one that replaces the contents of the edit buffer, and it succeeds, the current pathname will be set to the filename argument (the first filename argument in the case of the **next** command) and the alternate pathname will be set to the previous current pathname, if there was one.
2. In the case of the file read/write forms of the **read** and **write** commands, if there is no current pathname, the current pathname will be set to the filename argument.
3. Otherwise, the alternate pathname will be set to the filename argument.

For example, **:edit foo** and **:recover foo**, when successful, set the current pathname, and, if there was a previous current pathname, the alternate pathname. The commands **:write**, **!command**, and **:edit** set neither the current or alternate pathnames. If the **:edit foo** command were to fail for some reason, the alternate pathname would be set. The **read** and **write** commands set the alternate pathname to their *file* argument, unless the current pathname is not set, in which case they set the current pathname to their *file* arguments. The alternate pathname was not historically set by the **:source** command. IEEE Std 1003.1-200x requires conformance to historical practice. Implementations adding commands that take filenames as arguments are encouraged to set the alternate pathname as described here.

Historically, *ex* and *vi* read the **.exrc** file in the *$HOME* directory twice, if the editor was executed in the *$HOME* directory. IEEE Std 1003.1-200x prohibits this behavior.

Historically, the 4 BSD *ex* and *vi* read the *$HOME* and local **.exrc** files if they were owned by the real ID of the user, or the **sourceany** option was set, regardless of other considerations. This was a security problem because it is possible to put normal UNIX system commands inside a **.exrc** file. IEEE Std 1003.1-200x does not specify the **sourceany** option, and historical implementations are encouraged to delete it.

The **.exrc** files must be owned by the real ID of the user, and not writeable by anyone other than the owner. The appropriate privileges exception is intended to permit users to acquire special privileges, but continue to use the **.exrc** files in their home directories.

System V Release 3.2 and later *vi* implementations added the option **[no]exrc**. The behavior is that local **.exrc** files are read-only if the **exrc** option is set. The default for the **exrc** option was off, so by default, local **.exrc** files were not read. The problem this was intended to solve was that System V permitted users to give away files, so there is no possible ownership or writeability test to ensure that the file is safe. This is still a security problem on systems where users can give away files, but there is nothing additional that IEEE Std 1003.1-200x can do. The implementation-defined exception is intended to permit groups to have local **.exrc** files that are shared by users, by creating pseudo-users to own the shared files.

IEEE Std 1003.1-200x does not mention system-wide *ex* and *vi* start-up files. While they exist in several implementations of *ex* and *vi*, they are not present in any implementations considered historical practice by IEEE Std 1003.1-200x. Implementations that have such files should use them only if they are owned by the real user ID or an appropriate user (for example, root on UNIX systems) and if they are not writeable by any user other than their owner. System-wide start-up files should be read before the *EXINIT* variable, **$HOME/.exrc** or local **.exrc** files are evaluated.

Historically, any *ex* command could be entered in the *EXINIT* variable or the **.exrc** file, although ones requiring that the edit buffer already contain lines of text generally caused historical implementations of the editor to drop core. IEEE Std 1003.1-200x requires that any *ex* command be permitted in the *EXINIT* variable and **.exrc** files, for simplicity of specification and consistency, although many of them will obviously fail under many circumstances.

The initialization of the contents of the edit buffer uses the phrase ‘‘the effect shall be’’ with regard to various *ex* commands. The intent of this phrase is that edit buffer contents loaded during the initialization phase not be lost; that is, loading the edit buffer should fail if the **.exrc** file read in the contents of a file and did not subsequently write the edit buffer. An additional intent of this phrase is to specify that the initial current line and column is set as specified for the individual *ex* commands.

Historically, the −**t** option behaved as if the tag search were a +*command*; that is, it was executed from the last line of the file specified by the tag. This resulted in the search failing if the pattern was a forward search pattern and the **wrapscan** edit option was not set. IEEE Std 1003.1-200x does not permit this behavior, requiring that the search for the tag pattern be performed on the entire file, and, if not found, that the current line be set to a more reasonable location in the file.

Historically, the empty edit buffer presented for editing when a file was not specified by the user was unnamed. This is permitted by IEEE Std 1003.1-200x; however, implementations are encouraged to provide users a temporary filename for this buffer because it permits them the use of *ex* commands that use the current pathname during temporary edit sessions.

Historically, the file specified using the −**t** option was not part of the current argument list. This practice is permitted by IEEE Std 1003.1-200x; however, implementations are encouraged to include its name in the current argument list for consistency.

Historically, the −**c** command was generally not executed until a file that already exists was edited. IEEE Std 1003.1-200x requires conformance to this historical practice. Commands that could cause the −**c** command to be executed include the *ex* commands **edit**, **next**, **recover**, **rewind**, and **tag**, and the *vi* commands <control>-ˆ and <control>-]. Historically, reading a file into an edit buffer did not cause the −**c** command to be executed (even though it might set the current pathname) with the exception that it did cause the **−c** command to be executed if: the editor was in *ex* mode, the edit buffer had no current pathname, the edit buffer was empty, and no read commands had yet been attempted. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Historically, the **−r** option was the same as a normal edit session if there was no recovery information available for the file. This allowed users to enter:

```
vi −r *.c
```

and recover whatever files were recoverable. In some implementations, recovery was attempted only on the first file named, and the file was not entered into the argument list; in others, recovery was attempted for each file named. In addition, some historical implementations ignored **−r** if **−t** was specified or did not support command line *file* arguments with the **−t** option. For consistency and simplicity of specification, IEEE Std 1003.1-200x disallows these special cases, and requires that recovery be attempted the first time each file is edited.

Historically, *vi* initialized the **‘** and **’** marks, but *ex* did not. This meant that if the first command in *ex* mode was **visual** or if an *ex* command was executed first (for example, *vi* +10 *file*), *vi* was entered without the marks being initialized. Because the standard developers believed the marks to be generally useful, and for consistency and simplicity of specification, IEEE Std 1003.1-200x requires that they always be initialized if in open or visual mode, or if in *ex* mode and the edit buffer is not empty. Not initializing it in *ex* mode if the edit buffer is empty is historical practice; however, it has always been possible to set (and use) marks in empty edit buffers in open and visual mode edit sessions.

Addressing

Historically, *ex* and *vi* accepted the additional addressing forms `'\/'` and `'\?'`. They were equivalent to `"//"` and `"??"`, respectively. They are not required by IEEE Std 1003.1-200x, mostly because nobody can remember whether they ever did anything different historically.

Historically, *ex* and *vi* permitted an address of zero for several commands, and permitted the **%** address in empty files for others. For consistency, IEEE Std 1003.1-200x requires support for the former in the few commands where it makes sense, and disallows it otherwise. In addition, because IEEE Std 1003.1-200x requires that **%** be logically equivalent to `"1,$"`, it is also supported where it makes sense and disallowed otherwise.

Historically, the **%** address could not be followed by further addresses. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that additional addresses be supported.

All of the following are valid *addresses*: |

`+++`	Three lines after the current line.
`/re/−`	One line before the next occurrence of *re*.
`−2`	Two lines before the current line.
`3 −−−− 2`	Line one (note intermediate negative address).
`1 2 3`	Line six.

Any number of addresses can be provided to commands taking addresses; for example, `"1,2,3,4,5p"` prints lines 4 and 5, because two is the greatest valid number of addresses accepted by the **print** command. This, in combination with the semicolon delimiter, permits users to create commands based on ordered patterns in the file. For example, the command **3;/foo/;+2print** will display the first line after line 3 that contains the pattern *foo*, plus the next two lines. Note that the address **3;** must be evaluated before being discarded because the search origin for the **/foo/** command depends on this.

Historically, values could be added to addresses by including them after one or more <blank>s; for example, **3 − 5p** wrote the seventh line of the file, and **/foo/ 5** was the same as **/foo/+5**. However, only absolute values could be added; for example, **5 /foo/** was an error. IEEE Std 1003.1-200x requires conformance to historical practice. Address offsets are separately specified from addresses because they could historically be provided to visual mode search commands.

Historically, any missing addresses defaulted to the current line. This was true for leading and trailing comma-delimited addresses, and for trailing semicolon-delimited addresses. For consistency, IEEE Std 1003.1-200x requires it for leading semicolon addresses as well.

Historically, *ex* and *vi* accepted the `'^'` character as both an address and as a flag offset for commands. In both cases it was identical to the `'−'` character. IEEE Std 1003.1-200x does not require or prohibit this behavior.

Historically, the enhancements to basic regular expressions could be used in addressing; for example, `'~'`, `'\<'`, and `'\>'`. IEEE Std 1003.1-200x requires conformance to historical practice; that is, that regular expression usage be consistent, and that regular expression enhancements be supported wherever regular expressions are used.

Command Line Parsing in ex

Historical *ex* command parsing was even more complex than that described here. IEEE Std 1003.1-200x requires the subset of the command parsing that the standard developers believed was documented and that users could reasonably be expected to use in a portable fashion, and that was historically consistent between implementations. (The discarded functionality is obscure, at best.) Historical implementations will require changes in order to comply with IEEE Std 1003.1-200x; however, users are not expected to notice any of these changes. Most of the complexity in *ex* parsing is to handle three special termination cases:

1. The **!**, **global**, **v**, and the filter versions of the **read** and **write** commands are delimited by <newline>s (they can contain vertical-line characters that are usually shell pipes).
2. The **ex**, **edit**, **next**, and **visual** in open and visual mode commands all take *ex* commands, optionally containing vertical-line characters, as their first arguments.
3. The **s** command takes a regular expression as its first argument, and uses the delimiting characters to delimit the command.

Historically, vertical-line characters in the **+***command* argument of the **ex**, **edit**, **next**, **vi**, and **visual** commands, and in the *pattern* and *replacement* parts of the **s** command, did not delimit the command, and in the filter cases for **read** and **write**, and the **!**, **global**, and **v** commands, they did not delimit the command at all. For example, the following commands are all valid:

```
:edit +25 | s/abc/ABC/ file.c
:s/ | /PIPE/
:read !spell % | columnate
:global/pattern/p | l
:s/a/b/ | s/c/d | set
```

Historically, empty or <blank> filled lines in **.exrc** files and **source**d files (as well as *EXINIT* variables and *ex* command scripts) were treated as default commands; that is, **print** commands. IEEE Std 1003.1-200x specifically requires that they be ignored when encountered in **.exrc** and **source**d files to eliminate a common source of new user error.

Historically, *ex* commands with multiple adjacent (or <blank>-separated) vertical lines were handled oddly when executed from *ex* mode. For example, the command **| | |** <carriage-return>, when the cursor was on line 1, displayed lines 2, 3, and 5 of the file. In addition, the command **|** would only display the line after the next line, instead of the next two lines. The former worked more logically when executed from *vi* mode, and displayed lines 2, 3, and 4. IEEE Std 1003.1-200x requires the *vi* behavior; that is, a single default command and line number increment for each command separator, and trailing <newline>s after vertical-line separators are discarded.

Historically, *ex* permitted a single extra colon as a leading command character; for example, **:g/pattern/:p** was a valid command. IEEE Std 1003.1-200x generalizes this to require that any number of leading colon characters be stripped.

Historically, any prefix of the **delete** command could be followed without intervening <blank>s by a flag character because in the command **d p**, *p* is interpreted as the buffer *p*. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, the **k** command could be followed by the mark name without intervening <blank>s. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, the **s** command could be immediately followed by flag and option characters; for example, **s/e/E/|s|sgc3p** was a valid command. However, flag characters could not stand alone; for example, the commands **sp** and **s l** would fail, while the command **sgp** and **s gl** would succeed. (Obviously, the '#' flag character was used as a delimiter character if it followed the command.) Another issue was that option characters had to precede flag characters even when the command was fully specified; for example, the command **s/e/E/pg** would fail, while the command **s/e/E/gp** would succeed. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, the first command name that had a prefix matching the input from the user was the executed command; for example, **ve**, **ver**, and **vers** all executed the **version** command. Commands were in a specific order, however, so that **a** matched **append**, not **abbreviate**. IEEE Std 1003.1-200x requires conformance to historical practice. The restriction on command search order for implementations with extensions is to avoid the addition of commands such that the historical prefixes would fail to work portably.

Historical implementations of *ex* and *vi* did not correctly handle multiple *ex* commands, separated by vertical-line characters, that entered or exited visual mode or the editor. Because implementations of *vi* exist that do not exhibit this failure mode, IEEE Std 1003.1-200x does not permit it.

The requirement that alphabetic command names consist of all following alphabetic characters up to the next non-alphabetic character means that alphabetic command names must be separated from their arguments by one or more non-alphabetic characters, normally a <blank> or '!' character, except as specified for the exceptions, the **delete**, **k**, and **s** commands.

Historically, the repeated execution of the *ex* default **print** commands (<control>-D, *eof*, <newline>, <carriage-return>) erased any prompting character and displayed the next lines without scrolling the terminal; that is, immediately below any previously displayed lines. This provided a cleaner presentation of the lines in the file for the user. IEEE Std 1003.1-200x does not require this behavior because it may be impossible in some situations; however, implementations are strongly encouraged to provide this semantic if possible.

Historically, it was possible to change files in the middle of a command, and have the rest of the command executed in the new file; for example:

```
:edit +25 file.c | s/abc/ABC/ | 1
```

was a valid command, and the substitution was attempted in the newly edited file. IEEE Std 1003.1-200x requires conformance to historical practice. The following commands are examples that exercise the *ex* parser:

```
echo 'foo | bar' > file1; echo 'foo/bar' > file2;
vi
:edit +1 | s/|/PIPE/ | w file1 | e file2 | 1 | s/\//SLASH/ | wq
```

Historically, there was no protection in editor implementations to avoid *ex* **global**, **v**, **@**, or ***** commands changing edit buffers during execution of their associated commands. Because this would almost invariably result in catastrophic failure of the editor, and implementations exist that do exhibit these problems, IEEE Std 1003.1-200x requires that changing the edit buffer during a **global** or **v** command, or during a **@** or ***** command for which there will be more than a single execution, be an error. Implementations supporting multiple edit buffers simultaneously are strongly encouraged to apply the same semantics to switching between buffers as well.

The *ex* command quoting required by IEEE Std 1003.1-200x is a superset of the quoting in historical implementations of the editor. For example, it was not historically possible to escape a <blank> in a filename; for example, **:edit foo**`\\\` **bar** would report that too many filenames had been entered for the edit command, and there was no method of escaping a <blank> in the first argument of an **edit**, **ex**, **next**, or **visual** command at all. IEEE Std 1003.1-200x extends historical practice, requiring that quoting behavior be made consistent across all *ex* commands, except for the **map**, **unmap**, **abbreviate**, and **unabbreviate** commands, which historically used <control>-V instead of backslashes for quoting. For those four commands, IEEE Std 1003.1-200x requires conformance to historical practice.

Backslash quoting in *ex* is non-intuitive. Backslash escapes are ignored unless they escape a special character; for example, when performing *file* argument expansion, the string `"\\%"` is equivalent to `'\%'`, not `"\<`*current path name*`>"`. This can be confusing for users because backslash is usually one of the characters that causes shell expansion to be performed, and therefore shell quoting rules must be taken into consideration. Generally, quoting characters are only considered if they escape a special character, and a quoting character must be provided for each layer of parsing for which the character is special. As another example, only a single backslash is necessary for the `'\l'` sequence in substitute replacement patterns, because the character `'l'` is not special to any parsing layer above it.

<control>-V quoting in *ex* is slightly different from backslash quoting. In the four commands where <control>-V quoting applies (**abbreviate**, **unabbreviate**, **map**, and **unmap**), any character may be escaped by a <control>-V whether it would have a special meaning or not. IEEE Std 1003.1-200x requires conformance to historical practice.

Historical implementations of the editor did not require delimiters within character classes to be escaped; for example, the command **:s/[/]//** on the string `"xxx/yyy"` would delete the `'/'` from the string. IEEE Std 1003.1-200x disallows this historical practice for consistency and because it places a large burden on implementations by requiring that knowledge of regular expressions be built into the editor parser.

Historically, quoting <newline>s in *ex* commands was handled inconsistently. In most cases, the <newline> always terminated the command, regardless of any preceding escape character, because backslash characters did not escape <newline>s for most *ex* commands. However, some *ex* commands (for example, **s**, **map**, and **abbreviation**) permitted <newline>s to be escaped (although in the case of **map** and **abbreviation**, <control>-V characters escaped them instead of backslashes). This was true in not only the command line, but also **.exrc** and **source**d files. For example, the command:

```
map = foo<control-V><newline>bar
```

would succeed, although it was sometimes difficult to get the <control>-V and the inserted <newline> passed to the *ex* parser. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that it be possible to escape <newline>s in *ex* commands at all times, using backslashes for most *ex* commands, and using <control>-V characters for the **map** and **abbreviation** commands. For example, the command **print**<newline>**list** is required to be parsed as the single command **print**<newline>**list**. While this differs from historical practice, IEEE Std 1003.1-200x developers believed it unlikely that any script or user depended on the historical behavior.

Historically, an error in a command specified using the **–c** option did not cause the rest of the **–c** commands to be discarded. IEEE Std 1003.1-200x disallows this for consistency with mapped keys, the **@**, **global**, **source**, and **v** commands, the *EXINIT* environment variable, and the **.exrc** files.

Input Editing in ex

One of the common uses of the historical *ex* editor is over slow network connections. Editors that run in canonical mode can require far less traffic to and from, and far less processing on, the host machine, as well as more easily supporting block-mode terminals. For these reasons, IEEE Std 1003.1-200x requires that *ex* be implemented using canonical mode input processing, as was done historically.

IEEE Std 1003.1-200x does not require the historical 4 BSD input editing characters ‘‘word erase’’ or ‘‘literal next’’. For this reason, it is unspecified how they are handled by *ex*, although they must have the required effect. Implementations that resolve them after the line has been ended using a <newline> or <control>-M character, and implementations that rely on the underlying system terminal support for this processing, are both conforming. Implementations are strongly urged to use the underlying system functionality, if at all possible, for compatibility with other system text input interfaces.

Historically, when the *eof* character was used to decrement the **autoindent** level, the cursor moved to display the new end of the **autoindent** characters, but did not move the cursor to a new line, nor did it erase the <control>-D character from the line. IEEE Std 1003.1-200x does not specify that the cursor remain on the same line or that the rest of the line is erased; however, implementations are strongly encouraged to provide the best possible user interface; that is, the cursor should remain on the same line, and any <control>-D character on the line should be erased.

IEEE Std 1003.1-200x does not require the historical 4 BSD input editing character ‘‘reprint’’, traditionally <control>-R, which redisplayed the current input from the user. For this reason, and because the functionality cannot be implemented after the line has been terminated by the user, IEEE Std 1003.1-200x makes no requirements about this functionality. Implementations are strongly urged to make this historical functionality available, if possible.

Historically, <control>-Q did not perform a literal next function in *ex*, as it did in *vi*. IEEE Std 1003.1-200x requires conformance to historical practice to avoid breaking historical *ex* scripts and **.exrc** files.

eof

Whether the *eof* character immediately modifies the **autoindent** characters in the prompt is left unspecified so that implementations can conform in the presence of systems that do not support this functionality. Implementations are encouraged to modify the line and redisplay it immediately, if possible.

The specification of the handling of the *eof* character differs from historical practice only in that *eof* characters are not discarded if they follow normal characters in the text input. Historically, they were always discarded.

Command Descriptions in ex

Historically, several commands (for example, **global**, **v**, **visual**, **s**, **write**, **wq**, **yank**, **!**, **<**, **>**, **&**, and **~**) were executable in empty files (that is, the default address(es) were 0), or permitted explicit addresses of 0 (for example, 0 was a valid address, or 0,0 was a valid range). Addresses of 0, or command execution in an empty file, make sense only for commands that add new text to the edit buffer or write commands (because users may wish to write empty files). IEEE Std 1003.1-200x requires this behavior for such commands and disallows it otherwise, for consistency and simplicity of specification.

A count to an *ex* command has been historically corrected to be no greater than the last line in a file; for example, in a five-line file, the command **1,6print** would fail, but the command **1print300** would succeed. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, the use of flags in *ex* commands could be obscure. General historical practice was as described by IEEE Std 1003.1-200x, but there were some special cases. For example, the **list**, **number**, and **print** commands ignored trailing address offsets; for example, **3p +++#** would display line 3, and 3 would be the current line after the execution of the command. The **open** and **visual** commands ignored both the trailing offsets and the trailing flags. Also, flags specified to the **open** and **visual** commands interacted badly with the **list** edit option, and setting and then unsetting it during the open/visual session would cause *vi* to stop displaying lines in the specified format. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit any of these exceptions to the general rule.

IEEE Std 1003.1-200x uses the word *copy* in several places when discussing buffers. This is not intended to imply implementation.

Historically, *ex* users could not specify numeric buffers because of the ambiguity this would cause; for example, in the command **3 delete 2**, it is unclear whether 2 is a buffer name or a *count*. IEEE Std 1003.1-200x requires conformance to historical practice by default, but does not preclude extensions.

Historically, the contents of the unnamed buffer were frequently discarded after commands that did not explicitly affect it; for example, when using the **edit** command to switch files. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

The *ex* utility did not historically have access to the numeric buffers, and, furthermore, deleting lines in *ex* did not modify their contents. For example, if, after doing a delete in *vi*, the user switched to *ex*, did another delete, and then switched back to *vi*, the contents of the numeric buffers would not have changed. IEEE Std 1003.1-200x requires conformance to historical practice. Numeric buffers are described in the *ex* utility in order to confine the description of buffers to a single location in IEEE Std 1003.1-200x.

The metacharacters that trigger shell expansion in *file* arguments match historical practice, as does the method for doing shell expansion. Implementations wishing to provide users with the flexibility to alter the set of metacharacters are encouraged to provide a **shellmeta** string edit option.

Historically, *ex* commands executed from *vi* refreshed the screen when it did not strictly need to do so; for example, **:!date > /dev/null** does not require a screen refresh because the output of the UNIX *date* command requires only a single line of the screen. IEEE Std 1003.1-200x requires that the screen be refreshed if it has been overwritten, but makes no requirements as to how an implementation should make that determination. Implementations may prompt and refresh the screen regardless.

Abbreviate

Historical practice was that characters that were entered as part of an abbreviation replacement were subject to **map** expansions, the **showmatch** edit option, further abbreviation expansions, and so on; that is, they were logically pushed onto the terminal input queue, and were not a simple replacement. IEEE Std 1003.1-200x requires conformance to historical practice. Historical practice was that whenever a non-word character (that had not been escaped by a <control>-V) was entered after a word character, *vi* would check for abbreviations. The check was based on the type of the character entered before the word character of the word/non-word pair that triggered the check. The word character of the word/non-word pair that triggered the check and all characters entered before the trigger pair that were of that type were included in the check, with the exception of <blank>s, which always delimited the abbreviation.

This means that, for the abbreviation to work, the *lhs* must end with a word character, there can be no transitions from word to non-word characters (or *vice versar*) other than between the last and next-to-last characters in the *lhs*, and there can be no <blank>s in the *lhs*. In addition, because of the historical quoting rules, it was impossible to enter a literal <control>-V in the *lhs*. IEEE Std 1003.1-200x requires conformance to historical practice. Historical implementations did not inform users when abbreviations that could never be used were entered; implementations are strongly encouraged to do so.

For example, the following abbreviations will work:

```
:ab (p  REPLACE
:ab p   REPLACE
:ab ((p REPLACE
```

The following abbreviations will not work:

```
:ab (   REPLACE
:ab (pp REPLACE
```

Historical practice is that words on the *vi* colon command line were subject to abbreviation expansion, including the arguments to the **abbrev** (and more interestingly) the **unabbrev** command. Because there are implementations that do not do abbreviation expansion for the first argument to those commands, this is permitted, but not required, by IEEE Std 1003.1-200x. However, the following sequence:

```
:ab foo bar
:ab foo baz
```

resulted in the addition of an abbreviation of `"baz"` for the string `"bar"` in historical *ex*/*vi*, and the sequence:

```
:ab foo1 bar
:ab foo2 bar
:unabbreviate foo2
```

deleted the abbreviation `"foo1"`, not `"foo2"`. These behaviors are not permitted by IEEE Std 1003.1-200x because they clearly violate the expectations of the user.

It was historical practice that <control>-V, not backslash, characters be interpreted as escaping subsequent characters in the **abbreviate** command. IEEE Std 1003.1-200x requires conformance to historical practice; however, it should be noted that an abbreviation containing a <blank> will never work.

Append

Historically, any text following a vertical-line command separator after an **append**, **change**, or **insert** command became part of the insert text. For example, in the command:

```
:g/pattern/append|stuff1
```

a line containing the text `"stuff1"` would be appended to each line matching pattern. It was also historically valid to enter:

```
:append|stuff1
stuff2
.
```

and the text on the *ex* command line would be appended along with the text inserted after it. There was an historical bug, however, that the user had to enter two terminating lines (the `'.'` lines) to terminate text input mode in this case. IEEE Std 1003.1-200x requires conformance to historical practice, but disallows the historical need for multiple terminating lines.

Change

See the RATIONALE for the **append** command. Historical practice for cursor positioning after the change command when no text is input, is as described in IEEE Std 1003.1-200x. However, one System V implementation is known to have been modified such that the cursor is positioned on the first address specified, and not on the line before the first address. IEEE Std 1003.1-200x disallows this modification for consistency.

Historically, the **change** command did not support buffer arguments, although some implementations allow the specification of an optional buffer. This behavior is neither required nor disallowed by IEEE Std 1003.1-200x.

Change Directory

A common extension in *ex* implementations is to use the elements of a **cdpath** edit option as prefix directories for *path* arguments to **chdir** that are relative pathnames and that do not have `'.'` or `".."` as their first component. Elements in the **cdpath** edit option are colon-separated. The initial value of the **cdpath** edit option is the value of the shell *CDPATH* environment variable. This feature was not included in IEEE Std 1003.1-200x because it does not exist in any of the implementations considered historical practice.

Copy

Historical implementations of *ex* permitted copies to lines inside of the specified range; for example, **:2,5copy3** was a valid command. IEEE Std 1003.1-200x requires conformance to historical practice.

Delete

IEEE Std 1003.1-200x requires support for the historical parsing of a **delete** command followed by flags, without any intervening <blank>s. For example:

1dp	Deletes the first line and prints the line that was second.
1delep	As for **1dp**.
1d	Deletes the first line, saving it in buffer *p*.
1d p1l	(Pee-one-ell.) Deletes the first line, saving it in buffer *p*, and listing the line that was second.

Edit

Historically, any *ex* command could be entered as a **+***command* argument to the **edit** command, although some (for example, **insert** and **append**) were known to confuse historical implementations. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that any command be supported as an argument to the **edit** command.

Historically, the command argument was executed with the current line set to the last line of the file, regardless of whether the **edit** command was executed from visual mode or not. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, the **+***command* specified to the **edit** and **next** commands was delimited by the first <blank>, and there was no way to quote them. For consistency, IEEE Std 1003.1-200x requires that the usual *ex* backslash quoting be provided.

Historically, specifying the **+***command* argument to the edit command required a filename to be specified as well; for example, **:edit +100** would always fail. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this usage to fail for that reason.

Historically, only the cursor position of the last file edited was remembered by the editor. IEEE Std 1003.1-200x requires that this be supported; however, implementations are permitted to remember and restore the cursor position for any file previously edited.

File

Historical versions of the *ex* editor **file** command displayed a current line and number of lines in the edit buffer of 0 when the file was empty, while the *vi* <control>-G command displayed a current line and number of lines in the edit buffer of 1 in the same situation. IEEE Std 1003.1-200x does not permit this discrepancy, instead requiring that a message be displayed indicating that the file is empty.

Global

The two-pass operation of the **global** and **v** commands is not intended to imply implementation, only the required result of the operation.

The current line and column are set as specified for the individual *ex* commands. This requirement is cumulative; that is, the current line and column must track across all the commands executed by the **global** or **v** commands.

Insert

See the RATIONALE for the **append** command.

Historically, **insert** could not be used with an address of zero; that is, not when the edit buffer was empty. IEEE Std 1003.1-200x requires that this command behave consistently with the **append** command.

Join

The action of the **join** command in relation to the special characters is only defined for the POSIX locale because the correct amount of white space after a period varies; in Japanese none is required, in French only a single space, and so on.

List

The historical output of the **list** command was potentially ambiguous. The standard developers believed correcting this to be more important than adhering to historical practice, and IEEE Std 1003.1-200x requires unambiguous output.

Map

Historically, command mode maps only applied to command names; for example, if the character `'x'` was mapped to `'y'`, the command **fx** searched for the `'x'` character, not the `'y'` character. IEEE Std 1003.1-200x requires this behavior. Historically, entering <control>-V as the first character of a *vi* command was an error. Several implementations have extended the semantics of *vi* such that <control>-V means that the subsequent command character is not mapped. This is permitted, but not required, by IEEE Std 1003.1-200x. Regardless, using <control>-V to escape the second or later character in a sequence of characters that might match a **map** command, or any character in text input mode, is historical practice, and stops the entered keys from matching a map. IEEE Std 1003.1-200x requires conformance to historical practice.

Historical implementations permitted digits to be used as a **map** command *lhs*, but then ignored the map. IEEE Std 1003.1-200x requires that the mapped digits not be ignored.

The historical implementation of the **map** command did not permit **map** commands that were more than a single character in length if the first character was printable. This behavior is permitted, but not required, by IEEE Std 1003.1-200x.

Historically, mapped characters were remapped unless the **remap** edit option was not set, or the prefix of the mapped characters matched the mapping characters; for example, in the **map**:

```
:map ab abcd
```

the characters `"ab"` were used as is and were not remapped, but the characters `"cd"` were mapped if appropriate. This can cause infinite loops in the *vi* mapping mechanisms. IEEE Std 1003.1-200x requires conformance to historical practice, and that such loops be interruptible.

Text input maps had the same problems with expanding the *lhs* for the *ex* **map!** and **unmap!** command as did the *ex* **abbreviate** and **unabbreviate** commands. See the RATIONALE for the *ex* **abbreviate** command. IEEE Std 1003.1-200x requires similar modification of some historical practice for the **map** and **unmap** commands, as described for the **abbreviate** and **unabbreviate** commands.

Historically, **map**s that were subsets of other **map**s behaved differently depending on the order in which they were defined. For example:

```
:map! ab     short
:map! abc    long
```

would always translate the characters `"ab"` to `"short"`, regardless of how fast the characters `"abc"` were entered. If the entry order was reversed:

```
:map! abc    long
:map! ab     short
```

the characters `"ab"` would cause the editor to pause, waiting for the completing `'c'` character, and the characters might never be mapped to `"short"`. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that the shortest match be used at all times.

The length of time the editor spends waiting for the characters to complete the *lhs* is unspecified because the timing capabilities of systems are often inexact and variable, and it may depend on other factors such as the speed of the connection. The time should be long enough for the user to be able to complete the sequence, but not long enough for the user to have to wait. Some implementations of *vi* have added a **keytime** option, which permits users to set the number of 0,1 seconds the editor waits for the completing characters. Because mapped terminal function and cursor keys tend to start with an <ESC> character, and <ESC> is the key ending *vi* text input mode, **map**s starting with <ESC> characters are generally exempted from this timeout period, or, at least timed out differently.

Mark

Historically, users were able to set the ‘‘previous context’’ marks explicitly. In addition, the *ex* commands **’** and **'** and the *vi* commands **’**, **‘**, **'**, and **'** all referred to the same mark. In addition, the previous context marks were not set if the command, with which the address setting the mark was associated, failed. IEEE Std 1003.1-200x requires conformance to historical practice. Historically, if marked lines were deleted, the mark was also deleted, but would reappear if the change was undone. IEEE Std 1003.1-200x requires conformance to historical practice.

The description of the special events that set the **‘** and **’** marks matches historical practice. For example, historically the command **/a/,/b/** did not set the **‘** and **’** marks, but the command **/a/,/b/delete** did.

Next

Historically, any *ex* command could be entered as a +*command* argument to the **next** command, although some (for example, **insert** and **append**) were known to confuse historical implementations. IEEE Std 1003.1-200x requires that any command be permitted and that it behave as specified. The **next** command can accept more than one file, so usage such as:

```
next ‘ls [abc] ‘
```

is valid; it need not be valid for the **edit** or **read** commands, for example, because they expect only one filename.

Historically, the **next** command behaved differently from the **:rewind** command in that it ignored the force flag if the **autowrite** flag was set. For consistency, IEEE Std 1003.1-200x does not permit this behavior.

Historically, the **next** command positioned the cursor as if the file had never been edited before, regardless. IEEE Std 1003.1-200x does not permit this behavior, for consistency with the **edit** command.

Implementations wanting to provide a counterpart to the **next** command that edited the previous file have used the command **prev[ious],** which takes no *file* argument.

IEEE Std 1003.1-200x does not require this command.

Open

Historically, the **open** command would fail if the **open** edit option was not set. IEEE Std 1003.1-200x does not mention the **open** edit option and does not require this behavior. Some historical implementations do not permit entering open mode from open or visual mode, only from *ex* mode. For consistency, IEEE Std 1003.1-200x does not permit this behavior.

Historically, entering open mode from the command line (that is, *vi* **+open**) resulted in anomalous behaviors; for example, the *ex* file and *set* commands, and the *vi* command <control>-G did not work. For consistency, IEEE Std 1003.1-200x does not permit this behavior.

Historically, the **open** command only permitted `'/'` characters to be used as the search pattern delimiter. For consistency, IEEE Std 1003.1-200x requires that the search delimiters used by the **s**, **global**, and **v** commands be accepted as well.

Preserve

The **preserve** command does not historically cause the file to be considered unmodified for the purposes of future commands that may exit the editor. IEEE Std 1003.1-200x requires conformance to historical practice.

Historical documentation stated that mail was not sent to the user when preserve was executed; however, historical implementations did send mail in this case. IEEE Std 1003.1-200x requires conformance to the historical implementations.

Print

The writing of NUL by the **print** command is not specified as a special case because the standard developers did not want to require *ex* to support NUL characters. Historically, characters were displayed using the ARPA standard mappings, which are as follows:

1. Printable characters are left alone.
2. Control characters less than \177 are represented as `'^'` followed by the character offset from the `'@'` character in the ASCII map; for example, \007 is represented as `'^G'`.
3. \177 is represented as `'^'` followed by `'?'`.

The display of characters having their eighth bit set was less standard. Existing implementations use hex (0x00), octal (\000), and a meta-bit display. (The latter displayed bytes that had their eighth bit set as the two characters `"M-"` followed by the seven-bit display as described above.) The latter probably has the best claim to historical practice because it was used for the **–v** option of 4 BSD and 4 BSD-derived versions of the *cat* utility since 1980.

No specific display format is required by IEEE Std 1003.1-200x.

Explicit dependence on the ASCII character set has been avoided where possible, hence the use of the phrase an ‘‘implementation-defined multi-character sequence’’ for the display of non-printable characters in preference to the historical usage of, for instance, `"^I"` for the <tab>. Implementations are encouraged to conform to historical practice in the absence of any strong reason to diverge.

Historically, all *ex* commands beginning with the letter `'p'` could be entered using capitalized versions of the commands; for example, **P[rint]**, **Pre[serve]**, and **Pu[t]** were all valid command names. IEEE Std 1003.1-200x permits, but does not require, this historical practice because capital forms of the commands are used by some implementations for other purposes.

Put

Historically, an *ex* **put** command, executed from open or visual mode, was the same as the open or visual mode **P** command, if the buffer was named and was cut in character mode, and the same as the **p** command if the buffer was named and cut in line mode. If the unnamed buffer was the source of the text, the entire line from which the text was taken was usually **put**, and the buffer was handled as if in line mode, but it was possible to get extremely anomalous behavior. In addition, using the **Q** command to switch into *ex* mode, and then doing a **put** often resulted in errors as well, such as appending text that was unrelated to the (supposed) contents of the buffer. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit these behaviors. All *ex* **put** commands are required to operate in line mode, and the contents of the buffers are not altered by changing the mode of the editor.

Read

Historically, an *ex* **read** command executed from open or visual mode, executed in an empty file, left an empty line as the first line of the file. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior. Historically, a **read** in open or visual mode from a program left the cursor at the last line read in, not the first. For consistency, IEEE Std 1003.1-200x does not permit this behavior.

Historical implementations of *ex* were unable to undo **read** commands that read from the output of a program. For consistency, IEEE Std 1003.1-200x does not permit this behavior.

Historically, the *ex* and *vi* message after a successful **read** or **write** command specified ‘‘characters’’, not ‘‘bytes’’. IEEE Std 1003.1-200x requires that the number of bytes be displayed, not the number of characters, because it may be difficult in multi-byte implementations to determine the number of characters read. Implementations are encouraged to clarify the message displayed to the user.

Historically, reads were not permitted on files other than type regular, except that FIFO files could be read (probably only because they did not exist when *ex* and *vi* were originally written). Because the historical *ex* evaluated **read!** and **read !** equivalently, there can be no optional way to force the read. IEEE Std 1003.1-200x permits, but does not require, this behavior.

Recover

Some historical implementations of the editor permitted users to recover the edit buffer contents from a previous edit session, and then exit without saving those contents (or explicitly discarding them). The intent of IEEE Std 1003.1-200x in requiring that the edit buffer be treated as already modified is to prevent this user error.

Rewind

Historical implementations supported the **rewind** command when the user was editing the first file in the list; that is, the file that the **rewind** command would edit. IEEE Std 1003.1-200x requires conformance to historical practice.

Substitute

Historically, *ex* accepted an **r** option to the **s** command. The effect of the **r** option was to use the last regular expression used in any command as the pattern, the same as the **˜** command. The **r** option is not required by IEEE Std 1003.1-200x. Historically, the **c** and **g** options were toggled; for example, the command **:s/abc/def/** was the same as **s/abc/def/ccccgggg**. For simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

The tilde command is often used to replace the last search RE. For example, in the sequence:

```
s/red/blue/
/green
~
```

the **˜** command is equivalent to:

```
s/green/blue/
```

Historically, *ex* accepted all of the following forms:

```
s/abc/def/
s/abc/def
s/abc/
s/abc
```

IEEE Std 1003.1-200x requires conformance to this historical practice.

The **s** command presumes that the `'^'` character only occupies a single column in the display. Much of the *ex* and *vi* specification presumes that the <space> only occupies a single column in the display. There are no known character sets for which this is not true.

Historically, the final column position for the substitute commands was based on previous column movements; a search for a pattern followed by a substitution would leave the column position unchanged, while a 0 command followed by a substitution would change the column position to the first non-<blank>. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that the final column position always be set to the first non-<blank>.

Set

Historical implementations redisplayed all of the options for each occurrence of the **all** keyword. IEEE Std 1003.1-200x permits, but does not require, this behavior.

Tag

No requirement is made as to where *ex* and *vi* shall look for the file referenced by the tag entry. Historical practice has been to look for the path found in the **tags** file, based on the current directory. A useful extension found in some implementations is to look based on the directory containing the tags file that held the entry, as well. No requirement is made as to which reference for the tag in the tags file is used. This is deliberate, in order to permit extensions such as multiple entries in a tags file for a tag.

Because users often specify many different tags files, some of which need not be relevant or exist at any particular time, IEEE Std 1003.1-200x requires that error messages about problem tags files be displayed only if the requested tag is not found, and then, only once for each time that the **tag** edit option is changed.

The requirement that the current edit buffer be unmodified is only necessary if the file indicated by the tag entry is not the same as the current file (as defined by the current pathname).

Historically, the file would be reloaded if the filename had changed, as well as if the filename was different from the current pathname. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior, requiring that the name be the only factor in the decision.

Historically, *vi* only searched for tags in the current file from the current cursor to the end of the file, and therefore, if the **wrapscan** option was not set, tags occurring before the current cursor were not found. IEEE Std 1003.1-200x considers this a bug, and implementations are required to search for the first occurrence in the file, regardless.

Undo

The **undo** description deliberately uses the word ‘‘modified’’. The **undo** command is not intended to undo commands that replace the contents of the edit buffer, such as **edit**, **next**, **tag**, or **recover**.

Cursor positioning after the **undo** command was inconsistent in the historical *vi*, sometimes attempting to restore the original cursor position (**global**, **undo**, and **v** commands), and sometimes, in the presence of maps, placing the cursor on the last line added or changed instead of the first. IEEE Std 1003.1-200x requires a simplified behavior for consistency and simplicity of specification.

Version

The **version** command cannot be exactly specified since there is no widely-accepted definition of what the version information should contain. Implementations are encouraged to do something reasonably intelligent.

Write

Historically, the *ex* and *vi* message after a successful **read** or **write** command specified ‘‘characters’’, not ‘‘bytes’’. IEEE Std 1003.1-200x requires that the number of bytes be displayed, not the number of characters because it may be difficult in multi-byte implementations to determine the number of characters written. Implementations are encouraged to clarify the message displayed to the user.

Implementation-defined tests are permitted so that implementations can make additional checks; for example, for locks or file modification times.

Historically, attempting to append to a nonexistent file caused an error. It has been left unspecified in IEEE Std 1003.1-200x to permit implementations to let the **write** succeed, so that the append semantics are similar to those of the historical *csh*.

Historical *vi* permitted empty edit buffers to be written. However, since the way *vi* got around dealing with ‘‘empty’’ files was to always have a line in the edit buffer, no matter what, it wrote them as files of a single, empty line. IEEE Std 1003.1-200x does not permit this behavior.

Historically, *ex* restored standard output and standard error to their values as of when *ex* was invoked, before writes to programs were performed. This could disturb the terminal configuration as well as be a security issue for some terminals. IEEE Std 1003.1-200x does not permit this, requiring that the program output be captured and displayed as if by the *ex* **print** command.

Adjust Window

Historically, the line count was set to the value of the **scroll** option if the type character was end-of-file. This feature was broken on most historical implementations long ago, however, and is not documented anywhere. For this reason, IEEE Std 1003.1-200x is resolutely silent.

Historically, the **z** command was <blank>-sensitive and **z +** and **z –** did different things than **z+** and **z–** because the type could not be distinguished from a flag. (The commands **z .** and **z =** were historically invalid.) IEEE Std 1003.1-200x requires conformance to this historical practice.

Historically, the **z** command was further <blank>-sensitive in that the *count* could not be <blank>-delimited; for example, the commands **z= 5** and **z– 5** were also invalid. Because the *count* is not ambiguous with respect to either the type character or the flags, this is not permitted by IEEE Std 1003.1-200x.

Escape

Historically, *ex* filter commands only read the standard output of the commands, letting standard error appear on the terminal as usual. The *vi* utility, however, read both standard output and standard error. IEEE Std 1003.1-200x requires the latter behavior for both *ex* and *vi*, for consistency.

Shift Left and Shift Right

Historically, it was possible to add shift characters to increase the effect of the command; for example, **<<<** outdented (or **>>>** indented) the lines 3 levels of indentation instead of the default 1. IEEE Std 1003.1-200x requires conformance to historical practice.

<control>-D

Historically, the <control>-D command erased the prompt, providing the user with an unbroken presentation of lines from the edit buffer. This is not required by IEEE Std 1003.1-200x; implementations are encouraged to provide it if possible. Historically, the <control>-D command took, and then ignored, a *count*. IEEE Std 1003.1-200x does not permit this behavior.

Write Line Number

Historically, the *ex* **=** command, when executed in *ex* mode in an empty edit buffer, reported 0, and from open or visual mode, reported 1. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Execute

Historically, *ex* did not correctly handle the inclusion of text input commands (that is, **append**, **insert**, and **change**) in executed buffers. IEEE Std 1003.1-200x does not permit this exclusion for consistency.

Historically, the logical contents of the buffer being executed did not change if the buffer itself were modified by the commands being executed; that is, buffer execution did not support self-modifying code. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, the **@** command took a range of lines, and the **@** buffer was executed once per line, with the current line (`'.'`) set to each specified line. IEEE Std 1003.1-200x requires conformance to historical practice.

Some historical implementations did not notice if errors occurred during buffer execution. This, coupled with the ability to specify a range of lines for the *ex* **@** command, makes it trivial to cause them to drop core. IEEE Std 1003.1-200x requires that implementations stop buffer execution if any error occurs, if the specified line doesn't exist, or if the contents of the edit buffer itself are replaced (for example, the buffer executes the *ex* **:edit** command).

Regular Expressions in ex

Historical practice is that the characters in the replacement part of the last **s** command—that is, those matched by entering a `'~'` in the regular expression—were not further expanded by the regular expression engine. So, if the characters contained the string `"a.,"` they would match `'a'` followed by `".,"` and not `'a'` followed by any character. IEEE Std 1003.1-200x requires conformance to historical practice.

Edit Options in ex

The following paragraphs describe the historical behavior of some edit options that were not, for whatever reason, included in IEEE Std 1003.1-200x. Implementations are strongly encouraged to only use these names if the functionality described here is fully supported.

extended	The **extended** edit option has been used in some implementations of *vi* to provide extended regular expressions instead of basic regular expressions This option was omitted from IEEE Std 1003.1-200x because it is not widespread historical practice.
flash	The **flash** edit option historically caused the screen to flash instead of beeping on error. This option was omitted from IEEE Std 1003.1-200x because it is not found in some historical implementations.
hardtabs	The **hardtabs** edit option historically defined the number of columns between hardware tab settings. This option was omitted from IEEE Std 1003.1-200x because it was believed to no longer be generally useful.
modeline	The **modeline** (sometimes named **modelines**) edit option historically caused *ex* or *vi* to read the five first and last lines of the file for editor commands. This option is a security problem, and vendors are strongly encouraged to delete it from historical implementations.
open	The **open** edit option historically disallowed the *ex* **open** and **visual** commands. This edit option was omitted because these commands are required by IEEE Std 1003.1-200x.
optimize	The **optimize** edit option historically expedited text throughput by setting the terminal to not do automatic carriage returns when printing more than one logical line of output. This option was omitted from IEEE Std 1003.1-200x because it was intended for terminals without addressable cursors, which are rarely, if ever, still used.
ruler	The **ruler** edit option has been used in some implementations of *vi* to present a current row/column ruler for the user. This option was omitted from IEEE Std 1003.1-200x because it is not widespread historical practice.
sourceany	The **sourceany** edit option historically caused *ex* or *vi* to source start-up files that were owned by users other than the user running the editor. This option is a security problem, and vendors are strongly encouraged to remove it from their implementations.
timeout	The **timeout** edit option historically enabled the (now standard) feature of only waiting for a short period before returning keys that could be part of a macro. This feature was omitted from IEEE Std 1003.1-200x because its behavior is now standard, it is not widely useful, and it was rarely documented.

verbose The **verbose** edit option has been used in some implementations of *vi* to cause *vi* to output error messages for common errors; for example, attempting to move the cursor past the beginning or end of the line instead of only alerting the screen. (The historical *vi* only alerted the terminal and presented no message for such errors. The historical editor option **terse** did not select when to present error messages, it only made existing error messages more or less verbose.) This option was omitted from IEEE Std 1003.1-200x because it is not widespread historical practice; however, implementors are encouraged to use it if they wish to provide error messages for naive users.

wraplen The **wraplen** edit option has been used in some implementations of *vi* to specify an automatic margin measured from the left margin instead of from the right margin. This is useful when multiple screen sizes are being used to edit a single file. This option was omitted from IEEE Std 1003.1-200x because it is not widespread historical practice; however, implementors are encouraged to use it if they add this functionality.

autoindent, ai

Historically, the command **0a** did not do any autoindentation, regardless of the current indentation of line 1. IEEE Std 1003.1-200x requires that any indentation present in line 1 be used.

autoprint, ap

Historically, the **autoprint** edit option was not completely consistent or based solely on modifications to the edit buffer. Exceptions were the **read** command (when reading from a file, but not from a filter), the **append**, **change**, **insert**, **global**, and **v** commands, all of which were not affected by **autoprint**, and the **tag** command, which was affected by **autoprint**. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, the **autoprint** option only applied to the last of multiple commands entered using vertical-bar delimiters; for example, **delete** <newline> was affected by **autoprint**, but **delete | version** <newline> was not. IEEE Std 1003.1-200x requires conformance to historical practice.

autowrite, aw

Appending the '!' character to the *ex* **next** command to avoid performing an automatic write was not supported in historical implementations. IEEE Std 1003.1-200x requires that the behavior match the other *ex* commands for consistency.

ignorecase, ic

Historical implementations of case-insensitive matching (the **ignorecase** edit option) lead to counterintuitive situations when uppercase characters were used in range expressions. Historically, the process was as follows:

1. Take a line of text from the edit buffer.
2. Convert uppercase to lowercase in text line.
3. Convert uppercase to lowercase in regular expressions, except in character class specifications.
4. Match regular expressions against text.

This would mean that, with **ignorecase** in effect, the text:

```
The cat sat on the mat
```

would be matched by

```
/ˆthe/
```

but not by:

```
/ˆ[A–Z]he/
```

For consistency with other commands implementing regular expressions, IEEE Std 1003.1-200x does not permit this behavior.

paragraphs, para

Earlier versions of IEEE Std 1003.1-200x made the default **paragraphs** and **sections** edit options implementation-defined, arguing they were historically oriented to the UNIX system *troff* text formatter, and a ‘‘portable user’’ could use the **{**, **}**, **[[**, **]]**, **(**, and **)** commands in open or visual mode and have the cursor stop in unexpected places. IEEE Std 1003.1-200x specifies their values in the POSIX locale because the unusual grouping (they only work when grouped into two characters at a time) means that they cannot be used for general purpose movement, regardless.

readonly

Implementations are encouraged to provide the best possible information to the user as to the read-only status of the file, with the exception that they should not consider the current special privileges of the process. This provides users a safety net because they must force the overwrite of read-only files, even when running with additional privileges.

The **readonly** edit option specification largely conforms to historical practice. The only difference is that historical implementations did not notice that the user had set the **readonly** edit option in cases where the file was already marked read-only for some reason, and would therefore reinitialize the **readonly** edit option the next time the contents of the edit buffer were replaced. This behavior is disallowed by IEEE Std 1003.1-200x.

report

The requirement that lines copied to a buffer interact differently than deleted lines is historical practice. For example, if the **report** edit option is set to 3, deleting 3 lines will cause a report to be written, but 4 lines must be copied before a report is written.

The requirement that the *ex* **global**, **v**, **open**, **undo**, and **visual** commands present reports based on the total number of lines added or deleted during the command execution, and that commands executed by the **global** and **v** commands not present reports, is historical practice. IEEE Std 1003.1-200x extends historical practice by requiring that buffer execution be treated similarly. The reasons for this are two-fold. Historically, only the report by the last command executed from the buffer would be seen by the user, as each new report would overwrite the last. In addition, the standard developers believed that buffer execution had more in common with **global** and **v** commands than it did with other *ex* commands, and should behave similarly, for consistency and simplicity of specification.

showmatch, sm

The length of time the cursor spends on the matching character is unspecified because the timing capabilities of systems are often inexact and variable. The time should be long enough for the user to notice, but not long enough for the user to become annoyed. Some implementations of *vi* have added a **matchtime** option that permits users to set the number of 0,1 second intervals the cursor pauses on the matching character.

showmode

The **showmode** option has been used in some historical implementations of *ex* and *vi* to display the current editing mode when in open or visual mode. The editing modes have generally included ''command'' and ''input'', and sometimes other modes such as ''replace'' and ''change''. The string was usually displayed on the bottom line of the screen at the far right-hand corner. In addition, a preceding `'*'` character often denoted if the contents of the edit buffer had been modified. The latter display has sometimes been part of the **showmode** option, and sometimes based on another option. This option was not available in the 4 BSD historical implementation of *vi*, but was viewed as generally useful, particularly to novice users, and is required by IEEE Std 1003.1-200x.

The **smd** shorthand for the **showmode** option was not present in all historical implementations of the editor. IEEE Std 1003.1-200x requires it, for consistency.

Not all historical implementations of the editor displayed a mode string for command mode, differentiating command mode from text input mode by the absence of a mode string. IEEE Std 1003.1-200x permits this behavior for consistency with historical practice, but implementations are encouraged to provide a display string for both modes.

slowopen

Historically the **slowopen** option was automatically set if the terminal baud rate was less than 1 200 baud, or if the baud rate was 1 200 baud and the **redraw** option was not set. The **slowopen** option had two effects. First, when inserting characters in the middle of a line, characters after the cursor would not be pushed ahead, but would appear to be overwritten. Second, when creating a new line of text, lines after the current line would not be scrolled down, but would appear to be overwritten. In both cases, ending text input mode would cause the screen to be refreshed to match the actual contents of the edit buffer. Finally, terminals that were sufficiently intelligent caused the editor to ignore the **slowopen** option. IEEE Std 1003.1-200x permits most historical behavior, extending historical practice to require **slowopen** behaviors if the edit option is set by the user.

tags

The default path for tags files is left unspecified as implementations may have their own **tags** implementations that do not correspond to the historical ones. The default **tags** option value should probably at least include the file **./tags**.

term

Historical implementations of *ex* and *vi* ignored changes to the **term** edit option after the initial terminal information was loaded. This is permitted by IEEE Std 1003.1-200x; however, implementations are encouraged to permit the user to modify their terminal type at any time.

terse

Historically, the **terse** edit option optionally provided a shorter, less descriptive error message, for some error messages. This is permitted, but not required, by IEEE Std 1003.1-200x. Historically, most common visual mode errors (for example, trying to move the cursor past the end of a line) did not result in an error message, but simply alerted the terminal. Implementations wishing to provide messages for novice users are urged to do so based on the **edit** option **verbose**, and not **terse**.

window

In historical implementations, the default for the **window** edit option was based on the baud rate as follows:

1. If the baud rate was less than 1 200, the **edit** option **w300** set the window value; for example, the line:

   ```
   set w300=12
   ```

   would set the window option to 12 if the baud rate was less than 1 200.
2. If the baud rate was equal to 1 200, the **edit** option **w1200** set the window value.
3. If the baud rate was greater than 1 200, the **edit** option **w9600** set the window value.

The **w300**, **w1200**, and **w9600** options do not appear in IEEE Std 1003.1-200x because of their dependence on specific baud rates.

In historical implementations, the size of the window displayed by various commands was related to, but not necessarily the same as, the **window** edit option. For example, the size of the window was set by the *ex* command **visual 10**, but it did not change the value of the **window** edit option. However, changing the value of the **window** edit option did change the number of lines that were displayed when the screen was repainted. IEEE Std 1003.1-200x does not permit this behavior in the interests of consistency and simplicity of specification, and requires that all commands that change the number of lines that are displayed do it by setting the value of the **window** edit option.

wrapmargin, wm

Historically, the **wrapmargin** option did not affect maps inserting characters that also had associated *count*s; for example **:map K 5aABC DEF**. Unfortunately, there are widely used maps that depend on this behavior. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Historically, **wrapmargin** was calculated using the column display width of all characters on the screen. For example, an implementation using `"^I"` to represent <tab>s when the **list** edit option was set, where `'^'` and `'I'` each took up a single column on the screen, would calculate the **wrapmargin** based on a value of 2 for each <tab>. The **number** edit option similarly changed the effective length of the line as well. IEEE Std 1003.1-200x requires conformance to historical practice.

FUTURE DIRECTIONS

None.

ed, *sed*, *stty*, *vi*, the System Interfaces volume of IEEE Std 1003.1-200x, *access*( )

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed, removing the **+***command* and – options.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the *map* command description, the sequence **#***digit* is added.
- The **directory**, **edcompatible**, **redraw**, and **slowopen** edit options are added.

The *ex* utility is extensively changed for alignment with the IEEE P1003.2b draft standard. This includes changes as a result of the IEEE PASC Interpretations 1003.2 #31, #38, #49, #50, #51, #52, #55, #56, #57, #61, #62, #63, #64, #65, and #78.

NAME

expand — convert tabs to spaces

SYNOPSIS

UP `expand [−t tablist][file ...]`

DESCRIPTION

The *expand* utility shall write files or the standard input to the standard output with <tab>s replaced with one or more <space>s needed to pad to the next tab stop. Any <backspace>s shall be copied to the output and cause the column position count for tab stop calculations to be decremented; the column position count shall not be decremented below zero.

OPTIONS

The *expand* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−t *tablist* Specify the tab stops. The application shall ensure that the argument *tablist* consists of either a single positive decimal integer or a list of tabstops. If a single number is given, tabs shall be set that number of column positions apart instead of the default 8.

If a list of tabstops is given, the application shall ensure that it consists of a list of two or more positive decimal integers, separated by <blank>s or commas, in ascending order. The tabs shall be set at those specific column positions. Each tab stop *N* shall be an integer value greater than zero, and the list is in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position *N* shall cause the next character output to be in the (*N*+1)th column position on that line.

In the event of *expand* having to process a <tab> at a position beyond the last of those specified in a multiple tab-stop list, the <tab> shall be replaced by a single <space> in the output.

OPERANDS

The following operand shall be supported:

file The pathname of a text file to be used as input.

STDIN

See the INPUT FILES section.

INPUT FILES

Input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *expand*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the processing of <tab>s and <space>s, and for the determination of the width in column positions each character would occupy on an output device.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be equivalent to the input files with <tab>s converted into the appropriate number of <space>s.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion
>0	An error occurred.

CONSEQUENCES OF ERRORS

The *expand* utility shall terminate with an error message and non-zero exit status upon encountering difficulties accessing one of the *file* operands.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *expand* utility is useful for preprocessing text files (before sorting, looking at specific columns, and so on) that contain <tab>s.

See the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.103, Column Position.

The *tablist* option-argument consists of integers in ascending order. Utility Syntax Guideline 8 mandates that *expand* shall accept the integers (within the single argument) separated using either commas or <blank>s.

FUTURE DIRECTIONS

None.

SEE ALSO

tabs, *unexpand*

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent SYNOPSIS is removed.

The *LC_CTYPE* environment variable description is updated to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

expr — evaluate arguments as an expression

SYNOPSIS

`expr` *`operand`*

DESCRIPTION

The *expr* utility shall evaluate an expression and write the result to standard output.

OPTIONS

None.

OPERANDS

The single expression evaluated by *expr* shall be formed from the operands, as described in the EXTENDED DESCRIPTION section. The application shall ensure that each of the expression operator symbols:

```
(   )   |   &   =   >   >=   <   <=   !=   +   –   *   /   %   :
```

and the symbols *integer* and *string* in the table are provided as separate arguments to *expr*.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *expr*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions and by the string comparison operators.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and the behavior of character classes within regular expressions.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *expr* utility shall evaluate the expression and write the result, followed by a <newline>, to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The formation of the expression to be evaluated is shown in the following table. The symbols *expr*, *expr1*, and *expr2* represent expressions formed from *integer* and *string* symbols and the expression operator symbols (all separate arguments) by recursive application of the constructs described in the table. The expressions are listed in order of increasing precedence, with equal-precedence operators grouped between horizontal lines. All of the operators shall be left-associative.

Expression	Description
expr1 | _expr2_	Returns the evaluation of _expr1_ if it is neither null nor zero; otherwise, returns the evaluation of _expr2_ if it is not null; otherwise, zero.
expr1 & _expr2_	Returns the evaluation of _expr1_ if neither expression evaluates to null or zero; otherwise, returns zero.
	Returns the result of a decimal integer comparison if both arguments are integers; otherwise, returns the result of a string comparison using the locale-specific collation sequence. The result of each comparison is 1 if the specified relationship is true, or 0 if the relationship is false.
expr1 = _expr2_	Equal.
expr1 > _expr2_	Greater than.
expr1 >= _expr2_	Greater than or equal.
expr1 < _expr2_	Less than.
expr1 <= _expr2_	Less than or equal.
expr1 != _expr2_	Not equal.
expr1 + _expr2_	Addition of decimal integer-valued arguments.
expr1 − _expr2_	Subtraction of decimal integer-valued arguments.
expr1 * _expr2_	Multiplication of decimal integer-valued arguments.
expr1 / _expr2_	Integer division of decimal integer-valued arguments, producing an integer result.
expr1 % _expr2_	Remainder of integer division of decimal integer-valued arguments.
expr1 : _expr2_	Matching expression; see below.
(_expr_)	Grouping symbols. Any expression can be placed within parentheses. Parentheses can be nested to a depth of {EXPR_NEST_MAX}.
integer	An argument consisting only of an (optional) unary minus followed by digits.
string	A string argument; see below.

Matching Expression

The `':'` matching operator shall compare the string resulting from the evaluation of *expr1* with the regular expression pattern resulting from the evaluation of *expr2*. Regular expression syntax shall be that defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions, except that all patterns are anchored to the beginning of the string (that is, only sequences starting at the first character of a string are matched by the regular expression) and, therefore, it is unspecified whether `'^'` is a special character in that context. Usually, the matching operator shall return a string representing the number of characters matched (`'0'` on failure). Alternatively, if the pattern contains at least one regular expression subexpression `"[\(...\)]"`, the string corresponding to `"\1"` shall be returned.

String Operand

A string argument is an argument that cannot be identified as an *integer* argument or as one of the expression operator symbols shown in the OPERANDS section.

The use of string arguments **length**, **substr**, **index**, or **match** produces unspecified results.

EXIT STATUS

The following exit values shall be returned:

0 The *expression* evaluates to neither null nor zero.

1 The *expression* evaluates to null or zero.

2 Invalid *expression*.

>2 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

After argument processing by the shell, *expr* is not required to be able to tell the difference between an operator and an operand except by the value. If `"$a"` is `'='`, the command:

```
expr $a = '='
```

looks like:

```
expr = = =
```

as the arguments are passed to *expr* (and they all may be taken as the `'='` operator). The following works reliably:

```
expr X$a = X=
```

Also note that this volume of IEEE Std 1003.1-200x permits implementations to extend utilities. The *expr* utility permits the integer arguments to be preceded with a unary minus. This means that an integer argument could look like an option. Therefore, the conforming application must employ the `"--"` construct of Guideline 10 of the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines to protect its operands if there is any chance the first operand might be a negative integer (or any string with a leading minus).

EXAMPLES

The *expr* utility has a rather difficult syntax:

- Many of the operators are also shell control operators or reserved words, so they have to be escaped on the command line.

- Each part of the expression is composed of separate arguments, so liberal usage of <blank>s is required. For example:

Invalid	**Valid**
`expr 1+2`	`expr 1 + 2`
`expr "1 + 2"`	`expr 1 + 2`
`expr 1 + (2 * 3)`	`expr 1 + \( 2 \* 3 \)`

In many cases, the arithmetic and string features provided as part of the shell command language are easier to use than their equivalents in *expr*. Newly written scripts should avoid *expr* in favor of the new features within the shell; see Section 2.5 (on page 2235) and Section 2.6.4 (on page 2243).

The following command:

```
a=$(expr $a + 1)
```

adds 1 to the variable *a*.

The following command, for `"$a"` equal to either **/usr/abc/file** or just **file**:

```
expr $a : '.*/\(.*\)' \| $a
```

returns the last segment of a pathname (that is, **file**). Applications should avoid the character `'/'` used alone as an argument: *expr* may interpret it as the division operator.

The following command:

```
expr "//$a" : '.*/\(.*\)'
```

is a better representation of the previous example. The addition of the `"//"` characters eliminates any ambiguity about the division operator and simplifies the whole expression. Also note that pathnames may contain characters contained in the *IFS* variable and should be quoted to avoid having `"$a"` expand into multiple arguments.

The following command:

```
expr "$VAR" : '.*'
```

returns the number of characters in *VAR*.

RATIONALE

In an early proposal, EREs were used in the matching expression syntax. This was changed to BREs to avoid breaking historical applications.

The use of a leading circumflex in the BRE is unspecified because many historical implementations have treated it as a special character, despite their system documentation. For example:

```
expr foo : ^foo     expr ^foo : ^foo
```

return 3 and 0, respectively, on those systems; their documentation would imply the reverse. Thus, the anchoring condition is left unspecified to avoid breaking historical scripts relying on this undocumented feature.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 2.

NAME

fc — process the command history list

SYNOPSIS

UP

```
fc [−r][−e editor] [first[last]]
fc −l[−nr] [first[last]]
fc −s[old=new][first]
```

DESCRIPTION

The *fc* utility shall list, or shall edit and re-execute, commands previously entered to an interactive *sh*.

The command history list shall reference commands by number. The first number in the list is selected arbitrarily. The relationship of a number to its command shall not change except when the user logs in and no other process is accessing the list, at which time the system may reset the numbering to start the oldest retained command at another number (usually 1). When the number reaches an implementation-defined upper limit, which shall be no smaller than the value in *HISTSIZE* or 32 767 (whichever is greater), the shell may wrap the numbers, starting the next command with a lower number (usually 1). However, despite this optional wrapping of numbers, *fc* shall maintain the time-ordering sequence of the commands. For example, if four commands in sequence are given the numbers 32 766, 32 767, 1 (wrapped), and 2 as they are executed, command 32 767 is considered the command previous to 1, even though its number is higher.

When commands are edited (when the **−l** option is not specified), the resulting lines shall be entered at the end of the history list and then re-executed by *sh*. The *fc* command that caused the editing shall not be entered into the history list. If the editor returns a non-zero exit status, this shall suppress the entry into the history list and the command re-execution. Any command line variable assignments or redirection operators used with *fc* shall affect both the *fc* command itself as well as the command that results; for example:

```
fc −s −− −1 2>/dev/null
```

reinvokes the previous command, suppressing standard error for both *fc* and the previous command.

OPTIONS

The *fc* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−e *editor*	Use the editor named by *editor* to edit the commands. The *editor* string is a utility name, subject to search via the *PATH* variable (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables). The value in the *FCEDIT* variable shall be used as a default when **−e** is not specified. If *FCEDIT* is null or unset, *ed* shall be used as the editor.
−l	(The letter ell.) List the commands rather than invoking an editor on them. The commands shall be written in the sequence indicated by the *first* and *last* operands, as affected by **−r**, with each command preceded by the command number.
−n	Suppress command numbers when listing with **−l**.
−r	Reverse the order of the commands listed (with **−l**) or edited (with neither **−l** nor **−s**).

−s Reexecute the command without invoking an editor.

OPERANDS

The following operands shall be supported:

first, *last*

Select the commands to list or edit. The number of previous commands that can be accessed shall be determined by the value of the *HISTSIZE* variable. The value of *first* or *last* or both shall be one of the following:

[+]*number* A positive number representing a command number; command numbers can be displayed with the **−l** option.

−*number* A negative decimal number representing the command that was executed *number* of commands previously. For example, −1 is the immediately previous command.

string A string indicating the most recently entered command that begins with that string. If the *old*=*new* operand is not also specified with **−s**, the string form of the *first* operand cannot contain an embedded equal sign.

When the synopsis form with **−s** is used:

- If *first* is omitted, the previous command shall be used.

For the synopsis forms without **−s**:

- If *last* is omitted, *last* shall default to the previous command when **−l** is specified; otherwise, it shall default to *first*.
- If *first* and *last* are both omitted, the previous 16 commands shall be listed or the previous single command shall be edited (based on the **−l** option).
- If *first* and *last* are both present, all of the commands from *first* to *last* shall be edited (without **−l**) or listed (with **−l**). Editing multiple commands shall be accomplished by presenting to the editor all of the commands at one time, each command starting on a new line. If *first* represents a newer command than *last*, the commands shall be listed or edited in reverse sequence, equivalent to using **−r**. For example, the following commands on the first line are equivalent to the corresponding commands on the second:

```
fc −r 10 20    fc    30 40
fc    20 10    fc −r 40 30
```

- When a range of commands is used, it shall not be an error to specify *first* or *last* values that are not in the history list; *fc* shall substitute the value representing the oldest or newest command in the list, as appropriate. For example, if there are only ten commands in the history list, numbered 1 to 10:

```
fc −l
fc 1 99
```

  shall list and edit, respectively, all ten commands.

old=*new* Replace the first occurrence of string *old* in the commands to be re-executed by the string *new*.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *fc*:

FCEDIT	This variable, when expanded by the shell, shall determine the default value for the **−e** *editor* option's *editor* option-argument. If *FCEDIT* is null or unset, *ed* shall be used as the editor.
HISTFILE	Determine a pathname naming a command history file. If the *HISTFILE* variable is not set, the shell may attempt to access or create a file **.sh_history** in the directory referred to by the *HOME* environment variable. If the shell cannot obtain both read and write access to, or create, the history file, it shall use an unspecified mechanism that allows the history to operate properly. (References to history ''file'' in this section shall be understood to mean this unspecified mechanism in such cases.) An implementation may choose to access this variable only when initializing the history file; this initialization shall occur when *fc* or *sh* first attempt to retrieve entries from, or add entries to, the file, as the result of commands issued by the user, the file named by the *ENV* variable, or implementation-defined system start-up files. In some historical shells, the history file is initialized just after the *ENV* file has been processed. Therefore, it is implementation-defined whether changes made to *HISTFILE* after the history file has been initialized are effective. Implementations may choose to disable the history list mechanism for users with appropriate privileges who do not set *HISTFILE*; the specific circumstances under which this occurs are implementation-defined. If more than one instance of the shell is using the same history file, it is unspecified how updates to the history file from those shells interact. As entries are deleted from the history file, they shall be deleted oldest first. It is unspecified when history file entries are physically removed from the history file.
HISTSIZE	Determine a decimal number representing the limit to the number of previous commands that are accessible. If this variable is unset, an unspecified default greater than or equal to 128 shall be used. The maximum number of commands in the history list is unspecified, but shall be at least 128. An implementation may choose to access this variable only when initializing the history file, as described under *HISTFILE*. Therefore, it is unspecified whether changes made to *HISTSIZE* after the history file has been initialized are effective.
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the **–l** option is used to list commands, the format of each command in the list shall be as follows:

```
"%d\t%s\n", <line number>, <command>
```

If both the **–l** and **–n** options are specified, the format of each command shall be:

```
"\t%s\n", <command>
```

If the <*command*> consists of more than one line, the lines after the first shall be displayed as:

```
"\t%s\n", <continued-command>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion of the listing.
>0	An error occurred.

Otherwise, the exit status shall be that of the commands executed by *fc*.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since editors sometimes use file descriptors as integral parts of their editing, redirecting their file descriptors as part of the *fc* command can produce unexpected results. For example, if *vi* is the *FCEDIT* editor, the command:

```
fc –s | more
```

does not work correctly on many systems.

Users on windowing systems may want to have separate history files for each window by setting *HISTFILE* as follows:

```
HISTFILE=$HOME/.sh_hist$$
```

EXAMPLES

None.

RATIONALE

This utility is based on the *fc* built-in of the KornShell.

An early proposal specified the **–e** option as **[–e** *editor* **[***old*= *new* **]]**, which is not historical practice. Historical practice in *fc* of either **[–e** *editor***]** or **[–e** – **[** *old*= *new* **]]** is acceptable, but not both together. To clarify this, a new option **–s** was introduced replacing the **[–e –]**. This resolves the conflict and makes *fc* conform to the Utility Syntax Guidelines.

HISTFILE	Some implementations of the KornShell check for the superuser and do not create a history file unless *HISTFILE* is set. This is done primarily to avoid creating unlinked files in the root file system when logging in during single-user mode. *HISTFILE* must be set for the superuser to have history.
HISTSIZE	Needed to limit the size of history files. It is the intent of the standard developers that when two shells share the same history file, commands that are entered in one shell shall be accessible by the other shell. Because of the difficulties of synchronization over a network, the exact nature of the interaction is unspecified.

The initialization process for the history file can be dependent on the system start-up files, in that they may contain commands that effectively preempt the settings the user has for *HISTFILE* and *HISTSIZE*. For example, function definition commands are recorded in the history file. If the system administrator includes function definitions in some system start-up file called before the *ENV* file, the history file is initialized before the user can influence its characteristics. In some historical shells, the history file is initialized just after the *ENV* file has been processed. Because of these situations, the text requires the initialization process to be implementation-defined.

Consideration was given to omitting the *fc* utility in favor of the command line editing feature in *sh*. For example, in *vi* editing mode, typing `"<ESC> v"` is equivalent to:

```
EDITOR=vi fc
```

However, the *fc* utility allows the user the flexibility to edit multiple commands simultaneously (such as *fc* 10 20) and to use editors other than those supported by *sh* for command line editing.

In the KornShell, the alias **r** (‘‘re-do’’) is preset to *fc* −**e** − (equivalent to the POSIX *fc* −**s**). This is probably an easier command name to remember than *fc* (‘‘fix command’’), but it does not meet the Utility Syntax Guidelines. Renaming *fc* to *hist* or *redo* was considered, but since this description closely matches historical KornShell practice already, such a renaming was seen as gratuitous. Users are free to create aliases whenever odd historical names such as *fc*, *awk*, *cat*, *grep*, or *yacc* are standardized by POSIX.

Command numbers have no ordering effects; they are like serial numbers. The −**r** option and −*number* operand address the sequence of command execution, regardless of serial numbers. So, for example, if the command number wrapped back to 1 at some arbitrary point, there would be no ambiguity associated with traversing the wrap point. For example, if the command history were:

```
32766: echo 1
32767: echo 2
1: echo 3
```

the number −2 refers to command 32 767 because it is the second previous command, regardless of serial number.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

In the ENVIRONMENT VARIABLES section, the text ‘‘user’s home directory’’ is updated to ‘‘directory referred to by the *HOME* environment variable’’.

NAME

fg — run jobs in the foreground

SYNOPSIS

UP
```
fg [job_id]
```

DESCRIPTION

If job control is enabled (see the description of *set* **–m**), the *fg* utility shall move a background job from the current environment (see Section 2.12 (on page 2263)) into the foreground.

Using *fg* to place a job into the foreground shall remove its process ID from the list of those ‘‘known in the current shell execution environment’’; see Section 2.9.3.1 (on page 2252).

OPTIONS

None.

OPERANDS

The following operand shall be supported:

job_id	Specify the job to be run as a foreground job. If no *job_id* operand is given, the *job_id* for the job that was most recently suspended, placed in the background or run as a background job, shall be used. The format of *job_id* is described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.203, Job Control Job ID.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *fg*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *fg* utility shall write the command line of the job to standard output in the following format:

```
"%s\n", <command>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If job control is disabled, the *fg* utility shall exit with an error and no job shall be placed in the foreground.

APPLICATION USAGE

The *fg* utility does not work as expected when it is operating in its own utility execution environment because that environment has no applicable jobs to manipulate. See the APPLICATION USAGE section for *bg* (on page 2410). For this reason, *fg* is generally implemented as a shell regular built-in.

EXAMPLES

None.

RATIONALE

The extensions to the shell specified in this volume of IEEE Std 1003.1-200x have mostly been based on features provided by the KornShell. The job control features provided by *bg*, *fg*, and *jobs* are also based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell versions were selected for this volume of IEEE Std 1003.1-200x to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).

FUTURE DIRECTIONS

None.

SEE ALSO

bg, *kill*, *jobs*, *wait*

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The JC marking is removed from the SYNOPSIS since job control is mandatory is this issue.

NAME

file — determine file type

SYNOPSIS

UP
```
file [−dhi][−M file][−m file] file ...
```

DESCRIPTION

The *file* utility shall perform a series of tests on each specified *file* in an attempt to classify it:

1. If the file is not a regular file, its file type shall be identified. The file types directory, FIFO, socket, block special, and character special shall be identified as such. Other implementation-defined file types may also be identified.
2. If the file is a regular file, and:
   a. The file is zero-length, it shall be identified as an empty file.
   b. The file is not zero-length, *file* shall examine an initial segment of the file and shall make a guess at identifying its contents or whether it is an executable binary file. (The answer is not guaranteed to be correct.)

If *file* does not exist, cannot be read, or its file status could not be determined, the output shall indicate that the file was processed, but that its type could not be determined.

If *file* is a symbolic link, by default the link shall be resolved and *file* shall test the type of file referenced by the symbolic link.

OPTIONS

The *file* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

−d	Apply any default system tests to the file.
−h	When a symbolic link is encountered, identify the file as a symbolic link. If **−h** is not specified and *file* is a symbolic link that refers to a nonexistent file, *file* shall identify the file as a symbolic link, as if **−h** had been specified.
−i	If a file is a regular file, do not attempt to classify the type of the file further, but identify the file as specified in the STDOUT section, using a <*type*> string that contains the string `"regular file"`.
−M *file*	Specify the name of a file containing tests that shall be applied to a file in order to classify it (see the EXTENDED DESCRIPTION). No default system tests shall be applied.
−m *file*	Specify the name of a file containing tests that shall be applied to a file in order to classify it (see the EXTENDED DESCRIPTION).

If multiple instances of the **−m**, **−d**, or **−M** options are specified, the concatenation of the tests specified, in the order specified, shall be the set of tests that are applied. If a **−M** option is specified, no tests other than those specified using the **−d**, **−M**, and **−m** options shall be applied to the file. If neither the **−d** nor **−M** options are specified, any default system tests shall be applied after any tests specified using the **−m** option.

OPERANDS

The following operand shall be supported:

file	A pathname of a file to be tested.

STDIN

Not used.

INPUT FILES

The *file* can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *file*:

	LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
	LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
	LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
	LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

In the POSIX locale, the following format shall be used to identify each operand, *file* specified:

```
"%s: %s\n", <file>, <type>
```

The values for <*type*> are unspecified, except that in the POSIX locale, if *file* is identified as one of the types listed in the following table, <*type*> shall contain (but is not limited to) the corresponding string. Each space shown in the strings shall be exactly one <space>.

Table 4-8 File Utility Output Strings

If *file* is a:	**<*type*> shall contain the string:**
Directory	directory
FIFO	fifo
Socket	socket
Block special	block special
Character special	character special
Executable binary	executable
Empty regular file	empty
Symbolic link	symbolic link to
ar archive library (see *ar*)	archive
Extended *cpio* format (see *pax*)	cpio archive
Extended *tar* format (see **ustar** in *pax*)	tar archive
Shell script	commands text
C-language source	c program text
FORTRAN source	fortran program text

If *file* is identified as a symbolic link (see **−h**), the following alternative output format shall be used:

```
"%s: %s %s\n", <file>, <type>, <contents of link>"
```

If the file named by the *file* operand does not exist or cannot be read, the string `"cannot open"` shall be included as part of the <*type*> field, but this shall not be considered an error that affects the exit status. If the type of the file named by the *file* operand cannot be determined, the string `"data"` shall be included as part of the <*type*> field, but this shall not be considered an error that affects the exit status.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

A file specified as an option-argument to the **−m** or **−M** options shall contain one test per line, which shall be applied to the file. If the test succeeds, the message field of the line shall be printed and no further tests shall be applied, with the exception that tests on immediately following lines beginning with a single `'>'` character shall be applied.

Each line shall be composed of the following four <blank>-separated fields:

offset An unsigned number (optionally preceded by a single `'>'` character) specifying the *offset*, in bytes, of the value in the file that is to be compared against the *value* field of the line. If the file is shorter than the specified offset, the test shall fail.

If the *offset* begins with the character `'>'`, the test contained in the line shall not be applied to the file unless the test on the last line for which the *offset* did not begin with a `'>'` was successful. By default, the *offset* shall be interpreted as an unsigned decimal number. With a leading 0x or 0X, the *offset* shall be interpreted as a hexadecimal number; otherwise, with a leading 0, the *offset* shall be interpreted as an octal number.

type The type of the value in the file to be tested. The type shall consist of the type specification characters `c`, `d`, `f`, `s`, and `u`, specifying character, signed decimal, floating point, string, and unsigned decimal, respectively.

The *type* string shall be interpreted as the bytes from the file starting at the specified *offset* and including the same number of bytes specified by the *value* field. If insufficient bytes remain in the file past the *offset* to match the *value* field, the test shall fail.

The type specification characters `d`, `f`, and `u` can be followed by an optional unsigned decimal integer that specifies the number of bytes represented by the type. The type specification character `f` can be followed by an optional `F`, `D`, or `L`, indicating that the value is of type **float**, **double**, or **long double**, respectively. The type specification characters `d` and `u` can be followed by an optional `C`, `S`, `I`, or `L`, indicating that the value is of type **char**, **short**, **int**, or **long**, respectively.

The default number of bytes represented by the type specifiers `d`, `f`, and `u` shall correspond to their respective C-language types as follows. If the system claims conformance to the C-Language Development Utilities option, those specifiers shall correspond to the default sizes used in the *c99* utility. Otherwise, the default sizes shall be implementation-defined.

For the type specifier characters `d` and `u`, the default number of bytes shall correspond to the size of a basic integer type of the implementation. For these specifier characters, the implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types **char**, **short**, **int**, or **long**. These numbers can also be specified by an application as the characters `C`, `S`, `I`, and `L`, respectively. The byte order used when interpreting numeric values is implementation-defined, but shall correspond to the order in which a constant of the corresponding type is stored in memory on the system.

For the type specifier `f`, the default number of bytes shall correspond to the number of bytes in the basic double precision floating-point data type of the underlying implementation. The implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types **float**, **double**, and **long double**. These numbers can also be specified by an application as the characters `F`, `D`, and `L`, respectively.

All type specifiers, except for `s`, can be followed by a mask specifier of the form &*number*. The mask value shall be AND'ed with the value before the comparison with the value from the file is made. By default, the mask shall be interpreted as an unsigned decimal number. With a leading 0x or 0X, the mask shall be interpreted as an unsigned hexadecimal number; otherwise, with a leading 0, the mask shall be interpreted as an unsigned octal number.

The strings **byte**, **short**, **long**, and **string** shall also be supported as type fields, being interpreted as `dC`, `dS`, `dL`, and `s`, respectively.

value The *value* to be compared with the value from the file.

If the specifier from the type field is `s` or **string**, then interpret the value as a string. Otherwise, interpret it as a number. If the value is a string, then the test shall succeed only when a string value exactly matches the bytes from the file.

If the *value* is a string, it can contain the following sequences:

character The backslash-escape sequences as specified in the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). The results of using any other character, other than an octal digit, following the backslash are unspecified.

octal	Octal sequences that can be used to represent characters with specific coded values. An octal sequence shall consist of a backslash followed by the longest sequence of one, two, or three octal-digit characters (01234567). If the size of a byte on the system is greater than 9 bits, the valid escape sequence used to represent a byte is implementation-defined.

By default, any value that is not a string shall be interpreted as a signed decimal number. Any such value, with a leading 0x or 0X, shall be interpreted as an unsigned hexadecimal number; otherwise, with a leading zero, the value shall be interpreted as an unsigned octal number.

If the value is not a string, it can be preceded by a character indicating the comparison to be performed. Permissible characters and the comparisons they specify are as follows:

=	The test shall succeed if the value from the file equals the *value* field.
<	The test shall succeed if the value from the file is less than the *value* field.
>	The test shall succeed if the value from the file is greater than the *value* field.
&	The test shall succeed if all of the bits in the *value* field are set in the value from the file.
^	The test shall succeed if at least one of the bits in the *value* field is not set in the value from the file.
x	The test shall succeed if the file is large enough to contain a value of the type specified starting at the offset specified.

message	The *message* to be printed if the test succeeds. The *message* shall be interpreted using the notation for the *printf* formatting specification; see *printf*. If the *value* field was a string, then the value from the file shall be the argument for the *printf* formatting specification; otherwise, the value from the file shall be the argument.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *file* utility can only be required to guess at many of the file types because only exhaustive testing can determine some types with certainty. For example, binary data on some implementations might match the initial segment of an executable or a *tar* archive. |

Note that the table indicates that the output contains the stated string. Systems may add text before or after the string. For executables, as an example, the machine architecture and various facts about how the file was link-edited may be included.

EXAMPLES

Determine whether an argument is a binary executable file:

```
file "$1" | grep −Fq executable &&
    printf "%s is executable.\n" "$1"
```

RATIONALE

The −**f** option was omitted because the same effect can (and should) be obtained using the *xargs* utility.

Historical versions of the *file* utility attempt to identify the following types of files: symbolic link, directory, character special, block special, socket, *tar* archive, *cpio* archive, SCCS archive, archive library, empty, *compress* output, *pack* output, binary data, C source, FORTRAN source, assembler source, *nroff*/*troff*/*eqn*/*tbl* source *troff* output, shell script, C shell script, English text, ASCII text, various executables, APL workspace, compiled terminfo entries, and CURSES screen images. Only those types that are reasonably well specified in POSIX or are directly related to POSIX utilities are listed in the table.

Implementations that support symbolic links are encouraged to use the string `"symbolic link"` to identify them.

Historical systems have used a ‘‘magic file’’ named **/etc/magic** to help identify file types. Because it is generally useful for users and scripts to be able to identify special file types, the −**m** flag and a portable format for user-created magic files has been specified. No requirement is made that an implementation of *file* use this method of identifying files, only that users be permitted to add their own classifying tests.

In addition, three options have been added to historical practice. The −**d** flag has been added to permit users to cause their tests to follow any default system tests. The −**i** flag has been added to permit users to test portably for regular files in shell scripts. The −**M** flag has been added to permit users to ignore any default system tests.

The historical −**c** option was omitted as not particularly useful to users or portable shell scripts. In addition, a reasonable implementation of the *file* utility would report any errors found each time the magic file is read.

The historical format of the magic file was the same as that specified by the Rationale in the previous version of IEEE Std 1003.1-200x for the *offset*, *value*, and *message* fields; however, it used less precise type fields than the format specified by the current normative text. The new type field values are a superset of the historical ones.

The following is an example magic file:

```
0  short     070707              cpio archive
0  short     0143561             Byte-swapped cpio archive
0  string    070707              ASCII cpio archive
0  long      0177555             Very old archive
0  short     0177545             Old archive
0  short     017437              Old packed data
0  string    \037\036            Packed data
0  string    \377\037            Compacted data
0  string    \037\235            Compressed data
>2 byte&0x80 >0                  Block compressed
>2 byte&0x1f x                   %d bits
0  string    \032\001            Compiled Terminfo Entry
0  short     0433                Curses screen image
0  short     0434                Curses screen image
```

```
0  string    <ar>                 System V Release 1 archive
0  string    !<arch>\n__.SYMDEF  Archive random library
0  string    !<arch>              Archive
0  string    ARF_BEGARF           PHIGS clear text archive
0  long      0x137A2950           Scalable OpenFont binary
0  long      0x137A2951           Encrypted scalable OpenFont binary
```

The use of a basic integer data type is intended to allow the implementation to choose a word size commonly used by applications on that architecture.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

Options and an EXTENDED DESCRIPTION are added as specified in the IEEE P1003.2b draft standard.

IEEE PASC Interpretations 1003.2 #192 and #178 are applied.

NAME

find — find files

SYNOPSIS

`find [−H | −L] path ... [operand_expression ...]`

DESCRIPTION

The *find* utility shall recursively descend the directory hierarchy from each file specified by *path*, evaluating a Boolean expression composed of the primaries described in the OPERANDS section for each file encountered.

The *find* utility shall be able to descend to arbitrary depths in a file hierarchy and shall not fail due to path length limitations (unless a *path* operand specified by the application exceeds {PATH_MAX} requirements).

The *find* utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, *find* shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

OPTIONS

The *find* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

−H Cause the file information and file type evaluated for each symbolic link encountered on the command line to be those of the file referenced by the link, and not the link itself. If the referenced file does not exist, the file information and type shall be for the link itself. File information for all symbolic links not on the command line shall be that of the link itself.

−L Cause the file information and file type evaluated for each symbolic link to be those of the file referenced by the link, and not the link itself.

Specifying more than one of the mutually-exclusive options −**H** and −**L** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operands shall be supported:

The *path* operand is a pathname of a starting point in the directory hierarchy.

The first argument that starts with a `'−'`, or is a `'!'` or a `'('`, and all subsequent arguments shall be interpreted as an *expression* made up of the following primaries and operators. In the descriptions, wherever *n* is used as a primary argument, it shall be interpreted as a decimal integer optionally preceded by a plus (`'+'`) or minus (`'−'`) sign, as follows:

+*n* More than *n*.

n Exactly *n*.

−*n* Less than *n*.

The following primaries shall be supported:

−**name** *pattern*
The primary shall evaluate as true if the basename of the filename being examined matches *pattern* using the pattern matching notation described in Section 2.13 (on page 2264).

−nouser The primary shall evaluate as true if the file belongs to a user ID for which the *getpwuid*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x (or equivalent) returns NULL.

−nogroup The primary shall evaluate as true if the file belongs to a group ID for which the *getgrgid*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x (or equivalent) returns NULL.

−xdev The primary always shall evaluate as true; it shall cause *find* not to continue descending past directories that have a different device ID (*st_dev*, see the *stat*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x). If any −**xdev** primary is specified, it shall apply to the entire expression even if the −**xdev** primary would not normally be evaluated.

−prune The primary always shall evaluate as true; it shall cause *find* not to descend the current pathname if it is a directory. If the −**depth** primary is specified, the −**prune** primary shall have no effect.

−perm [−]*mode*

The *mode* argument is used to represent file mode bits. It shall be identical in format to the *symbolic_mode* operand described in *chmod* (on page 2438), and shall be interpreted as follows. To start, a template shall be assumed with all file mode bits cleared. An *op* symbol of `'+'` shall set the appropriate mode bits in the template; `'−'` shall clear the appropriate bits; `'='` shall set the appropriate mode bits, without regard to the contents of process' file mode creation mask. The *op* symbol of `'−'` cannot be the first character of *mode*; this avoids ambiguity with the optional leading hyphen. Since the initial mode is all bits off, there are not any symbolic modes that need to use `'−'` as the first character.

If the hyphen is omitted, the primary shall evaluate as true when the file permission bits exactly match the value of the resulting template.

Otherwise, if *mode* is prefixed by a hyphen, the primary shall evaluate as true if at least all the bits in the resulting template are set in the file permission bits.

−perm [−]*onum*

If the hyphen is omitted, the primary shall evaluate as true when the file permission bits exactly match the value of the octal number *onum* and only the bits corresponding to the octal mask 07777 shall be compared. (See the description of the octal *mode* in *chmod* (on page 2438).) Otherwise, if *onum* is prefixed by a hyphen, the primary shall evaluate as true if at least all of the bits specified in *onum* that are also set in the octal mask 07777 are set.

−type *c* The primary shall evaluate as true if the type of the file is *c*, where *c* is `'b'`, `'c'`, `'d'`, `'l'`, `'p'`, `'f'`, or `'s'` for block special file, character special file, directory, symbolic link, FIFO, regular file, or socket, respectively.

−links *n* The primary shall evaluate as true if the file has *n* links.

−user *uname* The primary shall evaluate as true if the file belongs to the user *uname*. If *uname* is a decimal integer and the *getpwnam*( ) (or equivalent) function does not return a valid user name, *uname* shall be interpreted as a user ID.

−group *gname*

The primary shall evaluate as true if the file belongs to the group *gname*. If *gname* is a decimal integer and the *getgrnam*( ) (or equivalent) function does not return a valid group name, *gname* shall be interpreted as a group ID.

−size *n*[**c**] The primary shall evaluate as true if the file size in bytes, divided by 512 and rounded up to the next integer, is *n*. If *n* is followed by the character `'c'`, the size shall be in bytes.

−atime *n* The primary shall evaluate as true if the file access time subtracted from the initialization time, divided by 86 400 (with any remainder discarded), is *n*.

−ctime *n* The primary shall evaluate as true if the time of last change of file status information subtracted from the initialization time, divided by 86 400 (with any remainder discarded), is *n*.

−mtime *n* The primary shall evaluate as true if the file modification time subtracted from the initialization time, divided by 86 400 (with any remainder discarded), is *n*.

−exec *utility_name* **[***argument* ...**] ;**
−exec *utility_name* **[***argument* ...**] ;** {} +

The end of the primary expression shall be punctuated by a semicolon or by a plus sign. Only a plus sign that follows an argument containing the two characters `"{}"` shall punctuate the end of the primary expression. Other uses of the plus sign shall not be treated as special.

If the primary expression is punctuated by a semicolon, the utility *utility_name* shall be invoked once for each pathname and the primary shall evaluate as true if the utility returns a zero value as exit status. A *utility_name* or *argument* containing only the two characters `"{}"` shall be replaced by the current pathname.

If the primary expression is punctuated by a plus sign, the primary shall always evaluate as true, and the pathnames for which the primary is evaluated shall be aggregated into sets. The utility *utility_name* shall be invoked once for each set of aggregated pathnames. Each invocation shall begin after the last pathname in the set is aggregated, and shall be completed before the *find* utility exits and before the first pathname in the next set (if any) is aggregated for this primary, but it is otherwise unspecified whether the invocation occurs before, during, or after the evaluations of other primaries. If any invocation returns a non-zero value as exit status, the *find* utility shall return a non-zero exit status. An argument containing only the two characters `"{}"` shall be replaced by the set of aggregated pathnames, with each pathname passed as a separate argument to the invoked utility in the same order that it was aggregated. The size of any set of two or more pathnames shall be limited such that execution of the utility does not cause the system's {ARG_MAX} limit to be exceeded. If more than one argument containing only the two characters `"{}"` is present, the behavior is unspecified.

If a *utility_name* or *argument* string contains the two characters `"{}"`, but not just the two characters `"{}"`, it is implementation-defined whether *find* replaces those two characters or uses the string without change. The current directory for the invocation of *utility_name* shall be the same as the current directory when the *find* utility was started. If the *utility_name* names any of the special built-in utilities (see Section 2.14 (on page 2266)), the results are undefined.

−ok *utility_name* **[***argument* ...**] ;**

The **−ok** primary shall be equivalent to **−exec**, except that the use of a plus sign to punctuate the end of the primary expression need not be supported, and *find* shall request affirmation of the invocation of *utility_name* using the current file as an argument by writing to standard error as described in the STDERR section. If the response on standard input is affirmative, the utility shall be invoked. Otherwise, the command shall not be invoked and the value of the **−ok** operand shall be false.

–print The primary always shall evaluate as true; it shall cause the current pathname to be written to standard output.

–newer *file* The primary shall evaluate as true if the modification time of the current file is more recent than the modification time of the file named by the pathname *file*.

–depth The primary shall always evaluate as true; it shall cause descent of the directory hierarchy to be done so that all entries in a directory are acted on before the directory itself. If a **–depth** primary is not specified, all entries in a directory shall be acted on after the directory itself. If any **–depth** primary is specified, it shall apply to the entire expression even if the **–depth** primary would not normally be evaluated.

The primaries can be combined using the following operators (in order of decreasing precedence):

(*expression*) True if *expression* is true.

! *expression* Negation of a primary; the unary NOT operator.

expression **[–a]** *expression*

Conjunction of primaries; the AND operator is implied by the juxtaposition of two primaries or made explicit by the optional **–a** operator. The second expression shall not be evaluated if the first expression is false.

expression **–o** *expression*

Alternation of primaries; the OR operator. The second expression shall not be evaluated if the first expression is true.

If no *expression* is present, **–print** shall be used as the expression. Otherwise, if the given expression does not contain any of the primaries **–exec**, **–ok**, or **–print**, the given expression shall be effectively replaced by:

```
( given_expression ) -print
```

The **–user**, **–group**, and **–newer** primaries each shall evaluate their respective arguments only once.

STDIN

If the **–ok** primary is used, the response shall be read from the standard input. An entire line shall be read as the response. Otherwise, the standard input shall not be used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *find*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE

Determine the locale for the behavior of ranges, equivalence classes and multi-character collating elements used in the pattern matching notation for the **–n** option and in the extended regular expression defined for the **yesexpr** locale

	keyword in the *LC_MESSAGES* category.
LC_CTYPE	This variable determines the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments), the behavior of character classes within the pattern matching notation used for the −**n** option, and the behavior of character classes within regular expressions used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.
LC_MESSAGES	Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PATH	Determine the location of the *utility_name* for the −**exec** and −**ok** primaries, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The −**print** primary shall cause the current pathnames to be written to standard output. The format shall be:

```
"%s\n", <path>
```

STDERR

The −**ok** primary shall write a prompt to standard error containing at least the *utility_name* to be invoked and the current pathname. In the POSIX locale, the last non-<blank> in the prompt shall be `'?'`. The exact format used is unspecified.

Otherwise, the standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All *path* operands were traversed successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

When used in operands, pattern matching notation, semicolons, opening parentheses, and closing parentheses are special to the shell and must be quoted (see Section 2.2 (on page 2232)).

The bit that is traditionally used for sticky (historically 01000) is specified in the −**perm** primary using the octal number argument form. Since this bit is not defined by this volume of IEEE Std 1003.1-200x, applications must not assume that it actually refers to the traditional sticky bit.

EXAMPLES

1. The following commands are equivalent:

   ```
   find .
   find . −print
   ```

   They both write out the entire directory hierarchy from the current directory.

2. The following command:

   ```
   find / \( −name tmp −o −name ’*.xx’ \) −atime +7 −exec rm {} \;
   ```

   removes all files named **tmp** or ending in **.xx** that have not been accessed for seven or more 24-hour periods.

3. The following command:

   ```
   find . −perm −o+w,+s
   ```

   prints (−**print** is assumed) the names of all files in or below the current directory, with all of the file permission bits S_ISUID, S_ISGID, and S_IWOTH set.

4. The following command:

   ```
   find . −name SCCS −prune −o −print
   ```

   recursively prints pathnames of all files in the current directory and below, but skips directories named SCCS and files in them.

5. The following command:

   ```
   find . −print −name SCCS −prune
   ```

   behaves as in the previous example, but prints the names of the SCCS directories.

6. The following command is roughly equivalent to the −**nt** extension to *test*:

   ```
   if [ −n "$(find file1 −prune −newer file2)" ]; then
       printf %s\\n "file1 is newer than file2"
   fi
   ```

7. The descriptions of −**atime**, −**ctime**, and −**mtime** use the terminology *n* ‘‘86 400 second periods (days)’’. For example, a file accessed at 23:59 is selected by:

   ```
   find . −atime −1 −print
   ```

   at 00:01 the next day (less than 24 hours later, not more than one day ago); the midnight boundary between days has no effect on the 24-hour calculation.

RATIONALE

The −**a** operator was retained as an optional operator for compatibility with historical shell scripts, even though it is redundant with expression concatenation.

The descriptions of the `'−'` modifier on the *mode* and *onum* arguments to the −**perm** primary agree with historical practice on BSD and System V implementations. System V and BSD documentation both describe it in terms of checking additional bits; in fact, it uses the same bits, but checks for having at least all of the matching bits set instead of having exactly the matching bits set.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because:

- Implementations may desire more descriptive prompts than those used on historical implementations.
- Since the historical prompt strings do not terminate with <newline>s, there is no portable way for another program to interact with the prompts of this utility via pipes.

Therefore, an application using this prompting option relies on the system to provide the most suitable dialog directly with the user, based on the general guidelines specified.

The −**name** *file* operand was changed to use the shell pattern matching notation so that *find* is consistent with other utilities using pattern matching.

The −**size** operand refers to the size of a file, rather than the number of blocks it may occupy in the file system. The intent is that the *st_size* field defined in the System Interfaces volume of IEEE Std 1003.1-200x should be used, not the *st_blocks* found in historical implementations. There are at least two reasons for this:

1. In both System V and BSD, *find* only uses *st_size* in size calculations for the operands specified by this volume of IEEE Std 1003.1-200x. (BSD uses *st_blocks* only when processing the −**ls** primary.)
2. Users usually think of file size in terms of bytes, which is also the unit used by the *ls* utility for the output from the −**l** option. (In both System V and BSD, *ls* uses *st_size* for the −**l** option size field and uses *st_blocks* for the *ls* −**s** calculations. This volume of IEEE Std 1003.1-200x does not specify *ls* −**s**.)

The descriptions of −**atime**, −**ctime**, and −**mtime** were changed from the SVID description of *n* ‘‘days’’ to ‘‘24-hour periods’’. The description is also different in terms of the exact timeframe for the *n* case (*versus* the +*n* or −*n*), but it matches all known historical implementations. It refers to one 86 400 second period in the past, not any time from the beginning of that period to the current time. For example, −**atime** 3 is true if the file was accessed any time in the period from 72 hours to 48 hours ago.

Historical implementations do not modify `"{}"` when it appears as a substring of an −**exec** or −**ok** *utility_name* or argument string. There have been numerous user requests for this extension, so this volume of IEEE Std 1003.1-200x allows the desired behavior. At least one recent implementation does support this feature, but encountered several problems in managing memory allocation and dealing with multiple occurrences of `"{}"` in a string while it was being developed, so it is not yet required behavior.

Assuming the presence of −**print** was added to correct a historical pitfall that plagues novice users, it is entirely upward-compatible from the historical System V *find* utility. In its simplest form (*find directory*), it could be confused with the historical BSD fast *find*. The BSD developers agreed that adding −**print** as a default expression was the correct decision and have added the fast *find* functionality within a new utility called *locate*.

Historically, the −**L** option was implemented using the primary −**follow**. The −**H** and −**L** options were added for two reasons. First, they offer a finer granularity of control and consistency with other programs that walk file hierarchies. Second, the −**follow** primary always evaluated to true.

As they were historically really global variables that took effect before the traversal began, some valid expressions had unexpected results. An example is the expression −**print** −**o** −**follow**. Because −**print** always evaluates to true, the standard order of evaluation implies that −**follow** would never be evaluated. This was never the case. Historical practice for the −**follow** primary, however, is not consistent. Some implementations always follow symbolic links on the command line whether −**follow** is specified or not. Others follow symbolic links on the command line only if −**follow** is specified. Both behaviors are provided by the −**H** and −**L** options, but scripts using the current −**follow** primary would be broken if the −**follow** option is specified to work either way.

Since the −**L** option resolves all symbolic links and the −**type** *l* primary is true for symbolic links that still exist after symbolic links have been resolved, the command:

```
find −L . −type l
```

prints a list of symbolic links reachable from the current directory that do not resolve to accessible files.

A feature of SVR4's *find* utility was the −**exec** primary's **+** terminator. This allowed filenames containing special characters (especially <newline>s) to be grouped together without the problems that occur if such filenames are piped to *xargs*. Other implementations have added other ways to get around this problem, notably a −**print0** primary that wrote filenames with a null byte terminator. This was considered here, but not adopted. Using a null terminator meant that any utility that was going to process *find*'s −**print0** output had to add a new option to parse the null terminators it would now be reading.

The `"−exec ... {} +"` syntax adopted was a result of IEEE PASC Interpretation 1003.2 #210. It should be noted that this is an incompatible change to the ISO/IEC 9899:1999 standard. For example, the following command prints all files with a `'−'` after their name if they are regular files, and a `'+'` otherwise:

```
find / −type f −exec echo {} − ';' −o −exec echo {} + ';'
```

The change invalidates usage like this. Even though the previous standard stated that this usage would work, in practice many did not support it and the standard developers felt it better to now state that this was not allowable.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The −**perm [**−**]***onum* primary is supported.

The *find* utility is aligned with the IEEE P1003.2b draft standard, to include processing of symbolic links and changes to the description of the **atime**, **ctime**, and **mtime** operands.

IEEE PASC Interpretation 1003.2 #210 is applied, extending the −**exec** operand.

NAME

fold — filter for folding lines

SYNOPSIS

```
fold [−bs][−w width][file...]
```

DESCRIPTION

The *fold* utility is a filter that shall fold lines from its input files, breaking the lines to have a maximum of *width* column positions (or bytes, if the **−b** option is specified). Lines shall be broken by the insertion of a <newline> such that each output line (referred to later in this section as a *segment*) is the maximum width possible that does not exceed the specified number of column positions (or bytes). A line shall not be broken in the middle of a character. The behavior is undefined if *width* is less than the number of columns any single character in the input would occupy.

If the <carriage-return>s, <backspace>s, or <tab>s are encountered in the input, and the **−b** option is not specified, they shall be treated specially:

<backspace>	The current count of line width shall be decremented by one, although the count never shall become negative. The *fold* utility shall not insert a <newline> immediately before or after any <backspace>.
<carriage-return>	The current count of line width shall be set to zero. The *fold* utility shall not insert a <newline> immediately before or after any <carriage-return>.
<tab>	Each <tab> encountered shall advance the column position pointer to the next tab stop. Tab stops shall be at each column position *n* such that *n* modulo 8 equals 1.

OPTIONS

The *fold* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−b	Count *width* in bytes rather than column positions.
−s	If a segment of a line contains a <blank> within the first *width* column positions (or bytes), break the line after the last such <blank> meeting the width constraints. If there is no <blank> meeting the requirements, the **−s** option shall have no effect for that output segment of the input line.
−w *width*	Specify the maximum line length, in column positions (or bytes if **−b** is specified). The results are unspecified if *width* is not a positive decimal number. The default value shall be 80.

OPERANDS

The following operand shall be supported:

file	A pathname of a text file to be folded. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified. See the INPUT FILES section.

INPUT FILES

If the −**b** option is specified, the input files shall be text files except that the lines are not limited to {LINE_MAX} bytes in length. If the −**b** option is not specified, the input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *fold*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), and for the determination of the width in column positions each character would occupy on a constant-width font output device.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be a file containing a sequence of characters whose order shall be preserved from the input files, possibly with inserted <newline>s.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All input files were processed successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *cut* and *fold* utilities can be used to create text files out of files with arbitrary line lengths. The *cut* utility should be used when the number of lines (or records) needs to remain constant. The *fold* utility should be used when the contents of long lines need to be kept contiguous.

The *fold* utility is frequently used to send text files to printers that truncate, rather than fold, lines wider than the printer is able to print (usually 80 or 132 column positions).

EXAMPLES

An example invocation that submits a file of possibly long lines to the printer (under the assumption that the user knows the line width of the printer to be assigned by *lp*):

```
fold −w 132 bigfile | lp
```

RATIONALE

Although terminal input in canonical processing mode requires the erase character (frequently set to <backspace>) to erase the previous character (not byte or column position), terminal output is not buffered and is extremely difficult, if not impossible, to parse correctly; the interpretation depends entirely on the physical device that actually displays/prints/stores the output. In all known internationalized implementations, the utilities producing output for mixed column-width output assume that a <backspace> backs up one column position and outputs enough <backspace>s to return to the start of the character when <backspace> is used to provide local line motions to support underlining and emboldening operations. Since *fold* without the −**b** option is dealing with these same constraints, <backspace> is always treated as backing up one column position rather than backing up one character.

Historical versions of the *fold* utility assumed 1 byte was one character and occupied one column position when written out. This is no longer always true. Since the most common usage of *fold* is believed to be folding long lines for output to limited-length output devices, this capability was preserved as the default case. The −**b** option was added so that applications could *fold* files with arbitrary length lines into text files that could then be processed by the standard utilities. Note that although the width for the −**b** option is in bytes, a line is never split in the middle of a character. (It is unspecified what happens if a width is specified that is too small to hold a single character found in the input followed by a <newline>.)

The tab stops are hardcoded to be every eighth column to meet historical practice. No new method of specifying other tab stops was invented.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

fort77 — FORTRAN compiler (**FORTRAN**)

SYNOPSIS

FD

```
fort77 [-c][-g][-L directory]... [-O optlevel][-o outfile][-s][-w]
    operand...
```

DESCRIPTION

The *fort77* utility is the interface to the FORTRAN compilation system; it shall accept the full FORTRAN-77 language defined by the ANSI X3.9-1978 standard. The system conceptually consists of a compiler and link editor. The files referenced by *operand*s are compiled and linked to produce an executable file. It is unspecified whether the linking occurs entirely within the operation of *fort77*; some implementations may produce objects that are not fully resolved until the file is executed.

If the **−c** option is present, for all pathname operands of the form *file*.**f**, the files:

`$(basename pathname.f).o`

shall be created or overwritten as the result of successful compilation. If the **−c** option is not specified, it is unspecified whether such **.o** files are created or deleted for the *file*.**f** operands.

If there are no options that prevent link editing (such as **−c**) and all operands compile and link without error, the resulting executable file shall be written into the file named by the **−o** option (if present) or to the file **a.out**. The executable file shall be created as specified in the System Interfaces volume of IEEE Std 1003.1-200x, except that the file permissions shall be set to:

S_IRWXO | S_IRWXG | S_IRWXU

and that the bits specified by the *umask* of the process shall be cleared.

OPTIONS

The *fort77* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that:

- The **−l** *library* operands have the format of options, but their position within a list of operands affects the order in which libraries are searched.
- The order of specifying the multiple **−L** options is significant.
- Conforming applications shall specify each option separately; that is, grouping option letters (for example, **−cg**) need not be recognized by all implementations.

The following options shall be supported:

−c	Suppress the link-edit phase of the compilation, and do not remove any object files that are produced.
−g	Produce symbolic information in the object or executable files; the nature of this information is unspecified, and may be modified by implementation-defined interactions with other options.
−s	Produce object or executable files, or both, from which symbolic and other information not required for proper execution using the *exec* family of functions defined in the System Interfaces volume of IEEE Std 1003.1-200x has been removed (stripped). If both **−g** and **−s** options are present, the action taken is unspecified.
−o *outfile*	Use the pathname *outfile*, instead of the default **a.out**, for the executable file produced. If the **−o** option is present with **−c**, the result is unspecified.

–L *directory* Change the algorithm of searching for the libraries named in **–l** operands to look in the directory named by the *directory* pathname before looking in the usual places. Directories named in **–L** options shall be searched in the specified order. At least ten instances of this option shall be supported in a single *fort77* command invocation. If a directory specified by a **–L** option contains a file named **libf.a**, the results are unspecified.

–O *optlevel* Specify the level of code optimization. If the *optlevel* option-argument is the digit `'0'`, all special code optimizations shall be disabled. If it is the digit `'1'`, the nature of the optimization is unspecified. If the **–O** option is omitted, the nature of the system's default optimization is unspecified. It is unspecified whether code generated in the presence of the **–O** 0 option is the same as that generated when **–O** is omitted. Other *optlevel* values may be supported.

–w Suppress warnings.

Multiple instances of **–L** options can be specified.

OPERANDS

An *operand* is either in the form of a pathname or the form **–l** *library*. At least one operand of the pathname form shall be specified. The following operands shall be supported:

file.**f** The pathname of a FORTRAN source file to be compiled and optionally passed to the link editor. The filename operand shall be of this form if the **–c** option is used.

file.**a** A library of object files typically produced by *ar*, and passed directly to the link editor. Implementations may recognize implementation-defined suffixes other than **.a** as denoting object file libraries.

file.**o** An object file produced by *fort77* **–c** and passed directly to the link editor. Implementations may recognize implementation-defined suffixes other than **.o** as denoting object files.

The processing of other files is implementation-defined.

–l *library* (The letter ell.) Search the library named:

`lib`*`library`*`.a`

A library is searched when its name is encountered, so the placement of a **–l** operand is significant. Several standard libraries can be specified in this manner, as described in the EXTENDED DESCRIPTION section. Implementations may recognize implementation-defined suffixes other than **.a** as denoting libraries.

STDIN

Not used.

INPUT FILES

The input file shall be one of the following: a text file containing FORTRAN source code; an object file in the format produced by *fort77* **–c**; or a library of object files, in the format produced by archiving zero or more object files, using *ar*. Implementations may supply additional utilities that produce files in these formats. Additional input files are implementation-defined.

A <tab> encountered within the first six characters on a line of source code shall cause the compiler to interpret the following character as if it were the seventh character on the line (that is, in column 7).

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *fort77*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
TMPDIR	Determine the pathname that should override the default directory for temporary files, if any.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages. If more than one *file* operand ending in **.f** (or possibly other unspecified suffixes) is given, for each such file: |

```
"%s:\n", <file>
```

may be written to allow identification of the diagnostic message with the appropriate input file.

This utility may produce warning messages about certain conditions that do not warrant returning an error (non-zero) exit value.

OUTPUT FILES

Object files, listing files and executable files shall be produced in unspecified formats.

EXTENDED DESCRIPTION

Standard Libraries

The *fort77* utility shall recognize the following **–l** operand for the standard library:

–l f	This library contains all functions referenced in the ANSI X3.9-1978 standard. This operand shall not be required to be present to cause a search of this library.

In the absence of options that inhibit invocation of the link editor, such as **–c**, the *fort77* utility shall cause the equivalent of a **–l f** operand to be passed to the link editor as the last **–l** operand, causing it to be searched after all other object files and libraries are loaded.

It is unspecified whether the library **libf.a** exists as a regular file. The implementation may accept as **–l** operands names of objects that do not exist as regular files.

External Symbols

The FORTRAN compiler and link editor shall support the significance of external symbols up to a length of at least 31 bytes; case folding is permitted. The action taken upon encountering symbols exceeding the implementation-defined maximum symbol length is unspecified.

The compiler and link editor shall support a minimum of 511 external symbols per source or object file, and a minimum of 4 095 external symbols total. A diagnostic message is written to standard output if the implementation-defined limit is exceeded; other actions are unspecified.

EXIT STATUS

The following exit values shall be returned:

0	Successful compilation or link edit.
>0	An error occurred.

CONSEQUENCES OF ERRORS

When *fort77* encounters a compilation error, it shall write a diagnostic to standard error and continue to compile other source code operands. It shall return a non-zero exit status, but it is implementation-defined whether an object module is created. If the link edit is unsuccessful, a diagnostic message shall be written to standard error, and *fort77* shall exit with a non-zero status.

APPLICATION USAGE

None.

EXAMPLES

The following usage example compiles **xyz.f** and creates the executable file **foo**:

```
fort77 −o foo xyz.f
```

The following example compiles **xyz.f** and creates the object file **xyz.o**:

```
fort77 −c xyz.f
```

The following example compiles **xyz.f** and creates the executable file **a.out**:

```
fort77 xyz.f
```

The following example compiles **xyz.f**, links it with **b.o**, and creates the executable **a.out**:

```
fort77 xyz.f b.o
```

RATIONALE

The name of this utility was chosen as *fort77* to parallel the renaming of the C compiler. The name *f77* was not chosen to avoid problems with historical implementations. The ANSI X3.9-1978 standard was selected as a normative reference because the ISO / IEC version of FORTRAN-77 has been superseded by the ISO / IEC 1539: 1990 standard (Fortran-90).

The file inclusion and symbol definition **#define** mechanisms used by the *c99* utility were not included in this volume of IEEE Std 1003.1-200x—even though they are commonly implemented—since there is no requirement that the FORTRAN compiler use the C preprocessor.

The −**onetrip** option was not included in this volume of IEEE Std 1003.1-200x, even though many historical compilers support it, because it is derived from FORTRAN-66; it is an anachronism that should not be perpetuated.

Some implementations produce compilation listings. This aspect of FORTRAN has been left unspecified because there was controversy concerning the various methods proposed for implementing it: a −**V** option overlapped with historical vendor practice and a naming convention of creating files with **.l** suffixes collided with historical *lex* file naming practice.

There is no **–I** option in this version of this volume of IEEE Std 1003.1-200x to specify a directory for file inclusion. An INCLUDE directive has been a part of the Fortran-90 discussions, but an interface supporting that standard is not in the current scope.

It is noted that many FORTRAN compilers produce an object module even when compilation errors occur; during a subsequent compilation, the compiler may patch the object module rather than recompiling all the code. Consequently, it is left to the implementor whether or not an object file is created.

A reference to MIL-STD-1753 was removed from an early proposal in response to a request from the POSIX FORTRAN-binding standard developers. It was not the intention of the standard developers to require certification of the FORTRAN compiler, and IEEE Std 1003.9-1992 does not specify the military standard or any special preprocessing requirements. Furthermore, use of that document would have been inappropriate for an international standard.

The specification of optimization has been subject to changes through early proposals. At one time, **–O** and **–N** were Booleans: optimize and do not optimize (with an unspecified default). Some historical practice lead this to be changed to:

–O 0	No optimization.
–O 1	Some level of optimization.
–O *n*	Other, unspecified levels of optimization.

It is not always clear whether ‘‘good code generation’’ is the same thing as optimization. Simple optimizations of local actions do not usually affect the semantics of a program. The **–O** 0 option has been included to accommodate the very particular nature of scientific calculations in a highly optimized environment; compilers make errors. Some degree of optimization is expected, even if it is not documented here, and the ability to shut it off completely could be important when porting an application. An implementation may treat **–O** 0 as ‘‘do less than normal’’ if it wishes, but this is only meaningful if any of the operations it performs can affect the semantics of a program. It is highly dependent on the implementation whether doing less than normal is logical. It is not the intent of the **–O** 0 option to ask for inefficient code generation, but rather to assure that any semantically visible optimization is suppressed.

The specification of standard library access is consistent with the C compiler specification. Implementations are not required to have **/usr/lib/libf.a**, as many historical implementations do, but if not they are required to recognize **f** as a token.

External symbol size limits are in normative text; conforming applications need to know these limits. However, the minimum maximum symbol length should be taken as a constraint on a conforming application, not on an implementation, and consequently the action taken for a symbol exceeding the limit is unspecified. The minimum size for the external symbol table was added for similar reasons.

The CONSEQUENCES OF ERRORS section clearly specifies the behavior of the compiler when compilation or link-edit errors occur. The behavior of several historical implementations was examined, and the choice was made to be silent on the status of the executable, or **a.out**, file in the face of compiler or linker errors. If a linker writes the executable file, then links it on disk with *lseek*( )s and *write*( )s, the partially linked executable file can be left on disk and its execute bits turned off if the link edit fails. However, if the linker links the image in memory before writing the file to disk, it need not touch the executable file (if it already exists) because the link edit fails. Since both approaches are historical practice, a conforming application shall rely on the exit status of *fort77*, rather than on the existence or mode of the executable file.

The −**g** and −**s** options are not specified as mutually-exclusive. Historically these two options have been mutually-exclusive, but because both are so loosely specified, it seemed appropriate to leave their interaction unspecified.

The requirement that conforming applications specify compiler options separately is to reserve the multi-character option name space for vendor-specific compiler options, which are known to exist in many historical implementations. Implementations are not required to recognize, for example, −**gc** as if it were −**g** −**c**; nor are they forbidden from doing so. The SYNOPSIS shows all of the options separately to highlight this requirement on applications.

Echoing filenames to standard error is considered a diagnostic message because it would otherwise be difficult to associate an error message with the erring file. They are described with ‘‘may’’ to allow implementations to use other methods of identifying files and to parallel the description in *c99*.

FUTURE DIRECTIONS

A compilation system based on the ISO/IEC 1539:1990 standard (Fortran-90) may be considered for a future issue; it may have a different utility name from *fort77*.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the FORTRAN Development Utilities option.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

fuser — list process IDs of all processes that have one or more files open

SYNOPSIS

XSI
```
fuser [ -cfu ] file ...
```

DESCRIPTION

The *fuser* utility shall write to standard output the process IDs of processes running on the local system that have one or more named files open. For block special devices, all processes using any file on that device are listed.

The *fuser* utility shall write to standard error additional information about the named files indicating how the file is being used.

Any output for processes running on remote systems that have a named file open is unspecified.

A user may need appropriate privilege to invoke the *fuser* utility.

OPTIONS

The *fuser* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c	The file is treated as a mount point and the utility shall report on any files open in the file system.
−f	The report shall be only for the named files.
−u	The user name, in parentheses, associated with each process ID written to standard output shall be written to standard error.

OPERANDS

The following operand shall be supported:

file	A pathname on which the file or file system is to be reported.

STDIN

Not used.

INPUT FILES

The user database.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *fuser*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *fuser* utility shall write the process ID for each process using each file given as an operand to standard output in the following format:

```
"%d", <process_id>
```

STDERR

The *fuser* utility shall write diagnostic messages to standard error.

The *fuser* utility also shall write the following to standard error:

- The pathname of each named file is written followed immediately by a colon.
- For each process ID written to standard output, the character `'c'` shall be written to standard error if the process is using the file as its current directory and the character `'r'` shall be written to standard error if the process is using the file as its root directory. Implementations may write other alphabetic characters to indicate other uses of files.
- When the **−u** option is specified, characters indicating the use of the file shall be followed immediately by the user name, in parentheses, corresponding to the process' real user ID. If the user name cannot be resolved from the process' real user ID, the process' real user ID shall be written instead of the user name.

When standard output and standard error are directed to the same file, the output shall be interleaved so that the filename appears at the start of each line, followed by the process ID and characters indicating the use of the file. Then, if the **−u** option is specified, the user name or user ID for each process using that file shall be written. |

A <newline> shall be written to standard error after the last output described above for each *file* operand.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

The command:

```
fuser –fu .
```

writes to standard output the process IDs of processes that are using the current directory and writes to standard error an indication of how those processes are using the directory and the user names associated with the processes that are using the current directory.

RATIONALE

The definition of the *fuser* utility follows existing practice.

FUTURE DIRECTIONS

None.

SEE ALSO

None.

CHANGE HISTORY

First released in Issue 5.

NAME

gencat — generate a formatted message catalog

SYNOPSIS

XSI `gencat catfile msgfile...`

DESCRIPTION

The *gencat* utility shall merge the message text source files *msgfile* into a formatted message catalog *catfile*. The file *catfile* shall be created if it does not already exist. If *catfile* does exist, its messages shall be included in the new *catfile*. If set and message numbers collide, the new message text defined in *msgfile* shall replace the old message text currently contained in *catfile*.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

catfile	A pathname of the formatted message catalog. If '−' is specified, standard output shall be used. The format of the message catalog produced is unspecified.
msgfile	A pathname of a message text source file. If '−' is specified for an instance of *msgfile*, standard input shall be used. The format of message text source files is defined in the EXTENDED DESCRIPTION section.

STDIN

The standard input shall not be used unless a *msgfile* operand is specified as '−'.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *gencat*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall not be used unless the *catfile* operand is specified as '−'.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The content of a message text file shall be in the format defined as follows. Note that the fields of a message text source line are separated by a single <blank>. Any other <blank>s are considered as being part of the subsequent field.

$set *n comment*

This line specifies the set identifier of the following messages until the next **$set** or end-of-file appears. The *n* denotes the set identifier, which is defined as a number in the range [1, {NL_SETMAX}] (see the **<limits.h>** header defined in the System Interfaces volume of IEEE Std 1003.1-200x). The application shall ensure that set identifiers are presented in ascending order within a single source file, but need not be contiguous. Any string following the set identifier shall be treated as a comment. If no **$set** directive is specified in a message text source file, all messages shall be located in an implementation-defined default message set NL_SETD (see the **<nl_types.h>** header defined in the System Interfaces volume of IEEE Std 1003.1-200x).

$delset *n comment*

This line deletes message set *n* from an existing message catalog. The *n* denotes the set number [1, {NL_SETMAX}]. Any string following the set number shall be treated as a comment.

$ *comment* A line beginning with '$' followed by a <blank> shall be treated as a comment.

m message-text

The *m* denotes the message identifier, which is defined as a number in the range [1, {NL_MSGMAX}] (see the **<limits.h>** header defined in the System Interfaces volume of IEEE Std 1003.1-200x). The *message-text* shall be stored in the message catalog with the set identifier specified by the last **$set** directive, and with message identifier *m*. If the *message-text* is empty, and a <blank> field separator is present, an empty string shall be stored in the message catalog. If a message source line has a message number, but neither a field separator nor *message-text*, the existing message with that number (if any) shall be deleted from the catalog. The application shall ensure that message identifiers are in ascending order within a single set, but need not be contiguous. The application shall ensure that the length of *message-text* is in the range [0, {NL_TEXTMAX}] (see the **<limits.h>** header defined in the System Interfaces volume of IEEE Std 1003.1-200x).

$quote *n* This line specifies an optional quote character *c*, which can be used to surround *message-text* so that trailing spaces or null (empty) messages are visible in a message source line. By default, or if an empty **$quote** directive is supplied, no quoting of *message-text* shall be recognized.

Empty lines in a message text source file shall be ignored. The effects of lines starting with any character other than those defined above are implementation-defined.

Text strings can contain the special characters and escape sequences defined in the following table:

Description	Symbol	Sequence
<newline>	NL(LF)	`\n`
Horizontal tab	HT	`\t`
<vertical-tab>	VT	`\v`
<backspace>	BS	`\b`
<carriage-return>	CR	`\r`
<form-feed>	FF	`\f`
Backslash	`\`	`\\`
Bit pattern	`ddd`	`\ddd`

The escape sequence `"\ddd"` consists of backslash followed by one, two, or three octal digits, which shall be taken to specify the value of the desired character. If the character following a backslash is not one of those specified, the backslash shall be ignored.

Backslash (`'\'`) followed by a <newline> is also used to continue a string on the following line. Thus, the following two lines describe a single message string:

```
1 This line continues \
to the next line
```

which shall be equivalent to:

```
1 This line continues to the next line
```

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Message catalogs produced by *gencat* are binary encoded, meaning that their portability cannot be guaranteed between different types of machine. Thus, just as C programs need to be recompiled for each type of machine, so message catalogs must be recreated via *gencat*.

EXAMPLES

None.

CHANGE HISTORY

First released in Issue 3.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

get — get a version of an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI
```
get [−begkmnlLpst][−c cutoff][−i list][−r SID][−x list] file...
```

DESCRIPTION

The *get* utility shall generate a text file from each named SCCS *file* according to the specifications given by its options.

The generated text shall normally be written into a file called the **g-file** whose name is derived from the SCCS filename by simply removing the leading `"s."`.

OPTIONS

The *get* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−r *SID* Indicate the SCCS Identification String (SID) of the version (delta) of an SCCS file to be retrieved. The table shows, for the most useful cases, what version of an SCCS file is retrieved (as well as the SID of the version to be eventually created by *delta* if the **−e** option is also used), as a function of the SID specified.

−c *cutoff* Indicate the *cutoff* date-time, in the form:

YY[*MM*[*DD*[*HH*[*MM*[*SS*]]]]]

For the *YY* component, values in the range [69,99] shall refer to years 1969 to 1999 inclusive, and values in the range [00,68] shall refer to years 2000 to 2068 inclusive.

Note: It is expected that in a future version of IEEE Std 1003.1-200x the default century inferred from a 2-digit year will change. (This would apply to all commands accepting a 2-digit year as input.)

No changes (deltas) to the SCCS file that were created after the specified *cutoff* date-time shall be included in the generated text file. Units omitted from the date-time default to their maximum possible values; for example, **−c** 7502 is equivalent to **−c** 750228235959.

Any number of non-numeric characters may separate the various 2-digit pieces of the *cutoff* date-time. This feature allows the user to specify a *cutoff* date in the form: **−c** "77/2/2 9:22:25".

−e Indicate that the *get* is for the purpose of editing or making a change (delta) to the SCCS file via a subsequent use of *delta*. The **−e** option used in a *get* for a particular version (SID) of the SCCS file shall prevent further *get* commands from editing on the same SID until *delta* is executed or the **j** (joint edit) flag is set in the SCCS file. Concurrent use of *get* **−e** for different SIDs is always allowed.

If the **g-file** generated by *get* with a **−e** option is accidentally ruined in the process of editing, it may be regenerated by re-executing the *get* command with the **−k** option in place of the **−e** option.

SCCS file protection specified via the ceiling, floor, and authorized user list stored in the SCCS file shall be enforced when the **−e** option is used.

−b Use with the **−e** option to indicate that the new delta should have an SID in a new branch as shown in the table below. This option shall be ignored if the **b** flag is not present in the file or if the retrieved delta is not a leaf delta. (A leaf delta is one that has no successors on the SCCS file tree.)

Note: A branch delta may always be created from a non-leaf delta.

−i *list* Indicate a *list* of deltas to be included (forced to be applied) in the creation of the generated file. The *list* has the following syntax:

```
<list> ::= <range> | <list> , <range>
<range> ::= SID | SID − SID
```

SID, the SCCS Identification of a delta, may be in any form shown in the ''SID Specified'' column of the table in the EXTENDED DESCRIPTION section, except that the result of supplying a partial SID is unspecified. A diagnostic message shall be written if the first SID in the range is not an ancestor of the second SID in the range.

−x *list* Indicate a *list* of deltas to be excluded (forced not to be applied) in the creation of the generated file. See the **−i** option for the *list* format.

−k Suppress replacement of identification keywords (see below) in the retrieved text by their value. The **−k** option shall be implied by the **−e** option.

−l Write a delta summary into an **l-file**.

−L Write a delta summary to standard output. All informative output that normally is written to standard output shall be written to standard error instead, unless the **−s** option is used, in which case it shall be suppressed.

−p Write the text retrieved from the SCCS file to the standard output. No **g-file** shall be created. All informative output that normally goes to the standard output shall go to standard error instead, unless the **−s** option is used, in which case it shall disappear.

−s Suppress all informative output normally written to standard output. However, fatal error messages (which shall always be written to the standard error) shall remain unaffected.

−m Precede each text line retrieved from the SCCS file by the SID of the delta that inserted the text line in the SCCS file. The format shall be:

```
"%s\t%s", <SID>, <text line>
```

−n Precede each generated text line with the %**M**% identification keyword value (see below). The format shall be:

```
"%s\t%s", <%M% value>, <text line>
```

When both the **−m** and **−n** options are used, the <*text line*> shall be replaced by the **−m** option-generated format.

−g Suppress the actual retrieval of text from the SCCS file. It is primarily used to generate an **l-file**, or to verify the existence of a particular SID.

−t Use to access the most recently created (top) delta in a given release (for example, **−r 1**), or release and level (for example, **−r 1.2**).

OPERANDS

The following operands shall be supported:

file A pathname of an existing SCCS file or a directory. If *file* is a directory, the *get* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is '−', the standard input shall be read; each line of the standard input is taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only if the *file* operand is specified as '−'. Each line of the text file shall be interpreted as an SCCS pathname.

INPUT FILES

The SCCS files shall be files of an unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *get*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output (or standard error, if the −**p** option is used).
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
TZ	Determine the timezone in which the times and dates are written in the SCCS file are evaluated. If the *TZ* variable is unset or NULL, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

For each file processed, *get* shall write to standard output the SID being accessed and the number of lines retrieved from the SCCS file, in the following format:

```
"%s\n%d lines\n", <SID>, <number of lines>
```

If the −**e** option is used, the SID of the delta to be made shall appear after the SID accessed and before the number of lines generated, in the POSIX locale:

```
"%s\nnew delta %s\n%d lines\n", <SID accessed>,
    <SID to be made>, <number of lines>
```

If there is more than one named file or if a directory or standard input is named, each pathname shall be written before each of the lines shown in one of the preceding formats:

```
"\n%s:\n", <pathname>
```

If the −**L** option is used, a delta summary shall be written following the format specified below for **l-files**.

If the –**i** option is used, included deltas shall be listed following the notation, in the POSIX locale:

```
"Included:\n"
```

If the –**x** option is used, excluded deltas shall be listed following the notation, in the POSIX locale:

```
"Excluded:\n"
```

If the –**p** or –**L** options are specified, the standard output shall consist of the text retrieved from the SCCS file.

STDERR

The standard error shall be used only for diagnostic messages, except if the –**p** or –**L** options are specified, it shall include all informative messages normally sent to standard output.

OUTPUT FILES

Several auxiliary files may be created by *get*. These files are known generically as the **g-file**, **l-file**, **p-file**, and **z-file**. The letter before the hyphen is called the *tag*. An auxiliary filename shall be formed from the SCCS filename: the application shall ensure that the last component of all SCCS filenames is of the form **s.***module-name*; the auxiliary files shall be named by replacing the leading **s** with the tag. The **g-file** shall be an exception to this scheme: the **g-file** is named by removing the **s.** prefix. For example, for **s.xyz.c**, the auxiliary filenames would be **xyz.c**, **l.xyz.c**, **p.xyz.c**, and **z.xyz.c**, respectively.

The **g-file**, which contains the generated text, shall be created in the current directory (unless the –**p** option is used). A **g-file** shall be created in all cases, whether or not any lines of text were generated by the *get*. It shall be owned by the real user. If the –**k** option is used or implied, the **g-file** shall be writable by the owner only (read-only for everyone else); otherwise, it shall be read-only. Only the real user need have write permission in the current directory.

The **l-file** shall contain a table showing which deltas were applied in generating the retrieved text. The **l-file** shall be created in the current directory if the –**l** option is used; it shall be read-only and it is owned by the real user. Only the real user need have write permission in the current directory.

Lines in the **l-file** shall have the following format:

```
"%c%c%cΔ%s\t%sΔ%s\n", <code1>, <code2>, <code3>,
    <SID>, <date-time>, <login>
```

where the entries are:

<code1>	A <space> if the delta was applied; `'*'` otherwise.
<code2>	A <space> if the delta was applied or was not applied and ignored; `'*'` if the delta was not applied and was not ignored.
<code3>	A character indicating a special reason why the delta was or was not applied: **I** Included. **X** Excluded. **C** Cut off (by a –**c** option).
<date-time>	Date and time (using the format of the *date* utility's `%y/%m/%d %T` conversion specification format) of creation.
<login>	Login name of person who created *delta*.

The comments and MR data shall follow on subsequent lines, indented one <tab>. A blank line shall terminate each entry.

The **p-file** shall be used to pass information resulting from a *get* with a −**e** option along to *delta*. Its contents shall also be used to prevent a subsequent execution of *get* with a −**e** option for the same SID until *delta* is executed or the joint edit flag, **j**, is set in the SCCS file. The **p-file** shall be created in the directory containing the SCCS file and the application shall ensure that the effective user has write permission in that directory. It shall be writable by owner only, and owned by the effective user. Each line in the **p-file** shall have the following format:

```
"%sΔ%sΔ%sΔ%s%s%s\n", <g-file SID>,
    <SID of new delta>, <login-name of real user>,
    <date-time>, <i-value>, <x-value>
```

where <*i-value*> uses the format " " if no −**i** option was specified, and shall use the format:

```
"Δ−i%s", <−i option option-argument>
```

if a −**i** option was specified and <*x-value*> uses the format " " if no −**x** option was specified, and shall use the format:

```
"Δ−x%s", <−x option option-argument>
```

if a −**x** option was specified. There can be an arbitrary number of lines in the **p-file** at any time; no two lines shall have the same new delta SID.

The **z-file** shall serve as a lock-out mechanism against simultaneous updates. Its contents shall be the binary process ID of the command (that is, *get*) that created it. The **z-file** shall be created in the directory containing the SCCS file for the duration of *get*. The same protection restrictions as those for the **p-file** shall apply for the **z-file**. The **z-file** shall be created read-only.

EXTENDED DESCRIPTION

Determination of SCCS Identification String

SID* Specified	–b Keyletter Used†	Other Conditions	SID Retrieved	SID of Delta to be Created
none‡	no	R defaults to mR	mR.mL	mR.(mL+1)
none‡	yes	R defaults to mR	mR.mL	mR.mL.(mB+1).1
R	no	R > mR	mR.mL	R.1***
R	no	R = mR	mR.mL	mR.(mL+1)
R	yes	R > mR	mR.mL	mR.mL.(mB+1).1
R	yes	R = mR	mR.mL	mR.mL.(mB+1).1
R	–	R < mR and R does not exist	hR.mL**	hR.mL.(mB+1).1
R	–	Trunk successor in release > R and R exists	R.mL	R.mL.(mB+1).1
R.L	no	No trunk successor	R.L	R.(L+1)
R.L	yes	No trunk successor	R.L	R.L.(mB+1).1
R.L	–	Trunk successor in release ≥ R	R.L	R.L.(mB+1).1
R.L.B	no	No branch successor	R.L.B.mS	R.L.B.(mS+1)
R.L.B	yes	No branch successor	R.L.B.mS	R.L.(mB+1).1
R.L.B.S	no	No branch successor	R.L.B.S	R.L.B.(S+1)
R.L.B.S	yes	No branch successor	R.L.B.S	R.L.(mB+1).1
R.L.B.S	–	Branch successor	R.L.B.S	R.L.(mB+1).1

* R, L, B, and S are the release, level, branch, and sequence components of the SID, respectively; m means maximum. Thus, for example, R.mL means ''the maximum level number within release R''; R.L.(mB+1).1 means ''the first sequence number on the new branch (that is, maximum branch number plus one) of level L within release R''. Note that if the SID specified is of the form R.L, R.L.B, or R.L.B.S, each of the specified components shall exist.

** hR is the highest existing release that is lower than the specified, nonexistent, release R.

*** This is used to force creation of the first delta in a new release.

† The –**b** option is effective only if the **b** flag is present in the file. An entry of '–' means ''irrelevant''.

‡ This case applies if the **d** (default SID) flag is not present in the file. If the **d** flag is present in the file, then the SID obtained from the **d** flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.

System Date and Time

When a **g-file** is generated, the creation time of deltas in the SCCS file may be taken into account. If any of these times are apparently in the future, the behavior is unspecified.

Identification Keywords

Identifying information shall be inserted into the text retrieved from the SCCS file by replacing identification keywords with their value wherever they occur. The following keywords may be used in the text stored in an SCCS file:

%**M**%	Module name: either the value of the **m** flag in the file, or if absent, the name of the SCCS file with the leading **s.** removed.
%**I**%	SCCS identification (SID) (%**R**%.%**L**% or %**R**%.%**L**%.%**B**%.%**S**%) of the retrieved text.
%**R**%	Release.
%**L**%	Level.
%**B**%	Branch.
%**S**%	Sequence.
%**D**%	Current date (*YY*/*MM*/*DD*).
%**H**%	Current date (*MM*/*DD*/*YY*).
%**T**%	Current time (*HH*:*MM*:*SS*).
%**E**%	Date newest applied delta was created (*YY*/*MM*/*DD*).
%**G**%	Date newest applied delta was created (*MM*/*DD*/*YY*).
%**U**%	Time newest applied delta was created (*HH*:*MM*:*SS*).
%**Y**%	Module type: value of the **t** flag in the SCCS file.
%**F**%	SCCS filename.
%**P**%	SCCS absolute pathname.
%**Q**%	The value of the **q** flag in the file.
%**C**%	Current line number. This keyword is intended for identifying messages output by the program, such as ‘‘this should not have happened’’ type errors. It is not intended to be used on every line to provide sequence numbers.
%**Z**%	The four-character string `"@(#)"` recognizable by *what*.
%**W**%	A shorthand notation for constructing *what* strings: `%W%=%Z%%M%<tab>%I%`
%**A**%	Another shorthand notation for constructing *what* strings: `%A%=%Z%%Y%%M%%I%%Z%`

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Problems can arise if the system date and time have been modified (for example, put forward and then back again, or unsynchronized clocks across a network) and can also arise when different values of the *TZ* environment variable are used.

Problems of a similar nature can also arise for the operation of the *delta* utility, which compares the previous file body against the working file as part of its normal operation.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

The **–lp** option may be withdrawn in a future issue.

SEE ALSO

admin, *delta*, *prs*, *what*

CHANGE HISTORY

First released in Issue 2.

Issue 5

Correction to the first format string in STDOUT.

The interpretation of the *YY* component of the **–c** *cutoff* argument is noted.

Issue 6

The obsolescent SYNOPSIS is removed, removing the **–lp** option.

The Open Group Corrigendum U025/5 is applied, correcting text in the OPTIONS section.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The normative text is reworded to emphasize the term ‘‘shall’’ for implementation requirements.

The Open Group Corrigendum U048/1 is applied.

The EXTENDED DESCRIPTION section is updated to make partial SID handling unspecified, reflecting common usage, and to clarify SID ranges as per The Open Group Base Resolution bwg2001-007.

The Open Group Interpretation PIN4C.00014 is applied.

New text is added to the EXTENDED DESCRIPTION and APPLICATION USAGE sections regarding how the system date and time may be taken into account, and the *TZ* environment variable is added to the ENVIRONMENT VARIABLES section as per The Open Group Base Resolution bwg2001-007.

NAME

getconf — get configuration values

SYNOPSIS

```
getconf [ −v specification ] system_var
```

```
getconf [ −v specification ] path_var pathname
```

DESCRIPTION

In the first synopsis form, the *getconf* utility shall write to the standard output the value of the variable specified by the *system_var* operand.

In the second synopsis form, the *getconf* utility shall write to the standard output the value of the variable specified by the *path_var* operand for the path specified by the *pathname* operand.

The value of each configuration variable shall be determined as if it were obtained by calling the function from which it is defined to be available by this volume of IEEE Std 1003.1-200x or by the System Interfaces volume of IEEE Std 1003.1-200x (see the OPERANDS section). The value shall reflect conditions in the current operating environment.

OPTIONS

The *getconf* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−v *specification*

Indicate a specific specification and version for which configuration variables shall be determined. If this option is not specified, the values returned correspond to an implementation default conforming compilation environment.

If the command:

```
getconf _POSIX_V6_ILP32_OFF32
```

does not write `"−1\n"` or `"undefined\n"` to standard output, then commands of the form:

```
getconf −v POSIX_V6_ILP32_OFF32 ...
```

determine values for configuration variables corresponding to the POSIX_V6_ILP32_OFF32 compilation environment specified in *c99* (on page 2413), EXTENDED DESCRIPTION.

If the command:

```
getconf _POSIX_V6_ILP32_OFFBIG
```

does not write `"−1\n"` or `"undefined\n"` to standard output, then commands of the form:

```
getconf −v POSIX_V6_ILP32_OFFBIG ...
```

determine values for configuration variables corresponding to the POSIX_V6_ILP32_OFFBIG compilation environment specified in *c99* (on page 2413), EXTENDED DESCRIPTION.

If the command:

```
getconf _POSIX_V6_LP64_OFF64
```

does not write `"−1\n"` or `"undefined\n"` to standard output, then commands of the form:

```
getconf −v POSIX_V6_LP64_OFF64 ...
```

determine values for configuration variables corresponding to the POSIX_V6_LP64_OFF64 compilation environment specified in *c99* (on page 2413), EXTENDED DESCRIPTION.

If the command:

```
getconf _POSIX_V6_LPBIG_OFFBIG
```

does not write `"−1\n"` or `"undefined\n"` to standard output, then commands of the form:

```
getconf −v POSIX_V6_LPBIG_OFFBIG ...
```

determine values for configuration variables corresponding to the POSIX_V6_LPBIG_OFFBIG compilation environment specified in *c99* (on page 2413), EXTENDED DESCRIPTION.

OPERANDS

The following operands shall be supported:

path_var A name of a configuration variable. All of the variables in the *pathconf*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x are supported and the implementation may add other local variables.

pathname A pathname for which the variable specified by *path_var* is to be determined.

system_var A name of a configuration variable. All of the variables in the *confstr*( ) and *sysconf*( ) functions defined in the System Interfaces volume of IEEE Std 1003.1-200x shall be supported and the implementation may add other local values.

When the symbol listed in the first column of the following table is used as the *system_var* operand, *getconf* yields the same value as *confstr*( ) when called with the value in the second column:

system_var	***confstr*( ) Name Value**
PATH	_CS_PATH
POSIX_V6_ILP32_OFF32_CFLAGS	_CS_POSIX_V6_ILP32_OFF32_CFLAGS
POSIX_V6_ILP32_OFF32_LDFLAGS	_CS_POSIX_V6_ILP32_OFF32_LDFLAGS
POSIX_V6_ILP32_OFF32_LIBS	_CS_POSIX_V6_ILP32_OFF32_LIBS
POSIX_V6_ILP32_OFF32_LINTFLAGS	_CS_POSIX_V6_ILP32_OFF32_LINTFLAGS

XBS5_LPBIG_OFFBIG_LIBS (**LEGACY**)	_CS_XBS5_LPBIG_OFFBIG_LIBS
XBS5_LPBIG_OFFBIG_LINTFLAGS (**LEGACY**)	_CS_XBS5_LPBIG_OFFBIG_LINTFLAGS

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *getconf*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the specified variable is defined on the system and its value is described to be available from the *confstr*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x, its value shall be written in the following format:

```
"%s\n", <value>
```

Otherwise, if the specified variable is defined on the system, its value shall be written in the following format:

```
"%d\n", <value>
```

If the specified variable is valid, but is undefined on the system, *getconf* shall write using the following format:

```
"undefined\n"
```

If the variable name is invalid or an error occurs, nothing shall be written to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The specified variable is valid and information about its current state was written successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

The following example illustrates the value of {NGROUPS_MAX}:

```
getconf NGROUPS_MAX
```

The following example illustrates the value of {NAME_MAX} for a specific directory:

```
getconf NAME_MAX /usr
```

The following example shows how to deal more carefully with results that might be unspecified:

```
if value=$(getconf PATH_MAX /usr); then
    if [ "$value" = "undefined" ]; then
        echo PATH_MAX in /usr is infinite.
    else
        echo PATH_MAX in /usr is $value.
    fi
else
    echo Error in getconf.
fi
```

Note that:

```
sysconf(_SC_POSIX_C_BIND);
```

and:

```
system("getconf POSIX2_C_BIND");
```

in a C program could give different answers. The *sysconf*( ) call supplies a value that corresponds to the conditions when the program was either compiled or executed, depending on the implementation; the *system*( ) call to *getconf* always supplies a value corresponding to conditions when the program is executed.

RATIONALE

The original need for this utility, and for the *confstr*( ) function, was to provide a way of finding the configuration-defined default value for the *PATH* environment variable. Since *PATH* can be modified by the user to include directories that could contain utilities replacing the standard utilities, shell scripts need a way to determine the system-supplied *PATH* environment variable value that contains the correct search path for the standard utilities. It was later suggested that access to the other variables described in this volume of IEEE Std 1003.1-200x could also be useful to applications.

This functionality of *getconf* would not be adequately subsumed by another command such as:

```
grep var /etc/conf
```

because such a strategy would provide correct values for neither those variables that can vary at runtime, nor those that can vary depending on the path.

Early proposal versions of *getconf* specified exit status 1 when the specified variable was valid, but not defined on the system. The output string `"undefined"` is now used to specify this case with exit code 0 because so many things depend on an exit code of zero when an invoked utility is successful.

FUTURE DIRECTIONS

None.

SEE ALSO

c99, the System Interfaces volume of IEEE Std 1003.1-200x, *confstr*( ), *pathconf*( ), *sysconf*( )

CHANGE HISTORY

First released in Issue 4.

Issue 5

In the OPERANDS section:

- {NL_MAX} is changed to {NL_NMAX}.
- Entries beginning NL_ are deleted from the list of standard configuration variables.
- The list of variables previously marked UX is merged with the list marked EX.
- Operands are added to support new Option Groups.
- Operands are added so that *getconf* can determine supported programming environments.

Issue 6

The Open Group Corrigendum U029/4 is applied, correcting the example command in the last paragraph of the OPTIONS section.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Operands are added to determine supported programming environments.

This reference page is updated for alignment with the ISO/IEC 9899: 1999 standard. Specifically, new macros for *c99* programming environments are introduced.

XSI marked *system_var* (XBS5_*) values are marked LEGACY.

NAME

getopts — parse utility options

SYNOPSIS

`getopts` *`optstring name`* `[`*`arg`*`...]`

DESCRIPTION

The *getopts* utility shall retrieve options and option-arguments from a list of parameters. It shall support the Utility Syntax Guidelines 3 to 10, inclusive, described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

Each time it is invoked, the *getopts* utility shall place the value of the next option in the shell variable specified by the *name* operand and the index of the next argument to be processed in the shell variable *OPTIND*. Whenever the shell is invoked, *OPTIND* shall be initialized to 1.

When the option requires an option-argument, the *getopts* utility shall place it in the shell variable *OPTARG*. If no option was found, or if the option that was found does not have an option-argument, *OPTARG* shall be unset.

If an option character not contained in the *optstring* operand is found where an option character is expected, the shell variable specified by *name* shall be set to the question-mark (`'?'`) character. In this case, if the first character in *optstring* is a colon (`':'`), the shell variable *OPTARG* shall be set to the option character found, but no output shall be written to standard error; otherwise, the shell variable *OPTARG* shall be unset and a diagnostic message shall be written to standard error. This condition shall be considered to be an error detected in the way arguments were presented to the invoking application, but shall be not an error in *getopts* processing.

If an option-argument is missing:

- If the first character of *optstring* is a colon, the shell variable specified by *name* shall be set to the colon character and the shell variable *OPTARG* shall be set to the option character found.
- Otherwise, the shell variable specified by *name* shall be set to the question-mark character, the shell variable *OPTARG* shall be unset, and a diagnostic message shall be written to standard error. This condition shall be considered to be an error detected in the way arguments were presented to the invoking application, but shall not be an error in *getopts* processing; a diagnostic message shall be written as stated, but the exit status shall be zero.

When the end of options is encountered, the *getopts* utility shall exit with a return value greater than zero; the shell variable *OPTIND* shall be set to the index of the first non-option-argument, where the first `"−−"` argument is considered to be an option-argument if there are no other non-option-arguments appearing before it, or the value `"$#"+1` if there are no non-option-arguments; the *name* variable shall be set to the question-mark character. Any of the following shall identify the end of options: the special option `"−−"`, finding an argument that does not begin with a `'−'`, or encountering an error.

The shell variables *OPTIND* and *OPTARG* shall be local to the caller of *getopts* and shall not be exported by default.

The shell variable specified by the *name* operand, *OPTIND* and *OPTARG* shall affect the current shell execution environment; see Section 2.12 (on page 2263).

If the application sets *OPTIND* to the value 1, a new set of parameters can be used: either the current positional parameters or new *arg* values. Any other attempt to invoke *getopts* multiple times in a single shell execution environment with parameters (positional parameters or *arg* operands) that are not the same in all invocations, or with an *OPTIND* value modified to be a value other than 1, produces unspecified results.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

optstring	A string containing the option characters recognized by the utility invoking *getopts*. If a character is followed by a colon, the option shall be expected to have an argument, which should be supplied as a separate argument. Applications should specify an option character and its option-argument as separate arguments, but *getopts* shall interpret the characters following an option character requiring arguments as an argument whether or not this is done. An explicit null option-argument need not be recognized if it is not supplied as a separate argument when *getopts* is invoked. (See also the *getopt*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x.) The characters question-mark and colon shall not be used as option characters by an application. The use of other option characters that are not alphanumeric produces unspecified results. If the option-argument is not supplied as a separate argument from the option character, the value in *OPTARG* shall be stripped of the option character and the '−'. The first character in *optstring* determines how *getopts* behaves if an option character is not known or an option-argument is missing.
name	The name of a shell variable that shall be set by the *getopts* utility to the option character that was found.

The *getopts* utility by default shall parse positional parameters passed to the invoking shell procedure. If *arg*s are given, they shall be parsed instead of the positional parameters.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *getopts*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
OPTIND	This variable shall be used by the *getopts* utility as the index of the next argument to be processed.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Whenever an error is detected and the first character in the *optstring* operand is not a colon (`':'`), a diagnostic message shall be written to standard error with the following information in an unspecified format:

- The invoking program name shall be identified in the message. The invoking program name shall be the value of the shell special parameter 0 (see Section 2.5.2 (on page 2235)) at the time the *getopts* utility is invoked. A name equivalent to:

  ```
  basename "$0"
  ```

  may be used.

- If an option is found that was not specified in *optstring*, this error is identified and the invalid option character shall be identified in the message.

- If an option requiring an option-argument is found, but an option-argument is not found, this error shall be identified and the invalid option character shall be identified in the message.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 An option, specified or unspecified by *optstring*, was found.

>0 The end of options was encountered or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *getopts* affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(getopts abc value "$@")
nohup getopts ...
find . −exec getopts ... \;
```

it does not affect the shell variables in the caller's environment.

Note that shell functions share *OPTIND* with the calling shell even though the positional parameters are changed. If the calling shell and any of its functions uses *getopts* to parse arguments, the results are unspecified.

EXAMPLES

The following example script parses and displays its arguments:

```
aflag=
bflag=
```

```
while getopts ab: name
do
    case $name in
    a)    aflag=1;;
    b)    bflag=1
          bval="$OPTARG";;
    ?)   printf "Usage: %s: [-a] [-b value] args\n" $0
          exit 2;;
    esac
done
if [ ! -z "$aflag" ]; then
    printf "Option -a specified\n"
fi
if [ ! -z "$bflag" ]; then
    printf 'Option -b "%s" specified\n' "$bval"
fi
shift $(($OPTIND - 1))
printf "Remaining arguments are: %s\n" "$*"
```

RATIONALE

The *getopts* utility was chosen in preference to the System V *getopt* utility because *getopts* handles option-arguments containing <blank>s.

The *OPTARG* variable is not mentioned in the ENVIRONMENT VARIABLES section because it does not affect the execution of *getopts*; it is one of the few ''output-only'' variables used by the standard utilities.

The colon is not allowed as an option character because that is not historical behavior, and it violates the Utility Syntax Guidelines. The colon is now specified to behave as in the KornShell version of the *getopts* utility; when used as the first character in the *optstring* operand, it disables diagnostics concerning missing option-arguments and unexpected option characters. This replaces the use of the *OPTERR* variable that was specified in an early proposal.

The formats of the diagnostic messages produced by the *getopts* utility and the *getopt*() function are not fully specified because implementations with superior (''friendlier'') formats objected to the formats used by some historical implementations. The standard developers considered it important that the information in the messages used be uniform between *getopts* and *getopt*(). Exact duplication of the messages might not be possible, particularly if a utility is built on another system that has a different *getopt*() function, but the messages must have specific information included so that the program name, invalid option character, and type of error can be distinguished by a user.

Only a rare application program intercepts a *getopts* standard error message and wants to parse it. Therefore, implementations are free to choose the most usable messages they can devise. The following formats are used by many historical implementations:

```
"%s: illegal option -- %c\n", <program name>, <option character>
```

```
"%s: option requires an argument -- %c\n", <program name>, \
    <option character>
```

Historical shells with built-in versions of *getopt*() or *getopts* have used different formats, frequently not even indicating the option character found in error.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

grep — search a file for a pattern

SYNOPSIS

```
grep [−E| −F][−c| −l| −q][−insvx] −e pattern_list...
    [−f pattern_file]...[file...]

grep [−E| −F][−c| −l| −q][−insvx][−e pattern_list]...
    −f pattern_file...[file...]

grep [−E| −F][−c| −l| −q][−insvx] pattern_list[file...]
```

DESCRIPTION

The *grep* utility shall search the input files, selecting lines matching one or more patterns; the types of patterns are controlled by the options specified. The patterns are specified by the **−e** option, **−f** option, or the *pattern_list* operand. The *pattern_list*'s value shall consist of one or more patterns separated by <newline>s; the *pattern_file*'s contents shall consist of one or more patterns terminated by <newline>. By default, an input line shall be selected if any pattern, treated as an entire basic regular expression (BRE) as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions, matches any part of the line excluding the terminating <newline>; a null BRE shall match every line. By default, each selected input line shall be written to the standard output.

Regular expression matching shall be based on text lines. Since a <newline> separates or terminates patterns (see the **−e** and **−f** options below), regular expressions cannot contain a <newline>. Similarly, since patterns are matched against individual lines (excluding the terminating <newline>s) of the input, there is no way for a pattern to match a <newline> found in the input.

OPTIONS

The *grep* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−E Match using extended regular expressions. Treat each pattern specified as an ERE, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4, Extended Regular Expressions. If any entire ERE pattern matches some part of an input line excluding the terminating <newline>, the line shall be matched. A null ERE shall match every line.

−F Match using fixed strings. Treat each pattern specified as a string instead of a regular expression. If an input line contains any of the patterns as a contiguous sequence of bytes, the line shall be matched. A null string shall match every line.

−c Write only a count of selected lines to standard output.

−e *pattern_list*

Specify one or more patterns to be used during the search for input. The application shall ensure that patterns in *pattern_list* are separated by a <newline>. A null pattern can be specified by two adjacent <newline>s in *pattern_list*. Unless the **−E** or **−F** option is also specified, each pattern shall be treated as a BRE, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions. Multiple **−e** and **−f** options shall be accepted by the *grep* utility. All of the specified patterns shall be used when matching lines, but the order of evaluation is unspecified.

–f *pattern_file*	Read one or more patterns from the file named by the pathname *pattern_file*. Patterns in *pattern_file* shall be terminated by a <newline>. A null pattern can be specified by an empty line in *pattern_file*. Unless the **–E** or **–F** option is also specified, each pattern shall be treated as a BRE, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions.
–i	Perform pattern matching in searches without regard to case; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.2, Regular Expression General Requirements.
–l	(The letter ell.) Write only the names of files containing selected lines to standard output. Pathnames shall be written once per file searched. If the standard input is searched, a pathname of `"(standard input)"` shall be written, in the POSIX locale. In other locales, `"standard input"` may be replaced by something more appropriate in those locales.
–n	Precede each output line by its relative line number in the file, each file starting at line 1. The line number counter shall be reset for each file processed.
–q	Quiet. Nothing shall be written to the standard output, regardless of matching lines. Exit with zero status if an input line is selected.
–s	Suppress the error messages ordinarily written for nonexistent or unreadable files. Other error messages shall not be suppressed.
–v	Select lines not matching any of the specified patterns. If the **–v** option is not specified, selected lines shall be those that match any of the specified patterns.
–x	Consider only input lines that use all characters in the line excluding the terminating <newline> to match an entire fixed string or regular expression to be matching lines.

OPERANDS

The following operands shall be supported:

pattern_list	Specify one or more patterns to be used during the search for input. This operand shall be treated as if it were specified as **–e** *pattern_list*.
file	A pathname of a file to be searched for the patterns. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *grep*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes and multi-character collating elements within regular expressions.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the −**l** option is in effect, and the −**q** option is not, the following shall be written for each file containing at least one selected input line:

```
"%s\n", <file>
```

Otherwise, if more than one *file* argument appears, and −**q** is not specified, the *grep* utility shall prefix each output line by:

```
"%s:", <file>
```

The remainder of each output line shall depend on the other options specified:

- If the −**c** option is in effect, the remainder of each output line shall contain:

  ```
  "%d\n", <count>
  ```

- Otherwise, if −**c** is not in effect and the −**n** option is in effect, the following shall be written to standard output:

  ```
  "%d:", <line number>
  ```

- Finally, the following shall be written to standard output:

  ```
  "%s", <selected-line contents>
  ```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	One or more lines were selected.
1	No lines were selected.
>1	An error occurred.

CONSEQUENCES OF ERRORS

If the **−q** option is specified, the exit status shall be zero if an input line is selected, even if an error was detected. Otherwise, default actions shall be performed.

APPLICATION USAGE

Care should be taken when using characters in *pattern_list* that may also be meaningful to the command interpreter. It is safest to enclose the entire *pattern_list* argument in single quotes:

```
'...'
```

The **−e** *pattern_list* option has the same effect as the *pattern_list* operand, but is useful when *pattern_list* begins with the hyphen delimiter. It is also useful when it is more convenient to provide multiple patterns as separate arguments.

Multiple **−e** and **−f** options are accepted and *grep* uses all of the patterns it is given while matching input text lines. (Note that the order of evaluation is not specified. If an implementation finds a null string as a pattern, it is allowed to use that pattern first, matching every line, and effectively ignore any other patterns.)

The **−q** option provides a means of easily determining whether or not a pattern (or string) exists in a group of files. When searching several files, it provides a performance improvement (because it can quit as soon as it finds the first match) and requires less care by the user in choosing the set of files to supply as arguments (because it exits zero if it finds a match even if *grep* detected an access or read error on earlier *file* operands).

EXAMPLES

1. To find all uses of the word `"Posix"` (in any case) in file **text.mm** and write with line numbers:

   ```
   grep −i −n posix text.mm
   ```

2. To find all empty lines in the standard input:

   ```
   grep ^$
   ```

   or:

   ```
   grep −v .
   ```

3. Both of the following commands print all lines containing strings `"abc"` or `"def"` or both:

   ```
   grep −E 'abc|def'
   ```

   ```
   grep −F 'abc|def'
   ```

4. Both of the following commands print all lines matching exactly `"abc"` or `"def"`:

   ```
   grep −E '^abc$|^def$'
   ```

   ```
   grep −F −x 'abc|def'
   ```

RATIONALE

This *grep* has been enhanced in an upward-compatible way to provide the exact functionality of the historical *egrep* and *fgrep* commands as well. It was the clear intention of the standard developers to consolidate the three *grep*s into a single command.

The old *egrep* and *fgrep* commands are likely to be supported for many years to come as implementation extensions, allowing historical applications to operate unmodified.

Historical implementations usually silently ignored all but one of multiply-specified **−e** and **−f** options, but were not consistent as to which specification was actually used.

The **–b** option was omitted from the OPTIONS section because block numbers are implementation-defined.

The System V restriction on using – to mean standard input was omitted.

A definition of action taken when given a null BRE or ERE is specified. This is an error condition in some historical implementations.

The **–l** option previously indicated that its use was undefined when no files were explicitly named. This behavior was historical and placed an unnecessary restriction on future implementations. It has been removed.

The historical BSD *grep* **–s** option practice is easily duplicated by redirecting standard output to **/dev/null**. The **–s** option required here is from System V.

The **–x** option, historically available only with *fgrep*, is available here for all of the non-obsolescent versions.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The Open Group Corrigendum U029/5 is applied, correcting the SYNOPSIS.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

hash — remember or report utility locations

SYNOPSIS

XSI

```
hash [utility...]

hash −r
```

DESCRIPTION

The *hash* utility shall affect the way the current shell environment remembers the locations of utilities found as described in Section 2.9.1.1 (on page 2249). Depending on the arguments specified, it shall add utility locations to its list of remembered locations or it shall purge the contents of the list. When no arguments are specified, it shall report on the contents of the list.

Utilities provided as built-ins to the shell shall not be reported by *hash*.

OPTIONS

The *hash* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−r	Forget all previously remembered utility locations.

OPERANDS

The following operand shall be supported:

utility	The name of a utility to be searched for and added to the list of remembered locations. If *utility* contains one or more slashes, the results are unspecified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *hash*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PATH	Determine the location of *utility*, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output of *hash* shall be used when no arguments are specified. Its format is unspecified, but includes the pathname of each utility in the list of remembered locations for the current shell environment. This list shall consist of those utilities named in previous *hash* invocations that have been invoked, and may contain those invoked and found through the normal command search process.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *hash* affects the current shell execution environment, it is always provided as a shell regular built-in. If it is called in a separate utility execution environment, such as one of the following:

```
nohup hash −r
find . −type f | xargs hash
```

it does not affect the command search process of the caller's environment.

The *hash* utility may be implemented as an alias—for example, *alias* −**t** −, in which case utilities found through normal command search are not listed by the *hash* command.

The effects of *hash* −**r** can also be achieved portably by resetting the value of *PATH*; in the simplest form, this can be:

```
PATH="$PATH"
```

The use of *hash* with *utility* names is unnecessary for most applications, but may provide a performance improvement on a few implementations; normally, the hashing process is included by default.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 2.

NAME

head — copy the first part of files

SYNOPSIS

```
head [−n number][file...]
```

DESCRIPTION

The *head* utility shall copy its input files to the standard output, ending the output for each file at a designated point.

Copying shall end at the point in each input file indicated by the **−n** *number* option. The option-argument *number* shall be counted in units of lines.

OPTIONS

The *head* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−n *number*	The first *number* lines of each input file shall be copied to standard output. The application shall ensure that the *number* option-argument is a positive decimal integer.

If no options are specified, *head* shall act as if **−n 10** had been specified.

OPERANDS

The following operand shall be supported:

file	A pathname of an input file. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified. See the INPUT FILES section.

INPUT FILES

Input files shall be text files, but the line length is not restricted to {LINE_MAX} bytes.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *head*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall contain designated portions of the input files.

If multiple *file* operands are specified, *head* shall precede the output for each with the header:

```
"\n==> %s <==\n", <pathname>
```

except that the first header written shall not include the initial <newline>.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The obsolescent −*number* form is withdrawn in this version. Applications should use the −**n** *number* option.

EXAMPLES

To write the first ten lines of all files (except those with a leading period) in the directory:

```
head *
```

RATIONALE

Although it is possible to simulate *head* with *sed* 10q for a single file, the standard developers decided that the popularity of *head* on historical BSD systems warranted its inclusion alongside *tail*.

This standard version of *head* follows the Utility Syntax Guidelines. The −**n** option was added to this new interface so that *head* and *tail* would be more logically related.

There is no −**c** option (as there is in *tail*) because it is not historical practice and because other utilities in this volume of IEEE Std 1003.1-200x provide similar functionality.

FUTURE DIRECTIONS

None.

SEE ALSO

sed, *tail*

CHANGE HISTORY

First released in Issue 4.

Issue 6

The obsolescent −**number** form is withdrawn.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

iconv — codeset conversion

SYNOPSIS

```
iconv [−cs] −f fromcode −t tocode [file ...]

iconv −l
```

DESCRIPTION

The *iconv* utility shall convert the encoding of characters in *file* from one codeset to another and write the results to standard output.

When the options indicate that charmap files are used to specify the codesets (see OPTIONS), the codeset conversion shall be accomplished by performing a logical join on the symbolic character names in the two charmaps. The implementation need not support the use of charmap files for codeset conversion unless the POSIX2_LOCALEDEF symbol is defined on the system.

OPTIONS

The *iconv* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c Omit any invalid characters from the output. When **−c** is not used, the results of encountering invalid characters in the input stream (either those that are not valid members of the *fromcode* or those that have no corresponding value in *tocode*) shall be specified in the system documentation. The presence or absence of **−c** shall not affect the exit status of *iconv*.

−f *fromcode* Identify the codeset of the input file. If the option-argument contains a slash character, *iconv* shall attempt to use it as the pathname of a charmap file, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.4, Character Set Description File. If the pathname does not represent a valid, readable charmap file, the results are undefined. If the option-argument does not contain a slash, it shall be considered the name of one of the codeset descriptions provided by the system, in an unspecified format. The valid values of the option-argument without a slash are implementation-defined. If this option is omitted, the codeset of the current locale shall be used.

−l Write all supported *fromcode* and *tocode* values to standard output in an unspecified format.

−s Suppress any messages written to standard error concerning invalid characters. When **−s** is not used, the results of encountering invalid characters in the input stream (either those that are not valid members of the *fromcode* or those that have no corresponding value in *tocode*) shall be specified in the system documentation. The presence or absence of **−s** shall not affect the exit status of *iconv*.

−t *tocode* Identify the codeset to be used for the output file. The semantics shall be equivalent to the **−f** *fromcode* option. |

If either **−f** or **−t** represents a charmap file, but the other does not (or is omitted), or both **−f** and **−t** are omitted, the results are undefined.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If no *file* operands are specified, or if a *file* operand is `'−'`, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is '−'.

INPUT FILES

The input file shall be a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *iconv*:

	LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
	LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
	LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments). During translation of the file, this variable is superseded by the use of the *fromcode* option-argument.
	LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the **−l** option is used, the standard output shall contain all supported *fromcode* and *tocode* values, written in an unspecified format.

When the **−l** option is not used, the standard output shall contain the sequence of characters read from the input files, translated to the specified codeset. Nothing else shall be written to the standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The user must ensure that both charmap files use the same symbolic names for characters the two codesets have in common.

EXAMPLES

The following example converts the contents of file **mail.x400** from the ISO/IEC 6937:1994 standard codeset to the ISO/IEC 8859-1:1998 standard codeset, and stores the results in file **mail.local**:

```
iconv −f IS6937 −t IS8859 mail.x400 > mail.local
```

RATIONALE

The *iconv* utility can be used portably only when the user provides two charmap files as option-arguments. This is because a single charmap provided by the user cannot reliably be joined with the names in a system-provided character set description. The valid values for *fromcode* and *tocode* are implementation-defined and do not have to have any relation to the charmap mechanisms. As an aid to interactive users, the **−l** option was adopted from the Plan 9 operating system. It writes information concerning these implementation-defined values. The format is unspecified because there are many possible useful formats that could be chosen, such as a matrix of valid combinations of *fromcode* and *tocode*. The **−l** option is not intended for shell script usage; conforming applications will have to use charmaps.

FUTURE DIRECTIONS

None.

SEE ALSO

gencat

CHANGE HISTORY

First released in Issue 3.

Issue 6

This utility has been rewritten to align with the IEEE P1003.2b draft standard. Specifically, the ability to use charmap files for conversion has been added.

NAME

id — return user identity

SYNOPSIS

```
id [user]
id -G[-n] [user]
id -g[-nr] [user]
id -u[-nr] [user]
```

DESCRIPTION

If no *user* operand is provided, the *id* utility shall write the user and group IDs and the corresponding user and group names of the invoking process to standard output. If the effective and real IDs do not match, both shall be written. If multiple groups are supported by the underlying system (see the description of {NGROUPS_MAX} in the System Interfaces volume of IEEE Std 1003.1-200x), the supplementary group affiliations of the invoking process shall also be written.

If a *user* operand is provided and the process has the appropriate privileges, the user and group IDs of the selected user shall be written. In this case, effective IDs shall be assumed to be identical to real IDs. If the selected user has more than one allowable group membership listed in the group database, these shall be written in the same manner as the supplementary groups described in the preceding paragraph.

OPTIONS

The *id* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−G	Output all different group IDs (effective, real, and supplementary) only, using the format `"%u\n"`. If there is more than one distinct group affiliation, output each such affiliation, using the format `" %u"`, before the <newline> is output.
−g	Output only the effective group ID, using the format `"%u\n"`.
−n	Output the name in the format `"%s"` instead of the numeric ID using the format `"%u"`.
−r	Output the real ID instead of the effective ID.
−u	Output only the effective user ID, using the format `"%u\n"`.

OPERANDS

The following operand shall be supported:

user	The login name for which information is to be written.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *id*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables

used to determine the values of locale categories.)

LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The following formats shall be used when the *LC_MESSAGES* locale category specifies the POSIX locale. In other locales, the strings *uid*, *gid*, *euid*, *egid*, and *groups* may be replaced with more appropriate strings corresponding to the locale.

```
"uid=%u(%s) gid=%u(%s)\n", <real user ID>, <user-name>,
    <real group ID>, <group-name>
```

If the effective and real user IDs do not match, the following shall be inserted immediately before the `'\n'` character in the previous format:

```
" euid=%u(%s)"
```

with the following arguments added at the end of the argument list:

```
<effective user ID>, <effective user-name>
```

If the effective and real group IDs do not match, the following shall be inserted directly before the `'\n'` character in the format string (and after any addition resulting from the effective and real user IDs not matching):

```
" egid=%u(%s)"
```

with the following arguments added at the end of the argument list:

```
<effective group-ID>, <effective group name>
```

If the process has supplementary group affiliations or the selected user is allowed to belong to multiple groups, the first shall be added directly before the <newline> in the format string:

```
" groups=%u(%s)"
```

with the following arguments added at the end of the argument list:

```
<supplementary group ID>, <supplementary group name>
```

and the necessary number of the following added after that for any remaining supplementary group IDs:

```
",%u(%s)"
```

and the necessary number of the following arguments added at the end of the argument list:

```
<supplementary group ID>, <supplementary group name>
```

If any of the user ID, group ID, effective user ID, effective group ID, or supplementary/multiple group IDs cannot be mapped by the system into printable user or group names, the corresponding ("%s") and *name* argument shall be omitted from the corresponding format string.

When any of the options are specified, the output format shall be as described in the OPTIONS section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Output produced by the −**G** option and by the default case could potentially produce very long lines on systems that support large numbers of supplementary groups. (On systems with user and group IDs that are 32-bit integers and with group names with a maximum of 8 bytes per name, 93 supplementary groups plus distinct effective and real group and user IDs could theoretically overflow the 2 048-byte {LINE_MAX} text file line limit on the default output case. It would take about 186 supplementary groups to overflow the 2 048-byte barrier using *id* −**G**). This is not expected to be a problem in practice, but in cases where it is a concern, applications should consider using *fold* −**s** before postprocessing the output of *id*.

EXAMPLES

None.

RATIONALE

The functionality provided by the 4 BSD *groups* utility can be simulated using:

```
id −Gn [ user ]
```

The 4 BSD command *groups* was considered, but it was not included because it did not provide the functionality of the *id* utility of the SVID. Also, it was thought that it would be easier to modify *id* to provide the additional functionality necessary to systems with multiple groups than to invent another command.

The options −**u**, −**g**, −**n**, and −**r** were added to ease the use of *id* with shell commands substitution. Without these options it is necessary to use some preprocessor such as *sed* to select the desired piece of information. Since output such as that produced by:

```
id −u −n
```

is frequently wanted, it seemed desirable to add the options.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

ipcrm — remove an XSI message queue, semaphore set, or shared memory segment identifier

SYNOPSIS

XSI
```
ipcrm [ −q msgid | −Q msgkey | −s semid | −S semkey |
    −m shmid | −M shmkey ] ...
```

DESCRIPTION

The *ipcrm* utility shall remove zero or more message queues, semaphore sets, or shared memory segments. The interprocess communication facilities to be removed are specified by the options.

Only a user with appropriate privilege shall be allowed to remove an interprocess communication facility that was not created by or owned by the user invoking *ipcrm*.

OPTIONS

The *ipcrm* facility supports the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−q *msgid* Remove the message queue identifier *msgid* from the system and destroy the message queue and data structure associated with it.

−m *shmid* Remove the shared memory identifier *shmid* from the system. The shared memory segment and data structure associated with it shall be destroyed after the last detach.

−s *semid* Remove the semaphore identifier *semid* from the system and destroy the set of semaphores and data structure associated with it.

−Q *msgkey* Remove the message queue identifier, created with key *msgkey*, from the system and destroy the message queue and data structure associated with it.

−M *shmkey* Remove the shared memory identifier, created with key *shmkey*, from the system. The shared memory segment and data structure associated with it shall be destroyed after the last detach.

−S *semkey* Remove the semaphore identifier, created with key *semkey*, from the system and destroy the set of semaphores and data structure associated with it.

OPERANDS

CHANGE HISTORY

First released in Issue 5.

NAME

ipcs — report XSI interprocess communication facilities status

SYNOPSIS

XSI

```
ipcs [−qms][−a | −bcopt]
```

DESCRIPTION

The *ipcs* utility shall write information about active interprocess communication facilities.

Without options, information shall be written in short format for message queues, shared memory segments, and semaphores sets that are currently active in the system. Otherwise, the information that is displayed is controlled by the options specified.

OPTIONS

The *ipcs* facility supports the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The *ipcs* utility accepts the following options:

−q	Write information about active message queues.
−m	Write information about active shared memory segments.
−s	Write information about active semaphores sets.

If **−q**, **−m**, or **−s** are specified, only information about those facilities shall be written. If none of these three are specified, information about all three shall be written subject to the following options:

−a	Use all print options. (This is a shorthand notation for **−b**, **−c**, **−o**, **−p**, and **−t**.)
−b	Write information on maximum allowable size. (Maximum number of bytes in messages on queue for message queues, size of segments for shared memory, and number of semaphores in each set for semaphores.)
−c	Write creator's user name and group name; see below.
−o	Write information on outstanding usage. (Number of messages on queue and total number of bytes in messages on queue for message queues, and number of processes attached to shared memory segments.)
−p	Write process number information. (Process ID of last process to send a message and process ID of last process to receive a message on message queues, process ID of creating process, and process ID of last process to attach or detach on shared memory segments.)
−t	Write time information. (Time of the last control operation that changed the access permissions for all facilities, time of last *msgsnd*( ) and *msgrcv*( ) operations on message queues, time of last *shmat*( ) and *shmdt*( ) operations on shared memory, and time of last *semop*( ) operation on semaphores.)

OPERANDS

None.

STDIN

Not used.

INPUT FILES

- The group database
- The user database

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ipcs*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
TZ	Determine the timezone for the date and time strings written by *ipcs*. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

An introductory line shall be written with the format:

```
"IPC status from %s as of %s\n", <source>, <date>
```

where <*source*> indicates the source used to gather the statistics and <*date*> is the information that would be produced by the *date* command when invoked in the POSIX locale.

The *ipcs* utility then shall create up to three reports depending upon the −**q**, −**m**, and −**s** options. The first report shall indicate the status of message queues, the second report shall indicate the status of shared memory segments, and the third report shall indicate the status of semaphore sets.

If the corresponding facility is not installed or has not been used since the last reboot, then the report shall be written out in the format:

```
"%s facility not in system.\n", <facility>
```

where <*facility*> is *Message Queue*, *Shared Memory*, or *Semaphore*, as appropriate. If the facility has been installed and has been used since the last reboot, column headings separated by one or more spaces and followed by a <newline> shall be written as indicated below followed by the facility name written out using the format:

```
"%s:\n", <facility>
```

where <*facility*> is *Message Queues*, *Shared Memory*, or *Semaphores*, as appropriate. On the second and third reports the column headings need not be written if the last column headings written already provide column headings for all information in that report.

The column headings provided in the first column below and the meaning of the information in those columns shall be given in order below; the letters in parentheses indicate the options that shall cause the corresponding column to appear; ''all'' means that the column shall always appear. Each column is separated by one or more <space>s. Note that these options only determine what information is provided for each report; they do not determine which reports are written.

T (all) Type of facility:

`q`	Message queue.
`m`	Shared memory segment.
`s`	Semaphore.

This field is a single character written using the format `%c`.

ID (all) The identifier for the facility entry. This field shall be written using the format `%d`.

KEY (all) The key used as an argument to *msgget*( ), *semget*( ), or *shmget*( ) to create the facility entry.

Note: The key of a shared memory segment is changed to IPC_PRIVATE when the segment has been removed until all processes attached to the segment detach it.

This field shall be written using the format `0x%x`.

MODE (all) The facility access modes and flags. The mode shall consist of 11 characters that are interpreted as follows.

The first character shall be:

`S`	If a process is waiting on a *msgsnd*( ) operation.
–	If the above is not true.

The second character shall be:

`R`	If a process is waiting on a *msgrcv*( ) operation.
`C` or –	If the associated shared memory segment is to be cleared when the first attach operation is executed.
–	If none of the above is true.

The next nine characters shall be interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the usergroup of the facility entry; and the last to all others. Within each set, the first character indicates permission to read, the second character indicates permission to write or alter the facility entry, and the last character is a minus sign (`'−'`).

The permissions shall be indicated as follows:

r	If read permission is granted.
w	If write permission is granted.
a	If alter permission is granted.
–	If the indicated permission is not granted.

The first character following the permissions specifies if there is an alternate or additional access control method associated with the facility. If there is no alternate or additional access control method associated with the facility, a single <space> shall be written; otherwise, another printable character is written.

OWNER (all) The user name of the owner of the facility entry. If the user name of the owner is found in the user database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the user ID of the owner shall be written using the format `%d`.

GROUP (all) The group name of the owner of the facility entry. If the group name of the owner is found in the group database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the group ID of the owner shall be written using the format `%d`.

The following nine columns shall be only written out for message queues:

CREATOR (**a**,**c**) The user name of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the user ID of the creator shall be written using the format `%d`.

CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the group ID of the creator shall be written using the format `%d`.

CBYTES (**a**,**o**) The number of bytes in messages currently outstanding on the associated message queue. This field shall be written using the format `%d`.

QNUM (**a**,**o**) The number of messages currently outstanding on the associated message queue. This field shall be written using the format `%d`.

QBYTES (**a**,**b**) The maximum number of bytes allowed in messages outstanding on the associated message queue. This field shall be written using the format `%d`.

LSPID (**a**,**p**) The process ID of the last process to send a message to the associated queue. This field shall be written using the format:

`"%d", <pid>`

where <*pid*> is 0 if no message has been sent to the corresponding message queue; otherwise, <*pid*> shall be the process ID of the last process to send a message to the queue.

LRPID (**a**,**p**) The process ID of the last process to receive a message from the associated queue. This field shall be written using the format:

`"%d", <pid>`

where <*pid*> is 0 if no message has been received from the corresponding message queue; otherwise, <*pid*> shall be the process ID of the last process to receive a message from the queue.

STIME (**a**,**t**) The time the last message was sent to the associated queue. If a message has been sent to the corresponding message queue, the hour, minute, and second of the last time a message was sent to the queue shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

RTIME (**a**,**t**) The time the last message was received from the associated queue. If a message has been received from the corresponding message queue, the hour, minute, and second of the last time a message was received from the queue shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

The following eight columns shall be only written out for shared memory segments.

CREATOR (**a**,**c**) The user of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the user ID of the creator shall be written using the format `%d`.

CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the group ID of the creator shall be written using the format `%d`.

NATTCH (**a**,**o**) The number of processes attached to the associated shared memory segment. This field shall be written using the format `%d`.

SEGSZ (**a**,**b**) The size of the associated shared memory segment. This field shall be written using the format `%d`.

CPID (**a**,**p**) The process ID of the creator of the shared memory entry. This field shall be written using the format `%d`.

LPID (**a**,**p**) The process ID of the last process to attach or detach the shared memory segment. This field shall be written using the format:

`"%d", <pid>`

where <*pid*> is 0 if no process has attached the corresponding shared memory segment; otherwise, <*pid*> shall be the process ID of the last process to attach or detach the segment.

ATIME (**a**,**t**) The time the last attach on the associated shared memory segment was completed. If the corresponding shared memory segment has ever been attached, the hour, minute, and second of the last time the segment was attached shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

DTIME (**a**,**t**) The time the last detach on the associated shared memory segment was completed. If the corresponding shared memory segment has ever been detached, the hour, minute, and second of the last time the segment was detached shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

The following four columns shall be only written out for semaphore sets:

CREATOR (**a**,**c**) The user of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the user ID of the creator shall be written using the format `%d`.

CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the group ID of the creator shall be written using the format `%d`.

NSEMS	(**a**,**b**)	The number of semaphores in the set associated with the semaphore entry. This field shall be written using the format `%d`.
OTIME	(**a**,**t**)	The time the last semaphore operation on the set associated with the semaphore entry was completed. If a semaphore operation has ever been performed on the corresponding semaphore set, the hour, minute, and second of the last semaphore operation on the semaphore set shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

The following column shall be written for all three reports when it is requested:

CTIME	(**a**,**t**)	The time the associated entry was created or changed. The hour, minute, and second of the time when the associated entry was created shall be written using the format `%d:%2.2d:%2.2d`.

STDERR

The standard error shall be used only for diagnostic messages.

The Open Group Corrigendum U020/1 is applied, correcting the SYNOPSIS.

The Open Group Corrigendum U032/1 and U032/2 are applied, clarifying the output format.

The Open Group Base Resolution bwg98-004 is applied.

NAME

jobs — display status of jobs in the current session

SYNOPSIS

UP
```
jobs [−l| −p][job_id...]
```

DESCRIPTION

The *jobs* utility shall display the status of jobs that were started in the current shell environment; see Section 2.12 (on page 2263).

When *jobs* reports the termination status of a job, the shell shall remove its process ID from the list of those ‘‘known in the current shell execution environment’’; see Section 2.9.3.1 (on page 2252).

OPTIONS

The *jobs* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−l	(The letter ell.) Provide more information about each job listed. This information shall include the job number, current job, process group ID, state, and the command that formed the job.
−p	Display only the process IDs for the process group leaders of the selected jobs.

By default, the *jobs* utility shall display the status of all stopped jobs, running background jobs and all jobs whose status has changed and have not been reported by the shell.

OPERANDS

The following operand shall be supported:

job_id	Specifies the jobs for which the status is to be displayed. If no *job_id* is given, the status information for all jobs shall be displayed. The format of *job_id* is described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.203, Job Control Job ID.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *jobs*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of

diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the **–p** option is specified, the output shall consist of one line for each process ID:

`"%d\n", <process ID>`

Otherwise, if the **–l** option is not specified, the output shall be a series of lines of the form:

`"[%d] %c %s %s\n", <job-number>, <current>, <state>, <command>`

where the fields shall be as follows:

<*current*> The character `'+'` identifies the job that would be used as a default for the *fg* or *bg* utilities; this job can also be specified using the *job_id* %+ or `"%%"`. The character `'–'` identifies the job that would become the default if the current default job were to exit; this job can also be specified using the *job_id* %–. For other jobs, this field is a <space>. At most one job can be identified with `'+'` and at most one job can be identified with `'–'`. If there is any suspended job, then the current job shall be a suspended job. If there are at least two suspended jobs, then the previous job also shall be a suspended job.

<*job-number*> A number that can be used to identify the process group to the *wait*, *fg*, *bg*, and *kill* utilities. Using these utilities, the job can be identified by prefixing the job number with `'%'`.

<*state*> One of the following strings (in the POSIX locale):

Running Indicates that the job has not been suspended by a signal and has not exited.

Done Indicates that the job completed and returned exit status zero.

Done(*code*) Indicates that the job completed normally and that it exited with the specified non-zero exit status, *code*, expressed as a decimal number.

Stopped Indicates that the job was suspended by the SIGTSTP signal.

Stopped (**SIGTSTP**)
Indicates that the job was suspended by the SIGTSTP signal.

Stopped (**SIGSTOP**)
Indicates that the job was suspended by the SIGSTOP signal.

Stopped (**SIGTTIN**)
Indicates that the job was suspended by the SIGTTIN signal.

Stopped (**SIGTTOU**)
Indicates that the job was suspended by the SIGTTOU signal.

The implementation may substitute the string **Suspended** in place of **Stopped**. If the job was terminated by a signal, the format of <*state*> is unspecified, but it shall be visibly distinct from all of the other <*state*> formats shown here and shall indicate the name or description of the signal causing the termination.

<*command*> The associated command that was given to the shell.

If the **–l** option is specified, a field containing the process group ID shall be inserted before the <*state*> field. Also, more processes in a process group may be output on separate lines, using only the process ID and <*command*> fields.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The **–p** option is the only portable way to find out the process group of a job because different implementations have different strategies for defining the process group of the job. Usage such as $(*jobs* **–p**) provides a way of referring to the process group of the job in an implementation-independent way.

The *jobs* utility does not work as expected when it is operating in its own utility execution environment because that environment has no applicable jobs to manipulate. See the APPLICATION USAGE section for *bg* (on page 2410). For this reason, *jobs* is generally implemented as a shell regular built-in.

EXAMPLES

None.

RATIONALE

Both "%%" and "%+" are used to refer to the current job. Both forms are of equal validity—the "%%" mirroring "$$" and "%+" mirroring the output of *jobs*. Both forms reflect historical practice of the KornShell and the C shell with job control.

The job control features provided by *bg*, *fg*, and *jobs* are based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell versions were selected for this volume of IEEE Std 1003.1-200x to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).

The *jobs* utility is not dependent on the job control option, as are the seemingly related *bg* and *fg* utilities because *jobs* is useful for examining background jobs, regardless of the condition of job control. When the user has invoked a *set* **+m** command and job control has been turned off, *jobs* can still be used to examine the background jobs associated with that current session. Similarly, *kill* can then be used to kill background jobs with *kill*% <*background job number*>.

The output for terminated jobs is left unspecified to accommodate various historical systems. The following formats have been witnessed:

1. **Killed**(*signal name*)
2. *signal name*
3. *signal name*(**coredump**)
4. *signal description* – **core dumped**

Most users should be able to understand these formats, although it means that applications have trouble parsing them.

The calculation of job IDs was not described since this would suggest an implementation, which may impose unnecessary restrictions.

In an early proposal, a –**n** option was included to ‘‘Display the status of jobs that have changed, exited, or stopped since the last status report’’. It was removed because the shell always writes any changed status of jobs before each prompt.

FUTURE DIRECTIONS

None.

SEE ALSO

bg, *fg*, *kill*, *wait*

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The JC shading is removed as job control is mandatory in this issue.

NAME

join — relational database operator

SYNOPSIS

```
join [−a file_number | −v file_number][−e string][−o list][−t char]
    [−1 field][−2 field] file1 file2
```

DESCRIPTION

The *join* utility shall perform an equality join on the files *file1* and *file2*. The joined files shall be written to the standard output.

The join field is a field in each file on which the files are compared. The *join* utility shall write one line in the output for each pair of lines in *file1* and *file2* that have identical join fields. The output line by default shall consist of the join field, then the remaining fields from *file1*, then the remaining fields from *file2*. This format can be changed by using the **−o** option (see below). The **−a** option can be used to add unmatched lines to the output. The **−v** option can be used to output only unmatched lines.

The files *file1* and *file2* shall be ordered in the collating sequence of *sort* **−b** on the fields on which they shall be joined, by default the first in each line. All selected output shall be written in the same collating sequence.

The default input field separators shall be <blank>s. In this case, multiple separators shall count as one field separator, and leading separators shall be ignored. The default output field separator shall be a <space>.

The field separator and collating sequence can be changed by using the **−t** option (see below).

If the same key appears more than once in either file, all combinations of the set of remaining fields in *file1* and the set of remaining fields in *file2* are output in the order of the lines encountered.

If the input files are not in the appropriate collating sequence, the results are unspecified.

OPTIONS

The *join* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−a *file_number*
Produce a line for each unpairable line in file *file_number*, where *file_number* is 1 or 2, in addition to the default output. If both **−a**1 and **−a**2 are specified, all unpairable lines shall be output.

−e *string* Replace empty output fields in the list selected by **−o** with the string *string*.

−o *list* Construct the output line to comprise the fields specified in *list*, each element of which shall have one of the following two forms:

1. *file_number.field*, where *file_number* is a file number and *field* is a decimal integer field number
2. 0 (zero), representing the join field

The elements of *list* shall be either comma-separated or <blank>-separated, as specified in Guideline 8 of the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines. The fields specified by *list* shall be written for all selected output lines. Fields selected by *list* that do not appear in the input shall be treated as empty output fields. (See the **−e** option.) Only specifically requested fields shall be written. The application shall ensure that *list* is a single command line argument.

−t *char* Use character *char* as a separator, for both input and output. Every appearance of *char* in a line shall be significant. When this option is specified, the collating sequence shall be the same as *sort* without the **−b** option. |

−v *file_number*
Instead of the default output, produce a line only for each unpairable line in *file_number*, where *file_number* is 1 or 2. If both **−v**1 and **−v**2 are specified, all unpairable lines shall be output.

−1 *field* Join on the *field*th field of file 1. Fields are decimal integers starting with 1.

−2 *field* Join on the *field*th field of file 2. Fields are decimal integers starting with 1.

OPERANDS

The following operands shall be supported:

file1, *file2*
A pathname of a file to be joined. If either of the *file1* or *file2* operands is `'−'`, the standard input shall be used in its place.

STDIN

The standard input shall be used only if the *file1* or *file2* operand is `'−'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *join*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale of the collating sequence *join* expects to have been used when the input files were sorted.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *join* utility output shall be a concatenation of selected character fields. When the −**o** option is not specified, the output shall be:

```
"%s%s%s\n", <join field>, <other file1 fields>,
    <other file2 fields>
```

If the join field is not the first field in a file, the <*other file fields*> for that file shall be:

```
<fields preceding join field>, <fields following join field>
```

When the −**o** option is specified, the output format shall be:

```
"%s\n", <concatenation of fields>
```

where the concatenation of fields is described by the −**o** option, above.

For either format, each field (except the last) shall be written with its trailing separator character. If the separator is the default (<blank>s), a single <space> shall be written after each field (except the last).

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All input files were output successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Pathnames consisting of numeric digits or of the form *string.string* should not be specified directly following the −**o** list.

EXAMPLES

The −**o** 0 field essentially selects the union of the join fields. For example, given file **phone**:

```
!Name           Phone Number
Don             +1 123-456-7890
Hal             +1 234-567-8901
Yasushi         +2 345-678-9012
```

and file **fax**:

```
!Name           Fax Number
Don             +1 123-456-7899
Keith           +1 456-789-0122
Yasushi         +2 345-678-9011
```

(where the large expanses of white space are meant to each represent a single <tab>), the command:

```
join −t "<tab>" −a 1 −a 2 −e ’(unknown)’ −o 0,1.2,2.2 phone fax
```

would produce:

```
!Name           Phone Number            Fax Number
Don             +1 123-456-7890         +1 123-456-7899
Hal             +1 234-567-8901         (unknown)
Keith           (unknown)               +1 456-789-0122
Yasushi         +2 345-678-9012         +2 345-678-9011
```

Multiple instances of the same key will produce combinatorial results. The following:

```
fa:
    a x
    a y
    a z
fb:
    a p
```

will produce:

```
a x p
a y p
a z p
```

And the following:

```
fa:
    a b c
    a d e
fb:
    a w x
    a y z
    a o p
```

will produce:

```
a b c w x
a b c y z
a b c o p
a d e w x
a d e y z
a d e o p
```

RATIONALE

The −**e** option is only effective when used with −**o** because, unless specific fields are identified using −**o**, *join* is not aware of what fields might be empty. The exception to this is the join field, but identifying an empty join field with the −**e** string is not historical practice and some scripts might break if this were changed.

The 0 field in the −**o** list was adopted from the Tenth Edition version of *join* to satisfy international objections that the *join* in the base documents do not support the ‘‘full join’’ or ‘‘outer join’’ described in relational database literature. Although it has been possible to include a join field in the output (by default, or by field number using −**o**), the join field could not be included for an unpaired line selected by −**a**. The −**o** 0 field essentially selects the union of the join fields.

This sort of outer join was not possible with the *join* commands in the base documents. The −**o** 0 field was chosen because it is an upward-compatible change for applications. An alternative was considered: have the join field represent the union of the fields in the files (where they are identical for matched lines, and one or both are null for unmatched lines). This was not adopted because it would break some historical applications.

The ability to specify *file2* as – is not historical practice; it was added for completeness.

The –**v** option is not historical practice, but was considered necessary because it permitted the writing of *only* those lines that do not match on the join field, as opposed to the –**a** option, which prints both lines that do and do not match. This additional facility is parallel with the –**v** option of *grep*.

Some historical implementations have been encountered where a blank line in one of the input files was considered to be the end of the file; the description in this volume of IEEE Std 1003.1-200x does not cite this as an allowable case.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent –**j** options and the multi-argument –**o** option are withdrawn in this issue.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

kill — terminate or signal processes

SYNOPSIS

```
kill -s signal_name pid ...
kill -l [exit_status]
XSI kill [-signal_name] pid ...
kill [-signal_number] pid ...
```

DESCRIPTION

The *kill* utility shall send a signal to the process or processes specified by each *pid* operand.

For each *pid* operand, the *kill* utility shall perform actions equivalent to the *kill*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x called with the following arguments:

- The value of the *pid* operand shall be used as the *pid* argument.
- The *sig* argument is the value specified by the **–s** option, –*signal_number* option, or the –*signal_name* option, or by SIGTERM, if none of these options is specified.

OPTIONS

The *kill* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, XSI except that in the last two SYMOPSIS forms, the –*signal_number* and –*signal_name* options are usually more than a single character.

The following options shall be supported:

–l (The letter ell.) Write all values of *signal_name* supported by the implementation, if no operand is given. If an *exit_status* operand is given and it is a value of the `'?'` shell special parameter (see Section 2.5.2 (on page 2235) and *wait* (on page 3239)) corresponding to a process that was terminated by a signal, the *signal_name* corresponding to the signal that terminated the process shall be written. If an *exit_status* operand is given and it is the unsigned decimal integer value of a signal number, the *signal_name* (the symbolic constant name without the **SIG** prefix defined in the Base Definitions volume of IEEE Std 1003.1-200x) corresponding to that signal shall be written. Otherwise, the results are unspecified.

–s *signal_name*

Specify the signal to send, using one of the symbolic names defined in the **<signal.h>** header. Values of *signal_name* shall be recognized in a case-independent fashion, without the **SIG** prefix. In addition, the symbolic name 0 shall be recognized, representing the signal value zero. The corresponding signal shall be sent instead of SIGTERM.

XSI –*signal_name*

Equivalent to –**s** *signal_name*.

XSI –*signal_number*

Specify a non-negative decimal integer, *signal_number*, representing the signal to be used instead of SIGTERM, as the *sig* argument in the effective call to *kill*( ). The correspondence between integer values and the *sig* value used is shown in the following table.

The effects of specifying any *signal_number* other than those listed in the table are undefined.

signal_number	*sig* **Value**
0	0
1	SIGHUP
2	SIGINT
3	SIGQUIT
6	SIGABRT
9	SIGKILL
14	SIGALRM
15	SIGTERM

XSI

If the first argument is a negative integer, it shall be interpreted as a −*signal_number* option, not as a negative *pid* operand specifying a process group.

OPERANDS

The following operands shall be supported:

pid One of the following:

1. A decimal integer specifying a process or process group to be signaled. The process or processes selected by positive, negative and zero values of the *pid* operand shall be as described for the *kill*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x. If process number 0 is specified, all processes in the current process group shall be signaled. For the effects of negative *pid* numbers, see the *kill*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x. If the first *pid* operand is negative, it should be preceded by "−−" to keep it from being interpreted as an option.
2. A job control job ID (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.203, Job Control Job ID) that identifies a background process group to be signaled. The job control job ID notation is applicable only for invocations of *kill* in the current shell execution environment; see Section 2.12 (on page 2263).

exit_status A decimal integer specifying a signal number or the exit status of a process terminated by a signal.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *kill*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the **–l** option is not specified, the standard output shall not be used.

When the **–l** option is specified, the symbolic name of each signal shall be written in the following format:

```
"%s%c", <signal_name>, <separator>
```

where the <*signal_name*> is in uppercase, without the **SIG** prefix, and the <*separator*> shall be either a <newline> or a <space>. For the last signal written, <*separator*> shall be a <newline>.

When both the **–l** option and *exit_status* operand are specified, the symbolic name of the corresponding signal shall be written in the following format:

```
"%s\n", <signal_name>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	At least one matching process was found for each *pid* operand, and the specified signal was successfully processed for at least one matching process.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Process numbers can be found by using *ps*.

The job control job ID notation is not required to work as expected when *kill* is operating in its own utility execution environment. In either of the following examples:

```
nohup kill %1 &
system("kill %1");
```

the *kill* operates in a different environment and does not share the shell's understanding of job numbers.

EXAMPLES

Any of the commands:

```
kill –9 100 –165
kill –s kill 100 –165
kill –s KILL 100 –165
```

sends the SIGKILL signal to the process whose process ID is 100 and to all processes whose process group ID is 165, assuming the sending process has permission to send that signal to the specified processes, and that they exist.

The System Interfaces volume of IEEE Std 1003.1-200x and this volume of IEEE Std 1003.1-200x do not require specific signal numbers for any *signal_names*. Even the −*signal_number* option provides symbolic (although numeric) names for signals. If a process is terminated by a signal, its exit status indicates the signal that killed it, but the exact values are not specified. The *kill* −**l** option, however, can be used to map decimal signal numbers and exit status values into the name of a signal. The following example reports the status of a terminated job:

```
job
stat=$?
if [ $stat −eq 0 ]
then
    echo job completed successfully.
elif [ $stat −gt 128 ]
then
    echo job terminated by signal SIG$(kill −l $stat).
else
    echo job terminated with error code $stat.
fi
```

To send the default signal to a process group (say 123), an application should use a command similar to one of the following: |

```
kill −TERM −123
kill −− −123
```

RATIONALE

The −**l** option originated from the C shell, and is also implemented in the KornShell. The C shell output can consist of multiple output lines because the signal names do not always fit on a single line on some terminal screens. The KornShell output also included the implementation-defined signal numbers and was considered by the standard developers to be too difficult for scripts to parse conveniently. The specified output format is intended not only to accommodate the historical C shell output, but also to permit an entirely vertical or entirely horizontal listing on systems for which this is appropriate.

An early proposal invented the name SIGNULL as a *signal_name* for signal 0 (used by the System Interfaces volume of IEEE Std 1003.1-200x to test for the existence of a process without sending it a signal). Since the *signal_name* 0 can be used in this case unambiguously, SIGNULL has been removed.

An early proposal also required symbolic *signal_names* to be recognized with or without the **SIG** prefix. Historical versions of *kill* have not written the **SIG** prefix for the −**l** option and have not recognized the **SIG** prefix on *signal_names*. Since neither applications portability nor ease-of-use would be improved by requiring this extension, it is no longer required.

To avoid an ambiguity of an initial negative number argument specifying either a signal number or a process group, IEEE Std 1003.1-200x mandates that it is always considered the former by implementations that support the XSI option. It also requires that conforming applications always use the "−−" options terminator argument when specifying a process group, unless an option is also specified. |

The −**s** option was added in response to international interest in providing some form of *kill* that meets the Utility Syntax Guidelines. |

The job control job ID notation is not required to work as expected when *kill* is operating in its own utility execution environment. In either of the following examples:

```
nohup kill %1 &
system("kill %1");
```

the *kill* operates in a different environment and does not understand how the shell has managed its job numbers.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent versions of the SYNOPSIS were turned into non-obsolescent features of the XSI option, corresponding to a similar change in the *trap* special built-in.

NAME

lex — generate programs for lexical tasks (**DEVELOPMENT**)

SYNOPSIS

CD
```
lex [−t][−n|−v][file ...]
```

DESCRIPTION

The *lex* utility shall generate C programs to be used in lexical processing of character input, and that can be used as an interface to *yacc*. The C programs shall be generated from *lex* source code and conform to the ISO C standard. Usually, the *lex* utility shall write the program it generates to the file **lex.yy.c**; the state of this file is unspecified if *lex* exits with a non-zero exit status. See the EXTENDED DESCRIPTION section for a complete description of the *lex* input language.

OPTIONS

The *lex* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−n	Suppress the summary of statistics usually written with the **−v** option. If no table sizes are specified in the *lex* source code and the **−v** option is not specified, then **−n** is implied.
−t	Write the resulting program to standard output instead of **lex.yy.c**.
−v	Write a summary of *lex* statistics to the standard output. (See the discussion of *lex* table sizes in **Definitions in lex** (on page 2736).) If the **−t** option is specified and **−n** is not specified, this report shall be written to standard error. If table sizes are specified in the *lex* source code, and if the **−n** option is not specified, the **−v** option may be enabled.

OPERANDS

The following operand shall be supported:

file	A pathname of an input file. If more than one such *file* is specified, all files shall be concatenated to produce a single *lex* program. If no *file* operands are specified, or if a *file* operand is `'−'`, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, or if a *file* operand is `'−'`. See INPUT FILES.

INPUT FILES

The input files shall be text files containing *lex* source code, as described in the EXTENDED DESCRIPTION section.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *lex*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes and multi-

character collating elements within regular expressions. If this variable is not set to the POSIX locale, the results are unspecified.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), and the behavior of character classes within regular expressions. If this variable is not set to the POSIX locale, the results are unspecified.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the **–t** option is specified, the text file of C source code output of *lex* shall be written to standard output.

If the **–t** option is not specified:

- Implementation-defined informational, error, and warning messages concerning the contents of *lex* source code input shall be written to either the standard output or standard error.
- If the **–v** option is specified and the **–n** option is not specified, *lex* statistics shall also be written to either the standard output or standard error, in an implementation-defined format. These statistics may also be generated if table sizes are specified with a '%' operator in the *Definitions* section, as long as the **–n** option is not specified.

STDERR

If the **–t** option is specified, implementation-defined informational, error, and warning messages concerning the contents of *lex* source code input shall be written to the standard error.

If the **–t** option is not specified:

1. Implementation-defined informational, error, and warning messages concerning the contents of *lex* source code input shall be written to either the standard output or standard error.
2. If the **–v** option is specified and the **–n** option is not specified, *lex* statistics shall also be written to either the standard output or standard error, in an implementation-defined format. These statistics may also be generated if table sizes are specified with a '%' operator in the *Definitions* section, as long as the **–n** option is not specified.

OUTPUT FILES

A text file containing C source code shall be written to **lex.yy.c**, or to the standard output if the **–t** option is present.

EXTENDED DESCRIPTION

Each input file shall contain *lex* source code, which is a table of regular expressions with corresponding actions in the form of C program fragments. |

When **lex.yy.c** is compiled and linked with the *lex* library (using the **–l l** operand with *c99*), the resulting program shall read character input from the standard input and shall partition it into strings that match the given expressions. |

When an expression is matched, these actions shall occur:

- The input string that was matched shall be left in *yytext* as a null-terminated string; *yytext* shall either be an external character array or a pointer to a character string. As explained in **Definitions in lex**, the type can be explicitly selected using the **%array** or **%pointer** declarations, but the default is implementation-defined.
- The external **int** *yyleng* shall be set to the length of the matching string.
- The expression's corresponding program fragment, or action, shall be executed.

During pattern matching, *lex* shall search the set of patterns for the single longest possible match. Among rules that match the same number of characters, the rule given first shall be chosen.

The general format of *lex* source shall be:

Definitions
%%
Rules
%%
*User*Subroutines

The first `"%%"` is required to mark the beginning of the rules (regular expressions and actions); the second `"%%"` is required only if user subroutines follow.

Any line in the *Definitions* section beginning with a <blank> shall be assumed to be a C program fragment and shall be copied to the external definition area of the **lex.yy.c** file. Similarly, anything in the *Definitions* section included between delimiter lines containing only `"%{"` and `"%}"` shall also be copied unchanged to the external definition area of the **lex.yy.c** file.

Any such input (beginning with a <blank> or within `"%{"` and `"%}"` delimiter lines) appearing at the beginning of the *Rules* section before any rules are specified shall be written to **lex.yy.c** after the declarations of variables for the *yylex*( ) function and before the first line of code in *yylex*( ). Thus, user variables local to *yylex*( ) can be declared here, as well as application code to execute upon entry to *yylex*( ).

The action taken by *lex* when encountering any input beginning with a <blank> or within `"%{"` and `"%}"` delimiter lines appearing in the *Rules* section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the *yylex*( ) function.

Definitions in lex

Definitions appear before the first `"%%"` delimiter. Any line in this section not contained between `"%{"` and `"%}"` lines and not beginning with a <blank> shall be assumed to define a *lex* substitution string. The format of these lines shall be:

```
name substitute
```

If a *name* does not meet the requirements for identifiers in the ISO C standard, the result is undefined. The string *substitute* shall replace the string {*name*} when it is used in a rule. The *name* string shall be recognized in this context only when the braces are provided and when it does not appear within a bracket expression or within double-quotes.

In the *Definitions* section, any line beginning with a `'%'` (percent sign) character and followed by an alphanumeric word beginning with either `'s'` or `'S'` shall define a set of start conditions. Any line beginning with a `'%'` followed by a word beginning with either `'x'` or `'X'` shall define a set of exclusive start conditions. When the generated scanner is in a `"%s"` state, patterns with no state specified shall be also active; in a "%x" state, such patterns shall not be active. The rest of the line, after the first word, shall be considered to be one or more <blank>-separated names of start conditions. Start condition names shall be constructed in the same way as definition names. Start conditions can be used to restrict the matching of regular expressions to one or more states as described in **Regular Expressions in lex** (on page 2738).

Implementations shall accept either of the following two mutually exclusive declarations in the *Definitions* section:

%array Declare the type of *yytext* to be a null-terminated character array.

%pointer Declare the type of *yytext* to be a pointer to a null-terminated character string.

The default type of *yytext* is implementation-defined. If an application refers to *yytext* outside of the scanner source file (that is, via an **extern**), the application shall include the appropriate **%array** or **%pointer** declaration in the scanner source file.

Implementations shall accept declarations in the *Definitions* section for setting certain internal table sizes. The declarations are shown in the following table.

Table 4-9 Table Size Declarations in *lex*

Declaration	Description	Minimum Value
%**p** *n*	Number of positions	2 500
%**n** *n*	Number of states	500
%**a** *n*	Number of transitions	2 000
%**e** *n*	Number of parse tree nodes	1 000
%**k** *n*	Number of packed character classes	1 000
%**o** *n*	Size of the output array	3 000

In the table, *n* represents a positive decimal integer, preceded by one or more <blank>s. The exact meaning of these table size numbers is implementation-defined. The implementation shall document how these numbers affect the *lex* utility and how they are related to any output that may be generated by the implementation should limitations be encountered during the execution of *lex*. It shall be possible to determine from this output which of the table size values needs to be modified to permit *lex* to successfully generate tables for the input language. The values in the column Minimum Value represent the lowest values conforming implementations shall provide.

Rules in lex

The rules in *lex* source files are a table in which the left column contains regular expressions and the right column contains actions (C program fragments) to be executed when the expressions are recognized.

```
ERE action
ERE action
...
```

The extended regular expression (*ERE*) portion of a row shall be separated from *action* by one or more <blank>s. A regular expression containing <blank>s shall be recognized under one of the following conditions:

- The entire expression appears within double-quotes.
- The <blank>s appear within double-quotes or square brackets.

- Each <blank> is preceded by a backslash character.

User Subroutines in lex

Anything in the user subroutines section shall be copied to **lex.yy.c** following *yylex*( ).

Regular Expressions in lex

The *lex* utility shall support the set of extended regular expressions (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4, Extended Regular Expressions), with the following additions and exceptions to the syntax:

`"..."` Any string enclosed in double-quotes shall represent the characters within the double-quotes as themselves, except that backslash escapes (which appear in the following table) shall be recognized. Any backslash-escape sequence shall be terminated by the closing quote. For example, `"\01""1"` represents a single string: the octal value 1 followed by the character `'1'`.

<*state*>*r*, <*state1*,*state2*,. . .>*r*

The regular expression *r* shall be matched only when the program is in one of the start conditions indicated by *state*, *state1*, and so on; see **Actions in lex** (on page 2740). (As an exception to the typographical conventions of the rest of this volume of IEEE Std 1003.1-200x, in this case <*state*> does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol.) The start condition shall be recognized as such only at the beginning of a regular expression.

r/*x* The regular expression *r* shall be matched only if it is followed by an occurrence of regular expression *x* (*x* is the instance of trailing context, further defined below). The token returned in *yytext* shall only match *r*. If the trailing portion of *r* matches the beginning of *x*, the result is unspecified. The *r* expression cannot include further trailing context or the `'$'` (match-end-of-line) operator; *x* cannot include the `'^'` (match-beginning-of-line) operator, nor trailing context, nor the `'$'` operator. That is, only one occurrence of trailing context is allowed in a *lex* regular expression, and the `'^'` operator only can be used at the beginning of such an expression.

{*name*} When *name* is one of the substitution symbols from the *Definitions* section, the string, including the enclosing braces, shall be replaced by the *substitute* value. The *substitute* value shall be treated in the extended regular expression as if it were enclosed in parentheses. No substitution shall occur if {*name*} occurs within a bracket expression or within double-quotes.

Within an ERE, a backslash character shall be considered to begin an escape sequence as specified in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). In addition, the escape sequences in the following table shall be recognized.

A literal <newline> cannot occur within an ERE; the escape sequence `'\n'` can be used to represent a <newline>. A <newline> shall not be matched by a period operator.

Table 4-10 Escape Sequences in *lex*

Escape Sequence	Description	Meaning
`\digits`	A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the one, two, or three-digit octal integer. If the size of a byte on the system is greater than nine bits, the valid escape sequence used to represent a byte is implementation-defined. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading `'\'` for each byte.
`\xdigits`	A backslash character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the hexadecimal integer.
`\c`	A backslash character followed by any character not described in this table or in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`).	The character `'c'`, unchanged.

Note: If a `'\x'` sequence needs to be immediately followed by a hexadecimal digit character, a sequence such as `"\x1""1"` can be used, which represents a character containing the value 1, followed by the character `'1'`.

The order of precedence given to extended regular expressions for *lex* differs from that specified in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4, Extended Regular Expressions. The order of precedence for *lex* shall be as shown in the following table, from high to low.

Note: The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true operators. The start condition, trailing context, and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

Table 4-11 ERE Precedence in *lex*

Extended Regular Expression	Precedence
collation-related bracket symbols	`[= =]  [: :]  [. .]`
escaped characters	`\<`*special character*`>`
bracket expression	`[ ]`
quoting	`"..."`
grouping	`( )`
definition	`{`*name*`}`
single-character RE duplication	`* + ?`
concatenation	
interval expression	`{m,n}`
alternation	`|`

The ERE anchoring operators `'^'` and `'$'`) do not appear in the table. With *lex* regular expressions, these operators are restricted in their use: the `'^'` operator can only be used at the beginning of an entire regular expression, and the `'$'` operator only at the end. The operators apply to the entire regular expression. Thus, for example, the pattern `"(^abc)|(def$)"` is undefined; it can instead be written as two separate rules, one with the regular expression `"^abc"` and one with `"def$"`, which share a common action via the special `'|'` action (see below). If the pattern were written `"^abc|def$"`, it would match either `"abc"` or `"def"` on a line by itself.

Unlike the general ERE rules, embedded anchoring is not allowed by most historical *lex* implementations. An example of embedded anchoring would be for patterns such as `"(^| )foo( |$)"` to match `"foo"` when it exists as a complete word. This functionality can be obtained using existing *lex* features:

```
^foo/[ \n]      |
" foo"/[ \n]    /* Found foo as a separate word. */
```

Note also that `'$'` is a form of trailing context (it is equivalent to `"/\n"`) and as such cannot be used with regular expressions containing another instance of the operator (see the preceding discussion of trailing context).

The additional regular expressions trailing-context operator `'/'` can be used as an ordinary character if presented within double-quotes, `"/"`; preceded by a backslash, `"\/"`; or within a bracket expression, `"[/]"`. The start-condition `'<'` and `'>'` operators shall be special only in a start condition at the beginning of a regular expression; elsewhere in the regular expression they shall be treated as ordinary characters.

Actions in lex

The action to be taken when an ERE is matched can be a C program fragment or the special actions described below; the program fragment can contain one or more C statements, and can also include special actions. The empty C statement `';'` shall be a valid action; any string in the **lex.yy.c** input that matches the pattern portion of such a rule is effectively ignored or skipped. However, the absence of an action shall not be valid, and the action *lex* takes in such a condition is undefined.

The specification for an action, including C statements and special actions, can extend across several lines if enclosed in braces:

```
ERE <one or more blanks> { program statement
                           program statement }
```

The default action when a string in the input to a **lex.yy.c** program is not matched by any expression shall be to copy the string to the output. Because the default behavior of a program generated by *lex* is to read the input and copy it to the output, a minimal *lex* source program that has just `"%%"` shall generate a C program that simply copies the input to the output unchanged.

Four special actions shall be available:

`|    ECHO;    REJECT;    BEGIN`

`|` The action `'|'` means that the action for the next rule is the action for this rule. Unlike the other three actions, `'|'` cannot be enclosed in braces or be semicolon-terminated; the application shall ensure that it is specified alone, with no other actions.

ECHO; Write the contents of the string *yytext* on the output.

REJECT; Usually only a single expression is matched by a given string in the input. **REJECT** means "continue to the next expression that matches the current input", and shall cause whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions `"xyz"` and `"xy"` and the input `"xyz"`, usually only the regular expression `"xyz"` would match. The next attempted match would start after **z.** If the last action in the `"xyz"` rule is **REJECT**, both this rule and the `"xy"` rule would be executed. The **REJECT** action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a **goto** to another part of *yylex*( ). The use of **REJECT** may result in somewhat larger and slower scanners.

BEGIN The action:

```
BEGIN newstate;
```

switches the state (start condition) to *newstate*. If the string *newstate* has not been declared previously as a start condition in the *Definitions* section, the results are unspecified. The initial state is indicated by the digit `'0'` or the token **INITIAL**.

The functions or macros described below are accessible to user code included in the *lex* input. It is unspecified whether they appear in the C code output of *lex*, or are accessible only through the **–l l** operand to *c99* (the *lex* library).

int *yylex*(**void**)
Performs lexical analysis on the input; this is the primary function generated by the *lex* utility. The function shall return zero when the end of input is reached; otherwise, it shall return non-zero values (tokens) determined by the actions that are selected.

int *yymore*(**void**)
When called, indicates that when the next input string is recognized, it is to be appended to the current value of *yytext* rather than replacing it; the value in *yyleng* shall be adjusted accordingly.

int *yyless*(**int** *n*)
Retains *n* initial characters in *yytext*, NUL-terminated, and treats the remaining characters as if they had not been read; the value in *yyleng* shall be adjusted accordingly.

int *input*(**void**)
Returns the next character from the input, or zero on end-of-file. It shall obtain input from the stream pointer *yyin*, although possibly via an intermediate buffer. Thus, once scanning has begun, the effect of altering the value of *yyin* is undefined. The character read shall be removed from the input stream of the scanner without any processing by the scanner.

int *unput*(**int** *c*)

Returns the character `'c'` to the input; *yytext* and *yyleng* are undefined until the next expression is matched. The result of using *unput*( ) for more characters than have been input is unspecified.

The following functions shall appear only in the *lex* library accessible through the **–l l** operand; they can therefore be redefined by a conforming application:

int *yywrap*(**void**)

Called by *yylex*( ) at end-of-file; the default *yywrap*( ) shall always return 1. If the application requires *yylex*( ) to continue processing with another source of input, then the application can include a function *yywrap*( ), which associates another file with the external variable **FILE *** *yyin* and shall return a value of zero.

int *main*(**int** *argc*, **char** **argv*[ ])

Calls *yylex*( ) to perform lexical analysis, then exits. The user code can contain *main*( ) to perform application-specific operations, calling *yylex*( ) as applicable.

Except for *input*( ), *unput*( ), and *main*( ), all external and static names generated by *lex* shall begin with the prefix **yy** or **YY**.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Conforming applications are warned that in the *Rules* section, an *ERE* without an action is not acceptable, but need not be detected as erroneous by *lex*. This may result in compilation or runtime errors.

The purpose of *input*( ) is to take characters off the input stream and discard them as far as the lexical analysis is concerned. A common use is to discard the body of a comment once the beginning of a comment is recognized.

The *lex* utility is not fully internationalized in its treatment of regular expressions in the *lex* source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer interpret the regular expressions given in the *lex* source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current *lex* technology. Furthermore, the very nature of the lexical analyzers produced by *lex* must be closely tied to the lexical requirements of the input language being described, which is frequently locale-specific anyway. (For example, writing an analyzer that is used for French text is not automatically useful for processing other languages.)

EXAMPLES

The following is an example of a *lex* program that implements a rudimentary scanner for a Pascal-like syntax:

```
%{
/* Need this for the call to atof() below. */
#include <math.h>
/* Need this for printf(), fopen(), and stdin below. */
#include <stdio.h>
%}
```

```
DIGIT    [0-9]
ID       [a-z][a-z0-9]*

%%

{DIGIT}+ {
    printf("An integer: %s (%d)\n", yytext,
        atoi(yytext));
    }

{DIGIT}+"."{DIGIT}*        {
    printf("A float: %s (%g)\n", yytext,
        atof(yytext));
    }

if|then|begin|end|procedure|function        {
    printf("A keyword: %s\n", yytext);
    }

{ID}    printf("An identifier: %s\n", yytext);

"+"|"-"|"*"|"/"        printf("An operator: %s\n", yytext);

"{"[^}\n]*"}"    /* Eat up one-line comments. */

[ \t\n]+        /* Eat up white space. */

.  printf("Unrecognized character: %s\n", yytext);

%%

int main(int argc, char *argv[])
{
    ++argv, --argc;  /* Skip over program name. */
    if (argc > 0)
        yyin = fopen(argv[0], "r");
    else
        yyin = stdin;

    yylex();
}
```

RATIONALE

Even though the **−c** option and references to the C language are retained in this description, *lex* may be generalized to other languages, as was done at one time for EFL, the Extended FORTRAN Language. Since the *lex* input specification is essentially language-independent, versions of this utility could be written to produce Ada, Modula-2, or Pascal code, and there are known historical implementations that do so.

The current description of *lex* bypasses the issue of dealing with internationalized EREs in the *lex* source code or generated lexical analyzer. If it follows the model used by *awk* (the source code is assumed to be presented in the POSIX locale, but input and output are in the locale specified by the environment variables), then the tables in the lexical analyzer produced by *lex* would interpret EREs specified in the *lex* source in terms of the environment variables specified when *lex* was executed. The desired effect would be to have the lexical analyzer interpret the EREs given in the *lex* source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current *lex* technology.

The description of octal and hexadecimal-digit escape sequences agrees with the ISO C standard use of escape sequences. See the RATIONALE for *ed* (on page 2537) for a discussion of bytes larger than 9 bits being represented by octal values. Hexadecimal values can represent larger bytes and multi-byte characters directly, using as many digits as required.

There is no detailed output format specification. The observed behavior of *lex* under four different historical implementations was that none of these implementations consistently reported the line numbers for error and warning messages. Furthermore, there was a desire that *lex* be allowed to output additional diagnostic messages. Leaving message formats unspecified avoids these formatting questions and problems with internationalization.

Although the `%x` specifier for *exclusive* start conditions is not historical practice, it is believed to be a minor change to historical implementations and greatly enhances the usability of *lex* programs since it permits an application to obtain the expected functionality with fewer statements.

The **%array** and **%pointer** declarations were added as a compromise between historical systems. The System V-based *lex* copies the matched text to a *yytext* array. The *flex* program, supported in BSD and GNU systems, uses a pointer. In the latter case, significant performance improvements are available for some scanners. Most historical programs should require no change in porting from one system to another because the string being referenced is null-terminated in both cases. (The method used by *flex* in its case is to null-terminate the token in place by remembering the character that used to come right after the token and replacing it before continuing on to the next scan.) Multi-file programs with external references to *yytext* outside the scanner source file should continue to operate on their historical systems, but would require one of the new declarations to be considered strictly portable.

The description of EREs avoids unnecessary duplication of ERE details because their meanings within a *lex* ERE are the same as that for the ERE in this volume of IEEE Std 1003.1-200x.

The reason for the undefined condition associated with text beginning with a <blank> or within `"%{"` and `"%}"` delimiter lines appearing in the *Rules* section is historical practice. Both the BSD and System V *lex* copy the indented (or enclosed) input in the *Rules* section (except at the beginning) to unreachable areas of the *yylex*( ) function (the code is written directly after a *break* statement). In some cases, the System V *lex* generates an error message or a syntax error, depending on the form of indented input.

The intention in breaking the list of functions into those that may appear in **lex.yy.c** *versus* those that only appear in **libl.a** is that only those functions in **libl.a** can be reliably redefined by a conforming application.

The descriptions of standard output and standard error are somewhat complicated because historical *lex* implementations chose to issue diagnostic messages to standard output (unless **–t** was given). This standard allows this behavior, but leaves an opening for the more expected behavior of using standard error for diagnostics. Also, the System V behavior of writing the statistics when any table sizes are given is allowed, while BSD-derived systems can avoid it. The programmer can always precisely obtain the desired results by using either the **–t** or **–n** options.

The OPERANDS section does not mention the use of – as a synonym for standard input; not all historical implementations support such usage for any of the *file* operands.

A description of the *translation table* was deleted from early proposals because of its relatively low usage in historical applications.

The change to the definition of the *input*( ) function that allows buffering of input presents the opportunity for major performance gains in some applications.

The following examples clarify the differences between *lex* regular expressions and regular expressions appearing elsewhere in this volume of IEEE Std 1003.1-200x. For regular expressions of the form `"r/x"`, the string matching *r* is always returned; confusion may arise when the beginning of *x* matches the trailing portion of *r*. For example, given the regular expression `"a*b/cc"` and the input `"aaabcc"`, *yytext* would contain the string `"aaab"` on this match. But given the regular expression `"x*/xy"` and the input `"xxxy"`, the token **xxx**, not **xx**, is returned by some implementations because **xxx** matches `"x*"`.

In the rule `"ab*/bc"`, the `"b*"` at the end of *r* extends *r*'s match into the beginning of the trailing context, so the result is unspecified. If this rule were `"ab/bc"`, however, the rule matches the text `"ab"` when it is followed by the text `"bc"`. In this latter case, the matching of *r* cannot extend into the beginning of *x*, so the result is specified.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the C-Language Development Utilities option.

The obsolescent –**c** option is withdrawn in this issue.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

link — call *link*( ) function

SYNOPSIS

XSI
```
link file1 file2
```

DESCRIPTION

The *link* utility shall perform the function call:

```
link(file1, file2);
```

A user may need appropriate privilege to invoke the *link* utility.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

file1	The pathname of an existing file.
file2	The pathname of the new directory entry to be created.

STDIN

Not used.

INPUT FILES

Not used.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *link*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

ln, *unlink*, the System Interfaces volume of IEEE Std 1003.1-200x, *link*( )

CHANGE HISTORY

First released in Issue 5.

NAME

ln — link files

SYNOPSIS

```
ln [−fs] source_file target_file

ln [−fs] source_file ... target_dir
```

DESCRIPTION

In the first synopsis form, the *ln* utility shall create a new directory entry (link) at the destination path specified by the *target_file* operand. If the **−s** option is specified, a symbolic link shall be created for the file specified by the *source_file* operand. This first synopsis form shall be assumed when the final operand does not name an existing directory; if more than two operands are specified and the final is not an existing directory, an error shall result.

In the second synopsis form, the *ln* utility shall create a new directory entry (link), or if the **−s** option is specified a symbolic link, for each file specified by a *source_file* operand, at a *destination* path in the existing directory named by *target_dir*.

If the last operand specifies an existing file of a type not specified by the System Interfaces volume of IEEE Std 1003.1-200x, the behavior is implementation-defined.

The corresponding *destination* path for each *source_file* shall be the concatenation of the target directory pathname, a slash character, and the last pathname component of the *source_file*. The second synopsis form shall be assumed when the final operand names an existing directory.

For each *source_file*:

1. If the *destination* path exists:
   a. If the **−f** option is not specified, *ln* shall write a diagnostic message to standard error, do nothing more with the current *source_file*, and go on to any remaining *source_files*.
   b. Actions shall be performed equivalent to the *unlink*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called using *destination* as the *path* argument. If this fails for any reason, *ln* shall write a diagnostic message to standard error, do nothing more with the current *source_file*, and go on to any remaining *source_files*.
2. If the **−s** option is specified, *ln* shall create a symbolic link named by the *destination* path and containing as its pathname *source_file*. The *ln* utility shall do nothing more with *source_file* and shall go on to any remaining files.
3. If *source_file* is a symbolic link, actions shall be performed equivalent to the *link*( ) function using the object that *source_file* references as the *path1* argument and the destination path as the *path2* argument. The *ln* utility shall do nothing more with *source_file* and shall go on to any remaining files.
4. Actions shall be performed equivalent to the *link*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x using *source_file* as the *path1* argument, and the *destination* path as the *path2* argument.

OPTIONS

The *ln* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−f	Force existing *destination* pathnames to be removed to allow the link.

−s	Create symbolic links instead of hard links.

OPERANDS

The following operands shall be supported:

source_file	A pathname of a file to be linked. If the **−s** option is specified, no restrictions on the type of file or on its existence shall be made. If the **−s** option is not specified, whether a directory can be linked is implementation-defined.
target_file	The pathname of the new directory entry to be created.
target_dir	A pathname of an existing directory in which the new directory entries are created.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ln*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All the specified files were linked successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

Some historic versions of *ln* (including the one specified by the SVID, unlink the destination file, if it exists, by default. If the mode does not permit writing, these versions prompt for confirmation before attempting the unlink. In these versions the −**f** option causes *ln* not to attempt to prompt for confirmation.

This allows *ln* to succeed in creating links when the target file already exists, even if the file itself is not writable (although the directory must be). Early proposals specified this functionality.

This volume of IEEE Std 1003.1-200x does not allow the *ln* utility to unlink existing destination paths by default for the following reasons:

- The *ln* utility has historically been used to provide locking for shell applications, a usage that is incompatible with *ln* unlinking the destination path by default. There was no corresponding technical advantage to adding this functionality.
- This functionality gave *ln* the ability to destroy the link structure of files, which changes the historical behavior of *ln*.
- This functionality is easily replicated with a combination of *rm* and *ln*.
- It is not historical practice in many systems; BSD and BSD-derived systems do not support this behavior. Unfortunately, whichever behavior is selected can cause scripts written expecting the other behavior to fail.
- It is preferable that *ln* perform in the same manner as the *link*( ) function, which does not permit the target to exist already.

This volume of IEEE Std 1003.1-200x retains the −**f** option to provide support for shell scripts depending on the SVID semantics. It seems likely that shell scripts would not be written to handle prompting by *ln* and would therefore have specified the −**f** option.

The −**f** option is an undocumented feature of many historical versions of the *ln* utility, allowing linking to directories. These versions require modification.

Early proposals of this volume of IEEE Std 1003.1-200x also required an −**i** option, which behaved like the −**i** options in *cp* and *mv*, prompting for confirmation before unlinking existing files. This was not historical practice for the *ln* utility and has been omitted.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The *ln* utility is updated to include symbolic link processing as defined in the IEEE P1003.2b draft standard.

NAME

locale — get locale-specific information

SYNOPSIS

```
locale [−a| −m]

locale [−ck] name...
```

DESCRIPTION

The *locale* utility shall write information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a *public locale* is one provided by the implementation that is accessible to the application.

When *locale* is invoked without any arguments, it shall summarize the current locale environment for each locale category as determined by the settings of the environment variables defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale.

When invoked with operands, it shall write values that have been assigned to the keywords in the locale categories, as follows:

- Specifying a keyword name shall select the named keyword and the category containing that keyword.
- Specifying a category name shall select the named category and all keywords in that category.

OPTIONS

The *locale* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−a	Write information about all available public locales. The available locales shall include **POSIX**, representing the POSIX locale. The manner in which the implementation determines what other locales are available is implementation-defined.
−c	Write the names of selected locale categories; see the STDOUT section. The **−c** option increases readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the **−k** option.
−k	Write the names and values of selected keywords. The implementation may omit values for some keywords; see the OPERANDS section.
−m	Write names of available charmaps; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set.

OPERANDS

The following operand shall be supported:

name	The name of a locale category as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale, the name of a keyword in a locale category, or the reserved name **charmap**. The named category or keyword shall be selected for output. If a single *name* represents both a locale category name and a keyword name in the current locale, the results are unspecified. Otherwise, both category and keyword names can be specified as *name* operands, in any sequence. It is implementation-defined whether any keyword values are written for the categories *LC_CTYPE* and *LC_COLLATE*.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *locale*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

XSI The application shall ensure that the *LANG*, *LC_**, and *NLSPATH* environment variables specify the current locale environment to be written out; they shall be used if the −**a** option is not specified.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If *locale* is invoked without any options or operands, the names and values of the *LANG* and *LC_** environment variables described in this volume of IEEE Std 1003.1-200x shall be written to the standard output, one variable per line, with *LANG* first, and each line using the following format. Only those variables set in the environment and not overridden by *LC_ALL* shall be written using this format:

```
"%s=%s\n", <variable_name>, <value>
```

The names of those *LC_** variables associated with locale categories defined in this volume of IEEE Std 1003.1-200x that are not set in the environment or are overridden by *LC_ALL* shall be written in the following format:

```
"%s=\""%s\""\n", <variable_name>, <implied value>
```

The <*implied value*> shall be the name of the locale that has been selected for that category by the implementation, based on the values in *LANG* and *LC_ALL*, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

The <*value*> and <*implied value*> shown above shall be properly quoted for possible later reentry to the shell. The <*value*> shall not be quoted using double-quotes (so that it can be distinguished by the user from the <*implied value*> case, which always requires double-quotes).

The *LC_ALL* variable shall be written last, using the first format shown above. If it is not set, it shall be written as:

```
"LC_ALL=\n"
```

If any arguments are specified:

1. If the −**a** option is specified, the names of all the public locales shall be written, each in the following format:

   `"%s\n", <locale name>`

2. If the −**c** option is specified, the names of all selected categories shall be written, each in the following format:

   `"%s\n", <category name>`

   If keywords are also selected for writing (see following items), the category name output shall precede the keyword output for that category.

   If the −**c** option is not specified, the names of the categories shall not be written; only the keywords, as selected by the <*name*> operand, shall be written.

3. If the −**k** option is specified, the names and values of selected keywords shall be written. If a value is non-numeric, it shall be written in the following format:

   `"%s=\"%s\"\n", <keyword name>, <keyword value>`

   If the keyword was **charmap**, the name of the charmap (if any) that was specified via the *localedef* −**f** option when the locale was created shall be written, with the word **charmap** as <*keyword name*>.

   If a value is numeric, it shall be written in one of the following formats:

   `"%s=%d\n", <keyword name>, <keyword value>`

   `"%s=%c%o\n", <keyword name>, <escape character>, <keyword value>`

   `"%s=%cx%x\n", <keyword name>, <escape character>, <keyword value>`

   where the <*escape character*> is that identified by the **escape_char** keyword in the current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3, Locale Definition.

   Compound keyword values (list entries) shall be separated in the output by semicolons. When included in keyword values, the semicolon, the double-quote, the backslash, and any control character shall be preceded (escaped) with the escape character.

4. If the −**k** option is not specified, selected keyword values shall be written, each in the following format:

   `"%s\n", <keyword value>`

   If the keyword was **charmap**, the name of the charmap (if any) that was specified via the *localedef* −**f** option when the locale was created shall be written.

5. If the −**m** option is specified, then a list of all available charmaps shall be written, each in the format:

   `"%s\n", <charmap>`

   where <*charmap*> is in a format suitable for use as the option-argument to the *localedef* −**f** option.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All the requested information was found and output successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If the *LANG* environment variable is not set or set to an empty value, or one of the *LC_** environment variables is set to an unrecognized value, the actual locales assumed (if any) are implementation-defined as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

Implementations are not required to write out the actual values for keywords in the categories *LC_CTYPE* and *LC_COLLATE*; however, they must write out the categories (allowing an application to determine, for example, which character classes are available).

EXAMPLES

In the following examples, the assumption is that locale environment variables are set as follows:

```
LANG=locale_x
LC_COLLATE=locale_y
```

The command *locale* would result in the following output:

```
LANG=locale_x
LC_CTYPE="locale_x"
LC_COLLATE=locale_y
LC_TIME="locale_x"
LC_NUMERIC="locale_x"
LC_MONETARY="locale_x"
LC_MESSAGES="locale_x"
LC_ALL=
```

The order of presentation of the categories is not specified by this volume of IEEE Std 1003.1-200x.

The command:

```
LC_ALL=POSIX locale −ck decimal_point
```

would produce:

```
LC_NUMERIC
decimal_point="."
```

The following command shows an application of *locale* to determine whether a user-supplied response is affirmative:

```
if printf "%s\n" "$response" | grep –Eq "$(locale yesexpr)"
then
    affirmative processing goes here
else
    non-affirmative processing goes here
fi
```

RATIONALE

The output for categories *LC_CTYPE* and *LC_COLLATE* has been made implementation-defined because there is a questionable value in having a shell script receive an entire array of characters. It is also difficult to return a logical collation description, short of returning a complete *localedef* source.

The –**m** option was included to allow applications to query for the existence of charmaps. The output is a list of the charmaps (implementation-supplied and user-supplied, if any) on the system.

The –**c** option was included for readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the –**k** option.

The **charmap** keyword, which returns the name of the charmap (if any) that was used when the current locale was created, was included to allow applications needing the information to retrieve it.

NAME

localedef — define locale environment

SYNOPSIS

`localedef [−c][−f charmap][−i sourcefile][−u code_set_name] name`

DESCRIPTION

The *localedef* utility shall convert source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale. It is implementation-defined whether users have the capability to create new locales, in addition to those supplied by the implementation. If the symbolic constant POSIX2_LOCALEDEF is defined, the system supports the creation of new locales. XSI On XSI-conformant systems, the symbolic constant POSIX2_LOCALEDEF shall be defined.

The utility shall read source definitions for one or more locale categories belonging to the same locale from the file named in the **−i** option (if specified) or from standard input.

The *name* operand identifies the target locale. The utility shall support the creation of *public*, or generally accessible locales, as well as *private*, or restricted-access locales. Implementations may restrict the capability to create or modify public locales to users with the appropriate privileges.

Each category source definition shall be identified by the corresponding environment variable name and terminated by an **END** *category-name* statement. The following categories shall be supported. In addition, the input may contain source for implementation-defined categories.

LC_CTYPE	Defines character classification and case conversion.
LC_COLLATE	Defines collation rules.
LC_MONETARY	Defines the format and symbols used in formatting of monetary information.
LC_NUMERIC	Defines the decimal delimiter, grouping, and grouping symbol for non-monetary numeric editing.
LC_TIME	Defines the format and content of date and time information.
LC_MESSAGES	Defines the format and values of affirmative and negative responses.

OPTIONS

The *localedef* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c	Create permanent output even if warning messages have been issued.
−f *charmap*	Specify the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. The format of the *charmap* is described under the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.4, Character Set Description File. The application shall ensure that this option is specified if symbolic names (other than collating symbols defined in a **collating-symbol** keyword) are used. If the **−f** option is not present, an implementation-defined character mapping shall be used.

–i *inputfile* The pathname of a file containing the source definitions. If this option is not present, source definitions shall be read from standard input. The format of the *inputfile* is described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3, Locale Definition.

–u *code_set_name*
Specify the name of a codeset used as the target mapping of character symbols and collating element symbols whose encoding values are defined in terms of the ISO / IEC 10646-1: 2000 standard position constant values.

OPERANDS

The following operand shall be supported:

name Identifies the locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale for a description of the use of this name. If the name contains one or more slash characters, *name* shall be interpreted as a pathname where the created locale definitions shall be stored. If *name* does not contain any slash characters, the interpretation of the name is implementation-defined and the locale shall be public. This capability may be restricted to users with appropriate privileges. (As a consequence of specifying one *name*, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)

STDIN

Unless the **–i** option is specified, the standard input shall be a text file containing one or more locale category source definitions, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3, Locale Definition. When lines are continued using the escape character mechanism, there is no limit to the length of the accumulated continued line.

INPUT FILES

The character set mapping file specified as the *charmap* option-argument is described under the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.4, Character Set Description File. If a locale category source definition contains a **copy** statement, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale, and the **copy** statement names a valid, existing locale, then *localedef* shall behave as if the source definition had contained a valid category source definition for the named locale.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *localedef*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
(This variable has no affect on *localedef*; the POSIX locale is used for this category.)

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). This variable has no affect on the processing of *localedef* input data; the POSIX locale is used for this purpose, regardless of the value of this variable.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The utility shall report all categories successfully processed, in an unspecified format.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The format of the created output is unspecified. If the *name* operand does not contain a slash, the existence of an output file for the locale is unspecified.

EXTENDED DESCRIPTION

When the **–u** option is used, the *code_set_name* option-argument shall be interpreted as an implementation-defined name of a codeset to which the ISO/IEC 10646-1:2000 standard position constant values shall be converted via an implementation-defined method. Both the ISO/IEC 10646-1:2000 standard position constant values and other formats (decimal, hexadecimal, or octal) shall be valid as encoding values within the *charmap* file. The codeset represented by the implementation-defined name can be any codeset that is supported by the implementation.

When conflicts occur between the *charmap* specification of <*code_set_name*>, <*mb_cur_max*>, or <*mb_cur_min*> and the implementation-defined interpretation of these respective items for the codeset represented by the **–u** option-argument *code_set_name*, the result is unspecified.

When conflicts occur between the *charmap* encoding values specified for symbolic names of characters of the portable character set and the implementation-defined assignment of character encoding values, the result is unspecified.

If a non-printable character in the *charmap* has a width specified that is not **–1**, *localedef* shall generate a warning.

EXIT STATUS

The following exit values shall be returned:

0	No errors occurred and the locales were successfully created.
1	Warnings occurred and the locales were successfully created.
2	The locale specification exceeded implementation limits or the coded character set or sets used were not supported by the implementation, and no locale was created.
3	The capability to create new locales is not supported by the implementation.
>3	Warnings or errors occurred and no output was created.

CONSEQUENCES OF ERRORS

If an error is detected, no permanent output shall be created.

If warnings occur, permanent output shall be created if the **–c** option was specified. The following conditions shall cause warning messages to be issued:

- If a symbolic name not found in the *charmap* file is used for the descriptions of the *LC_CTYPE* or *LC_COLLATE* categories (for other categories, this shall be an error condition).

- If the number of operands to the **order** keyword exceeds the {COLL_WEIGHTS_MAX} limit.
- If optional keywords not supported by the implementation are present in the source.
- If a non-printable character has a width specified other than −1.

Other implementation-defined conditions may also cause warnings.

APPLICATION USAGE

The *charmap* definition is optional, and is contained outside the locale definition. This allows both completely self-defined source files, and generic sources (applicable to more than one codeset). To aid portability, all *charmap* definitions must use the same symbolic names for the portable character set. As explained in the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.4, Character Set Description File, it is implementation-defined whether or not users or applications can provide additional character set description files. Therefore, the −**f** option might be operable only when an implementation-defined *charmap* is named.

EXAMPLES

None.

RATIONALE

The output produced by the *localedef* utility is implementation-defined. The *name* operand is used to identify the specific locale. (As a consequence, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

The −**u** option is added, as specified in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

logger — log messages

SYNOPSIS

`logger` *`string`* `...`

DESCRIPTION

The *logger* utility saves a message, in an unspecified manner and format, containing the *string* operands provided by the user. The messages are expected to be evaluated later by personnel performing system administration tasks.

It is implementation-defined whether messages written in locales other than the POSIX locale are effective.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

string	One of the string arguments whose contents are concatenated together, in the order specified, separated by single <space>s.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *logger*:

	LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
	LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
	LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
	LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error. (This means diagnostics from *logger* to the user or application, not diagnostic messages that the user is sending to the system administrator.)
XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

Unspecified.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

This utility allows logging of information for later use by a system administrator or programmer in determining why non-interactive utilities have failed. The locations of the saved messages, their format, and retention period are all unspecified. There is no method for a conforming application to read messages, once written. |

EXAMPLES

A batch application, running non-interactively, tries to read a configuration file and fails; it may attempt to notify the system administrator with:

```
logger myname: unable to read file foo. [timestamp]
```

RATIONALE

The standard developers believed strongly that some method of alerting administrators to errors was necessary. The obvious example is a batch utility, running non-interactively, that is unable to read its configuration files or that is unable to create or write its results file. However, the standard developers did not wish to define the format or delivery mechanisms as they have historically been (and will probably continue to be) very system-specific, as well as involving functionality clearly outside of the scope of this volume of IEEE Std 1003.1-200x.

The text with *LC_MESSAGES* about diagnostic messages means diagnostics from *logger* to the user or application, not diagnostic messages that the user is sending to the system administrator.

Multiple *string* arguments are allowed, similar to *echo*, for ease-of-use.

Like the utilities *mailx* and *lp*, *logger* is admittedly difficult to test. This was not deemed sufficient justification to exclude these utilities from this volume of IEEE Std 1003.1-200x. It is also arguable that they are, in fact, testable, but that the tests themselves are not portable.

FUTURE DIRECTIONS

None.

mailx, *write*

CHANGE HISTORY

First released in Issue 4.

NAME

logname — return the user's login name

SYNOPSIS

```
logname
```

DESCRIPTION

The *logname* utility shall write the user's login name to standard output. The login name shall be the string that would be returned by the *getlogin*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x. Under the conditions where the *getlogin*( ) function would fail, the *logname* utility shall write a diagnostic message to standard error and exit with a non-zero exit status.

OPTIONS

None.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *logname*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *logname* utility output shall be a single line consisting of the user's login name:

```
"%s\n", <login name>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *logname* utility explicitly ignores the *LOGNAME* environment variable because environment changes could produce erroneous results.

EXAMPLES

None.

RATIONALE

The **passwd** file is not listed as required because the implementation may have other means of mapping login names.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

lp — send files to a printer

SYNOPSIS

```
lp [−c][−d dest][−n copies][−msw][−o option]... [−t title][file...]
```

DESCRIPTION

The *lp* utility shall copy the input files to an output destination in an unspecified manner. The default output destination should be to a hardcopy device, such as a printer or microfilm recorder, that produces non-volatile, human-readable documents. If such a device is not available to the application, or if the system provides no such device, the *lp* utility shall exit with a non-zero exit status.

The actual writing to the output device may occur some time after the *lp* utility successfully exits. During the portion of the writing that corresponds to each input file, the implementation shall guarantee exclusive access to the device.

The *lp* utility shall associate a unique *request ID* with each request.

Normally, a banner page is produced to separate and identify each print job. This page may be suppressed by implementation-defined conditions, such as an operator command or one of the **−o** *option* values.

OPTIONS

The *lp* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c Exit only after further access to any of the input files is no longer required. The application can then safely delete or modify the files without affecting the output operation. Normally, files are not copied, but are linked whenever possible. If the **−c** option is not given, then the user should be careful not to remove any of the files before the request has been printed in its entirety. It should also be noted that in the absence of the **−c** option, any changes made to the named files after the request is made but before it is printed may be reflected in the printed output. On some implementations, **−c** may be on by default.

−d *dest* Specify a string that names the destination (*dest*). If *dest* is a printer, the request shall be printed only on that specific printer. If *dest* is a class of printers, the request shall be printed on the first available printer that is a member of the class. Under certain conditions (printer unavailability, file space limitation, and so on), requests for specific destinations need not be accepted. Destination names vary between systems.

If **−d** is not specified, and neither the *LPDEST* nor *PRINTER* environment variable is set, an unspecified destination is used. The **−d** *dest* option shall take precedence over *LPDEST*, which in turn shall take precedence over *PRINTER*. Results are undefined when *dest* contains a value that is not a valid destination name.

−m Send mail (see *mailx* (on page 2785)) after the files have been printed. By default, no mail is sent upon normal completion of the print request.

−n *copies* Write *copies* number of copies of the files, where *copies* is a positive decimal integer. The methods for producing multiple copies and for arranging the multiple copies when multiple *file* operands are used are unspecified, except that each file shall be output as an integral whole, not interleaved with portions of other files.

−o *option*	Specify printer-dependent or class-dependent *option*s. Several such *option*s may be collected by specifying the **−o** option more than once.
−s	Suppress messages from *lp*.
−t *title*	Write *title* on the banner page of the output.
−w	Write a message on the user's terminal after the files have been printed. If the user is not logged in, then mail shall be sent instead.

OPERANDS

The following operand shall be supported:

file	A pathname of a file to be output. If no *file* operands are specified, or if a *file* operand is '−', the standard input shall be used. If a *file* operand is used, but the **−c** option is not specified, the process performing the writing to the output device may have user and group permissions that differ from that of the process invoking *lp*.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is '−'. See the INPUT FILES section. |

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *lp*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
LC_TIME	Determine the format and contents of date and time strings displayed in the *lp* banner page, if any.
LPDEST	Determine the destination. If the *LPDEST* environment variable is not set, the *PRINTER* environment variable shall be used. The **−d** *dest* option takes precedence over *LPDEST*. Results are undefined when **−d** is not specified and *LPDEST* contains a value that is not a valid destination name.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PRINTER	Determine the output device or destination. If the *LPDEST* and *PRINTER* environment variables are not set, an unspecified output device is used. The **−d** *dest* option and the *LPDEST* environment variable shall take precedence over *PRINTER*. Results are undefined when **−d** is not specified, *LPDEST* is unset, and

PRINTER contains a value that is not a valid device or destination name.

TZ Determine the timezone used to calculate date and time strings displayed in the *lp* banner page, if any. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *lp* utility shall write a *request ID* to the standard output, unless **−s** is specified. The format of the message is unspecified. The request ID can be used on systems supporting the historical *cancel* and *lpstat* utilities.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All input files were processed successfully.
>0	No output device was available, or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *pr* and *fold* utilities can be used to achieve reasonable formatting for the implementation's default page size.

A conforming application can use one of the *file* operands only with the **−c** option or if the file is publicly readable and guaranteed to be available at the time of printing. This is because the standard gives the implementation the freedom to queue up the request for printing at some later time by a different process that might not be able to access the file.

EXAMPLES

1. To print file *file*:

```
lp −c file
```

2. To print multiple files with headers:

```
pr file1 file2 | lp
```

RATIONALE

The *lp* utility was designed to be a basic version of a utility that is already available in many historical implementations. The standard developers considered that it should be implementable simply as:

```
cat "$@" > /dev/lp
```

after appropriate processing of options, if that is how the implementation chose to do it and if exclusive access could be granted (so that two users did not write to the device simultaneously). Although in the future the standard developers may add other options to this utility, it should always be able to execute with no options or operands and send the standard input to an unspecified output device.

This volume of IEEE Std 1003.1-200x makes no representations concerning the format of the printed output, except that it must be ‘‘human-readable’’ and ‘‘non-volatile’’. Thus, writing by default to a disk or tape drive or a display terminal would not qualify. (Such destinations are not prohibited when **−d** *dest*, *LPDEST*, or *PRINTER* are used, however.)

This volume of IEEE Std 1003.1-200x is worded such that a ‘‘print job’’ consisting of multiple input files, possibly in multiple copies, is guaranteed to print so that any one file is not intermixed with another, but there is no statement that all the files or copies have to print out together.

The **−c** option may imply a spooling operation, but this is not required. The utility can be implemented to wait until the printer is ready and then wait until it is finished. Because of that, there is no attempt to define a queuing mechanism (priorities, classes of output, and so on).

On some historical systems, the request ID reported on the STDOUT can be used to later cancel or find the status of a request using utilities not defined in this volume of IEEE Std 1003.1-200x.

Although the historical System V *lp* and BSD *lpr* utilities have provided similar functionality, they used different names for the environment variable specifying the destination printer. Since the name of the utility here is *lp*, *LPDEST* (used by the System V *lp* utility) was given precedence over *PRINTER* (used by the BSD *lpr* utility). Since environments of users frequently contain one or the other environment variable, the *lp* utility is required to recognize both. If this was not done, many applications would send output to unexpected output devices when users moved from system to system.

Some have commented that *lp* has far too little functionality to make it worthwhile. Requests have proposed additional options or operands or both that added functionality. The requests included:

- Wording *requiring* the output to be ‘‘hardcopy’’
- A requirement for multiple printers
- Options for supporting various page-description languages

Given that a compliant system is not required to even have a printer, placing further restrictions upon the behavior of the printer is not useful. Since hardcopy format is so application-dependent, it is difficult, if not impossible, to select a reasonable subset of functionality that should be required on all compliant systems.

The term ‘‘unspecified’’ is used in this section in lieu of ‘‘implementation-defined’’ as most known implementations would not be able to make definitive statements in their conformance documents: the existence and usage of printers is very dependent on how the system administrator configures each individual system.

Since the default destination, device type, queuing mechanisms, and acceptable forms of input are all unspecified, usage guidelines for what a conforming application can do are as follows:

- Use the command in a pipeline, or with **−c**, so that there are no permission problems and the files can be safely deleted or modified.
- Limit output to text files of reasonable line lengths and printable characters and include no device-specific formatting information, such as a page description language. The meaning of ‘‘reasonable’’ in this context can only be answered as a quality-of-implementation issue, but it should be apparent from historical usage patterns in the industry and the locale. The *pr* and *fold* utilities can be used to achieve reasonable formatting for the default page size of the

implementation.

Alternatively, the application can arrange its installation in such a way that it requires the system administrator or operator to provide the appropriate information on *lp* options and environment variable values.

At a minimum, having this utility in this volume of IEEE Std 1003.1-200x tells the industry that conforming applications require a means to print output and provides at least a command name and *LPDEST* routing mechanism that can be used for discussions between vendors, application writers, and users. The use of ‘‘should’’ in the DESCRIPTION of *lp* clearly shows the intent of the standard developers, even if they cannot mandate that all systems (such as laptops) have printers.

This volume of IEEE Std 1003.1-200x does not specify what the ownership of the process performing the writing to the output device may be. If −**c** is not used, it is unspecified whether the process performing the writing to the output device has permission to read *file* if there are any restrictions in place on who may read *file* until after it is printed. Also, if −**c** is not used, the results of deleting *file* before it is printed are unspecified.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the requirement to associate a unique request ID, and the normal generation of a banner page is added.
- In the OPTIONS section:
  - The −**d** *dest* description is expanded, but references to *lpstat* are removed.
  - The −**m**, −**o**, −**s**, −**t**, and −**w** options are added.
- In the ENVIRONMENT VARIABLES section, *LC_TIME* may now affect the execution.
- The STDOUT section is added.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

NAME

ls — list directory contents

SYNOPSIS

XSI `ls [−CFRacdilqrtu1][−H | −L ][−fgmnopsx][file...]`

DESCRIPTION

For each operand that names a file of a type other than directory or symbolic link to a directory, *ls* shall write the name of the file as well as any requested, associated information. For each operand that names a file of type directory, *ls* shall write the names of files contained within the directory as well as any requested, associated information. If one of the **−d**, **−F**, or **−l** options are specified, and one of the **−H** or **−L** options are not specified, for each operand that names a file of type symbolic link to a directory, *ls* shall write the name of the file as well as any requested, associated information. If none of the **−d**, **−F**, or **−l** options are specified, or the **−H** or **−L** options are specified, for each operand that names a file of type symbolic link to a directory, *ls* shall write the names of files contained within the directory as well as any requested, associated information.

If no operands are specified, *ls* shall write the contents of the current directory. If more than one operand is specified, *ls* shall write non-directory operands first; it shall sort directory and non-directory operands separately according to the collating sequence in the current locale.

The *ls* utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, *ls* shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

OPTIONS

The *ls* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−C	Write multi-text-column output with entries sorted down the columns, according to the collating sequence. The number of text columns and the column separator characters are unspecified, but should be adapted to the nature of the output device.
−F	Do not follow symbolic links named as operands unless the **−H** or **−L** options are specified. Write a slash (`'/'`) immediately after each pathname that is a directory, an asterisk (`'*'`) after each that is executable, a vertical bar (`'|'`) after each that is a FIFO, and an at sign (`'@'`) after each that is a symbolic link. For other file types, other symbols may be written.
−H	If a symbolic link referencing a file of type directory is specified on the command line, *ls* shall evaluate the file information and file type to be those of the file referenced by the link, and not the link itself; however, *ls* shall write the name of the link itself and not the file referenced by the link.
−L	Evaluate the file information and file type for all symbolic links (whether named on the command line or encountered in a file hierarchy) to be those of the file referenced by the link, and not the link itself; however, *ls* shall write the name of the link itself and not the file referenced by the link. When **−L** is used with **−l**, write the contents of symbolic links in the long format (see the STDOUT section).
−R	Recursively list subdirectories encountered.
−a	Write out all directory entries, including those whose names begin with a period (`'.'`). Entries beginning with a period shall not be written out unless explicitly

		referenced, the **–a** option is supplied, or an implementation-defined condition shall cause them to be written.
	–c	Use time of last modification of the file status information (see **<sys/stat.h>** in the System Interfaces volume of IEEE Std 1003.1-200x) instead of last modification of the file itself for sorting (**–t**) or writing (**–l**).
	–d	Do not follow symbolic links named as operands unless the **–H** or **–L** options are specified. Do not treat directories differently than other types of files. The use of **–d** with **–R** produces unspecified results.
XSI	**–f**	Force each argument to be interpreted as a directory and list the name found in each slot. This option shall turn off **–l**, **–t**, **–s**, and **–r**, and shall turn on **–a**; the order is the order in which entries appear in the directory.
XSI	**–g**	The same as **–l**, except that the owner shall not be written.
	–i	For each file, write the file's file serial number (see *stat*( ) in the System Interfaces volume of IEEE Std 1003.1-200x).
	–l	(The letter ell.) Do not follow symbolic links named as operands unless the **–H** or **–L** options are specified. Write out in long format (see the STDOUT section). When **–l** (ell) is specified, –1 (one) shall be assumed.
XSI	**–m**	Stream output format; list files across the page, separated by commas.
XSI	**–n**	The same as **–l**, except that the owner's UID and GID numbers shall be written, rather than the associated character strings.
XSI	**–o**	The same as **–l**, except that the group shall not be written.
XSI	**–p**	Write a slash (`'/'`) after each filename if that file is a directory.
	–q	Force each instance of non-printable filename characters and <tab>s to be written as the question-mark (`'?'`) character. Implementations may provide this option by default if the output is to a terminal device.
	–r	Reverse the order of the sort to get reverse collating sequence or oldest first.
XSI	**–s**	Indicate the total number of file system blocks consumed by each file displayed. The block size is implementation-defined.
	–t	Sort with the primary key being time modified (most recently modified first) and the secondary key being filename in the collating sequence.
	–u	Use time of last access (see **<sys/stat.h>** in the System Interfaces volume of IEEE Std 1003.1-200x) instead of last modification of the file for sorting (**–t**) or writing (**–l**).
XSI	**–x**	The same as **–C**, except that the multi-text-column output is produced with entries sorted across, rather than down, the columns.
	–1	(The numeric digit one.) Force output to be one entry per line.

Specifying more than one of the options in the following mutually exclusive pairs shall not be considered an error: **–C** and **–l** (ell), XSI **–m** and **–l** (ell), **–x** and **–l** (ell), **–C** and **–1** (one), **–H** and **–L**, **–c** and **–u**. The last option specified in each pair shall determine the output format.

OPERANDS

The following operand shall be supported:

file	A pathname of a file to be written. If the file specified is not found, a diagnostic message shall be output on standard error.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ls*:

COLUMNS	Determine the user's preferred column position width for writing multiple text-column output. If this variable contains a string representing a decimal integer, the *ls* utility shall calculate how many pathname text columns to write (see **−C**) based on the width provided. If *COLUMNS* is not set or invalid, an implementation-defined number of column positions shall be assumed, based on the implementation's knowledge of the output device. The column width chosen to write the names of files in any given directory shall be constant. Filenames shall not be truncated to fit into the multiple text-column output.
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for character collation information in determining the pathname collation sequence.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and which characters are defined as printable (character class **print**).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_TIME	Determine the format and contents for date and time strings written by *ls*.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
TZ	Determine the timezone for date and time strings written by *ls*. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The default format shall be to list one entry per line to standard output; the exceptions are to terminals or when one of the **−C**, XSI **−m**, or **−x** options is specified. If the output is to a terminal, the format is implementation-defined.

XSI When −**m** is specified, the format used shall be:

```
"%s, %s, ...\n", <filename1>, <filename2>
```

where the largest number of filenames shall be written without exceeding the length of the line.

If the −**i** option is specified, the file's file serial number (see **<sys/stat.h>** in the System Interfaces volume of IEEE Std 1003.1-200x) shall be written in the following format before any other output for the corresponding entry:

```
%u ", <file serial number>
```

If the −**l** option is specified without −**L**, the following information shall be written:

```
"%s %u %s %s %u %s %s\n", <file mode>, <number of links>,
    <owner name>, <group name>, <number of bytes in the file>,
    <date and time>, <pathname>
```

If the file is a symbolic link, this information shall be about the link itself and the <*pathname*> field shall be of the form:

```
"%s −> %s", <pathname of link>, <contents of link>
```

If both −**l** and −**L** are specified, the following information shall be written:

```
"%s %u %s %s %u %s %s\n", <file mode>, <number of links>,
    <owner name>, <group name>, <number of bytes in the file>,
    <date and time>, <pathname of link>
```

where all fields except <*pathname of link*> shall be for the file resolved from the symbolic link.

XSI The −**g**, −**n**, and −**o** options use the same format as −**l**, but with omitted items and their associated <blank>s. See the OPTIONS section.

XSI In both the preceding −**l** forms, if <*owner name*> or <*group name*> cannot be determined, or if −**n** is given, they shall be replaced with their associated numeric values using the format `%u`.

The <*date and time*>, field shall contain the appropriate date and timestamp of when the file was last modified. In the POSIX locale, the field shall be the equivalent of the output of the following *date* command:

```
date "+%b %e %H:%M"
```

if the file has been modified in the last six months, or:

```
date "+%b %e %Y"
```

(where two <space>s are used between `%e` and `%Y`) if the file has not been modified in the last six months or if the modification date is in the future, except that, in both cases, the final <newline> produced by *date* shall not be included and the output shall be as if the *date* command were executed at the time of the last modification date of the file rather than the current time. When the *LC_TIME* locale category is not set to the POSIX locale, a different format and order of presentation of this field may be used.

If the file is a character special or block special file, the size of the file may be replaced with implementation-defined information associated with the device in question.

If the pathname was specified as a *file* operand, it shall be written as specified.

XSI The file mode written under the −**l**, −**g**, −**n**, and −**o** options shall consist of the following format:

```
"%c%s%s%s%c", <entry type>, <owner permissions>,
    <group permissions>, <other permissions>,
```

`<optional alternate access method flag>`

The <*optional alternate access method flag*> shall be a single <space> if there is no alternate or additional access control method associated with the file; otherwise, a printable character shall be used.

The <*entry type*> character shall describe the type of file, as follows:

`d`	Directory.
`b`	Block special file.
`c`	Character special file.
`l` (ell)	Symbolic link.
`p`	FIFO.
–	Regular file.

Implementations may add other characters to this list to represent other implementation-defined file types.

The next three fields shall be three characters each:

<*owner permissions*>
Permissions for the file owner class (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.4, File Access Permissions).

<*group permissions*>
Permissions for the file group class.

<*other permissions*>
Permissions for the file other class.

Each field shall have three character positions:

1. If `'r'`, the file is readable; if `'−'`, the file is not readable.
2. If `'w'`, the file is writable; if `'−'`, the file is not writable.
3. The first of the following that applies:

`S`	If in <*owner permissions*>, the file is not executable and set-user-ID mode is set. If in <*group permissions*>, the file is not executable and set-group-ID mode is set.
`s`	If in <*owner permissions*>, the file is executable and set-user-ID mode is set. If in <*group permissions*>, the file is executable and set-group-ID mode is set.
`x`	The file is executable or the directory is searchable.
–	None of the attributes of `'S'`, `'s'`, or `'x'` applies.

   Implementations may add other characters to this list for the third character position. Such additions shall, however, be written in lowercase if the file is executable or searchable, and in uppercase if it is not.

XSI If any of the **−l**, **−g**, **−n**, **−o**, or **−s** options is specified, each list of files within the directory shall be preceded by a status line indicating the number of file system blocks occupied by files in the directory in 512-byte units, rounded up to the next integral number of units, if necessary. In the POSIX locale, the format shall be:

`"total %u\n", <number of units in the directory>`

If more than one directory, or a combination of non-directory files and directories are written, either as a result of specifying multiple operands, or the −**R** option, each list of files within a directory shall be preceded by:

`"\n%s:\n", <directory name>`

If this string is the first thing to be written, the first <newline> shall not be written. This output shall precede the number of units in the directory.

XSI If the −**s** option is given, each file shall be written with the number of blocks used by the file. Along with −**C**, −**1**, −**m**, or −**x**, the number and a <space> shall precede the filename; with −**g**, −**l**, −**n**, or −**o**, they shall precede each line describing a file.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Many implementations use the equal sign (`'='`) to denote sockets bound to the file system for the −**F** option. Similarly, many historical implementations use the `'s'` character to denote sockets as the entry type characters for the −**l** option.

It is difficult for an application to use every part of the file modes field of *ls* −**l** in a portable manner. Certain file types and executable bits are not guaranteed to be exactly as shown, as implementations may have extensions. Applications can use this field to pass directly to a user printout or prompt, but actions based on its contents should generally be deferred, instead, to the *test* utility.

The output of *ls* (with the −**l** and related options) contains information that logically could be used by utilities such as *chmod* and *touch* to restore files to a known state. However, this information is presented in a format that cannot be used directly by those utilities or be easily translated into a format that can be used. A character has been added to the end of the permissions string so that applications at least have an indication that they may be working in an area they do not understand instead of assuming that they can translate the permissions string into something that can be used. Future issues or related documents may define one or more specific characters to be used based on different standard additional or alternative access control mechanisms.

As with many of the utilities that deal with filenames, the output of *ls* for multiple files or in one of the long listing formats must be used carefully on systems where filenames can contain embedded white space. Systems and system administrators should institute policies and user training to limit the use of such filenames.

The number of disk blocks occupied by the file that it reports varies depending on underlying file system type, block size units reported, and the method of calculating the number of blocks.

On some file system types, the number is the actual number of blocks occupied by the file (counting indirect blocks and ignoring holes in the file); on others it is calculated based on the file size (usually making an allowance for indirect blocks, but ignoring holes).

EXAMPLES

An example of a small directory tree being fully listed with *ls* –**laRF a** in the POSIX locale:

```
total 11
drwxr-xr-x   3 hlj      prog          64 Jul  4 12:07 ./
drwxrwxrwx   4 hlj      prog        3264 Jul  4 12:09 ../
drwxr-xr-x   2 hlj      prog          48 Jul  4 12:07 b/
-rwxr--r--   1 hlj      prog         572 Jul  4 12:07 foo*

a/b:
total 4
drwxr-xr-x   2 hlj      prog          48 Jul  4 12:07 ./
drwxr-xr-x   3 hlj      prog          64 Jul  4 12:07 ../
-rw-r--r--   1 hlj      prog         700 Jul  4 12:07 bar
```

RATIONALE

Some historical implementations of the *ls* utility show all entries in a directory except dot and dot-dot when a superuser invokes *ls* without specifying the –**a** option. When ‘‘normal’’ users invoke *ls* without specifying –**a**, they should not see information about any files with names beginning with period unless they were named as *file* operands.

Implementations are expected to traverse arbitrary depths when processing the –**R** option. The only limitation on depth should be based on running out of physical storage for keeping track of untraversed directories.

The –**1** (one) option is currently found in BSD and BSD-derived implementations only. It is required in this volume of IEEE Std 1003.1-200x so that conforming applications might ensure that output is one entry per line, even if the output is to a terminal.

Generally, this volume of IEEE Std 1003.1-200x is silent about what happens when options are given multiple times. In the cases of –**C**, –**l**, and –**1**, however, it does specify the results of these overlapping options. Since *ls* is one of the most aliased commands, it is important that the implementation perform intuitively. For example, if the alias were:

```
alias ls="ls –C"
```

and the user typed *ls* –**1**, single-text-column output should result, not an error.

The BSD *ls* provides a –**A** option (like –**a**, but dot and dot-dot are not written out). The small difference from –**a** did not seem important enough to require both.

Implementations may make –**q** the default for terminals to prevent trojan horse attacks on terminals with special escape sequences. This is not required because:

- Some control characters may be useful on some terminals; for example, a system might write them as `"\001"` or `"^A"`.
- Special behavior for terminals is not relevant to application portability.

An early proposal specified that the optional alternate access method flag had to be `'+'` if there was an alternate access method used on the file or <space> if there was not. This was changed to be <space> if there is not and a single printable character if there is. This was done for three reasons:

1. There are historical implementations using characters other than `'+'`.

2. There are implementations that vary this character used in that position to distinguish between various alternate access methods in use.
3. The standard developers did not want to preclude futures specifications that might need a way to specify more than one alternate access method.

Nonetheless, implementations providing a single alternate access method are encouraged to use '+'.

In an early proposal, the units used to specify the number of blocks occupied by files in a directory in an *ls* −**l** listing was implementation-defined. This was because BSD systems have historically used 1 024-byte units and System V systems have historically used 512-byte units. It was pointed out by BSD developers that their system has used 512-byte units in some places and 1 024-byte units in other places. (System V has consistently used 512.) Therefore, this volume of IEEE Std 1003.1-200x usually specifies 512. Future releases of BSD are expected to consistently provide 512 bytes as a default with a way of specifying 1 024-byte units where appropriate.

The <*date and time*> field in the −**l** format is specified only for the POSIX locale. As noted, the format can be different in other locales. No mechanism for defining this is present in this volume of IEEE Std 1003.1-200x, as the appropriate vehicle is a messaging system; that is, the format should be specified as a ''message''.

FUTURE DIRECTIONS

The −**s** uses implementation-defined units and cannot be used portably; it may be withdrawn in a future issue.

CHANGE HISTORY

First released in Issue 2.

Issue 5

Second FUTURE DIRECTION added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the −**F** option, other symbols are allowed for other file types.

Treatment of symbolic links is added, as defined in the IEEE P1003.2b draft standard.

NAME

m4 — macro processor (**DEVELOPMENT**)

SYNOPSIS

XSI
```
m4 [−s][−D name[=val]]...[−U name]... file...
```

DESCRIPTION

The *m4* utility is a macro processor that shall read one or more text files, process them according to their included macro statements, and write the results to standard output.

OPTIONS

The *m4* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of the **−D** and **−U** options shall be significant.

The following options shall be supported:

−s	Enable line synchronization output for the *c99* preprocessor phase (that is, **#line** directives).
−D *name*[=*val*]	Define *name* to *val* or to null if =*val* is omitted.
−U *name*	Undefine *name*.

OPERANDS

The following operand shall be supported:

file	A pathname of a text file to be processed. If no *file* is given, or if it is `'−'`, the standard input shall be read.

STDIN

The standard input shall be a text file that is used if no *file* operand is given, or if it is `'−'`.

INPUT FILES

The input file named by the *file* operand shall be a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *m4*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be the same as the input files, after being processed for macro expansion.

STDERR

The standard error shall be used to display strings with the **errprint** macro, macro tracing enabled by the **traceon** macro, the defined text for macros written by the **dumpdef** macro, or for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The *m4* utility shall compare each token from the input against the set of built-in and user-defined macros. If the token matches the name of a macro, then the token shall be replaced by the macro's defining text, if any, and rescanned for matching macro names. Once no portion of the token matches the name of a macro, it shall be written to standard output. Macros may have arguments, in which case the arguments shall be substituted into the defining text before it is rescanned.

Macro calls have the form:

```
name(arg1, arg2, ..., argn)
```

Macro names shall consist of letters, digits, and underscores, where the first character is not a digit. Tokens not of this form shall not be treated as macros.

The application shall ensure that the left parenthesis immediately follows the name of the macro. If a token matching the name of a macro is not followed by a left parenthesis, it is handled as a use of that macro without arguments.

If a macro name is followed by a left parenthesis, its arguments are the comma-separated tokens between the left parenthesis and the matching right parenthesis. Unquoted <blank>s and <newline>s preceding each argument shall be ignored. All other characters, including trailing <blank>s and <newline>s, are retained. Commas enclosed between left and right parenthesis characters do not delimit arguments.

Arguments are positionally defined and referenced. The string `"$1"` in the defining text shall be replaced by the first argument. Systems shall support at least nine arguments; only the first nine can be referenced, using the strings `"$1"` to `"$9"`, inclusive. The string `"$0"` is replaced with the name of the macro. The string `"$#"` is replaced by the number of arguments as a string. The string `"$*"` is replaced by a list of all of the arguments, separated by commas. The string `"$@"` is replaced by a list of all of the arguments separated by commas, and each argument is quoted using the current left and right quoting strings.

If fewer arguments are supplied than are in the macro definition, the omitted arguments are taken to be null. It is not an error if more arguments are supplied than are in the macro definition.

No special meaning is given to any characters enclosed between matching left and right quoting strings, but the quoting strings are themselves discarded. By default, the left quoting string consists of a grave accent (’‘’) and the right quoting string consists of an acute accent (’’’); see also the **changequote** macro.

Comments are written but not scanned for matching macro names; by default, the begin-comment string consists of the number sign character and the end-comment string consists of a

<newline>. See also the **changecom** and **dnl** macros.

The *m4* utility shall make available the following built-in macros. They can be redefined, but once this is done the original meaning is lost. Their values shall be null unless otherwise stated. In the descriptions below, the term *defining text* refers to the value of the macro: the second argument to the **define** macro, among other things. Except for the first argument to the **eval** macro, all numeric arguments to built-in macros shall be interpreted as decimal values. The string values produced as the defining text of the **decr**, **divnum**, **incr**, **index**, **len**, and **sysval** built-in macros shall be in the form of a decimal-constant as defined in the C language.

changecom	The **changecom** macro shall set the begin-comment and end-comment strings. With no arguments, the comment mechanism shall be disabled. With a single argument, that argument shall become the begin-comment string and the <newline> shall become the end-comment string. With two arguments, the first argument shall become the begin-comment string and the second argument shall become the end-comment string. Systems shall support comment strings of at least five characters.
changequote	The **changequote** macro shall set the begin-quote and end-quote strings. With no arguments, the quote strings shall be set to the default values (that is, ‘ ’). With a single argument, that argument shall become the begin-quote string and the <newline> shall become the end-quote string. With two arguments, the first argument shall become the begin-quote string and the second argument shall become the end-quote string. Systems shall support quote strings of at least five characters.
decr	The defining text of the **decr** macro shall be its first argument decremented by 1. It shall be an error to specify an argument containing any non-numeric characters.
define	The second argument shall become the defining text of the macro whose name is the first argument.
defn	The defining text of the **defn** macro shall be the quoted definition (using the current quoting strings) of its arguments.
divert	The *m4* utility maintains nine temporary buffers, numbered 1 to 9, inclusive. When the last of the input has been processed, any output that has been placed in these buffers shall be written to standard output in buffer-numerical order. The **divert** macro shall divert future output to the buffer specified by its argument. Specifying no argument or an argument of 0 shall resume the normal output process. Output diverted to a stream other than 0 to 9 shall be discarded. It shall be an error to specify an argument containing any non-numeric characters.
divnum	The defining text of the **divnum** macro shall be the number of the current output stream as a string.
dnl	The **dnl** macro shall cause *m4* to discard all input characters up to and including the next <newline>.
dumpdef	The **dumpdef** macro shall write the defined text to standard error for each of the macros specified as arguments, or, if no arguments are specified, for all macros.
errprint	The **errprint** macro shall write its arguments to standard error.
eval	The **eval** macro shall evaluate its first argument as an arithmetic expression, using 32-bit signed integer arithmetic. All of the C-language operators shall be supported, except for:

```
[]
->
++
--
(type)
unary *
sizeof
,
.
?:
unary &
```

and all assignment operators. It shall be an error to specify any of these operators. Precedence and associativity shall be as in the ISO C standard. Systems shall support octal and hexadecimal numbers as in the ISO C standard. The second argument, if specified, shall set the radix for the result; the default is 10. The third argument, if specified, sets the minimum number of digits in the result. It shall be an error to specify the second or third argument containing any non-numeric characters.

ifdef If the first argument to the **ifdef** macro is defined, the defining text shall be the second argument. Otherwise, the defining text shall be the third argument, if specified, or the null string, if not.

ifelse The **ifelse** macro takes three or more arguments. If the first two arguments compare as equal strings (after macro expansion of both arguments), the defining text shall be the third argument. If the first two arguments do not compare as equal strings and there are three arguments, the defining text shall be null. If the first two arguments do not compare as equal strings and there are four or five arguments, the defining text shall be the fourth argument. If the first two arguments do not compare as equal strings and there are six or more arguments, the first three arguments shall be discarded and processing shall restart with the remaining arguments.

include The defining text for the **include** macro shall be the contents of the file named by the first argument. It shall be an error if the file cannot be read.

incr The defining text of the **incr** macro shall be its first argument incremented by 1. It shall be an error to specify an argument containing any non-numeric characters.

index The defining text of the **index** macro shall be the first character position (as a string) in the first argument where a string matching the second argument begins (zero origin), or −1 if the second argument does not occur.

len The defining text of the **len** macro shall be the length (as a string) of the first argument.

m4exit Exit from the *m4* utility. If the first argument is specified, it is the exit code. The default is zero. It shall be an error to specify an argument containing any non-numeric characters.

m4wrap The first argument shall be processed when EOF is reached. If the **m4wrap** macro is used multiple times, the arguments specified shall be processed in the order in which the **m4wrap** macros were processed.

maketemp The defining text shall be the first argument, with any trailing `'X'` characters replaced with the current process ID as a string.

popdef	The **popdef** macro shall delete the current definition of its arguments, replacing that definition with the previous one. If there is no previous definition, the macro is undefined.
pushdef	The **pushdef** macro shall be equivalent to the **define** macro with the exception that it shall preserve any current definition for future retrieval using the **popdef** macro.
shift	The defining text for the **shift** macro shall be all of its arguments except for the first one.
sinclude	The **sinclude** macro shall be equivalent to the **include** macro, except that it shall not be an error if the file is inaccessible.
substr	The defining text for the **substr** macro shall be the substring of the first argument beginning at the zero-offset character position specified by the second argument. The third argument, if specified, shall be the number of characters to select; if not specified, the characters from the starting point to the end of the first argument shall become the defining text. It shall not be an error to specify a starting point beyond the end of the first argument and the defining text shall be null. It shall be an error to specify an argument containing any non-numeric characters.
syscmd	The **syscmd** macro shall interpret its first argument as a shell command line. The defining text shall be the string result of that command. No output redirection shall be performed by the *m4* utility. The exit status value from the command can be retrieved using the **sysval** macro.
sysval	The defining text of the **sysval** macro shall be the exit value of the utility last invoked by the **syscmd** macro (as a string).
traceon	The **traceon** macro shall enable tracing for the macros specified as arguments, or, if no arguments are specified, for all macros. The trace output shall be written to standard error in an unspecified format.
traceoff	The **traceoff** macro shall disable tracing for the macros specified as arguments, or, if no arguments are specified, for all macros.
translit	The defining text of the **translit** macro shall be the first argument with every character that occurs in the second argument replaced with the corresponding character from the third argument.
undefine	The **undefine** macro shall delete all definitions (including those preserved using the **pushdef** macro) of the macros named by its arguments.
undivert	The **undivert** macro shall cause immediate output of any text in temporary buffers named as arguments, or all temporary buffers if no arguments are specified. Buffers can be undiverted into other temporary buffers. Undiverting shall discard the contents of the temporary buffer. It shall be an error to specify an argument containing any non-numeric characters.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred

If the **m4exit** macro is used, the exit value can be specified by the input file.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The **defn** macro is useful for renaming macros, especially built-ins.

EXAMPLES

An example of a single *m4* input file capable of generating two output files follows. The file **file1.m4** could contain lines such as:

```
if(VER, 1, do_something)
if(VER, 2, do_something)
```

The makefile for the program might include:

```
file1.1.c : file1.m4
            m4 −D VER=1 file1.m4 > file1.1.c
            ...
file1.2.c : file1.m4
            m4 −D VER=2 file1.m4 > file1.2.c
            ...
```

The −**U** option can be used to undefine **VER**. If **file1.m4** contains:

```
if(VER, 1,  do_something)
if(VER, 2,  do_something)
ifndef(VER, do_something)
```

then the makefile would contain:

```
file1.0.c : file1.m4
            m4 −U VER file1.m4 > file1.0.c
            ...
file1.1.c : file1.m4
            m4 −D VER=1 file1.m4 > file1.1.c
            ...
file1.2.c : file1.m4
            m4 −D VER=2 file1.m4 > file1.2.c
            ...
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

c99

CHANGE HISTORY

First released in Issue 2.

Issue 5

The phrase “the defined text for macros written by the **dumpdef** macro” is added to the description of STDERR, and the description of **dumpdef** is updated to indicate that output is written to standard error. The description of **eval** is updated to indicate that the list of excluded C operators excludes unary '&' and '.'. In the description of **ifdef**, the phrase “and it is not defined to be zero” is deleted.

Issue 6

In the EXTENDED DESCRIPTION, the **eval** text is updated to include a `'&'` character in the excepted list.

The EXTENDED DESCRIPTION of **divert** is updated to clarify that there are only nine diversion buffers.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The Open Group Base Resolution bwg2000-006 is applied.

NAME

mailx — process messages

SYNOPSIS

Send Mode

```
mailx [−s subject] address...
```

Receive Mode

```
mailx −e
mailx [−HiNn][−F][−u user]
mailx −f[−HiNn][−F][file]
```

DESCRIPTION

The *mailx* utility provides a message sending and receiving facility. It has two major modes, selected by the options used: Send Mode and Receive Mode.

On systems that do not support the User Portability Utilities option, an application using *mailx* shall have the ability to send messages in an unspecified manner (Send Mode). Unless the first character of one or more lines is tilde (`'˜'`), all characters in the input message shall appear in the delivered message, but additional characters may be inserted in the message before it is retrieved.

On systems supporting the User Portability Utilities option, mail-receiving capabilities and other interactive features, Receive Mode, described below, also shall be enabled.

Send Mode

Send Mode can be used by applications or users to send messages from the text in standard input.

Receive Mode

Receive Mode is more oriented to interactive users. Mail can be read and sent in this interactive mode.

When reading mail, *mailx* provides commands to facilitate saving, deleting, and responding to messages. When sending mail, *mailx* allows editing, reviewing, and other modification of the message as it is entered.

Incoming mail shall be stored in one or more unspecified locations for each user, collectively called the system *mailbox* for that user. When *mailx* is invoked in Receive Mode, the system mailbox shall be the default place to find new mail. As messages are read, they shall be marked to be moved to a secondary file for storage, unless specific action is taken. This secondary file is called the **mbox** and is normally located in the directory referred to by the *HOME* environment variable (see *MBOX* in the ENVIRONMENT VARIABLES section for a description of this file). Messages shall remain in this file until explicitly removed. When the **−f** option is used to read mail messages from secondary files, messages shall be retained in those files unless specifically removed. All three of these locations—system mailbox, **mbox**, and secondary file—are referred to in this section as simply ‘‘mailboxes’’, unless more specific identification is required.

OPTIONS

The *mailx* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported. (Only the **−s** *subject* option shall be required on all systems. The other options are required only on systems supporting the User Portability Utilities option.)

−e	Test for the presence of mail in the system mailbox. The *mailx* utility shall write nothing and exit with a successful return code if there is mail to read.
−f	Read messages from the file named by the *file* operand instead of the system mailbox. (See also **folder**.) If no *file* operand is specified, read messages from the **mbox** instead of the system mailbox.
−F	Record the message in a file named after the first recipient. The name is the login-name portion of the address found first on the **To:** line in the mail header. Overrides the **record** variable, if set (see **Internal Variables in mailx** (on page 2792).)
−H	Write a header summary only.
−i	Ignore interrupts. (See also **ignore**).
−n	Do not initialize from the system default start-up file. See the EXTENDED DESCRIPTION section.
−N	Do not write an initial header summary.
−s *subject*	Set the **Subject** header field to *subject*. All characters in the *subject* string shall appear in the delivered message. The results are unspecified if *subject* is longer than {LINE_MAX} − 10 bytes or contains a <newline>.
−u *user*	Read the system mailbox of the login name *user*. This shall only be successful if the invoking user has the appropriate privileges to read the system mailbox of that user.

OPERANDS

The following operands shall be supported:

address	Addressee of message. When **−n** is specified and no user start-up files are accessed (see the EXTENDED DESCRIPTION section), the user or application shall ensure this is an address to pass to the mail delivery system. Any system or user start-up files may enable aliases (see **alias** under **Commands in mailx** (on page 2795)) that may modify the form of *address* before it is passed to the mail delivery system.
file	A pathname of a file to be read instead of the system mailbox when **−f** is specified. The meaning of the *file* option-argument shall be affected by the contents of the **folder** internal variable; see **Internal Variables in mailx** (on page 2792).

STDIN

When *mailx* is invoked in Send Mode (the first synopsis line), standard input shall be the message to be delivered to the specified addresses. When in Receive Mode, user commands shall be accepted from *stdin*. If the User Portability Utilities option is not supported, standard input lines beginning with a tilde ('~') character produce unspecified results.

If the User Portability Utilities option is supported, then in both Send and Receive Modes, standard input lines beginning with the escape character (usually tilde ('~')) shall affect processing as described in **Command Escapes in mailx** (on page 2803).

INPUT FILES

When *mailx* is used as described by this volume of IEEE Std 1003.1-200x, the *file* option-argument (see the **–f** option) and the **mbox** shall be text files containing mail messages, formatted as described in the OUTPUT FILES section. The nature of the system mailbox is unspecified; it need not be a file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mailx*:

DEAD	Determine the pathname of the file in which to save partial messages in case of interrupts or delivery errors. The default shall be **dead.letter** in the directory named by the *HOME* variable. The behavior of *mailx* in saving partial messages is unspecified if the User Portability Utilities option is not supported and *DEAD* is not defined with the value **/dev/null**.
EDITOR	Determine the name of a utility to invoke when the **edit** (see **Commands in mailx** (on page 2795)) or **˜e** (see **Command Escapes in mailx** (on page 2803)) command is used. The default editor is unspecified. XSI On XSI-conformant systems it is *ed*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.
HOME	Determine the pathname of the user's home directory.
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the handling of case-insensitive address and header-field comparisons.
LC_TIME	Determine the format and contents of the date and time strings written by *mailx*.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
LISTER	Determine a string representing the command for writing the contents of the **folder** directory to standard output when the **folders** command is given (see **folders** in **Commands in mailx** (on page 2795)). Any string acceptable as a *command_string* operand to the *sh* **–c** command shall be valid. If this variable is null or not set, the output command shall be *ls*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.
MAILRC	Determine the pathname of the start-up file. The default shall be **.mailrc** in the directory referred to by the *HOME* environment variable. The behavior of *mailx* is unspecified if the User Portability Utilities option is not supported and *MAILRC* is not defined with the value **/dev/null**.
MBOX	Determine a pathname of the file to save messages from the system mailbox that have been read. The **exit** command shall override this function, as shall saving the message explicitly in another file. The default shall be **mbox** in the directory

	named by the *HOME* variable. The effects of this variable are unspecified if the User Portability Utilities option is not supported.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
PAGER	Determine a string representing an output filtering or pagination command for writing the output to the terminal. Any string acceptable as a *command_string* operand to the *sh* **–c** command shall be valid. When standard output is a terminal device, the message output shall be piped through the command if the *mailx* internal variable **crt** is set to a value less the number of lines in the message; see **Internal Variables in mailx** (on page 2792). If the *PAGER* variable is null or not set, the paginator shall be either *more* or another paginator utility documented in the system documentation. The effects of this variable are unspecified if the User Portability Utilities option is not supported.
SHELL	Determine the name of a preferred command interpreter. The default shall be *sh*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.
TERM	Determine the name of the terminal type, to indicate in an unspecified manner, if the internal variable **screen** is not specified, the number of lines in a screenful of headers. If *TERM* is not set or is set to null, an unspecified default terminal type shall be used and the value of a screenful is unspecified. The effects of this variable are unspecified if the User Portability Utilities option is not supported.
TZ	This variable may determine the timezone used to calculate date and time strings written by *mailx*. If *TZ* is unset or null, an unspecified default timezone shall be used.
VISUAL	Determine a pathname of a utility to invoke when the **visual** command (see **Commands in mailx** (on page 2795)) or **˜v** command-escape (see **Command Escapes in mailx** (on page 2803)) is used. If this variable is null or not set, the full-screen editor shall be *vi*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

ASYNCHRONOUS EVENTS

When *mailx* is in Send Mode and standard input is not a terminal, it shall take the standard action for all signals.

In Receive Mode, or in Send Mode when standard input is a terminal, if a SIGINT signal is received:

1. If in command mode, the current command, if there is one, shall be aborted, and a command-mode prompt shall be written.
2. If in input mode:
    a. If **ignore** is set, *mailx* shall write `"@\n"`, discard the current input line, and continue processing, bypassing the message-abort mechanism described in item 2b.
    b. If the interrupt was received while sending mail, either when in Receive Mode or in Send Mode, a message shall be written, and another subsequent interrupt, with no other intervening characters typed, shall be required to abort the mail message. If in Receive Mode and another interrupt is received, a command-mode prompt shall be written. If in Send Mode and another interrupt is received, *mailx* shall terminate with a non-zero status.

    In both cases listed in item b, if the message is not empty:

i. If **save** is enabled and the file named by *DEAD* can be created, the message shall be written to the file named by *DEAD*. If the file exists, the message shall be written to replace the contents of the file.

ii. If **save** is not enabled, or the file named by *DEAD* cannot be created, the message shall not be saved.

The *mailx* utility shall take the standard action for all other signals.

STDOUT

In command and input modes, all output, including prompts and messages, shall be written to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

Various *mailx* commands and command escapes can create or add to files, including the **mbox**, the dead-letter file, and secondary mailboxes. When *mailx* is used as described in this volume of IEEE Std 1003.1-200x, these files shall be text files, formatted as follows:

```
line beginning with From<space>
[one or more header-lines; see Commands in mailx (on page 2795)]
empty line
[zero or more body lines
empty line]
[line beginning with From<space>...]
```

where each message begins with the **From** **<space>** line shown, preceded by the beginning of the file or an empty line. (The **From** **<space>** line is considered to be part of the message header, but not one of the header-lines referred to in **Commands in mailx** (on page 2795); thus, it shall not be affected by the **discard**, **ignore**, or **retain** commands.) The formats of the remainder of the **From** **<space>** line and any additional header lines are unspecified, except that none shall be empty. The format of a message body line is also unspecified, except that no line following an empty line shall start with **From** **<space>**; *mailx* shall modify any such user-entered message body lines (following an empty line and beginning with **From** **<space>**) by adding one or more characters to precede the `'F'`; it may add these characters to **From** **<space>** lines that are not preceded by an empty line.

When a message from the system mailbox or entered by the user is not a text file, it is implementation-defined how such a message is stored in files written by *mailx*.

EXTENDED DESCRIPTION

The entire EXTENDED DESCRIPTION section shall apply only to implementations supporting the User Portability Utilities option.

The *mailx* utility cannot guarantee support for all character encodings in all circumstances. For example, inter-system mail may be restricted to 7-bit data by the underlying network, 8-bit data need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used.

When *mailx* is invoked using one of the Receive Mode synopsis forms, it shall write a page of header-summary lines (if **−N** was not specified and there are messages, see below), followed by a prompt indicating that *mailx* can accept regular commands (see **Commands in mailx** (on page 2795)); this is termed *command mode*. The page of header-summary lines shall contain the first new message if there are new messages, or the first unread message if there are unread messages, or the first message. When *mailx* is invoked using the Send Mode synopsis and standard input is a terminal, if no subject is specified on the command line and the **asksub** variable is set, a prompt for the subject shall be written. At this point, *mailx* shall be in input mode. This input mode shall also be entered when using one of the Receive Mode synopsis forms and a reply or new message is composed using the **reply**, **Reply**, **followup**, **Followup**, or **mail** commands and standard input is a terminal. When the message is typed and the end of message is encountered, the message shall be passed to the mail delivery software. Commands can be entered by beginning a line with the escape character (by default, tilde (`'˜'`)) followed by a single command letter and optional arguments. See **Commands in mailx** (on page 2795) for a summary of these commands. It is unspecified what effect these commands will have if standard input is not a terminal when a message is entered using either the Send Mode synopsis, or the Read Mode commands **reply**, **Reply**, **followup**, **Followup**, or **mail**.

Note: For notational convenience, this section uses the default escape character, tilde, in all references and examples.

At any time, the behavior of *mailx* shall be governed by a set of environmental and internal variables. These are flags and valued parameters that can be set and cleared via the *mailx* **set** and **unset** commands.

Regular commands are of the form:

```
[command] [msglist] [argument ...]
```

If no *command* is specified in command mode, **next** shall be assumed. In input mode, commands shall be recognized by the escape character, and lines not treated as commands shall be taken as input for the message.

In command mode, each message shall be assigned a sequential number, starting with 1.

All messages have a state that shall affect how they are displayed in the header summary and how they are retained or deleted upon termination of *mailx*. There is at any time the notion of a *current* message, which shall be marked by a `'>'` at the beginning of a line in the header summary. When *mailx* is invoked using one of the Receive Mode synopsis forms, the current message shall be the first new message, if there is a new message, or the first unread message if there is an unread message, or the first message if there are any messages, or unspecified if there are no messages in the mailbox. Each command that takes an optional list of messages (*msglist*) or an optional single message (*message*) on which to operate shall leave the current message set to the highest-numbered message of the messages specified, unless the command deletes messages, in which case the current message shall be set to the first undeleted message (that is, a message not in the deleted state) after the highest-numbered message deleted by the command, if one exists, or the first undeleted message before the highest-numbered message deleted by the command, if one exists, or to an unspecified value if there are no remaining undeleted messages. All messages shall be in one of the following states:

new	The message is present in the system mailbox and has not been viewed by the user or moved to any other state. Messages in state *new* when *mailx* quits shall be retained in the system mailbox.
unread	The message has been present in the system mailbox for more than one invocation of *mailx* and has not been viewed by the user or moved to any other state. Messages in state *unread* when *mailx* quits shall be retained in the system mailbox.
read	The message has been processed by one of the following commands: **˜f**, **˜m**, **˜F**, **˜M**, **copy**, **mbox**, **next**, **pipe**, **print**, **Print**, **top**, **type**, **Type**, **undelete**. The **delete**, **dp**, and **dt** commands may also cause the next message to be marked as *read*, depending on the value of the **autoprint** variable. Messages that are in the system mailbox and in state *read* when *mailx* quits shall be saved in the **mbox**, unless the internal variable **hold** was set. Messages that are in the **mbox** or in a secondary mailbox and in state

	read when *mailx* quits shall be retained in their current location.
deleted	The message has been processed by one of the following commands: **delete**, **dp**, **dt**. Messages in state *deleted* when *mailx* quits shall be deleted. Deleted messages shall be ignored until *mailx* quits or changes mailboxes or they are specified to the undelete command; for example, the message specification /*string* shall only search the subject lines of messages that have not yet been deleted, unless the command operating on the list of messages is **undelete**. No deleted message or deleted message header shall be displayed by any *mailx* command other than **undelete**.
preserved	The message has been processed by a **preserve** command. When *mailx* quits, the message shall be retained in its current location.
saved	The message has been processed by one of the following commands: **save** or **write**. If the current mailbox is the system mailbox, and the internal variable **keepsave** is set, messages in the state saved shall be saved to the file designated by the *MBOX* variable (see the ENVIRONMENT VARIABLES section). If the current mailbox is the system mailbox, messages in the state *saved* shall be deleted from the current mailbox, when the **quit** or **file** command is used to exit the current mailbox.

The header-summary line for each message shall indicate the state of the message.

Many commands take an optional list of messages (*msglist*) on which to operate, which defaults to the current message. A *msglist* is a list of message specifications separated by <blank>s, which can include:

`n`	Message number *n*.
`+`	The next undeleted message, or the next deleted message for the **undelete** command.
–	The next previous undeleted message, or the next previous deleted message for the **undelete** command.
`.`	The current message.
`^`	The first undeleted message, or the first deleted message for the **undelete** command.
`$`	The last message.
`*`	All messages.
`n-m`	An inclusive range of message numbers.
address	All messages from *address*; any address as shown in a header summary shall be matchable in this form.
/*string*	All messages with *string* in the subject line (case ignored).
`:c`	All messages of type *c*, where *c* shall be one of:

`d`	Deleted messages.
`n`	New messages.
`o`	Old messages (any not in state *read* or *new*).
`r`	Read messages.
`u`	Unread messages.

Other commands take an optional message (*message*) on which to operate, which defaults to the current message. All of the forms allowed for *msglist* are also allowed for *message*, but if more than one message is specified, only the first shall be operated on.

Other arguments are usually arbitrary strings whose usage depends on the command involved.

Start-Up in mailx

At start-up time, *mailx* shall take the following steps in sequence:

1. Establish all variables at their stated default values.
2. Process command line options, overriding corresponding default values.
3. Import any of the *DEAD*, *EDITOR*, *MBOX*, *LISTER*, *PAGER*, *SHELL*, or *VISUAL* variables that are present in the environment, overriding the corresponding default values.
4. Read *mailx* commands from an unspecified system start-up file, unless the −**n** option is given, to initialize any internal *mailx* variables and aliases.
5. Process the start-up file of *mailx* commands named in the user *MAILRC* variable.

Most regular *mailx* commands are valid inside start-up files, the most common use being to set up initial display options and alias lists. The following commands shall be invalid in the start-up file: **!**, **edit**, **hold**, **mail**, **preserve**, **reply**, **Reply**, **shell**, **visual**, **Copy**, **followup**, and **Followup**. Any errors in the start-up file shall either cause *mailx* to terminate with a diagnostic message and a non-zero status or to continue after writing a diagnostic message, ignoring the remainder of the lines in the start-up file.

A blank line in a start-up file shall be ignored.

Internal Variables in mailx

The following variables are internal *mailx* variables. Each internal variable can be set via the *mailx* **set** command at any time. The **unset** and **set no** *name* commands can be used to erase variables.

In the following list, variables shown as:

`variable`

represent Boolean values. Variables shown as:

`variable=`*`value`*

shall be assigned string or numeric values. For string values, the rules in **Commands in mailx** (on page 2795) concerning filenames and quoting shall also apply. |

The defaults specified here may be changed by the implementation-defined system start-up file unless the user specifies the −**n** option.

allnet All network names whose login name components match shall be treated as identical. This shall cause the *msglist* message specifications to behave similarly. The default shall be **noallnet**. See also the **alternates** command and the **metoo** variable. |

append Append messages to the end of the **mbox** file upon termination instead of placing them at the beginning. The default shall be **noappend**. This variable shall not affect the **save** command when saving to the **mbox**.

ask, **asksub**
Prompt for a subject line on outgoing mail if one is not specified on the command

line with the **–s** option. The **ask** and **asksub** forms are synonyms; the system shall refer to **asksub** and **noasksub** in its messages, but shall accept **ask** and **noask** as user input to mean **asksub** and **noasksub**. It shall not be possible to set both **ask** and **noasksub**, or **noask** and **asksub**. The default shall be **asksub**, but no prompting shall be done if standard input is not a terminal.

askbcc	Prompt for the blind copy list. The default shall be **noaskbcc**.
askcc	Prompt for the copy list. The default shall be **noaskcc**.
autoprint	Enable automatic writing of messages after **delete** and **undelete** commands. The default shall be **noautoprint**.
bang	Enable the special-case treatment of exclamation marks (`'!'`) in escape command lines; see the **escape** command and **Command Escapes in mailx** (on page 2803). The default shall be **nobang**, disabling the expansion of `'!'` in the *command* argument to the **~!** command and the **~<!***command* escape.
cmd=*command*	Set the default command to be invoked by the **pipe** command. The default shall be **nocmd**.
crt=*number*	Pipe messages having more than *number* lines through the command specified by the value of the *PAGER* variable. The default shall be **nocrt**. If it is set to null, the value used is implementation-defined.
XSI **debug**	Enable verbose diagnostics for debugging. Messages are not delivered. The default shall be **nodebug**.
dot	When **dot** is set, a period on a line by itself during message input from a terminal shall also signify end-of-file (in addition to normal end-of-file). The default shall be **nodot**. If **ignoreeof** is set (see below), a setting of **nodot** shall be ignored and the period is the only method to terminate input mode.
escape=*c*	Set the command escape character to be the character `'c'`. By default, the command escape character shall be tilde. If **escape** is unset, tilde shall be used; if it is set to null, command escaping shall be disabled.
flipr	Reverse the meanings of the **R** and **r** commands. The default shall be **noflipr**.
folder=*directory*	The default directory for saving mail files. User-specified filenames beginning with a plus sign (`'+'`) shall be expanded by preceding the filename with this directory name to obtain the real pathname. If *directory* does not start with a slash (`'/'`), the contents of *HOME* shall be prefixed to it. The default shall be **nofolder**. If **folder** is unset or set to null, user-specified filenames beginning with `'+'` shall refer to files in the current directory that begin with the literal `'+'` character. See also **outfolder** below. The **folder** value need not affect the processing of the files named in *MBOX* and *DEAD*.
header	Enable writing of the header summary when entering *mailx* in Receive Mode. The default shall be **header**.
hold	Preserve all messages that are read in the system mailbox instead of putting them in the **mbox** save file. The default shall be **nohold**.
ignore	Ignore interrupts while entering messages. The default shall be **noignore**.
ignoreeof	Ignore normal end-of-file during message input. Input can be terminated only by entering a period (`'.'`) on a line by itself or by the **~.** command escape. The default

	shall be **noignoreeof**. See also **dot** above.
indentprefix=*string*	A string that shall be added as a prefix to each line that is inserted into the message by the **˜m** command escape. This variable shall default to one <tab>.
keep	When a system mailbox, secondary mailbox, or **mbox** is empty, truncate it to zero length instead of removing it. The default shall be **nokeep**.
keepsave	Keep the messages that have been saved from the system mailbox into other files in the file designated by the variable *MBOX*, instead of deleting them. The default shall be **nokeepsave**.
metoo	Suppress the deletion of the login name of the user from the recipient list when replying to a message or sending to a group. The default shall be **nometoo**.
XSI **onehop**	When responding to a message that was originally sent to several recipients, the other recipient addresses are normally forced to be relative to the originating author's machine for the response. This flag disables alteration of the recipients' addresses, improving efficiency in a network where all machines can send directly to all other machines (that is, one hop away). The default shall be **noonehop**.
outfolder	Cause the files used to record outgoing messages to be located in the directory specified by the **folder** variable unless the pathname is absolute. The default shall be **nooutfolder**. See the **record** variable.
page	Insert a <form-feed> after each message sent through the pipe created by the **pipe** command. The default shall be **nopage**.
prompt=*string*	Set the command-mode prompt to *string*. If *string* is null or if **noprompt** is set, no prompting shall occur. The default shall be to prompt with the string `"? "`.
quiet	Refrain from writing the opening message and version when entering *mailx*. The default shall be **noquiet**.
record=*file*	Record all outgoing mail in the file with the pathname *file*. The default shall be **norecord**. See also **outfolder** above.
save	Enable saving of messages in the dead-letter file on interrupt or delivery error. See the variable *DEAD* for the location of the dead-letter file. The default shall be **save**.
screen=*number*	Set the number of lines in a screenful of headers for the **headers** and **z** commands. If **screen** is not specified, a value based on the terminal type identified by the *TERM* environment variable, the window size, the baud rate, or some combination of these shall be used.
sendwait	Wait for the background mailer to finish before returning. The default shall be **nosendwait**.
showto	When the sender of the message was the user who is invoking *mailx*, write the information from the **To:** line instead of the **From:** line in the header summary. The default shall be **noshowto**.
sign=*string*	Set the variable inserted into the text of a message when the **˜a** command escape is given. The default shall be **nosign**. The character sequences `'\t'` and `'\n'` shall be recognized in the variable as <tab>s and <newline>s, respectively. (See also **˜i** in **Command Escapes in mailx** (on page 2803).)

Sign=*string* Set the variable inserted into the text of a message when the **˜A** command escape is given. The default shall be **noSign**. The character sequences `'\t'` and `'\n'` shall be recognized in the variable as <tab>s and <newline>s, respectively.

toplines=*number*
Set the number of lines of the message to write with the **top** command. The default shall be 5.

Commands in mailx

The following *mailx* commands shall be provided. In the following list, header refers to lines from the message header, as shown in the OUTPUT FILES section. Header-line refers to lines within the header that begin with one or more non-white-space characters, immediately followed by a colon and white space and continuing until the next line beginning with a non-white-space character or an empty line. Header-field refers to the portion of a header line prior to the first colon in that line.

For each of the commands listed below, the command can be entered as the abbreviation (those characters in the Synopsis command word preceding the `'['`), the full command (all characters shown for the command word, omitting the `'['` and `']'`), or any truncation of the full command down to the abbreviation. For example, the **exit** command (shown as **ex[it]** in the Synopsis) can be entered as **ex**, **exi**, or **exit**.

The arguments to commands can be quoted, using the following methods:

- An argument can be enclosed between paired double-quotes (" ") or single-quotes (' '); any white space, shell word expansion, or backslash characters within the quotes shall be treated literally as part of the argument. A double-quote shall be treated literally within single-quotes and *vice versa*. These special properties of the quote marks shall occur only when they are paired at the beginning and end of the argument.
- A backslash outside of the enclosing quotes shall be discarded and the following character treated literally as part of the argument.
- An unquoted backslash at the end of a command line shall be discarded and the next line shall continue the command.

Filenames, where expected, shall be subjected to the process of shell word expansions (see Section 2.6 (on page 2238)); if more than a single pathname results and the command is expecting one file, the effects are unspecified. If the filename begins with an unquoted plus sign, it shall not be expanded, but treated as the named file (less the leading plus) in the **folder** directory. (See the **folder** variable.)

Declare Aliases

Synopsis:
```
a[lias] [alias [address...]]
g[roup] [alias [address...]]
```

Add the given addresses to the alias specified by *alias*. The names shall be substituted when *alias* is used as a recipient address specified by the user in an outgoing message (that is, other recipients addressed indirectly through the **reply** command shall not be substituted in this manner). Mail address alias substitution shall apply only when the alias string is used as a full address; for example, when **hlj** is an alias, *hlj@posix.com* does not trigger the alias substitution. If no arguments are given, write a listing of the current aliases to standard output. If only an *alias* argument is given, write a listing of the specified alias to standard output. These listings need not reflect the same order of addresses that were entered.

Declare Alternatives

Synopsis: `alt[ernates] name...`

(See also the **metoo** command.) Declare a list of alternative names for the user's login. When responding to a message, these names shall be removed from the list of recipients for the response. The comparison of names shall be in a case-insensitive manner. With no arguments, **alternates** shall write the current list of alternative names.

Change Current Directory

Synopsis:
```
cd [directory]
ch[dir] [directory]
```

Change directory. If *directory* is not specified, the contents of *HOME* shall be used.

Copy Messages

Synopsis:
```
c[opy] [file]
c[opy] [msglist] file
C[opy] [msglist]
```

Copy messages to the file named by the pathname *file* without marking the messages as saved. Otherwise, it shall be equivalent to the **save** command.

In the capitalized form, save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the messages as saved. Otherwise, it shall be equivalent to the **Save** command.

Delete Messages

Synopsis: `d[elete] [msglist]`

Mark messages for deletion from the mailbox. The deletions shall not occur until *mailx* quits (see the **quit** command) or changes mailboxes (see the **folder** command). If **autoprint** is set and there are messages remaining after the **delete** command, the current message shall be written as described for the **print** command (see the **print** command); otherwise, the *mailx* prompt shall be written.

Discard Header Fields

Synopsis:
```
di[scard] [header-field...]
ig[nore] [header-field...]
```

Suppress the specified header fields when writing messages. Specified *header-fields* shall be added to the list of suppressed header fields. Examples of header fields to ignore are **status** and **cc**. The fields shall be included when the message is saved. The **Print** and **Type** commands shall override this command. The comparison of header fields shall be in a case-insensitive manner. If no arguments are specified, write a list of the currently suppressed header fields to standard output; the listing need not reflect the same order of header fields that were entered.

If both **retain** and **discard** commands are given, **discard** commands shall be ignored.

Delete Messages and Display

Synopsis:

```
dp [msglist]
dt [msglist]
```

Delete the specified messages as described for the **delete** command, except that the **autoprint** variable shall have no effect, and the current message shall be written only if it was set to a message after the last message deleted by the command. Otherwise, an informational message to the effect that there are no further messages in the mailbox shall be written, followed by the *mailx* prompt.

Echo a String

Synopsis:

```
ec[ho] string ...
```

Echo the given strings, equivalent to the shell *echo* utility.

Edit Messages

Synopsis:

```
e[dit] [msglist]
```

Edit the given messages. The messages shall be placed in a temporary file and the utility named by the *EDITOR* variable is invoked to edit each file in sequence. The default *EDITOR* is unspecified.

The **edit** command does not modify the contents of those messages in the mailbox.

Exit

Synopsis:

```
ex[it]
x[it]
```

Exit from *mailx* without changing the mailbox. No messages shall be saved in the **mbox** (see also **quit**).

Change Folder

Synopsis:

```
fi[le] [file]
fold[er] [file]
```

Quit (see the **quit** command) from the current file of messages and read in the file named by the pathname *file*. If no argument is given, the name and status of the current mailbox shall be written.

Several unquoted special characters shall be recognized when used as *file* names, with the following substitutions:

`%`	The system mailbox for the invoking user.
`%user`	The system mailbox for *user*.
`#`	The previous file.
`&`	The current **mbox**.
`+file`	The named file in the **folder** directory. (See the **folder** variable.)

The default file shall be the current mailbox.

Display List of Folders

Synopsis: `folders`

Write the names of the files in the directory set by the **folder** variable. The command specified by the *LISTER* environment variable shall be used (see the ENVIRONMENT VARIABLES section).

Follow Up Specified Messages

Synopsis:
```
fo[llowup] [message]
F[ollowup] [msglist]
```

In the lowercase form, respond to a message, recording the response in a file whose name is derived from the author of the message. See also the **save** and **copy** commands and **outfolder**.

In the capitalized form, respond to the first message in the *msglist*, sending the message to the author of each message in the *msglist*. The subject line shall be taken from the first message and the response shall be recorded in a file whose name is derived from the author of the first message. See also the **Save** and **Copy** commands and **outfolder**.

Both forms shall override the **record** variable, if set. |

Display Header Summary for Specified Messages

Synopsis: `f[rom] [msglist]`

Write the header summary for the specified messages.

Display Header Summary

Synopsis: `h[eaders] [message]`

Write the page of headers that includes the message specified. If the *message* argument is not specified, the current message shall not change. However, if the *message* argument is specified, the current message shall become the message that appears at the top of the page of headers that includes the message specified. The **screen** variable sets the number of headers per page. See also the **z** command.

Help

Synopsis:
```
hel[p]
?
```

Write a summary of commands.

Hold Messages

Synopsis:
```
ho[ld] [msglist]
pre[serve] [msglist]
```

Mark the messages in *msglist* to be retained in the mailbox when *mailx* terminates. This shall override any commands that might previously have marked the messages to be deleted. During the current invocation of *mailx*, only the **delete**, **dp**, or **dt** commands shall remove the *preserve* marking of a message.

Execute Commands Conditionally

Synopsis:
```
i[f] s|r
mail-commands
el[se]
mail-commands
en[dif]
```

Execute commands conditionally, where **if s** executes the following *mail-commands*, up to an **else** or **endif**, if the program is in Send Mode, and **if r** shall cause the *mail-commands* to be executed only in Receive Mode.

List Available Commands

Synopsis: `l[ist]`

Write a list of all commands available. No explanation shall be given.

Mail a Message

Synopsis: `m[ail] address...`

Mail a message to the specified addresses or aliases.

Direct Messages to mbox

Synopsis: `mb[ox] [msglist]`

Arrange for the given messages to end up in the **mbox** save file when *mailx* terminates normally. See *MBOX*. See also the **exit** and **quit** commands.

Process Next Specified Message

Synopsis: `n[ext] [message]`

If the current message has not been written (for example, by the **print** command) since *mailx* started or since any other message was the current message, behave as if the **print** command was entered. Otherwise, if there is an undeleted message after the current message, make it the current message and behave as if the **print** command was entered. Otherwise, an informational message to the effect that there are no further messages in the mailbox shall be written, followed by the *mailx* prompt.

Pipe Message

Synopsis:
```
pi[pe] [[msglist] command]
| [[msglist] command]
```

Pipe the messages through the given *command* by invoking the command interpreter specified by *SHELL* with two arguments: −**c** and *command*. (See also *sh* −**c**.) The application shall ensure that the command is given as a single argument. Quoting, described previously, can be used to accomplish this. If no arguments are given, the current message shall be piped through the command specified by the value of the **cmd** variable. If the **page** variable is set, a <form-feed> shall be inserted after each message.

Display Message with Headers

Synopsis: `P[rint] [msglist]`
`T[ype] [msglist]`

Write the specified messages, including all header lines, to standard output. Override suppression of lines by the **discard**, **ignore**, and **retain** commands. If **crt** is set, the messages longer than the number of lines specified by the **crt** variable shall be paged through the command specified by the *PAGER* environment variable.

Display Message

Synopsis: `p[rint] [msglist]`
`t[ype] [msglist]`

Write the specified messages to standard output. If **crt** is set, the messages longer than the number of lines specified by the **crt** variable shall be paged through the command specified by the *PAGER* environment variable.

Quit

Synopsis: `q[uit]`
`end-of-file`

Terminate *mailx*, storing messages that were read in **mbox** (if the current mailbox is the system mailbox and unless **hold** is set), deleting messages that have been explicitly saved (unless **keepsave** is set), discarding messages that have been deleted, and saving all remaining messages in the mailbox.

Reply to a Message List

Synopsis: `R[eply] [msglist]`
`R[espond] [msglist]`

Mail a reply message to the sender of each message in the *msglist*. The subject line shall be formed by concatenating **Re:**<space> (unless it already begins with that string) and the subject from the first message. If **record** is set to a filename, the response shall be saved at the end of that file.

See also the **flipr** variable.

Reply to a Message

Synopsis: `r[eply] [message]`
`r[espond] [message]`

Mail a reply message to all recipients included in the header of the message. The subject line shall be formed by concatenating **Re:**<space> (unless it already begins with that string) and the subject from the message. If **record** is set to a filename, the response shall be saved at the end of that file.

See also the **flipr** variable.

Retain Header Fields

Synopsis: `ret[ain] [header-field...]`

Retain the specified header fields when writing messages. This command shall override all **discard** and **ignore** commands. The comparison of header fields shall be in a case-insensitive manner. If no arguments are specified, write a list of the currently retained header fields to standard output; the listing need not reflect the same order of header fields that were entered.

Save Messages

Synopsis:
```
s[ave] [file]
s[ave] [msglist] file
S[ave] [msglist]
```

Save the specified messages in the file named by the pathname *file*, or the **mbox** if the *file* argument is omitted. The file shall be created if it does not exist; otherwise, the messages shall be appended to the file. The message shall be put in the state *saved*, and shall behave as specified in the description of the *saved* state when the current mailbox is exited by the **quit** or **file** command.

In the capitalized form, save the specified messages in a file whose name is derived from the author of the first message. The name of the file shall be taken to be the author's name with all network addressing stripped off. See also the **Copy**, **followup**, and **Followup** commands and **outfolder** variable.

Set Variables

Synopsis: `se[t] [name[=[string]] ...] [name=number ...] [noname ...]`

Define one or more variables called *name*. The variable can be given a null, string, or numeric value. Quoting and backslash escapes can occur anywhere in *string*, as described previously, as if the *string* portion of the argument were the entire argument. The forms *name* and *name*= shall be equivalent to *name*="" for variables that take string values. The **set** command without arguments shall write a list of all defined variables and their values. The **no** *name* form shall be equivalent to **unset** *name*.

Invoke a Shell

Synopsis: `sh[ell]`

Invoke an interactive command interpreter (see also *SHELL*).

Display Message Size

Synopsis: `si[ze] [msglist]`

Write the size in bytes of each of the specified messages.

Read mailx Commands From a File

Synopsis: `so[urce] file`

Read and execute commands from the file named by the pathname *file* and return to command mode.

Display Beginning of Messages

Synopsis: `to[p] [msglist]`

Write the top few lines of each of the specified messages. If the **toplines** variable is set, it is taken as the number of lines to write. The default shall be 5.

Touch Messages

Synopsis: `tou[ch] [msglist]`

Touch the specified messages. If any message in *msglist* is not specifically deleted nor saved in a file, it shall be placed in the **mbox** upon normal termination. See **exit** and **quit**.

Delete Aliases

Synopsis: `una[lias] [alias]...`

Delete the specified alias names. If a specified alias does not exist, the results are unspecified.

Undelete Messages

Synopsis: `u[ndelete] [msglist]`

Change the state of the specified messages from deleted to read. If **autoprint** is set, the last message of those restored shall be written. If *msglist* is not specified, the message shall be selected as follows:

- If there are any deleted messages that follow the current message, the first of these shall be chosen.
- Otherwise, the last deleted message that also precedes the current message shall be chosen.

Unset Variables

Synopsis: `uns[et] name...`

Cause the specified variables to be erased.

Edit Message with Full-Screen Editor

Synopsis: `v[isual] [msglist]`

Edit the given messages with a screen editor. Each message shall be placed in a temporary file, and the utility named by the *VISUAL* variable shall be invoked to edit each file in sequence. The default editor shall be *vi*.

The **visual** command does not modify the contents of those messages in the mailbox.

Write Messages to a File

Synopsis: `w[rite] [msglist] file`

Write the given messages to the file specified by the pathname *file*, minus the message header. Otherwise, it shall be equivalent to the **save** command.

Scroll Header Display

Synopsis: `z[+|−]`

Scroll the header display forward (if `'+'` is specified or if no option is specified) or backward (if `'−'` is specified) one screenful. The number of headers written shall be set by the **screen** variable.

Invoke Shell Command

Synopsis: `!command`

Invoke the command interpreter specified by *SHELL* with two arguments: **−c** and *command*. (See also *sh* **−c**.) If the **bang** variable is set, each unescaped occurrence of `'!'` in command shall be replaced with the command executed by the previous **!** command or **˜!** command escape.

Null Command

Synopsis: `# comment`

This null command (comment) shall be ignored by *mailx*.

Display Current Message Number

Synopsis: `=`

Write the current message number.

Command Escapes in mailx

The following commands can be entered only from input mode, by beginning a line with the escape character (by default, tilde (`'˜'`)). See the **escape** variable description for changing this special character. The format for the commands shall be:

`<escape-character><command-char><separator>[<arguments>]` |

where the <*separator*> can be zero or more <blank>s. |

In the following descriptions, the application shall ensure that the argument *command* (but not *mailx-command)* is a shell command string. Any string acceptable to the command interpreter specified by the *SHELL* variable when it is invoked as *SHELL* **−c** *command_string* shall be valid. The command can be presented as multiple arguments (that is, quoting is not required).

Command escapes that are listed with *msglist* or *mailx-command* arguments are invalid in Send Mode and produce unspecified results.

~! *command* Invoke the command interpreter specified by *SHELL* with two arguments: **−c** and *command*; and then return to input mode. If the **bang** variable is set, each unescaped occurrence of `'!'` in *command* shall be replaced with the command executed by the previous **!** command or **˜!** command escape.

~. Simulate end-of-file (terminate message input).

~: *mailx-command*, **˜_** *mailx-command*
Perform the command-level request.

~? Write a summary of command escapes.

~A This shall be equivalent to **˜i Sign**.

~a This shall be equivalent to **˜i sign**.

~b *name*. . .	Add the *name*s to the blind carbon copy (**Bcc**) list.
~c *name*. . .	Add the *name*s to the carbon copy (**Cc**) list.
~d	Read in the dead-letter file. See *DEAD* for a description of this file.
~e	Invoke the editor, as specified by the *EDITOR* environment variable, on the partial message.
~f [*msglist*]	Forward the specified messages. The specified messages shall be inserted into the current message without alteration. This command escape also shall insert message headers into the message with field selection affected by the **discard**, **ignore**, and **retain** commands.
~F [*msglist*]	This shall be the equivalent of the **˜f** command escape, except that all headers shall be included in the message, regardless of previous **discard**, **ignore**, and **retain** commands.
~h	If standard input is a terminal, prompt for a **Subject** line and the **To**, **Cc**, and **Bcc** lists. Other implementation-defined headers may also be presented for editing. If the field is written with an initial value, it can be edited as if it had just been typed.
~i *string*	Insert the value of the named variable, followed by a <newline>, into the text of the message. If the string is unset or null, the message shall not be changed.
~m [*msglist*]	Insert the specified messages into the message, prefixing non-empty lines with the string in the **indentprefix** variable. This command escape also shall insert message headers into the message, with field selection affected by the **discard**, **ignore**, and **retain** commands.
~M [*msglist*]	This shall be the equivalent of the **˜m** command escape, except that all headers shall be included in the message, regardless of previous **discard**, **ignore**, and **retain** commands.
~p	Write the message being entered. If the message is longer than **crt** lines (see **Internal Variables in mailx** (on page 2792)), the output shall be paginated as described for the *PAGER* variable.
~q	Quit (see the **quit** command) from input mode by simulating an interrupt. If the body of the message is not empty, the partial message shall be saved in the dead-letter file. See *DEAD* for a description of this file.
"**˜r** *file*, **˜<** *file*, **˜r** !*command*, **˜<** !*command*"	Read in the file specified by the pathname *file*. If the argument begins with an exclamation mark (`'!'`), the rest of the string shall be taken as an arbitrary system command; the command interpreter specified by *SHELL* shall be invoked with two arguments: **−c** and *command*. The standard output of *command* shall be inserted into the message.
~s *string*	Set the subject line to *string*.
~t *name*. . .	Add the given *name*s to the **To** list.
~v	Invoke the full-screen editor, as specified by the *VISUAL* environment variable, on the partial message.
~w *file*	Write the partial message, without the header, onto the file named by the pathname *file*. The file shall be created or the message shall be appended to it if the file exists.

~x	Exit as with **~q**, except the message shall not be saved in the dead-letter file.
~| *command*	Pipe the body of the message through the given *command* by invoking the command interpreter specified by *SHELL* with two arguments: **–c** and *command*. If the *command* returns a successful exit status, the standard output of the command shall replace the message. Otherwise, the message shall remain unchanged. If the *command* fails, an error message giving the exit status shall be written.

EXIT STATUS

When the **–e** option is specified, the following exit values are returned:

0	Mail was found.
>0	Mail was not found or an error occurred.

Otherwise, the following exit values are returned:

0	Successful completion; note that this status implies that all messages were *sent*, but it gives no assurances that any of them were actually *delivered*.
>0	An error occurred.

CONSEQUENCES OF ERRORS

When in input mode (Receive Mode) or Send Mode:

- If an error is encountered processing a command escape (see **Command Escapes in mailx** (on page 2803)), a diagnostic message shall be written to standard error, and the message being composed may be modified, but this condition shall not prevent the message from being sent.
- Other errors shall prevent the sending of the message.

When in command mode:

- Default.

APPLICATION USAGE

Delivery of messages to remote systems requires the existence of communication paths to such systems. These need not exist.

Input lines are limited to {LINE_MAX} bytes, but mailers between systems may impose more severe line-length restrictions. This volume of IEEE Std 1003.1-200x does not place any restrictions on the length of messages handled by *mailx*, and for delivery of local messages the only limitations should be the normal problems of available disk space for the target mail file. When sending messages to external machines, applications are advised to limit messages to less than 100,000 bytes because some mail gateways impose message-length restrictions.

The format of the system mailbox is intentionally unspecified. Not all systems implement system mailboxes as flat files, particularly with the advent of multimedia mail messages. Some system mailboxes may be multiple files, others records in a database. The internal format of the messages themselves are specified with the historical format from Version 7, but only after they have been saved in some file other than the system mailbox. This was done so that many historical applications expecting text-file mailboxes are not broken.

Some new formats for messages can be expected in the future, probably including binary data, bit maps, and various multimedia objects. As described here, *mailx* is not prohibited from handling such messages, but it must store them as text files in secondary mailboxes (unless some extension, such as a variable or command line option, is used to change the stored format). Its method of doing so is implementation-defined and might include translating the data into text file-compatible or readable form or omitting certain portions of the message from the stored output.

The **discard** and **ignore** commands are not inverses of the **retain** command. The **retain** command discards all header-fields except those explicitly retained. The **discard** command keeps all header-fields except those explicitly discarded. If headers exist on the retained header list, **discard** and **ignore** commands are ignored.

EXAMPLES

None.

RATIONALE

The standard developers felt strongly that a method for applications to send messages to specific users was necessary. The obvious example is a batch utility, running non-interactively, that wishes to communicate errors or results to a user. However, the actual format, delivery mechanism, and method of reading the message are clearly beyond the scope of this volume of IEEE Std 1003.1-200x.

The intent of this command is to provide a simple, portable interface for sending messages non-interactively. It merely defines a ''front-end'' to the historical mail system. It is suggested that implementations explicitly denote the sender and recipient in the body of the delivered message. Further specification of formats for either the message envelope or the message itself were deliberately not made, as the industry is in the midst of changing from the current standards to a more internationalized standard and it is probably incorrect, at this time, to require either one.

Implementations are encouraged to conform to the various delivery mechanisms described in the CCITT X.400 standards or to the equivalent Internet standards, described in Internet Request for Comment (RFC) documents RFC 819, RFC 822, RFC 920, RFC 921, and RFC 1123.

Many historical systems modified each body line that started with **From** by prefixing the `'F'` with `'>'`. It is unnecessary, but allowed, to do that when the string does not follow a blank line because it cannot be confused with the next header.

The *edit* and *visual* commands merely edit the specified messages in a temporary file. They do not modify the contents of those messages in the mailbox; such a capability could be added as an extension, such as by using different command names.

The restriction on a subject line being {LINE_MAX}−10 bytes is based on the historical format that consumes 10 bytes for **Subject:** and the trailing <newline>. Many historical mailers that a message may encounter on other systems are not able to handle lines that long, however.

Like the utilities *logger* and *lp*, *mailx* admittedly is difficult to test. This was not deemed sufficient justification to exclude this utility from this volume of IEEE Std 1003.1-200x. It is also arguable that it is, in fact, testable, but that the tests themselves are not portable.

When *mailx* is being used by an application that wishes to receive the results as if none of the User Portability Utilities option features were supported, the *DEAD* environment variable must be set to **/dev/null**. Otherwise, it may be subject to the file creations described in *mailx* ASYNCHRONOUS EVENTS. Similarly, if the *MAILRC* environment variable is not set to **/dev/null**, historical versions of *mailx* and *Mail* read initialization commands from a file before processing begins. Since the initialization that a user specifies could alter the contents of messages an application is trying to send, such applications must set *MAILRC* to **/dev/null**.

The description of *LC_TIME* uses ''may affect'' because many historical implementations do not or cannot manipulate the date and time strings in the incoming mail headers. Some headers found in incoming mail do not have enough information to determine the timezone in which the mail originated, and, therefore, *mailx* cannot convert the date and time strings into the internal form that then is parsed by routines like *strftime*( ) that can take *LC_TIME* settings into account.

Changing all these times to a user-specified format is allowed, but not required.

The paginator selected when *PAGER* is null or unset is partially unspecified to allow the System V historical practice of using *pg* as the default. Bypassing the pagination function, such as by declaring that *cat* is the paginator, would not meet with the intended meaning of this description. However, any ‘‘portable user’’ would have to set *PAGER* explicitly to get his or her preferred paginator on all systems. The paginator choice was made partially unspecified, unlike the *VISUAL* editor choice (mandated to be *vi*) because most historical pagers follow a common theme of user input, whereas editors differ dramatically.

Options to specify addresses as **cc** (carbon copy) or **bcc** (blind carbon copy) were considered to be format details and were omitted.

A zero exit status implies that all messages were *sent*, but it gives no assurances that any of them were actually *delivered*. The reliability of the delivery mechanism is unspecified and is an appropriate marketing distinction between systems.

In order to conform to the Utility Syntax Guidelines, a solution was required to the optional *file* option-argument to **−f**. By making *file* an operand, the guidelines are satisfied and users remain portable. However, it does force implementations to support usage such as:

```
mailx −fin mymail.box
```

The **no** *name* method of unsetting variables is not present in all historical systems, but it is in System V and provides a logical set of commands corresponding to the format of the display of options from the *mailx set* command without arguments.

The **ask** and **asksub** variables are the names selected by BSD and System V, respectively, for the same feature. They are synonyms in this volume of IEEE Std 1003.1-200x.

The *mailx echo* command was not documented in the BSD version and has been omitted here because it is not obviously useful for interactive users.

The default prompt on the System V *mailx* is a question mark, on BSD *Mail* an ampersand. Since this volume of IEEE Std 1003.1-200x chose the *mailx* name, it kept the System V default, assuming that BSD users would not have difficulty with this minor incompatibility (that they can override).

The meanings of **r** and **R** are reversed between System V *mailx* and SunOS *Mail*. Once again, since this volume of IEEE Std 1003.1-200x chose the *mailx* name, it kept the System V default, but allows the SunOS user to achieve the desired results using **flipr**, an internal variable in System V *mailx*, although it has not been documented in the SVID

The **indentprefix** variable, the **retain** and **unalias** commands, and the **~F** and **~M** command escapes were adopted from 4.3 BSD *Mail*.

The **version** command was not included because no sufficiently general specification of the version information could be devised that would still be useful to a portable user. This command name should be used by suppliers who wish to provide version information about the *mailx* command.

The ‘‘implementation-specific (unspecified) system start-up file’’ historically has been named **/etc/mailx.rc**, but this specific name and location are not required.

The intent of the wording for the **next** command is that if any command has already displayed the current message it should display a following message, but, otherwise, it should display the current message. Consider the command sequence:

```
next 3
delete 3
```

```
next
```

where the **autoprint** option was not set. The normative text specifies that the second **next** command should display a message following the third message, because even though the current message has not been displayed since it was set by the **delete** command, it has been displayed since the current message was anything other than message number 3. This does not always match historical practice in some implementations, where the command file address followed by **next** (or the default command) would skip the message for which the user had searched.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The description of the EDITOR environment variable is changed to indicate that *ed* is the default editor if this variable is not set. In previous issues, this default was not stated explicitly at this point but was implied further down in the text.

FUTURE DIRECTIONS section added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **–F** option is added.
- The **allnet**, **debug**, and **sendwait** internal variables are added.
- The **C**, **ec**, **fo**, **F**, and **S** *mailx* commands are added.

In the DESCRIPTION and ENVIRONMENT VARIABLES sections, text stating ‘‘*HOME* directory’’ is replaced by ‘‘directory referred to by the *HOME* environment variable’’.

The *mailx* utility is aligned with the IEEE P1003.2b draft standard, which included various clarifications to resolve IEEE PASC Interpretations submitted for the ISO POSIX-2:1993 standard. In particular, the changes here address IEEE PASC Interpretations 1003.2 #10, #11, #103, #106, #108, #114, #115, #122, and #129.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

NAME

make — maintain, update, and regenerate groups of programs (**DEVELOPMENT**)

SYNOPSIS

SD
```
make [−einpqrst][−f makefile]...[ −k| −S][macro=value]...
    [target_name...]
```

DESCRIPTION

The *make* utility shall update files that are derived from other files. A typical case is one where object files are derived from the corresponding source files. The *make* utility examines time relationships and shall update those derived files (called targets) that have modified times earlier than the modified times of the files (called prerequisites) from which they are derived. A description file (makefile) contains a description of the relationships between files, and the commands that need to be executed to update the targets to reflect changes in their prerequisites. Each specification, or rule, shall consist of a target, optional prerequisites, and optional commands to be executed when a prerequisite is newer than the target. There are two types of rule:

1. *Inference rules*, which have one target name with at least one period (`'.'`) and no slash (`'/'`)
2. *Target rules*, which can have more than one target name

In addition, *make* shall have a collection of built-in macros and inference rules that infer prerequisite relationships to simplify maintenance of programs.

To receive exactly the behavior described in this section, the user shall ensure that a portable makefile shall:

- Include the special target **.POSIX**
- Omit any special target reserved for implementations (a leading period followed by uppercase letters) that has not been specified by this section

The behavior of *make* is unspecified if either or both of these conditions are not met.

OPTIONS

The *make* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−e	Cause environment variables, including those with null values, to override macro assignments within makefiles.
−f *makefile*	Specify a different makefile. The argument *makefile* is a pathname of a description file, which is also referred to as the *makefile*. A pathname of `'−'` shall denote the standard input. There can be multiple instances of this option, and they shall be processed in the order specified. The effect of specifying the same option-argument more than once is unspecified.
−i	Ignore error codes returned by invoked commands. This mode is the same as if the special target **.IGNORE** were specified without prerequisites.
−k	Continue to update other targets that do not depend on the current target if a non-ignored error occurs while executing the commands to bring a target up-to-date.
−n	Write commands that would be executed on standard output, but do not execute them. However, lines with a plus sign (`'+'`) prefix shall be executed. In this mode,

lines with an at sign (`'@'`) character prefix shall be written to standard output.

−p Write to standard output the complete set of macro definitions and target descriptions. The output format is unspecified.

−q Return a zero exit value if the target file is up-to-date; otherwise, return an exit value of 1. Targets shall not be updated if this option is specified. However, a makefile command line (associated with the targets) with a plus sign (`'+'`) prefix shall be executed.

−r Clear the suffix list and does not use the built-in rules.

−S Terminate *make* if an error occurs while executing the commands to bring a target up-to-date. This shall be the default and the opposite of **−k**.

−s Do not write makefile command lines or touch messages (see **−t**) to standard output before executing. This mode shall be the same as if the special target **.SILENT** were specified without prerequisites.

−t Update the modification time of each target as though a *touch target* had been executed. Targets that have prerequisites but no commands (see **Target Rules** (on page 2813)), or that are already up-to-date, shall not be touched in this manner. Write messages to standard output for each target file indicating the name of the file and that it was touched. Normally, the makefile command lines associated with each target are not executed. However, a command line with a plus sign (`'+'`) prefix shall be executed.

Any options specified in the *MAKEFLAGS* environment variable shall be evaluated before any options specified on the *make* utility command line. If the **−k** and **−S** options are both specified on the *make* utility command line or by the *MAKEFLAGS* environment variable, the last option specified shall take precedence. If the **−f** or **−p** options appear in the *MAKEFLAGS* environment variable, the result is undefined.

OPERANDS

The following operands shall be supported:

target_name Target names, as defined in the EXTENDED DESCRIPTION section. If no target is specified, while *make* is processing the makefiles, the first target that *make* encounters that is not a special target or an inference rule shall be used.

macro=*value* Macro definitions, as defined in **Macros** (on page 2815).

If the *target_name* and *macro*=*value* operands are intermixed on the *make* utility command line, the results are unspecified.

STDIN

The standard input shall be used only if the *makefile* option-argument is `'−'`. See the INPUT FILES section.

INPUT FILES

The input file, otherwise known as the makefile, is a text file containing rules, macro definitions, and comments. See the EXTENDED DESCRIPTION section. |

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *make*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

MAKEFLAGS
This variable shall be interpreted as a character string representing a series of option characters to be used as the default options. The implementation shall accept both of the following formats (but need not accept them when intermixed):

- The characters are option letters without the leading hyphens or <blank> separation used on a *make* utility command line.
- The characters are formatted in a manner similar to a portion of the *make* utility command line: options are preceded by hyphens and <blank>-separated as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines. The *macro*=*value* macro definition operands can also be included. The difference between the contents of *MAKEFLAGS* and the *make* utility command line is that the contents of the variable shall not be subjected to the word expansions (see Section 2.6 (on page 2238)) associated with parsing the command line values.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

XSI *PROJECTDIR*
Provide a directory to be used to search for SCCS files not found in the current directory. In all of the following cases, the search for SCCS files is made in the directory **SCCS** in the identified directory. If the value of *PROJECTDIR* begins with a slash, it shall be considered an absolute pathname; otherwise, the value of *PROJECTDIR* is treated as a user name and that user's initial working directory shall be examined for a subdirectory **src** or **source**. If such a directory is found, it shall be used. Otherwise, the value is used as a relative pathname.

If *PROJECTDIR* is not set or has a null value, the search for SCCS files shall be made in the directory **SCCS** in the current directory.

The setting of *PROJECTDIR* affects all files listed in the remainder of this utility description for files with a component named **SCCS**.

The value of the *SHELL* environment variable shall not be used as a macro and shall not be modified by defining the **SHELL** macro in a makefile or on the command line. All other environment variables, including those with null values, shall be used as macros, as defined in **Macros** (on page 2815).

ASYNCHRONOUS EVENTS

If not already ignored, *make* shall trap SIGHUP, SIGTERM, SIGINT, and SIGQUIT and remove the current target unless the target is a directory or the target is a prerequisite of the special target **.PRECIOUS** or unless one of the **−n**, **−p**, or **−q** options was specified. Any targets removed in this manner shall be reported in diagnostic messages of unspecified format, written to standard error. After this cleanup process, if any, *make* shall take the standard action for all other signals.

STDOUT

The *make* utility shall write all commands to be executed to standard output unless the –**s** option was specified, the command is prefixed with an at sign, or the special target **.SILENT** has either the current target as a prerequisite or has no prerequisites. If *make* is invoked without any work needing to be done, it shall write a message to standard output indicating that no action was taken. If the –**t** option is present and a file is touched, *make* shall write to standard output a message of unspecified format indicating that the file was touched, including the filename of the file.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

Files can be created when the –**t** option is present. Additional files can also be created by the utilities invoked by *make*.

EXTENDED DESCRIPTION

The *make* utility attempts to perform the actions required to ensure that the specified targets are up-to-date. A target is considered out-of-date if it is older than any of its prerequisites or if it does not exist. The *make* utility shall treat all prerequisites as targets themselves and recursively ensure that they are up-to-date, processing them in the order in which they appear in the rule. The *make* utility shall use the modification times of files to determine whether the corresponding targets are out-of-date.

After *make* has ensured that all of the prerequisites of a target are up-to-date and if the target is out-of-date, the commands associated with the target entry shall be executed. If there are no commands listed for the target, the target shall be treated as up-to-date.

Makefile Syntax

A makefile can contain rules, macro definitions (see **Macros** (on page 2815)), and comments. There are two kinds of rules: *inference rules* and *target rules*. The *make* utility shall contain a set of built-in inference rules. If the –**r** option is present, the built-in rules shall not be used and the suffix list shall be cleared. Additional rules of both types can be specified in a makefile. If a rule is defined more than once, the value of the rule shall be that of the last one specified. Macros can also be defined more than once, and the value of the macro is specified in **Macros** (on page 2815). Comments start with a number sign ('#') and continue until an unescaped <newline> is reached.

By default, the following files shall be tried in sequence: **./makefile** and **./Makefile**. If neither **./makefile** or **./Makefile** are found, other implementation-defined files may also be tried. XSI On XSI-conformant systems, the additional files **./s.makefile**, **SCCS/s.makefile**, **./s.Makefile**, and **SCCS/s.Makefile** shall also be tried.

The –**f** option shall direct *make* to ignore any of these default files and use the specified argument as a makefile instead. If the '–' argument is specified, standard input shall be used.

The term *makefile* is used to refer to any rules provided by the user, whether in **./makefile** or its variants, or specified by the –**f** option.

The rules in makefiles shall consist of the following types of lines: target rules, including special targets (see **Target Rules** (on page 2813)), inference rules (see **Inference Rules** (on page 2816)), macro definitions (see **Macros** (on page 2815)), empty lines, and comments.

When an escaped <newline> (one preceded by a backslash) is found anywhere in the makefile except in a command line, it shall be replaced, along with any leading white space on the following line, with a single <space>. When an escaped <newline> is found in a command line in a makefile, the command line shall contain the backslash, the <newline>, and the next line, except that the first character of the next line shall not be included if it is a <tab>.

Makefile Execution

Makefile command lines shall be processed one at a time by writing the makefile command line to the standard output (unless one of the conditions listed under `'@'` suppresses the writing) and executing the command(s) in the line. A <tab> may precede the command to standard output. Command execution shall be as if the makefile command line were the argument to the *system*( ) function. The environment for the command being executed shall contain all of the variables in the environment of *make*.

By default, when *make* receives a non-zero status from the execution of a command, it shall terminate with an error message to standard error.

Makefile command lines can have one or more of the following prefixes: a hyphen (`'−'`), an at sign (`'@'`), or a plus sign (`'+'`). These shall modify the way in which *make* processes the command. When a command is written to standard output, the prefix shall not be included in the output.

– If the command prefix contains a hyphen, or the −**i** option is present, or the special target **.IGNORE** has either the current target as a prerequisite or has no prerequisites, any error found while executing the command shall be ignored.

@ If the command prefix contains an at sign and the *make* utility command line −**n** option is not specified, or the −**s** option is present, or the special target **.SILENT** has either the current target as a prerequisite or has no prerequisites, the command shall not be written to standard output before it is executed.

\+ If the command prefix contains a plus sign, this indicates a makefile command line that shall be executed even if −**n**, −**q**, or −**t** is specified.

Target Rules

Target rules are formatted as follows:

```
target [target...]: [prerequisite...][;command]
[<tab>command
<tab>command
...]
```

```
line that does not begin with <tab>
```

Target entries are specified by a <blank>-separated, non-null list of targets, then a colon, then a <blank>-separated, possibly empty list of prerequisites. Text following a semicolon, if any, and all following lines that begin with a <tab>, are makefile command lines to be executed to update the target. The first non-empty line that does not begin with a <tab> or `'#'` shall begin a new entry. An empty or blank line, or a line beginning with `'#'`, may begin a new entry.

Applications shall select target names from the set of characters consisting solely of periods, underscores, digits, and alphabetics from the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set). Implementations may allow other characters in target names as extensions. The interpretation of targets containing the characters `'%'` and `'"'` is implementation-defined.

A target that has prerequisites, but does not have any commands, can be used to add to the prerequisite list for that target. Only one target rule for any given target can contain commands.

Lines that begin with one of the following are called *special targets* and control the operation of *make*:

.DEFAULT If the makefile uses this special target, the application shall ensure that it is specified with commands, but without prerequisites. The commands shall be used by *make* if there are no other rules available to build a target.

.IGNORE Prerequisites of this special target are targets themselves; this shall cause errors from commands associated with them to be ignored in the same manner as specified by the −**i** option. Subsequent occurrences of **.IGNORE** shall add to the list of targets ignoring command errors. If no prerequisites are specified, *make* shall behave as if the −**i** option had been specified and errors from all commands associated with all targets shall be ignored.

.POSIX The application shall ensure that this special target is specified without prerequisites or commands. If it appears as the first non-comment line in the makefile, *make* shall process the makefile as specified by this section; otherwise, the behavior of *make* is unspecified.

.PRECIOUS Prerequisites of this special target shall not be removed if *make* receives one of the asynchronous events explicitly described in the ASYNCHRONOUS EVENTS section. Subsequent occurrences of **.PRECIOUS** shall add to the list of precious files. If no prerequisites are specified, all targets in the makefile shall be treated as if specified with **.PRECIOUS**.

XSI **.SCCS_GET** The application shall ensure that this special target is specified without prerequisites. If this special target is included in a makefile, the commands specified with this target shall replace the default commands associated with this special target (see **Default Rules** (on page 2819)). The commands specified with this target are used to get all SCCS files that are not found in the current directory.

When source files are named in a dependency list, *make* shall treat them just like any other target. Because the source file is presumed to be present in the directory, there is no need to add an entry for it to the makefile. When a target has no dependencies, but is present in the directory, *make* shall assume that that file is up-to-date. If, however, an SCCS file named **SCCS/s.***source_file* is found for a target *source_file*, *make* compares the timestamp of the target file with that of the **SCCS/s.source_file** to assure the target is up-to-date. If the target is missing, or if the SCCS file is newer, *make* shall automatically issue the commands specified for the **.SCCS_GET** special target to retrieve the most recent version. However, if the target is writable by anyone, *make* shall not retrieve a new version.

.SILENT Prerequisites of this special target are targets themselves; this shall cause commands associated with them to not be written to the standard output before they are executed. Subsequent occurrences of **.SILENT** shall add to the list of targets with silent commands. If no prerequisites are specified, *make* shall behave as if the −**s** option had been specified and no commands or touch messages associated with any target shall be written to standard output.

.SUFFIXES Prerequisites of **.SUFFIXES** shall be appended to the list of known suffixes and are used in conjunction with the inference rules (see **Inference Rules** (on page 2816)). If **.SUFFIXES** does not have any prerequisites, the list of known suffixes shall be cleared.

The special targets **.IGNORE**, **.POSIX**, **.PRECIOUS**, **.SILENT**, and **.SUFFIXES** shall be specified without commands.

Targets with names consisting of a leading period followed by the uppercase letters `"POSIX"` and then any other characters are reserved for future standardization. Targets with names consisting of a leading period followed by one or more uppercase letters are reserved for implementation extensions.

Macros

Macro definitions are in the form:

`string1 = [string2]`

The macro named *string1* is defined as having the value of *string2*, where *string2* is defined as all characters, if any, after the equal sign, up to a comment character (`'#'`) or an unescaped <newline>. Any <blank>s immediately before or after the equal sign shall be ignored.

Applications shall select macro names from the set of characters consisting solely of periods, underscores, digits, and alphabetics from the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set). A macro name shall not contain an equals sign. Implementations may allow other characters in macro names as extensions.

Macros can appear anywhere in the makefile. Macro expansions using the forms $(*string1*) or ${*string1*} shall be replaced by *string2*, as follows:

- Macros in target lines shall be evaluated when the target line is read.
- Macros in makefile command lines shall be evaluated when the command is executed.
- Macros in the string before the equals sign in a macro definition shall be evaluated when the macro assignment is made.
- Macros after the equals sign in a macro definition shall not be evaluated until the defined macro is used in a rule or command, or before the equals sign in a macro definition.

The parentheses or braces are optional if *string1* is a single character. The macro $$ shall be replaced by the single character `'$'`. If *string1* in a macro expansion contains a macro expansion, the results are unspecified.

Macro expansions using the forms $(*string1*[:*subst1*=[*subst2*]]) or ${*string1*[:*subst1*=[*subst2*]]} can be used to replace all occurrences of *subst1* with *subst2* when the macro substitution is performed. The *subst1* to be replaced shall be recognized when it is a suffix at the end of a word in *string1* (where a *word*, in this context, is defined to be a string delimited by the beginning of the line, a <blank> or <newline>). If *string1* in a macro expansion contains a macro expansion, the results are unspecified.

Macro expansions in *string1* of macro definition lines shall be evaluated when read. Macro expansions in *string2* of macro definition lines shall be performed when the macro identified by *string1* is expanded in a rule or command.

Macro definitions shall be taken from the following sources, in the following logical order, before the makefile(s) are read.

1. Macros specified on the *make* utility command line, in the order specified on the command line. It is unspecified whether the internal macros defined in **Internal Macros** (on page 2818) are accepted from this source.
2. Macros defined by the *MAKEFLAGS* environment variable, in the order specified in the environment variable. It is unspecified whether the internal macros defined in **Internal Macros** (on page 2818) are accepted from this source.

3. The contents of the environment, excluding the *MAKEFLAGS* and *SHELL* variables and including the variables with null values.

4. Macros defined in the inference rules built into *make*.

Macro definitions from these sources shall not override macro definitions from a lower-numbered source. Macro definitions from a single source (for example, the *make* utility command line, the *MAKEFLAGS* environment variable, or the other environment variables) shall override previous macro definitions from the same source.

Macros defined in the makefile(s) shall override macro definitions that occur before them in the makefile(s) and macro definitions from source 4. If the −**e** option is not specified, macros defined in the makefile(s) shall override macro definitions from source 3. Macros defined in the makefile(s) shall not override macro definitions from source 1 or source 2.

Before the makefile(s) are read, all of the *make* utility command line options (except −**f** and −**p**) and *make* utility command line macro definitions (except any for the *MAKEFLAGS* macro), not already included in the *MAKEFLAGS* macro, shall be added to the *MAKEFLAGS* macro, quoted in an implementation-defined manner such that when *MAKEFLAGS* is read by another instance of the *make* command, the original macro's value is recovered. Other implementation-defined options and macros may also be added to the *MAKEFLAGS* macro. If this modifies the value of the *MAKEFLAGS* macro, or, if the *MAKEFLAGS* macro is modified at any subsequent time, the *MAKEFLAGS* environment variable shall be modified to match the new value of the *MAKEFLAGS* macro. The result of setting *MAKEFLAGS* in the Makefile is unspecified.

Before the makefile(s) are read, all of the *make* utility command line macro definitions (except the *MAKEFLAGS* macro or the *SHELL* macro) shall be added to the environment of *make*. Other implementation-defined variables may also be added to the environment of *make*.

The **SHELL** macro shall be treated specially. It shall be provided by *make* and set to the pathname of the shell command language interpreter (see *sh* (on page 3048)). The *SHELL* environment variable shall not affect the value of the **SHELL** macro. If **SHELL** is defined in the makefile or is specified on the command line, it shall replace the original value of the **SHELL** macro, but shall not affect the *SHELL* environment variable. Other effects of defining **SHELL** in the makefile or on the command line are implementation-defined.

Inference Rules

Inference rules are formatted as follows:

```
target:
<tab>command
[<tab>command]
...

line that does not begin with <tab> or #
```

The application shall ensure that the *target* portion is a valid target name (see **Target Rules** (on page 2813)) of the form **.s2** or **.s1.s2** (where **.s1** and **.s2** are suffixes that have been given as prerequisites of the **.SUFFIXES** special target and *s1* and *s2* do not contain any slashes or periods.) If there is only one period in the target, it is a single-suffix inference rule. Targets with two periods are double-suffix inference rules. Inference rules can have only one target before the colon.

The application shall ensure that the makefile does not specify prerequisites for inference rules; no characters other than white space shall follow the colon in the first line, except when creating the *empty rule*, described below. Prerequisites are inferred, as described below.

Inference rules can be redefined. A target that matches an existing inference rule shall overwrite the old inference rule. An empty rule can be created with a command consisting of simply a semicolon (that is, the rule still exists and is found during inference rule search, but since it is empty, execution has no effect). The empty rule also can be formatted as follows:

```
rule: ;
```

where zero or more <blank>s separate the colon and semicolon.

The *make* utility uses the suffixes of targets and their prerequisites to infer how a target can be made up-to-date. A list of inference rules defines the commands to be executed. By default, *make* contains a built-in set of inference rules. Additional rules can be specified in the makefile.

The special target **.SUFFIXES** contains as its prerequisites a list of suffixes that shall be used by the inference rules. The order in which the suffixes are specified defines the order in which the inference rules for the suffixes are used. New suffixes shall be appended to the current list by specifying a **.SUFFIXES** special target in the makefile. A **.SUFFIXES** target with no prerequisites shall clear the list of suffixes. An empty **.SUFFIXES** target followed by a new **.SUFFIXES** list is required to change the order of the suffixes.

Normally, the user would provide an inference rule for each suffix. The inference rule to update a target with a suffix **.s1** from a prerequisite with a suffix **.s2** is specified as a target **.s2.s1**. The internal macros provide the means to specify general inference rules (see **Internal Macros** (on page 2818)).

When no target rule is found to update a target, the inference rules shall be checked. The suffix of the target (**.s1**) to be built is compared to the list of suffixes specified by the **.SUFFIXES** special targets. If the **.s1** suffix is found in **.SUFFIXES**, the inference rules shall be searched in the order defined for the first **.s2.s1** rule whose prerequisite file (**$*.s2**) exists. If the target is out-of-date with respect to this prerequisite, the commands for that inference rule shall be executed.

If the target to be built does not contain a suffix and there is no rule for the target, the single suffix inference rules shall be checked. The single-suffix inference rules define how to build a target if a file is found with a name that matches the target name with one of the single suffixes appended. A rule with one suffix **.s2** is the definition of how to build *target* from **target.s2**. The other suffix (**.s1**) is treated as null.

XSI A tilde (`'~'`) in the above rules refers to an SCCS file in the current directory. Thus, the rule **.c~.o** would transform an SCCS C-language source file into an object file (**.o**). Because the **s.** of the SCCS files is a prefix, it is incompatible with *make*'s suffix point of view. Hence, the `'~'` is a way of changing any file reference into an SCCS file reference.

Libraries

If a target or prerequisite contains parentheses, it shall be treated as a member of an archive library. For the *lib*(*member*.**o**) expression *lib* refers to the name of the archive library and *member*.**o** to the member name. The application shall ensure that the member is an object file with the **.o** suffix. The modification time of the expression is the modification time for the member as kept in the archive library; see *ar* (on page 2336). The **.a** suffix shall refer to an archive library. The **.s2.a** rule shall be used to update a member in the library from a file with a suffix **.s2**.

Internal Macros

The *make* utility shall maintain five internal macros that can be used in target and inference rules. In order to clearly define the meaning of these macros, some clarification of the terms *target rule*, *inference rule*, *target*, and *prerequisite* is necessary.

Target rules are specified by the user in a makefile for a particular target. Inference rules are user-specified or *make*-specified rules for a particular class of target name. Explicit prerequisites are those prerequisites specified in a makefile on target lines. Implicit prerequisites are those prerequisites that are generated when inference rules are used. Inference rules are applied to implicit prerequisites or to explicit prerequisites that do not have target rules defined for them in the makefile. Target rules are applied to targets specified in the makefile.

Before any target in the makefile is updated, each of its prerequisites (both explicit and implicit) shall be updated. This shall be accomplished by recursively processing each prerequisite. Upon recursion, each prerequisite shall become a target itself. Its prerequisites in turn shall be processed recursively until a target is found that has no prerequisites, at which point the recursion stops. The recursion then shall back up, updating each target as it goes.

In the definitions that follow, the word *target* refers to one of:

- A target specified in the makefile
- An explicit prerequisite specified in the makefile that becomes the target when *make* processes it during recursion
- An implicit prerequisite that becomes a target when *make* processes it during recursion

In the definitions that follow, the word *prerequisite* refers to one of the following:

- An explicit prerequisite specified in the makefile for a particular target
- An implicit prerequisite generated as a result of locating an appropriate inference rule and corresponding file that matches the suffix of the target

The five internal macros are:

$@ The $@ shall evaluate to the full target name of the current target, or the archive filename part of a library archive target. It shall be evaluated for both target and inference rules.

For example, in the **.c.a** inference rule, $@ represents the out-of-date **.a** file to be built. Similarly, in a makefile target rule to build **lib.a** from **file.c**, $@ represents the out-of-date **lib.a**.

$% The $% macro shall be evaluated only when the current target is an archive library member of the form *libname*(*member*.**o**). In these cases, $@ shall evaluate to *libname* and $% shall evaluates to *member*.**o**. The $% macro shall be evaluated for both target and inference rules.

For example, in a makefile target rule to build **lib.a**(**file.o**), $% represents **file.o**, as opposed to $@, which represents **lib.a**.

$? The $? macro shall evaluate to the list of prerequisites that are newer than the current target. It shall be evaluated for both target and inference rules.

For example, in a makefile target rule to build *prog* from **file1.o**, **file2.o**, and **file3.o**, and where *prog* is not out of date with respect to **file1.o**, but is out of date with respect to **file2.o** and **file3.o**, $? represents **file2.o** and **file3.o**.

$<	In an inference rule, the $< macro shall evaluate to the filename whose existence allowed the inference rule to be chosen for the target. In the **.DEFAULT** rule, the $< macro shall evaluate to the current target name. The meaning of the $< macro shall be otherwise unspecified. For example, in the **.c.a** inference rule, $< represents the prerequisite **.c** file.
$*	The $* macro shall evaluate to the current target name with its suffix deleted. It shall be evaluated at least for inference rules. For example, in the **.c.a** inference rule, $*.o represents the out-of-date **.o** file that corresponds to the prerequisite **.c** file.

Each of the internal macros has an alternative form. When an uppercase `'D'` or `'F'` is appended to any of the macros, the meaning shall be changed to the *directory part* for `'D'` and *filename part* for `'F'`. The directory part is the path prefix of the file without a trailing slash; for the current directory, the directory part is `'.'`. When the $? macro contains more than one prerequisite filename, the $(?D) and $(?F) (or ${?D} and ${?F}) macros expand to a list of directory name parts and filename parts respectively.

For the target *lib*(*member*.**o**) and the **s2.a** rule, the internal macros shall be defined as:

$<	*member*.**s2**
$*	*member*
$@	*lib*
$?	*member*.**s2**
$%	*member*.**o**

Default Rules

The default rules for *make* shall achieve results that are the same as if the following were used. Implementations that do not support the C-Language Development Utilities option may omit **CC**, **CFLAGS**, **YACC**, **YFLAGS**, **LEX**, **LFLAGS**, **LDFLAGS**, and the **.c**, **.y**, and **.l** inference rules. Implementations that do not support FORTRAN may omit **FC**, **FFLAGS**, and the **.f** inference rules. Implementations may provide additional macros and rules.

```
SPECIAL TARGETS

    $(FC) -c $(FFLAGS) $<
    $(AR) $(ARFLAGS) $@ $*.o
    rm -f $*.o
```

EXIT STATUS

When the −**q** option is specified, the *make* utility shall exit with one of the following values:

0	Successful completion.
1	The target was not up-to-date.
>1	An error occurred.

When the −**q** option is not specified, the *make* utility shall exit with one of the following values:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If there is a source file (such as **./source.c**) and there are two SCCS files corresponding to it (**./s.source.c** and **./SCCS/s.source.c**), on XSI-conformant systems *make* uses the SCCS file in the current directory. However, users are advised to use the underlying SCCS utilities (*admin*, *delta*, *get*, and so on) or the *sccs* utility for all source files in a given directory. If both forms are used for a given source file, future developers are very likely to be confused.

It is incumbent upon portable makefiles to specify the **.POSIX** special target in order to guarantee that they are not affected by local extensions.

The −**k** and −**S** options are both present so that the relationship between the command line, the *MAKEFLAGS* variable, and the makefile can be controlled precisely. If the **k** flag is passed in *MAKEFLAGS* and a command is of the form:

```
$(MAKE) −S foo
```

then the default behavior is restored for the child *make*.

When the −**n** option is specified, it is always added to *MAKEFLAGS*. This allows a recursive *make* −**n** *target* to be used to see all of the action that would be taken to update *target*.

Because of widespread historical practice, interpreting a ’#’ number sign inside a variable as the start of a comment has the unfortunate side effect of making it impossible to place a number sign in a variable, thus forbidding something like:

```
CFLAGS = "−D COMMENT_CHAR=’#’"
```

Many historical *make* utilities stop chaining together inference rules when an intermediate target is nonexistent. For example, it might be possible for a *make* to determine that both **.y.c** and **.c.o** could be used to convert a **.y** to a **.o**. Instead, in this case, *make* requires the use of a **.y.o** rule.

The best way to provide portable makefiles is to include all of the rules needed in the makefile itself. The rules provided use only features provided by other parts of this volume of IEEE Std 1003.1-200x. The default rules include rules for optional commands in this volume of IEEE Std 1003.1-200x. Only rules pertaining to commands that are provided are needed in an implementation's default set.

Macros used within other macros are evaluated when the new macro is used rather than when the new macro is defined. Therefore:

```
MACRO = value1
NEW   = $(MACRO)
MACRO = value2

target:
    echo $(NEW)
```

would produce *value2* and not *value1* since **NEW** was not expanded until it was needed in the *echo* command line.

Some historical applications have been known to intermix *target_name* and *macro=name* operands on the command line, expecting that all of the macros are processed before any of the targets are dealt with. Conforming applications do not do this, although some backward compatibility support may be included in some implementations.

The following characters in filenames may give trouble: ’=’, ’:’, ’‘’, ’’’, and ’@’. For inference rules, the description of $< and $? seem similar. However, an example shows the minor difference. In a makefile containing:

```
foo.o: foo.h
```

if **foo.h** is newer than **foo.o**, yet **foo.c** is older than **foo.o**, the built-in rule to make **foo.o** from **foo.c** is used, with $< equal to **foo.c** and $? equal to **foo.h**. If **foo.c** is also newer than **foo.o**, $< is equal to **foo.c** and $? is equal to **foo.h foo.c**.

EXAMPLES

1. The following command:

   ```
   make
   ```

   makes the first target found in the makefile.

2. The following command:

   ```
   make junk
   ```

   makes the target **junk**.

3. The following makefile says that **pgm** depends on two files, **a.o** and **b.o**, and that they in turn depend on their corresponding source files (**a.c** and **b.c**), and a common file **incl.h**:

   ```
   pgm: a.o b.o
       c99 a.o b.o -o pgm
   a.o: incl.h a.c
       c99 -c a.c
   b.o: incl.h b.c
       c99 -c b.c
   ```

4. An example for making optimized **.o** files from **.c** files is:

   ```
   .c.o:
       c99 -c -O $*.c
   ```

   or:

   ```
   .c.o:
       c99 -c -O $<
   ```

5. The most common use of the archive interface follows. Here, it is assumed that the source files are all C-language source:

   ```
   lib: lib(file1.o) lib(file2.o) lib(file3.o)
       @echo lib is now up-to-date
   ```

   The **.c.a** rule is used to make **file1.o**, **file2.o**, and **file3.o** and insert them into **lib**.

   The treatment of escaped <newline>s throughout the makefile is historical practice. For example, the inference rule:

   ```
   .c.o\
   :
   ```

   works, and the macro:

   ```
   f=  bar baz\
       biz
   a:
       echo ==$f==
   ```

echoes `"==bar baz biz=="`.

If $? were:

```
/usr/include/stdio.h /usr/include/unistd.h foo.h
```

then $(?D) would be:

```
/usr/include /usr/include .
```

and $(?F) would be:

```
stdio.h unistd.h foo.h
```

6. The contents of the built-in rules can be viewed by running:

```
make −p −f /dev/null 2>/dev/null
```

RATIONALE

The *make* utility described in this volume of IEEE Std 1003.1-200x is intended to provide the means for changing portable source code into executables that can be run on a IEEE Std 1003.1-200x-conforming system. It reflects the most common features present in System V and BSD *make*s.

Historically, the *make* utility has been an especially fertile ground for vendor and research organization-specific syntax modifications and extensions. Examples include:

- Syntax supporting parallel execution (such as from various multi-processor vendors, GNU, and others)
- Additional ''operators'' separating targets and their prerequisites (System V, BSD, and others)
- Specifying that command lines containing the strings `"${MAKE}"` and `"$(MAKE)"` are executed when the −**n** option is specified (GNU and System V)
- Modifications of the meaning of internal macros when referencing libraries (BSD and others)
- Using a single instance of the shell for all of the command lines of the target (BSD and others)
- Allowing spaces as well as tabs to delimit command lines (BSD)
- Adding C preprocessor-style ''include'' and ''ifdef'' constructs (System V, GNU, BSD, and others)
- Remote execution of command lines (Sprite and others)
- Specifying additional special targets (BSD, System V, and most others)

Additionally, many vendors and research organizations have rethought the basic concepts of *make*, creating vastly extended, as well as completely new, syntaxes. Each of these versions of *make* fulfills the needs of a different community of users; it is unreasonable for this volume of IEEE Std 1003.1-200x to require behavior that would be incompatible (and probably inferior) to historical practice for such a community.

In similar circumstances, when the industry has enough sufficiently incompatible formats as to make them irreconcilable, this volume of IEEE Std 1003.1-200x has followed one or both of two courses of action. Commands have been renamed (*cksum*, *echo*, and *pax*) and/or command line options have been provided to select the desired behavior (*grep*, *od*, and *pax*).

Because the syntax specified for the *make* utility is, by and large, a subset of the syntaxes accepted by almost all versions of *make*, it was decided that it would be counter-productive to change the name. And since the makefile itself is a basic unit of portability, it would not be completely effective to reserve a new option letter, such as *make* −**P**, to achieve the portable behavior. Therefore, the special target **.POSIX** was added to the makefile, allowing users to specify ''standard'' behavior. This special target does not preclude extensions in the *make* utility, nor does it preclude such extensions being used by the makefile specifying the target; it does, however, preclude any extensions from being applied that could alter the behavior of previously valid syntax; such extensions must be controlled via command line options or new special targets. It is incumbent upon portable makefiles to specify the **.POSIX** special target in order to guarantee that they are not affected by local extensions.

The portable version of *make* described in this reference page is not intended to be the state-of-the-art software generation tool and, as such, some newer and more leading-edge features have not been included. An attempt has been made to describe the portable makefile in a manner that does not preclude such extensions as long as they do not disturb the portable behavior described here.

When the −**n** option is specified, it is always added to *MAKEFLAGS*. This allows a recursive *make* −**n** *target* to be used to see all of the action that would be taken to update *target*.

The definition of *MAKEFLAGS* allows both the System V letter string and the BSD command line formats. The two formats are sufficiently different to allow implementations to support both without ambiguity.

Early proposals stated that an ''unquoted'' number sign was treated as the start of a comment. The *make* utility does not pay any attention to quotes. A number sign starts a comment regardless of its surroundings.

The text about ''other implementation-defined pathnames may also be tried'' in addition to **./makefile** and **./Makefile** is to allow such extensions as **SCCS/s.Makefile** and other variations. It was made an implementation-defined requirement (as opposed to unspecified behavior) to highlight surprising implementations that might select something unexpected like **/etc/Makefile**. XSI-conformant systems also try **./s.makefile**, **SCCS/s.makefile**, **./s.Makefile**, and **SCCS/s.Makefile**.

Early proposals contained the macro **NPROC** as a means of specifying that *make* should use *n* processes to do the work required. While this feature is a valuable extension for many systems, it is not common usage and could require other non-trivial extensions to makefile syntax. This extension is not required by this volume of IEEE Std 1003.1-200x, but could be provided as a compatible extension. The macro **PARALLEL** is used by some historical systems with essentially the same meaning (but without using a name that is a common system limit value). It is suggested that implementors recognize the existing use of **NPROC** and/or **PARALLEL** as extensions to *make*.

The default rules are based on System V. The default **CC=** value is *c99* instead of *cc* because this volume of IEEE Std 1003.1-200x does not standardize the utility named *cc*. Thus, every conforming application would be required to define **CC=***c99* to expect to run. There is no advantage conferred by the hope that the makefile might hit the ''preferred'' compiler because this cannot be guaranteed to work. Also, since the portable makescript can only use the *c99* options, no advantage is conferred in terms of what the script can do. It is a quality-of-implementation issue as to whether *c99* is as valuable as *cc*.

The −**d** option to *make* is frequently used to produce debugging information, but is too implementation-defined to add to this volume of IEEE Std 1003.1-200x.

The −**p** option is not passed in *MAKEFLAGS* on most historical implementations and to change this would cause many implementations to break without sufficiently increased portability.

Commands that begin with a plus sign (`'+'`) are executed even if the −**n** option is present. Based on the GNU version of *make*, the behavior of −**n** when the plus-sign prefix is encountered has been extended to apply to −**q** and −**t** as well. However, the System V convention of forcing command execution with −**n** when the command line of a target contains either of the strings `"$(MAKE)"` or `"${MAKE}"` has not been adopted. This functionality appeared in early proposals, but the danger of this approach was pointed out with the following example of a portion of a makefile:

```
subdir:
    cd subdir; rm all_the_files; $(MAKE)
```

The loss of the System V behavior in this case is well-balanced by the safety afforded to other makefiles that were not aware of this situation. In any event, the command line plus-sign prefix can provide the desired functionality.

The double colon in the target rule format is supported in BSD systems to allow more than one target line containing the same target name to have commands associated with it. Since this is not functionality described in the SVID or XPG3 it has been allowed as an extension, but not mandated.

The default rules are provided with text specifying that the built-in rules shall be the same *as if* the listed set were used. The intent is that implementations should be able to use the rules without change, but will be allowed to alter them in ways that do not affect the primary behavior.

The best way to provide portable makefiles is to include all of the rules needed in the makefile itself. The rules provided use only features provided by other portions of this volume of IEEE Std 1003.1-200x. The default rules include rules for optional commands in this volume of IEEE Std 1003.1-200x. Only rules pertaining to commands that are provided are needed in the default set of an implementation.

One point of discussion was whether to drop the default rules list from this volume of IEEE Std 1003.1-200x. They provide convenience, but do not enhance portability of applications. The prime benefit is in portability of users who wish to type *make command* and have the command build from a **command.c** file.

The historical *MAKESHELL* feature was omitted. In some implementations it is used to let a user override the shell to be used to run *make* commands. This was confusing; for a portable *make*, the shell should be chosen by the makefile writer or specified on the *make* command line and not by a user running *make*.

The *make* utilities in most historical implementations process the prerequisites of a target in left-to-right order, and the makefile format requires this. It supports the standard idiom used in many makefiles that produce *yacc* programs; for example:

```
foo: y.tab.o lex.o main.o
    $(CC) $(CFLAGS) −o $@ t.tab.o lex.o main.o
```

In this example, if *make* chose any arbitrary order, the **lex.o** might not be made with the correct **y.tab.h**. Although there may be better ways to express this relationship, it is widely used historically. Implementations that desire to update prerequisites in parallel should require an explicit extension to *make* or the makefile format to accomplish it, as described previously.

The algorithm for determining a new entry for target rules is partially unspecified. Some historical *make*s allow blank, empty, or comment lines within the collection of commands marked by leading <tab>s. A conforming makefile must ensure that each command starts with a <tab>, but implementations are free to ignore blank, empty, and comment lines without triggering the start of a new entry.

The ASYNCHRONOUS EVENTS section includes having SIGTERM and SIGHUP, along with the more traditional SIGINT and SIGQUIT, remove the current target unless directed not to do so. SIGTERM and SIGHUP were added to parallel other utilities that have historically cleaned up their work as a result of these signals. When *make* receives any signal other than SIGQUIT, it is required to resend itself the signal it received so that it exits with a status that reflects the signal. The results from SIGQUIT are partially unspecified because, on systems that create **core** files upon receipt of SIGQUIT, the **core** from *make* would conflict with a core file from the command that was running when the SIGQUIT arrived. The main concern was to prevent damaged files from appearing up-to-date when *make* is rerun.

The **.PRECIOUS** special target was extended to affect all targets globally (by specifying no prerequisites). The **.IGNORE** and **.SILENT** special targets were extended to allow prerequisites; it was judged to be more useful in some cases to be able to turn off errors or echoing for a list of targets than for the entire makefile. These extensions to the *make* in System V were made to match historical practice from the BSD *make*.

Macros are not exported to the environment of commands to be run. This was never the case in any historical *make* and would have serious consequences. The environment is the same as the environment to *make* except that *MAKEFLAGS* and macros defined on the *make* command line are added.

Some implementations do not use *system*( ) for all command lines, as required by the portable makefile format; as a performance enhancement, they select lines without shell metacharacters for direct execution by *execve*( ). There is no requirement that *system*( ) be used specifically, but merely that the same results be achieved. The metacharacters typically used to bypass the direct *execve*( ) execution have been any of:

`= | ˆ ( ) ; & < > * ? [ ] : $ ‘ ’ " \ \n`

The default in some advanced versions of *make* is to group all the command lines for a target and execute them using a single shell invocation; the System V method is to pass each line individually to a separate shell. The single-shell method has the advantages in performance and the lack of a requirement for many continued lines. However, converting to this newer method has caused portability problems with many historical makefiles, so the behavior with the POSIX makefile is specified to be the same as that of System V. It is suggested that the special target **.ONESHELL** be used as an implementation extension to achieve the single-shell grouping for a target or group of targets.

Novice users of *make* have had difficulty with the historical need to start commands with a <tab>. Since it is often difficult to discern differences between <tab>s and <space>s on terminals or printed listings, confusing bugs can arise. In early proposals, an attempt was made to correct this problem by allowing leading <blank>s instead of <tab>s. However, implementors reported many makefiles that failed in subtle ways following this change, and it is difficult to implement a *make* that unambiguously can differentiate between macro and command lines. There is extensive historical practice of allowing leading spaces before macro definitions. Forcing macro lines into column 1 would be a significant backwards-compatibility problem for some makefiles. Therefore, historical practice was restored.

The System V INCLUDE feature was considered, but not included. This would treat a line that began in the first column and contained INCLUDE <*filename*> as an indication to read <*filename*> at that point in the makefile. This is difficult to use in a portable way, and it raises concerns about nesting levels and diagnostics. System V, BSD, GNU, and others have used different methods for including files.

The System V dynamic dependency feature was not included. It would support:

```
cat: $$@.c
```

that would expand to;

```
cat: cat.c
```

This feature exists only in the new version of System V *make* and, while useful, is not in wide usage. This means that macros are expanded twice for prerequisites: once at makefile parse time and once at target update time.

Consideration was given to adding metarules to the POSIX *make*. This would make **%.o: %.c** the same as **.c.o:**. This is quite useful and available from some vendors, but it would cause too many changes to this *make* to support. It would have introduced rule chaining and new substitution rules. However, the rules for target names have been set to reserve the `'%'` and `'"'` characters. These are traditionally used to implement metarules and quoting of target names, respectively. Implementors are strongly encouraged to use these characters only for these purposes.

A request was made to extend the suffix delimiter character from a period to any character. The metarules feature in newer *make*s solves this problem in a more general way. This volume of IEEE Std 1003.1-200x is staying with the more conservative historical definition.

The standard output format for the **−p** option is not described because it is primarily a debugging option and because the format is not generally useful to programs. In historical implementations the output is not suitable for use in generating makefiles. The **−p** format has been variable across historical implementations. Therefore, the definition of **−p** was only to provide a consistently named option for obtaining *make* script debugging information.

Some historical implementations have not cleared the suffix list with **−r**.

Implementations should be aware that some historical applications have intermixed *target_name* and *macro*=*value* operands on the command line, expecting that all of the macros are processed before any of the targets are dealt with. Conforming applications do not do this, but some backwards-compatibility support may be warranted.

Empty inference rules are specified with a semicolon command rather than omitting all commands, as described in an early proposal. The latter case has no traditional meaning and is reserved for implementation extensions, such as in GNU *make*.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the Software Development Utilities option.

The Open Group Corrigendum U029/1 is applied, correcting a typographical error in the SPECIAL TARGETS section.

In the ENVIRONMENT VARIABLES section, the *PROJECTDIR* description is updated from ‘‘otherwise, the home directory of a user of that name is examined’’ to ‘‘otherwise, the value of *PROJECTDIR* is treated as a user name and that user’s initial working directory is examined’’.

It is specified whether the command line is related to the makefile or to the *make* command, and the macro processing rules are updated to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

PASC Interpretation 1003.2 #193 is applied.

NAME

man — display system documentation

SYNOPSIS

```
man [−k] name...
```

DESCRIPTION

The *man* utility shall write information about each of the *name* operands. If *name* is the name of a standard utility, *man* at a minimum shall write a message describing the syntax used by the standard utility, its options, and operands. If more information is available, the *man* utility shall provide it in an implementation-defined manner.

An implementation may provide information for values of *name* other than the standard utilities. Standard utilities that are listed as optional and that are not supported by the implementation either shall cause a brief message indicating that fact to be displayed or shall cause a full display of information as described previously.

OPTIONS

The *man* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−k Interpret *name* operands as keywords to be used in searching a utilities summary database that contains a brief purpose entry for each standard utility and write lines from the summary database that match any of the keywords. The keyword search shall produce results that are the equivalent of the output of the following command:

```
grep −Ei '
name
name
...
' summary-database
```

This assumes that the *summary-database* is a text file with a single entry per line; this organization is not required and the example using *grep* **−Ei** is merely illustrative of the type of search intended. The purpose entry to be included in the database shall consist of a terse description of the purpose of the utility.

OPERANDS

The following operand shall be supported:

name A keyword or the name of a standard utility. When **−k** is not specified and *name* does not represent one of the standard utilities, the results are unspecified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *man*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and in the summary database). The value of *LC_CTYPE* need not affect the format of the information written about the name operands.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PAGER	Determine an output filtering command for writing the output to a terminal. Any string acceptable as a *command_string* operand to the *sh* −**c** command shall be valid. When standard output is a terminal device, the reference page output shall be piped through the command. If the *PAGER* variable is null or not set, the command shall be either *more* or another paginator utility documented in the system documentation.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *man* utility shall write text describing the syntax of the utility *name*, its options and its operands, or, when −**k** is specified, lines from the summary database. The format of this text is implementation-defined.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

It is recognized that the *man* utility is only of minimal usefulness as specified. The opinion of the standard developers was strongly divided as to how much or how little information *man* should be required to provide. They considered, however, that the provision of some portable way of accessing documentation would aid user portability. The arguments against a fuller specification were:

- Large quantities of documentation should not be required on a system that does not have excess disk space.
- The current manual system does not present information in a manner that greatly aids user portability.
- A ‘‘better help system’’ is currently an area in which vendors feel that they can add value to their POSIX implementations.

The −**f** option was considered, but due to implementation differences, it was not included in this volume of IEEE Std 1003.1-200x.

The description was changed to be more specific about what has to be displayed for a utility. The standard developers considered it insufficient to allow a display of only the synopsis without giving a short description of what each option and operand does.

The ‘‘purpose’’ entry to be included in the database can be similar to the section title (less the numeric prefix) from this volume of IEEE Std 1003.1-200x for each utility. These titles are similar to those used in historical systems for this purpose.

See *mailx* for rationale concerning the default paginator.

The caveat in the *LC_CTYPE* description was added because it is not a requirement that an implementation provide reference pages for all of its supported locales on each system; changing *LC_CTYPE* does not necessarily translate the reference page into another language. This is equivalent to the current state of *LC_MESSAGES* in IEEE Std 1003.1-200x—locale-specific messages are not yet a requirement.

The historical *MANPATH* variable is not included in POSIX because no attempt is made to specify naming conventions for reference page files, nor even to mandate that they are files at all. On some implementations they could be a true database, a hypertext file, or even fixed strings within the *man* executable. The standard developers considered the portability of reference pages to be outside their scope of work. However, users should be aware that *MANPATH* is implemented on a number of historical systems and that it can be used to tailor the search pattern for reference pages from the various categories (utilities, functions, file formats, and so on) when the system administrator reveals the location and conventions for reference pages on the system.

The keyword search can rely on at least the text of the section titles from these utility descriptions, and the implementation may add more keywords. The term ‘‘section titles’’ refers to the strings such as:

```
man − Display system documentation
ps − Report process status
```

FUTURE DIRECTIONS

more

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

NAME

mesg — permit or deny messages

SYNOPSIS

UP
```
mesg [y|n]
```

DESCRIPTION

The *mesg* utility shall control whether other users are allowed to send messages via *write*, *talk*, or other utilities to a terminal device. The terminal device affected shall be determined by searching for the first terminal in the sequence of devices associated with standard input, standard output, and standard error, respectively. With no arguments, *mesg* shall report the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state.

OPTIONS

None.

OPERANDS

The following operands shall be supported in the POSIX locale:

`y`	Grant permission to other users to send messages to the terminal device.
`n`	Deny permission to other users to send messages to the terminal device.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mesg*:

	LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
	LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
	LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
	LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written (by *mesg*) to standard error.
XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

If no operand is specified, *mesg* shall display the current terminal state in an unspecified format.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Receiving messages is allowed.
1	Receiving messages is not allowed.
>1	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The mechanism by which the message status of the terminal is changed is unspecified. Therefore, unspecified actions may cause the status of the terminal to change after *mesg* has successfully completed. These actions may include, but are not limited to: another invocation of the *mesg* utility, login procedures; invocation of the *stty* utility, invocation of the *chmod* utility or *chmod*( ) function, and so on.

EXAMPLES

None.

RATIONALE

The terminal changed by *mesg* is that associated with the standard input, output, or error, rather than the controlling terminal for the session. This is because users logged in more than once should be able to change any of their login terminals without having to stop the job running in those sessions. This is not a security problem involving the terminals of other users because appropriate privileges would be required to affect the terminal of another user.

The method of checking each of the first three file descriptors in sequence until a terminal is found was adopted from System V.

The file **/dev/tty** is not specified for the terminal device because it was thought to be too restrictive. Typical environment changes for the **n** operand are that write permissions are removed for *others* and *group* from the appropriate device. It was decided to leave the actual description of what is done as unspecified because of potential differences between implementations.

The format for standard output is unspecified because of differences between historical implementations. This output is generally not useful to shell scripts (they can use the exit status), so exact parsing of the output is unnecessary.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

NAME

mkdir — make directories

SYNOPSIS

```
mkdir [−p][−m mode] dir...
```

DESCRIPTION

The *mkdir* utility shall create the directories specified by the operands, in the order specified.

For each *dir* operand, the *mkdir* utility shall perform actions equivalent to the *mkdir*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

1. The *dir* operand is used as the *path* argument.
2. The value of the bitwise-inclusive OR of S_IRWXU, S_IRWXG, and S_IRWXO is used as the *mode* argument. (If the **−m** option is specified, the *mode* option-argument overrides this default.)

OPTIONS

The *mkdir* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−m *mode* Set the file permission bits of the newly-created directory to the specified *mode* value. The *mode* option-argument shall be the same as the *mode* operand defined for the *chmod* utility. In the *symbolic_mode* strings, the *op* characters `'+'` and `'−'` shall be interpreted relative to an assumed initial mode of *a*=*rwx*; `'+'` shall add permissions to the default mode, `'−'` shall delete permissions from the default mode.

−p Create any missing intermediate pathname components.

For each *dir* operand that does not name an existing directory, effects equivalent to those caused by the following command shall occur:

```
mkdir −p −m $(umask −S),u+wx $(dirname dir) &&
mkdir [−m mode] dir
```

where the **−m** *mode* option represents that option supplied to the original invocation of *mkdir*, if any.

Each *dir* operand that names an existing directory shall be ignored without error.

OPERANDS

The following operand shall be supported:

dir A pathname of a directory to be created.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mkdir*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All the specified directories were created successfully or the −**p** option was specified and all the specified directories now exist.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The default file mode for directories is *a*=*rwx* (777 on most systems) with selected permissions removed in accordance with the file mode creation mask. For intermediate pathname components created by *mkdir*, the mode is the default modified by *u*+*wx* so that the subdirectories can always be created regardless of the file mode creation mask; if different ultimate permissions are desired for the intermediate directories, they can be changed afterwards with *chmod*.

Note that some of the requested directories may have been created even if an error occurs.

EXAMPLES

None.

RATIONALE

The System V −**m** option was included to control the file mode.

The System V −**p** option was included to create any needed intermediate directories and to complement the functionality provided by *rmdir* for removing directories in the path prefix as they become empty. Because no error is produced if any path component already exists, the −**p** option is also useful to ensure that a particular directory exists.

The functionality of *mkdir* is described substantially through a reference to the *mkdir*( ) function in the System Interfaces volume of IEEE Std 1003.1-200x. For example, by default, the mode of the directory is affected by the file mode creation mask in accordance with the specified behavior of the *mkdir*( ) function. In this way, there is less duplication of effort required for describing details of the directory creation.

FUTURE DIRECTIONS

None.

Issue 5

FUTURE DIRECTIONS section added.

NAME

mkfifo — make FIFO special files

SYNOPSIS

```
mkfifo [−m mode] file...
```

DESCRIPTION

The *mkfifo* utility shall create the FIFO special files specified by the operands, in the order specified.

For each *file* operand, the *mkfifo* utility shall perform actions equivalent to the *mkfifo*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

1. The *file* operand is used as the *path* argument.
2. The value of the bitwise-inclusive OR of S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP, S_IROTH, and S_IWOTH is used as the *mode* argument. (If the −**m** option is specified, the value of the *mkfifo*( ) *mode* argument is unspecified, but the FIFO shall at no time have permissions less restrictive than the −**m** *mode* option-argument.)

OPTIONS

The *mkfifo* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−**m** *mode*	Set the file permission bits of the newly-created FIFO to the specified *mode* value. The *mode* option-argument shall be the same as the *mode* operand defined for the *chmod* utility. In the *symbolic_mode* strings, the *op* characters `'+'` and `'−'` shall be interpreted relative to an assumed initial mode of *a*=*rw*.

OPERANDS

The following operand shall be supported:

file	A pathname of the FIFO special file to be created.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mkfifo*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All the specified FIFO special files were created successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

This utility was added to permit shell applications to create FIFO special files.

The −**m** option was added to control the file mode, for consistency with the similar functionality provided the *mkdir* utility.

Early proposals included a −**p** option similar to the *mkdir* −**p** option that created intermediate directories leading up to the FIFO specified by the final component. This was removed because it is not commonly needed and is not common practice with similar utilities.

The functionality of *mkfifo* is described substantially through a reference to the *mkfifo*( ) function in the System Interfaces volume of IEEE Std 1003.1-200x. For example, by default, the mode of the FIFO file is affected by the file mode creation mask in accordance with the specified behavior of the *mkfifo*( ) function. In this way, there is less duplication of effort required for describing details of the file creation.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

NAME

more — display files on a page-by-page basis

SYNOPSIS

UP
```
more [−ceisu][−n number][−p command][−t tagstring][file ...]
```

DESCRIPTION

The *more* utility shall read files and either write them to the terminal on a page-by-page basis or filter them to standard output. If standard output is not a terminal device, all input files shall be copied to standard output in their entirety, without modification, except as specified for the **−s** option. If standard output is a terminal device, the files shall be written a number of lines (one screenful) at a time under the control of user commands. See the EXTENDED DESCRIPTION section.

Certain block-mode terminals do not have all the capabilities necessary to support the complete *more* definition; they are incapable of accepting commands that are not terminated with a <newline>. Implementations that support such terminals shall provide an operating mode to *more* in which all commands can be terminated with a <newline> on those terminals. This mode:

- Shall be documented in the system documentation
- Shall, at invocation, inform the user of the terminal deficiency that requires the <newline> usage and provide instructions on how this warning can be suppressed in future invocations
- Shall not be required for implementations supporting only fully capable terminals
- Shall not affect commands already requiring <newline>s
- Shall not affect users on the capable terminals from using *more* as described in this volume of IEEE Std 1003.1-200x

OPTIONS

The *more* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c	If a screen is to be written that has no lines in common with the current screen, or *more* is writing its first screen, *more* shall not scroll the screen, but instead shall redraw each line of the screen in turn, from the top of the screen to the bottom. In addition, if *more* is writing its first screen, the screen shall be cleared. This option may be silently ignored on devices with insufficient terminal capabilities.
−e	By default, *more* shall exit immediately after writing the last line of the last file in the argument list. If the **−e** option is specified: 1. If there is only a single file in the argument list and that file was completely displayed on a single screen, *more* shall exit immediately after writing the last line of that file. 2. Otherwise, *more* shall exit only after reaching end-of-file on the last file in the argument list twice without an intervening operation. See the EXTENDED DESCRIPTION section.
−i	Perform pattern matching in searches without regard to case; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.2, Regular Expression General Requirements .

−n *number*	Specify the number of lines per screenful. The *number* argument is a positive decimal integer. The **−n** option shall override any values obtained from any other source.
−p *command*	Each time a screen from a new file is displayed or redisplayed (including as a result of *more* commands; for example, **:p**), execute the *more* command(s) in the command arguments in the order specified, as if entered by the user after the first screen has been displayed. No intermediate results shall be displayed (that is, if the command is a movement to a screen different from the normal first screen, only the screen resulting from the command shall be displayed.) If any of the commands fail for any reason, an informational message to this effect shall be written, and no further commands specified using the **−p** option shall be executed for this file.
−s	Behave as if consecutive empty lines were a single empty line.
−t *tagstring*	Write the screenful of the file containing the tag named by the *tagstring* argument. See the *ctags* utility. The tags feature represented by **−t** *tagstring* and the **:t** command is optional. It shall be provided on any system that also provides a conforming implementation of *ctags*; otherwise, the use of **−t** produces undefined results. The filename resulting from the **−t** option shall be logically added as a prefix to the list of command line files, as if specified by the user. If the tag named by the *tagstring* argument is not found, it shall be an error, and *more* shall take no further action. If the tag specifies a line number, the first line of the display shall contain the beginning of that line. If the tag specifies a pattern, the first line of the display shall contain the beginning of the matching text from the first line of the file that contains that pattern. If the line does not exist in the file or matching text is not found, an informational message to this effect shall be displayed, and *more* shall display the default screen as if **−t** had not been specified. If both the **−t** *tagstring* and **−p** *command* options are given, the **−t** *tagstring* shall be processed first; that is, the file and starting line for the display shall be as specified by **−t**, and then the **−p** *more* command shall be executed. If the line (matching text) specified by the **−t** command does not exist (is not found), no **−p** *more* command shall be executed for this file at any time.
−u	Treat a <backspace> as a printable control character, displayed as an implementation-defined character sequence (see the EXTENDED DESCRIPTION section), suppressing backspacing and the special handling that produces underlined or standout mode text on some terminal types. Also, do not ignore a <carriage-return> at the end of a line.

OPERANDS

The following operand shall be supported:

file	A pathname of an input file. If no *file* operands are specified, the standard input shall be used. If a *file* is '−', the standard input shall be read at that point in the sequence.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is '−'.

INPUT FILES

The input files being examined shall be text files. If standard output is a terminal, standard error shall be used to read commands from the user. If standard output is a terminal, standard error is not readable, and command input is needed, *more* may attempt to obtain user commands from the controlling terminal (for example, **/dev/tty**); otherwise, *more* shall terminate with an error indicating that it was unable to read user commands. If standard output is not a terminal, no error shall result if standard error cannot be opened for reading.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *more*:

COLUMNS	Override the system-selected horizontal display line size. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.
EDITOR	Used by the **v** command to select an editor. See the EXTENDED DESCRIPTION section.
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
LINES	Override the system-selected vertical screen size, used as the number of lines in a screenful. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null. The **−n** option shall take precedence over the *LINES* variable for determining the number of lines in a screenful.
MORE	Determine a string containing options described in the OPTIONS section preceded with hyphens and <blank>-separated as on the command line. Any command line options shall be processed after those in the *MORE* variable, as if the command line were: `more $MORE options operands` The *MORE* variable shall take precedence over the *TERM* and *LINES* variables for determining the number of lines in a screenful.

TERM	Determine the name of the terminal type. If this variable is unset or null, an unspecified default terminal type is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used to write the contents of the input files.

STDERR

The standard error shall be used for diagnostic messages and user commands (see the INPUT FILES section), and, if standard output is a terminal device, to write a prompting string. The prompting string shall appear on the screen line below the last line of the file displayed in the current screenful. The prompt shall contain the name of the file currently being examined and shall contain an end-of-file indication and the name of the next file, if any, when prompting at the end-of-file. If an error or informational message is displayed, it is unspecified whether it is contained in the prompt. If it is not contained in the prompt, it shall be displayed and then the user shall be prompted for a continuation character, at which point another message or the user prompt may be displayed. The prompt is otherwise unspecified. It is unspecified whether informational messages are written for other user commands.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The following subsection describes the behavior of *more* when the standard output is a terminal device. If the standard output is not a terminal device, no options other than **–s** shall have any effect, and all input files shall be copied to standard output otherwise unmodified, at which time *more* shall exit without further action.

The number of lines available per screen shall be determined by the **–n** option, if present, or by examining values in the environment (see the ENVIRONMENT VARIABLES section). If neither method yields a number, an unspecified number of lines shall be used.

The maximum number of lines written shall be one less than this number, because the screen line after the last line written shall be used to write a user prompt and user input. If the number of lines in the screen is less than two, the results are undefined. It is unspecified whether user input is permitted to be longer than the remainder of the single line where the prompt has been written.

The number of columns available per line shall be determined by examining values in the environment (see the ENVIRONMENT VARIABLES section), with a default value as described in Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

Lines that are longer than the display shall be folded; the length at which folding occurs is unspecified, but should be appropriate for the output device. Folding may occur between glyphs of single characters that take up multiple display columns.

When standard output is a terminal and **–u** is not specified, *more* shall treat <backspace>s and <carriage-return>s specially:

- A character, followed first by a sequence of *n* <backspace>s (where *n* is the same as the number of column positions that the character occupies), then by *n* underscore characters ('_'), shall cause that character to be written as underlined text, if the terminal type supports that. The *n* underscore characters, followed first by *n* <backspace>s, then any character with *n* column positions, shall also cause that character to be written as underlined text, if the terminal type supports that.

- A sequence of *n* <backspace>s (where *n* is the same as the number of column positions that the previous character occupies) that appears between two identical printable characters shall cause the first of those two characters to be written as emboldened text (that is, visually brighter, standout mode, or inverse-video mode), if the terminal type supports that, and the second to be discarded. Immediately subsequent occurrences of <backspace>/character pairs for that same character also shall be discarded. (For example, the sequence `"a\ba\ba\ba"` is interpreted as a single emboldened `'a'`.)

- The *more* utility shall logically discard all other <backspace>s from the line as well as the character which precedes them, if any.

- A <carriage-return> at the end of a line shall be ignored, rather than being written as a non-printable character, as described in the next paragraph.

It is implementation-defined how other non-printable characters are written. Implementations should use the same format that they use for the *ex* **print** command; see the OPTIONS section within the *ed* utility. It is unspecified whether a multi-column character shall be separated if it crosses a display line boundary; it shall not be discarded. The behavior is unspecified if the number of columns on the display is less than the number of columns any single character in the line being displayed would occupy.

When each new file is displayed (or redisplayed), *more* shall write the first screen of the file. Once the initial screen has been written, *more* shall prompt for a user command. If the execution of the user command results in a screen that has lines in common with the current screen, and the device has sufficient terminal capabilities, *more* shall scroll the screen; otherwise, it is unspecified whether the screen is scrolled or redrawn.

For all files but the last (including standard input if no file was specified, and for the last file as well, if the −**e** option was not specified), when *more* has written the last line in the file, *more* shall prompt for a user command. This prompt shall contain the name of the next file as well as an indication that *more* has reached end-of-file. If the user command is **f**, <control>-F, <space>, **j**, <newline>, **d**, <control>-D, or **s**, *more* shall display the next file. Otherwise, if displaying the last file, *more* shall exit. Otherwise, *more* shall execute the user command specified.

Several of the commands described in this section display a previous screen from the input stream. In the case that text is being taken from a non-rewindable stream, such as a pipe, it is implementation-defined how much backwards motion is supported. If a command cannot be executed because of a limitation on backwards motion, an error message to this effect shall be displayed, the current screen shall not change, and the user shall be prompted for another command.

If a command cannot be performed because there are insufficient lines to display, *more* shall alert the terminal. If a command cannot be performed because there are insufficient lines to display or a **/** command fails: if the input is the standard input, the last screen in the file may be displayed; otherwise, the current file and screen shall not change, and the user shall be prompted for another command.

The interactive commands in the following sections shall be supported. Some commands can be preceded by a decimal integer, called *count* in the following descriptions. If not specified with the command, *count* shall default to 1. In the following descriptions, *pattern* is a basic regular expression, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions. The term ‘‘examine’’ is historical usage meaning ‘‘open the file for viewing’’; for example, *more* **foo** would be expressed as examining file **foo**.

In the following descriptions, unless otherwise specified, *line* is a line in the *more* display, not a line from the file being examined.

In the following descriptions, the *current position* refers to two things:

1. The position of the current line on the screen
2. The line number (in the file) of the current line on the screen

Usually, the line on the screen corresponding to the current position is the third line on the screen. If this is not possible (there are fewer than three lines to display or this is the first page of the file, or it is the last page of the file), then the current position is either the first or last line on the screen as described later.

Help

Synopsis: `h`

Write a summary of these commands and other implementation-defined commands. The behavior shall be as if the *more* utility were executed with the −**e** option on a file that contained the summary information. The user shall be prompted as described earlier in this section when end-of-file is reached. If the user command is one of those specified to continue to the next file, *more* shall return to the file and screen state from which the **h** command was executed.

Scroll Forward One Screenful

Synopsis:

```
[count]f
[count]<control>-F
```

Scroll forward *count* lines, with a default of one screenful. If *count* is more than the screen size, only the final screenful shall be written.

Scroll Backward One Screenful

Synopsis:

```
[count]b
[count]<control>-B
```

Scroll backward *count* lines, with a default of one screenful (see the −**n** option). If *count* is more than the screen size, only the final screenful shall be written.

Scroll Forward One Line

Synopsis:

```
[count]<space>
[count]j
[count]<newline>
```

Scroll forward *count* lines. The default *count* for the <space> shall be one screenful; for **j** and <newline>, one line. The entire *count* lines shall be written, even if *count* is more than the screen size.

Scroll Backward One Line

Synopsis: `[count]k`

Scroll backward *count* lines. The entire *count* lines shall be written, even if *count* is more than the screen size.

Scroll Forward One Half Screenful

Synopsis:
```
[count]d
[count]<control>-D
```

Scroll forward *count* lines, with a default of one half of the screen size. If *count* is specified, it shall become the new default for subsequent **d**, <control>-D, and **u** commands.

Skip Forward One Line

Synopsis:
```
[count]s
```

Display the screenful beginning with the line *count* lines after the last line on the current screen. If *count* would cause the current position to be such that less than one screenful would be written, the last screenful in the file shall be written.

Scroll Backward One Half Screenful

Synopsis:
```
[count]u
[count]<control>-U
```

Scroll backward *count* lines, with a default of one half of the screen size. If *count* is specified, it shall become the new default for subsequent **d**, <control>–D, **u**, and <control>–U commands. The entire *count* lines shall be written, even if *count* is more than the screen size.

Go to Beginning of File

Synopsis:
```
[count]g
```

Display the screenful beginning with line *count*.

Go to End-of-File

Synopsis:
```
[count]G
```

If *count* is specified, display the screenful beginning with the line *count*. Otherwise, display the last screenful of the file.

Refresh the Screen

Synopsis:
```
r
<control>-L
```

Refresh the screen.

Discard and Refresh

Synopsis:
```
R
```

Refresh the screen, discarding any buffered input. If the current file is non-seekable, buffered input shall not be discarded and the **R** command shall be equivalent to the **r** command.

Mark Position

Synopsis: `m`*`letter`*

Mark the current position with the letter named by *letter*, where *letter* represents the name of one of the lowercase letters of the portable character set. When a new file is examined, all marks may be lost.

Return to Mark

Synopsis: `'`*`letter`*

Return to the position that was previously marked with the letter named by *letter*, making that line the current position.

Return to Previous Position

Synopsis: `''`

Return to the position from which the last large movement command was executed (where a ‘‘large movement’’ is defined as any movement of more than a screenful of lines). If no such movements have been made, return to the beginning of the file.

Search Forward for Pattern

Synopsis: **[***`count`***]**`/`**[**`!`**]***`pattern`*`<newline>`

Display the screenful beginning with the *count*th line containing the pattern. The search shall start after the first line currently displayed. The null regular expression (`'/'` followed by a <newline>) shall repeat the search using the previous regular expression, with a default *count*. If the character `'!'` is included, the matching lines shall be those that do not contain the *pattern*. If no match is found for the *pattern*, a message to that effect shall be displayed.

Search Backward for Pattern

Synopsis: **[***`count`***]**`?`**[**`!`**]***`pattern`*`<newline>`

Display the screenful beginning with the *count*th previous line containing the pattern. The search shall start on the last line before the first line currently displayed. The null regular expression (`'?'` followed by a <newline>) shall repeat the search using the previous regular expression, with a default *count*. If the character `'!'` is included, matching lines shall be those that do not contain the *pattern*.

If no match is found for the *pattern*, a message to that effect shall be displayed.

Repeat Search

Synopsis: **[***`count`***]**`n`

Repeat the previous search for *count*th line containing the last *pattern* (or not containing the last *pattern*, if the previous search was `"/!"` or `"?!"`).

Repeat Search in Reverse

Synopsis: `[count]N`

Repeat the search in the opposite direction of the previous search for the *count*th line containing the last *pattern* (or not containing the last *pattern*, if the previous search was `"/!"` or `"?!"`).

Examine New File

Synopsis: `:e [filename]<newline>`

Examine a new file. If the *filename* argument is not specified, the current file (see the **:n** and **:p** commands below) shall be re-examined. The *filename* shall be subjected to the process of shell word expansions (see Section 2.6 (on page 2238)); if more than a single pathname results, the effects are unspecified. If *filename* is a number sign (`'#'`), the previously examined file shall be re-examined. If *filename* is not accessible for any reason (including that it is a non-seekable file), an error message to this effect shall be displayed and the current file and screen shall not change.

Examine Next File

Synopsis: `[count]:n`

Examine the next file. If a number *count* is specified, the *count*th next file shall be examined. If *filename* refers to a non-seekable file, the results are unspecified.

Examine Previous File

Synopsis: `[count]:p`

Examine the previous file. If a number *count* is specified, the *count*th previous file shall be examined. If *filename* refers to a non-seekable file, the results are unspecified.

Go to Tag

Synopsis: `:t tagstring<newline>`

If the file containing the tag named by the *tagstring* argument is not the current file, examine the file, as if the **:e** command was executed with that file as the argument. Otherwise, or in addition, display the screenful beginning with the tag, as described for the **–t** option (see the OPTIONS section). If the *ctags* utility is not supported by the system, the use of **:t** produces undefined results.

Invoke Editor

Synopsis: `v`

Invoke an editor to edit the current file being examined. If standard input is being examined, the results are unspecified. The name of the editor shall be taken from the environment variable *EDITOR*, or shall default to *vi*. If the last pathname component in *EDITOR* is either *vi* or *ex*, the editor shall be invoked with a **–c** *linenumber* command line argument, where *linenumber* is the line number of the file line containing the display line currently displayed as the first line of the screen. It is implementation-defined whether line-setting options are passed to editors other than *vi* and *ex*.

When the editor exits, *more* shall resume with the same file and screen as when the editor was invoked.

Display Position

Synopsis: `=`
`<control>-G`

Write a message for which the information references the first byte of the line after the last line of the file on the screen. This message shall include the name of the file currently being examined, its number relative to the total number of files there are to examine, the line number in the file, the byte number and the total bytes in the file, and what percentage of the file precedes the current position. If *more* is reading from standard input, or the file is shorter than a single screen, the line number, the byte number, the total bytes, and the percentage need not be written.

Quit

Synopsis: `q`
`:q`
`ZZ`

Exit *more*.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

If an error is encountered accessing a file when using the **:n** command, *more* shall attempt to examine the next file in the argument list, but the final exit status shall be affected. If an error is encountered accessing a file via the **:p** command, *more* shall attempt to examine the previous file in the argument list, but the final exit status shall be affected. If an error is encountered accessing a file via the **:e** command, *more* shall remain in the current file and the final exit status shall not be affected.

APPLICATION USAGE

When the standard output is not a terminal, only the −**s** filter-modification option is effective. This is based on historical practice. For example, a typical implementation of *man* pipes its output through *more* −**s** to squeeze excess white space for terminal users. When *man* is piped to *lp*, however, it is undesirable for this squeezing to happen.

EXAMPLES

The −**p** allows arbitrary commands to be executed at the start of each file. Examples are:

more −**p G** *file1 file2*
Examine each file starting with its last screenful.

more −**p** 100 *file1 file2*
Examine each file starting with line 100 in the current position (usually the third line, so line 98 would be the first line written).

more −**p** /100 *file1 file2*
Examine each file starting with the first line containing the string `"100"` in the current position

RATIONALE

The *more* utility, available in BSD and BSD-derived systems, was chosen as the prototype for the POSIX file display program since it is more widely available than either the public-domain program *less* or than *pg*, a pager provided in System V. The 4.4 BSD *more* is the model for the features selected; it is almost fully upward-compatible from the 4.3 BSD version in wide use and has become more amenable for *vi* users. Several features originally derived from various file editors, found in both *less* and *pg*, have been added to this volume of IEEE Std 1003.1-200x as they have proved extremely popular with users.

There are inconsistencies between *more* and *vi* that result from historical practice. For example, the single-character commands **h**, **f**, **b**, and <space> are screen movers in *more*, but cursor movers in *vi*. These inconsistencies were maintained because the cursor movements are not applicable to *more* and the powerful functionality achieved without the use of the control key justifies the differences.

The tags interface has been included in a program that is not a text editor because it promotes another degree of consistent operation with *vi*. It is conceivable that the paging environment of *more* would be superior for browsing source code files in some circumstances.

The operating mode referred to for block-mode terminals effectively adds a <newline> to each Synopsis line that currently has none. So, for example, **d**<newline> would page one screenful. The mode could be triggered by a command line option, environment variable, or some other method. The details are not imposed by this volume of IEEE Std 1003.1-200x because there are so few systems known to support such terminals. Nevertheless, it was considered that all systems should be able to support *more* given the exception cited for this small community of terminals because, in comparison to *vi*, the cursor movements are few and the command set relatively amenable to the optional <newline>s.

Some versions of *more* provide a shell escaping mechanism similar to the *ex* **!** command. The standard developers did not consider that this was necessary in a paginator, particularly given the wide acceptance of multiple window terminals and job control features. (They chose to retain such features in the editors and *mailx* because the shell interaction also gives an opportunity to modify the editing buffer, which is not applicable to *more*).

The −**p** (position) option replaces the **+** command because of the Utility Syntax Guidelines. In early proposals, it took a *pattern* argument, but historical *less* provided the *more* general facility of a command. It would have been desirable to use the same −**c** as *ex* and *vi*, but the letter was already in use.

The text stating ‘‘from a non-rewindable stream ... implementations may limit the amount of backwards motion supported’’ would allow an implementation that permitted no backwards motion beyond text already on the screen. It was not possible to require a minimum amount of backwards motion that would be effective for all conceivable device types. The implementation should allow the user to back up as far as possible, within device and reasonable memory allocation constraints.

Historically, non-printable characters were displayed using the ARPA standard mappings, which are as follows:

1. Printable characters are left alone.
2. Control characters less than \177 are represented as followed by the character offset from the `'@'` character in the ASCII map; for example, \007 is represented as `'G'`.
3. \177 is represented as followed by `'?'`.

The display of characters having their eighth bit set was less standard. Existing implementations use hex (0x00), octal (\000), and a meta-bit display. (The latter displayed characters with their eighth bit set as the two characters `"M−,"` followed by the seven bit display as described previously.) The latter probably has the best claim to historical practice because it was used with the −**v** option of 4 BSD and 4 BSD-derived versions of the *cat* utility since 1980.

No specific display format is required by IEEE Std 1003.1-200x. Implementations are encouraged to conform to historic practice in the absence of any strong reason to diverge.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

The utility has been extensively reworked for alignment with the IEEE P1003.2b draft standard:

- Changes have been made as result of IEEE PASC Interpretations 1003.2 #37 and #109.
- The *more* utility should be able to handle underlined and emboldened displays of characters that are wider than a single column position.

NAME

mv — move files

SYNOPSIS

```
mv [−fi] source_file target_file

mv [−fi] source_file... target_file
```

DESCRIPTION

In the first synopsis form, the *mv* utility shall move the file named by the *source_file* operand to the *destination* specified by the *target_file*. This first synopsis form is assumed when the final operand does not name an existing directory and is not a symbolic link referring to an existing directory.

In the second synopsis form, *mv* shall move each file named by a *source_file* operand to a *destination* file in the existing directory named by the *target_dir* operand, or referenced if *target_dir* is a symbolic link referring to an existing directory. The *destination* path for each *source_file* shall be the concatenation of the target directory, a single slash character, and the last pathname component of the *source_file*. This second form is assumed when the final operand names an existing directory.

If any operand specifies an existing file of a type not specified by the System Interfaces volume of IEEE Std 1003.1-200x, the behavior is implementation-defined.

For each *source_file* the following steps shall be taken:

1. If the destination path exists, the **−f** option is not specified, and either of the following conditions is true:

    a. The permissions of the destination path do not permit writing and the standard input is a terminal.

    b. The **−i** option is specified.

    the *mv* utility shall write a prompt to standard error and read a line from standard input. If the response is not affirmative, *mv* shall do nothing more with the current *source_file* and go on to any remaining *source_file*s.

2. The *mv* utility shall perform actions equivalent to the *rename*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

    a. The *source_file* operand is used as the *old* argument.

    b. The destination path is used as the *new* argument.

    If this succeeds, *mv* shall do nothing more with the current *source_file* and go on to any remaining *source_file*s. If this fails for any reasons other than those described for the *errno* [EXDEV] in the System Interfaces volume of IEEE Std 1003.1-200x, *mv* shall write a diagnostic message to standard error, do nothing more with the current *source_file*, and go on to any remaining *source_file*s.

3. If the destination path exists, and it is a file of type directory and *source_file* is not a file of type directory, or it is a file not of type directory and *source_file* is a file of type directory, *mv* shall write a diagnostic message to standard error, do nothing more with the current *source_file*, and go on to any remaining *source_file*s.

4. If the destination path exists, *mv* shall attempt to remove it. If this fails for any reason, *mv* shall write a diagnostic message to standard error, do nothing more with the current *source_file*, and go on to any remaining *source_file*s.

5. The file hierarchy rooted in *source_file* shall be duplicated as a file hierarchy rooted in the *destination* path. If *source_file* or any of the files below it in the hierarchy are symbolic links, the links themselves shall be duplicated, including their contents, rather than any files to which they refer. The following characteristics of each file in the file hierarchy shall be duplicated:

   - The time of last data modification and time of last access
   - The user ID and group ID
   - The file mode

   If the user ID, group ID, or file mode of a regular file cannot be duplicated, the file mode bits S_ISUID and S_ISGID shall not be duplicated.

   When files are duplicated to another file system, the implementation may require that the process invoking *mv* has read access to each file being duplicated.

   If the duplication of the file hierarchy fails for any reason, *mv* shall write a diagnostic message to standard error, do nothing more with the current *source_file*, and go on to any remaining *source_file*s.

   If the duplication of the file characteristics fails for any reason, *mv* shall write a diagnostic message to standard error, but this failure shall not cause *mv* to modify its exit status.

6. The file hierarchy rooted in *source_file* shall be removed. If this fails for any reason, *mv* shall write a diagnostic message to the standard error, do nothing more with the current *source_file*, and go on to any remaining *source_file*s.

OPTIONS

The *mv* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–f	Do not prompt for confirmation if the destination path exists. Any previous occurrences of the **–i** option is ignored.
–i	Prompt for confirmation if the destination path exists. Any previous occurrences of the **–f** option is ignored.

Specifying more than one of the **–f** or **–i** options shall not be considered an error. The last option specified shall determine the behavior of *mv*.

OPERANDS

The following operands shall be supported:

source_file	A pathname of a file or directory to be moved.
target_file	A new pathname for the file or directory being moved.
target_dir	A pathname of an existing directory into which to move the input files.

STDIN

The standard input shall be used to read an input line in response to each prompt specified in the STDERR section. Otherwise, the standard input shall not be used. |

INPUT FILES

The input files specified by each *source_file* operand can be of any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mv*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes and multi-character collating elements used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.
LC_MESSAGES	Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Prompts shall be written to the standard error under the conditions specified in the DESCRIPTION section. The prompts shall contain the *destination* pathname, but their format is otherwise unspecified. Otherwise, the standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files may be of any file type.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All input files were moved successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

If the copying or removal of *source_file* is prematurely terminated by a signal or error, *mv* may leave a partial copy of *source_file* at the source or destination. The *mv* utility shall not modify both *source_file* and the destination path simultaneously; termination at any point shall leave either *source_file* or the destination path complete.

APPLICATION USAGE

Some implementations mark for update the *st_ctime* field of renamed files and some do not. Applications which make use of the *st_ctime* field may behave differently with respect to renamed files unless they are designed to allow for either behavior.

EXAMPLES

If the current directory contains only files **a** (of any type defined by the System Interfaces volume of IEEE Std 1003.1-200x), **b** (also of any type), and a directory **c**:

```
mv a b c
mv c d
```

results with the original files **a** and **b** residing in the directory **d** in the current directory.

RATIONALE

Early proposals diverged from the SVID and BSD historical practice in that they required that when the destination path exists, the −**f** option is not specified, and input is not a terminal, *mv* fails. This was done for compatibility with *cp*. The current text returns to historical practice. It should be noted that this is consistent with the *rename*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x, which does not require write permission on the target.

For absolute clarity, paragraph (1), describing the behavior of *mv* when prompting for confirmation, should be interpreted in the following manner:

```
if (exists AND (NOT f_option) AND
    ((not_writable AND input_is_terminal) OR i_option))
```

The −**i** option exists on BSD systems, giving applications and users a way to avoid accidentally unlinking files when moving others. When the standard input is not a terminal, the 4.3 BSD *mv* deletes all existing destination paths without prompting, even when −**i** is specified; this is inconsistent with the behavior of the 4.3 BSD *cp* utility, which always generates an error when the file is unwritable and the standard input is not a terminal. The standard developers decided that use of −**i** is a request for interaction, so when the *destination* path exists, the utility takes instructions from whatever responds to standard input.

The *rename*( ) function is able to move directories within the same file system. Some historical versions of *mv* have been able to move directories, but not to a different file system. The standard developers considered that this was an annoying inconsistency, so this volume of IEEE Std 1003.1-200x requires directories to be able to be moved even across file systems. There is no −**R** option to confirm that moving a directory is actually intended, since such an option was not required for moving directories in historical practice. Requiring the application to specify it sometimes, depending on the destination, seemed just as inconsistent. The semantics of the *rename*( ) function were preserved as much as possible. For example, *mv* is not permitted to ‘‘rename’’ files to or from directories, even though they might be empty and removable.

Historic implementations of *mv* did not exit with a non-zero exit status if they were unable to duplicate any file characteristics when moving a file across file systems, nor did they write a diagnostic message for the user. The former behavior has been preserved to prevent scripts from breaking; a diagnostic message is now required, however, so that users are alerted that the file characteristics have changed.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application not using the −**f** option or using the −**i** option relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

When *mv* is dealing with a single file system and *source_file* is a symbolic link, the link itself is moved as a consequence of the dependence on the *rename*( ) functionality, per the DESCRIPTION. Across file systems, this has to be made explicit.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The *mv* utility is changed to describe processing of symbolic links as specified in the IEEE P1003.2b draft standard.

The APPLICATION USAGE section is added.

NAME

newgrp — change to a new group

SYNOPSIS

UP `newgrp [−l][group`

DESCRIPTION

The *newgrp* utility shall create a new shell execution environment with a new real and effective group identification. Of the attributes listed in Section 2.12 (on page 2263), the new shell execution environment shall retain the working directory, file creation mask, and exported variables from the previous environment (that is, open files, traps, unexported variables, alias definitions, shell functions, and *set* options may be lost). All other aspects of the process environment that are preserved by the *exec* family of functions defined in the System Interfaces volume of IEEE Std 1003.1-200x shall also be preserved by *newgrp*; whether other aspects are preserved is unspecified.

A failure to assign the new group identifications (for example, for security or password-related reasons) shall not prevent the new shell execution environment from being created.

The *newgrp* utility shall affect the supplemental groups for the process as follows:

- On systems where the effective group ID is normally in the supplementary group list (or whenever the old effective group ID actually is in the supplementary group list):
  - If the new effective group ID is also in the supplementary group list, *newgrp* shall change the effective group ID.
  - If the new effective group ID is not in the supplementary group list, *newgrp* shall add the new effective group ID to the list, if there is room to add it.
- On systems where the effective group ID is not normally in the supplementary group list (or whenever the old effective group ID is not in the supplementary group list):
  - If the new effective group ID is in the supplementary group list, *newgrp* shall delete it.
  - If the old effective group ID is not in the supplementary list, *newgrp* shall add it if there is room.

Note: The System Interfaces volume of IEEE Std 1003.1-200x does not specify whether the effective group ID of a process is included in its supplementary group list.

With no operands, *newgrp* shall change the effective group back to the groups identified in the user's user entry, and shall set the list of supplementary groups to that set in the user's group database entries.

If a password is required for the specified group, and the user is not listed as a member of that group in the group database, the user shall be prompted to enter the correct password for that group. If the user is listed as a member of that group, no password shall be requested. If no password is required for the specified group, it is implementation-defined whether users not listed as members of that group can change to that group. Whether or not a password is required, implementation-defined system accounting or security mechanisms may impose additional authorization restrictions that may cause *newgrp* to write a diagnostic message and suppress the changing of the group identification. |

OPTIONS

The *newgrp* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

–l	(The letter ell.) Change the environment to what would be expected if the user actually logged in again.

OPERANDS

The following operand shall be supported:

group	A group name from the group database or a non-negative numeric group ID. Specifies the group ID to which the real and effective group IDs shall be set. If *group* is a non-negative numeric string and exists in the group database as a group name (see *getgrnam*( )), the numeric group ID associated with that group name shall be used as the group ID.

STDIN

Not used.

INPUT FILES

The file **/dev/tty** shall be used to read a single line of text for password checking, when one is required.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *newgrp*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used for diagnostic messages and a prompt string for a password, if one is required. Diagnostic messages may be written in cases where the exit status is not available. See the EXIT STATUS section.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If *newgrp* succeeds in creating a new shell execution environment, whether or not the group identification was changed successfully, the exit status shall be the exit status of the shell. Otherwise, the following exit value shall be returned:

>0 An error occurred.

CONSEQUENCES OF ERRORS

The invoking shell may terminate.

APPLICATION USAGE

There is no convenient way to enter a password into the Group Database. Use of group passwords is not encouraged, because by their very nature they encourage poor security practices. Group passwords may disappear in the future.

A common implementation of *newgrp* is that the current shell uses *exec* to overlay itself with *newgrp*, which in turn overlays itself with a new shell after changing group. On some implementations, however, this may not occur and *newgrp* may be invoked as a subprocess.

The *newgrp* command is intended only for use from an interactive terminal. It does not offer a useful interface for the support of applications.

The exit status of *newgrp* is generally inapplicable. If *newgrp* is used in a script, in most cases it successfully invokes a new shell and the rest of the original shell script is bypassed when the new shell exits. Used interactively, *newgrp* displays diagnostic messages to indicate problems. But usage such as:

```
newgrp foo
echo $?
```

is not useful because the new shell might not have access to any status *newgrp* may have generated (and most historical systems do not provide this status). A zero status echoed here does not necessarily indicate that the user has changed to the new group successfully. Following *newgrp* with the *id* command provides a portable means of determining whether the group change was successful or not.

EXAMPLES

None.

RATIONALE

Most historical implementations use one of the *exec* functions to implement the behavior of *newgrp*. Errors detected before the *exec* leave the environment unchanged, while errors detected after the *exec* leave the user in a changed environment. While it would be useful to have *newgrp* issue a diagnostic message to tell the user that the environment changed, it would be inappropriate to require this change to some historical implementations.

The password mechanism is allowed in the group database, but how this would be implemented is not specified.

The *newgrp* utility was retained in this volume of IEEE Std 1003.1-200x, even given the existence of the multiple group permissions feature in the System Interfaces volume of IEEE Std 1003.1-200x, for several reasons. First, in some implementations, the group ownership of a newly created file is determined by the group of the directory in which the file is created, as allowed by the System Interfaces volume of IEEE Std 1003.1-200x; on other implementations, the group ownership of a newly created file is determined by the effective group ID. On implementations of the latter type, *newgrp* allows files to be created with a specific group ownership. Finally, many implementations use the real group ID in accounting, and on such systems, *newgrp* allows the accounting identity of the user to be changed.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

The text describing supplemental groups is no longer conditional on {NGROUPS_MAX} being greater than 1. This is because {NGROUPS_MAX} now has a minimum value of 8. This is a FIPS requirement.

NAME

nice — invoke a utility with an altered nice value

SYNOPSIS

UP
```
nice [−n increment] utility [argument...]
```

DESCRIPTION

The *nice* utility shall invoke a utility, requesting that it be run with a different nice value (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.239, Nice Value). With no options and only if the user has appropriate privileges, the executed utility shall be run with a nice value that is some implementation-defined quantity less than or equal to the nice value of the current process. If the user lacks appropriate privileges to affect the nice value in the requested manner, the *nice* utility shall not affect the nice value; in this case, a warning message may be written to standard error, but this shall not prevent the invocation of *utility* or affect the exit status.

OPTIONS

The *nice* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option is supported:

−n *increment*	A positive or negative decimal integer which shall have the same effect on the execution of the utility as if the utility had called the *nice*( ) function with the numeric value of the *increment* option-argument. |

OPERANDS

The following operands shall be supported:

utility	The name of a utility that is to be invoked. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2266), the results are undefined.
argument	Any string to be supplied as an argument when invoking the utility named by the *utility* operand.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *nice*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
	PATH	Determine the search path used to locate the utility to be invoked. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If the *utility* utility is invoked, the exit status of *nice* shall be the exit status of *utility*; otherwise, the *nice* utility shall exit with one of the following values:

1-125	An error occurred in the *nice* utility.
126	The utility specified by *utility* was found but could not be invoked.
127	The utility specified by *utility* could not be found.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The only guaranteed portable uses of this utility are:

nice utility
    Run *utility* with the default lower nice value.

nice –**n** <*positive integer*> *utility*
    Run *utility* with a lower nice value.

On some implementations they have no discernible effect on the invoked utility and on some others they are exactly equivalent.

Historical systems have frequently supported the <*positive integer*> up to 20. Since there is no error penalty associated with guessing a number that is too high, users without access to the system conformance document (to see what limits are actually in place) could use the historical 1 to 20 range or attempt to use very large numbers if the job should be truly low priority.

The nice value value of a process can be displayed using the command:

```
ps –o nice
```

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ‘‘failure to find a utility’’ from ‘‘invoked utility exited with an error indication’’. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ‘‘normal error conditions’’ and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

EXAMPLES

None.

RATIONALE

Due to the text about the limits of the nice value being implementation-defined, *nice* is not actually required to change the nice value of the executed command; the limits could be zero differences from the system default, although the implementor is required to document this fact in the conformance document.

The 4.3 BSD version of *nice* does not check if *increment* is a valid decimal integer. The command *nice* −**x** *utility*, for example, would be treated the same as the command *nice* −−**1** *utility*. If the user does not have appropriate privileges, this results in a ‘‘permission denied’’ error. This is considered a bug.

When a user without appropriate privileges gives a negative *increment*, System V treats it like the command *nice* −**0** *utility*, while 4.3 BSD writes a ‘‘permission denied’’ message and does not run the utility. Neither was considered clearly superior, so the behavior was left unspecified.

The C shell has a built-in version of *nice* that has a different interface from the one described in this volume of IEEE Std 1003.1-200x.

The term ‘‘utility’’ is used, rather than ‘‘command’’, to highlight the fact that shell compound commands, pipelines, and so on, cannot be used. Special built-ins also cannot be used. However, ‘‘utility’’ includes user application programs and shell scripts, not just utilities defined in this volume of IEEE Std 1003.1-200x.

Historical implementations of *nice* provide a nice value range of 40 or 41 discrete steps, with the default nice value being the midpoint of that range. By default, they lower the nice value of the executed utility by 10.

Some historical documentation states that the *increment* value must be within a fixed range. This is misleading; the valid *increment* values on any invocation are determined by the current process nice value, which is not always the default.

The definition of nice value is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions such as the realtime priorities in the System Interfaces volume of IEEE Std 1003.1-200x make the notion of a single underlying priority for all scheduling policies problematic. Some implementations may implement the *nice*-related features to affect all processes on the system, others to affect just the general time-sharing activities implied by this volume of IEEE Std 1003.1-200x, and others may have no effect at all. Because of the use of ‘‘implementation-defined’’ in *nice* and *renice*, a wide range of implementation strategies are possible. |

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

NAME

nl — line numbering filter

SYNOPSIS

XSI
```
nl [−p][−b type][−d delim][−f type][−h type][−i incr][−l num][−n format]
    [−s sep][−v startnum][−w width][file]
```

DESCRIPTION

The *nl* utility shall read lines from the named *file* or the standard input if no *file* is named and shall reproduce the lines to standard output. Lines shall be numbered on the left. Additional functionality may be provided in accordance with the command options in effect.

The *nl* utility views the text it reads in terms of logical pages. Line numbering shall be reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer (for example, no numbering of header and footer lines while numbering blank lines only in the body).

The starts of logical page sections shall be signaled by input lines containing nothing but the following delimiter characters:

Line	Start of
`\:\:\:`	Header
`\:\:`	Body
`\:`	Footer

Unless otherwise specified, *nl* shall assume the text being read is in a single logical page body.

OPTIONS

The *nl* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines. Only one file can be named.

The following options shall be supported:

−b *type* Specify which logical page body lines shall be numbered. Recognized *types* and their meaning are:

- **a** Number all lines.
- **t** Number only non-empty lines.
- **n** No line numbering.
- **p***string* Number only lines that contain the basic regular expression specified in *string*.

The default *type* for logical page body shall be **t** (text lines numbered).

−d *delim* Specify the delimiter characters that indicate the start of a logical page section. These can be changed from the default characters `"\:"` to two user-specified characters. If only one character is entered, the second character shall remain the default character `':'`.

−f *type* Specify the same as **b** *type* except for footer. The default for logical page footer shall be **n** (no lines numbered).

−h *type* Specify the same as **b** *type* except for header. The default *type* for logical page header shall be **n** (no lines numbered).

−i *incr*	Specify the increment value used to number logical page lines. The default shall be 1.
−l *num*	Specify the number of blank lines to be considered as one. For example, **−l 2** results in only the second adjacent blank line being numbered (if the appropriate **−h a**, **−b a**, or **−f a** option is set). The default shall be 1.
−n *format*	Specify the line numbering format. Recognized values are: **ln**, left justified, leading zeros suppressed; **rn**, right justified, leading zeros suppressed; **rz**, right justified, leading zeros kept. The default *format* shall be **rn** (right justified).
−p	Specify that numbering should not be restarted at logical page delimiters.
−s *sep*	Specify the characters used in separating the line number and the corresponding text line. The default *sep* shall be a <tab>.
−v *startnum*	Specify the initial value used to number logical page lines. The default shall be 1.
−w *width*	Specify the number of characters to be used for the line number. The default *width* shall be 6.

OPERANDS

The following operand shall be supported:

file	A pathname of a text file to be line-numbered.

STDIN

The standard input is a text file that is used if no *file* operand is given.

INPUT FILES

The input file named by the *file* operand is a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *nl*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes and multi-character collating elements within regular expressions.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, and for deciding which characters are in character class **graph** (for the **−b t**, **−f t**, and **−h t** options).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be a text file in the following format:

```
"%s%s%s", <line number>, <separator>, <input line>
```

where <*line number*> is one of the following numeric formats:

`%6d`	When the **rn** format is used (the default; see −**n**).
`%06d`	When the **rz** format is used.
`%−6d`	When the *ln* format is used.
<empty>	When line numbers are suppressed for a portion of the page; the <*separator*> is also suppressed.

In the preceding list, the number 6 is the default width; the −**w** option can change this value.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

In using the −**d** *delim* option, care should be taken to escape characters that have special meaning to the command interpreter.

EXAMPLES

The command:

```
nl −v 10 −i 10 −d \!+ file1
```

numbers *file1* starting at line number 10 with an increment of 10. The logical page delimiter is `"!+"`. Note that the `'!'` has to be escaped when using *csh* as a command interpreter because of its history substitution syntax. For *ksh* and *sh* the escape is not necessary, but does not do any harm.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 2.

Issue 5

The option [–**f** *type*] is added to the SYNOPSIS. The option descriptions are presented in alphabetic order. The description of –**bt** is changed to ''Number only non-empty lines''.

Issue 6

The obsolescent behavior allowing the options to be intermingled with the optional *file* operand is removed.

NAME

nm — write the name list of an object file (**DEVELOPMENT**)

SYNOPSIS

UP SD XSI
```
nm [−APv][−efox][ −g| −u][−t format] file...
```

DESCRIPTION

This utility shall be provided on systems that support both the User Portability Utilities option and the Software Development Utilities option. On other systems it is optional. Certain options are only available on XSI-conformant systems.

The *nm* utility shall display symbolic information appearing in the object file, executable file or object-file library named by *file*. If no symbolic information is available for a valid input file, the *nm* utility shall report that fact, but not consider it an error condition.

XSI The default base used when numeric values are written is unspecified. On XSI-conformant systems, it shall be decimal.

OPTIONS

The *nm* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

	−A	Write the full pathname or library name of an object on each line.
XSI	**−e**	Write only external (global) and static symbol information.
XSI	**−f**	Produce full output. Write redundant symbols (**.text**, **.data**, and **.bss**), normally suppressed.
	−g	Write only external (global) symbol information.
XSI	**−o**	Write numeric values in octal (equivalent to **−t o**).
	−P	Write information in a portable output format, as specified in the STDOUT section.
	−t *format*	Write each numeric value in the specified format. The format shall be dependent on the single character used as the *format* option-argument:
XSI		`d` The offset is written in decimal (default).
		`o` The offset is written in octal.
		`x` The offset is written in hexadecimal.
	−u	Write only undefined symbols.
	−v	Sort output by value instead of alphabetically.
XSI	**−x**	Write numeric values in hexadecimal (equivalent to **−t x**).

OPERANDS

The following operand shall be supported:

file	A pathname of an object file, executable file, or object-file library.

STDIN

See the INPUT FILES section.

INPUT FILES

The input file shall be an object file, an object-file library whose format is the same as those produced by the *ar* utility for link editing, or an executable file. The *nm* utility may accept additional implementation-defined object library formats for the input file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *nm*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for character collation information for the symbol-name and symbol-value collation sequences.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If symbolic information is present in the input files, then for each file or for each member of an archive, the *nm* utility shall write the following information to standard output. By default, the format is unspecified, but the output shall be sorted alphabetically by symbol name:

- Library or object name, if **–A** is specified
- Symbol name
- Symbol type, which shall either be one of the following single characters or an implementation-defined type represented by a single character:

`A`	Global absolute symbol.
`a`	Local absolute symbol.
`B`	Global ‘‘bss’’ (that is, uninitialized data space) symbol.
`b`	Local bss symbol.
`D`	Global data symbol.
`d`	Local data symbol.
`T`	Global text symbol.
`t`	Local text symbol.
`U`	Undefined symbol.

- Value of the symbol
- The size associated with the symbol, if applicable

This information may be supplemented by additional information specific to the implementation.

If the −**P** option is specified, the previous information shall be displayed using the following portable format. The three versions differ depending on whether −**t d**, −**t o**, or −**t x** was specified, respectively:

```
"%s%s %s %d %d\n", <library/object name>, <name>, <type>,
    <value>, <size>
```

```
"%s%s %s %o %o\n", <library/object name>, <name>, <type>,
    <value>, <size>
```

```
"%s%s %s %x %x\n", <library/object name>, <name>, <type>,
    <value>, <size>
```

where

<*library/object name*> shall be formatted as follows:

- If −**A** is not specified, <*library/object name*> shall be an empty string.
- If −**A** is specified and the corresponding *file* operand does not name a library:

  ```
  "%s: ", <file>
  ```

- If −**A** is specified and the corresponding *file* operand names a library. In this case, <*object file*> shall name the object file in the library containing the symbol being described:

  ```
  "%s[%s]: ", <file>, <object file>
  ```

If −**A** is not specified, then if more than one *file* operand is specified or if only one *file* operand is specified and it names a library, *nm* shall write a line identifying the object containing the following symbols before the lines containing those symbols, in the form:

- If the corresponding *file* operand does not name a library:

  ```
  "%s:\n", <file>
  ```

- If the corresponding *file* operand names a library; in this case, <*object file*> shall be the name of the file in the library containing the following symbols:

  ```
  "%s[%s]:\n", <file>, <object file>
  ```

If −**P** is specified, but −**t** is not, the format shall be as if −**t x** had been specified.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Mechanisms for dynamic linking make this utility less meaningful when applied to an executable file because a dynamically linked executable may omit numerous library routines that would be found in a statically linked executable.

EXAMPLES

None.

RATIONALE

Historical implementations of *nm* have used different bases for numeric output and supplied different default types of symbols that were reported. The −**t** *format* option, similar to that used in *od* and *strings*, can be used to specify the numeric base; −**g** and −**u** can be used to restrict the amount of output or the types of symbols included in the output.

The compromise of using −**t** *format versus* using −**d**, −**o**, and other similar options was necessary because of differences in the meaning of −**o** between implementations. The −**o** option from BSD has been provided here as −**A** to avoid confusion with the −**o** from System V (which has been provided here as −**t** and as −**o** on XSI-conformant systems).

The option list was significantly reduced from that provided by historical implementations.

The *nm* description is a subset of both the System V and BSD *nm* utilities with no specified default output.

It was recognized that mechanisms for dynamic linking make this utility less meaningful when applied to an executable file (because a dynamically linked executable file may omit numerous library routines that would be found in a statically linked executable file), but the value of *nm* during software development was judged to outweigh other limitations.

The default output format of *nm* is not specified because of differences in historical implementations. The −**P** option was added to allow some type of portable output format. After a comparison of the different formats used in SunOS, BSD, SVR3, and SVR4, it was decided to create one that did not match the current format of any of these four systems. The format devised is easy to parse by humans, easy to parse in shell scripts, and does not need to vary depending on locale (because no English descriptions are included). All of the systems currently have the information available to use this format.

The format given in *nm* STDOUT uses spaces between the fields, which may be any number of <blank>s required to align the columns. The single-character types were selected to match historical practice, and the requirement that implementation additions also be single characters made parsing the information easier for shell scripts.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as supported when both the User Portability Utilities option and the Software Development Utilities option are supported.

NAME

nohup — invoke a utility immune to hangups

SYNOPSIS

```
nohup utility [argument...]
```

DESCRIPTION

The *nohup* utility shall invoke the utility named by the *utility* operand with arguments supplied as the *argument* operands. At the time the named *utility* is invoked, the SIGHUP signal shall be set to be ignored.

If the standard output is a terminal, all output written by the named *utility* to its standard output shall be appended to the end of the file **nohup.out** in the current directory. If **nohup.out** cannot be created or opened for appending, the output shall be appended to the end of the file **nohup.out** in the directory specified by the *HOME* environment variable. If neither file can be created or opened for appending, *utility* shall not be invoked. If a file is created, the file's permission bits shall be set to S_IRUSR | S_IWUSR.

If the standard error is a terminal, all output written by the named *utility* to its standard error shall be redirected to the same file descriptor as the standard output.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

utility	The name of a utility that is to be invoked. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2266), the results are undefined.
argument	Any string to be supplied as an argument when invoking the utility named by the *utility* operand.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *nohup*:

HOME	Determine the pathname of the user's home directory: if the output file **nohup.out** cannot be created in the current directory, the *nohup* utility shall use the directory named by *HOME* to create the file.
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of

diagnostic messages written to standard error.

XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
PATH	Determine the search path that is used to locate the utility to be invoked. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

ASYNCHRONOUS EVENTS

The *nohup* utility shall take the standard action for all signals except that SIGHUP shall be ignored.

STDOUT

If the standard output is not a terminal, the standard output of *nohup* shall be the standard output generated by the execution of the *utility* specified by the operands. Otherwise, nothing shall be written to the standard output.

STDERR

If the standard output is a terminal, a message shall be written to the standard error, indicating the name of the file to which the output is being appended. The name of the file shall be either **nohup.out** or **$HOME/nohup.out**.

OUTPUT FILES

If the standard output is a terminal, all output written by the named *utility* to the standard output and standard error is appended to the file **nohup.out**, which is created if it does not already exist.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

126	The utility specified by *utility* was found but could not be invoked.
127	An error occurred in the *nohup* utility or the utility specified by *utility* could not be found.

Otherwise, the exit status of *nohup* shall be that of the utility specified by the *utility* operand.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ‘‘failure to find a utility’’ from ‘‘invoked utility exited with an error indication’’. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ‘‘normal error conditions’’ and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

EXAMPLES

It is frequently desirable to apply *nohup* to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the *nohup* applies to everything in the file.

Alternatively, the following command can be used to apply *nohup* to a complex command:

```
nohup sh −c 'complex-command-line'
```

RATIONALE

The 4.3 BSD version ignores SIGTERM and SIGHUP, and if **./nohup.out** cannot be used, it fails instead of trying to use **$HOME/nohup.out**.

The *csh* utility has a built-in version of *nohup* that acts differently from the POSIX Shell and Utilities *nohup*.

The term *utility* is used, rather than *command*, to highlight the fact that shell compound commands, pipelines, special built-ins, and so on, cannot be used directly. However, *utility* includes user application programs and shell scripts, not just the standard utilities.

Historical versions of the *nohup* utility use default file creation semantics. Some more recent versions use the permissions specified here as an added security precaution.

Some historical implementations ignore SIGQUIT in addition to SIGHUP; others ignore SIGTERM. An early proposal allowed, but did not require, SIGQUIT to be ignored. Several reviewers objected that *nohup* should only modify the handling of SIGHUP as required by this volume of IEEE Std 1003.1-200x.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

od — dump files in various formats

SYNOPSIS

```
od [−v][−A address_base][−j skip][−N count][−t type_string]...
    [file...]
```

XSI
```
od [−bcdosx][file] [[+]offset[.][b]]
```

DESCRIPTION

The *od* utility shall write the contents of its input files to standard output in a user-specified format.

OPTIONS

XSI The *od* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of presentation of the **−t** options and the **−bcdosx** options is significant.

The following options shall be supported:

−A *address_base*
Specify the input offset base. See the EXTENDED DESCRIPTION section. The application shall ensure that the *address_base* option-argument is a character. The characters `'d'`, `'o'`, and `'x'` specify that the offset base shall be written in decimal, octal, or hexadecimal, respectively. The character `'n'` specifies that the offset shall not be written.

XSI **−b** Interpret bytes in octal. This shall be equivalent to **−t o1**.

XSI **−c** Interpret bytes as characters specified by the current setting of the *LC_CTYPE* category. Certain non-graphic characters appear as C escapes: `"NUL=\0"`, `"BS=\b"`, `"FF=\f"`, `"NL=\n"`, `"CR=\r"`, `"HT=\t"`; others appear as 3-digit octal numbers.

XSI **−d** Interpret *words* (two-byte units) in unsigned decimal. This shall be equivalent to **−t u2**.

−j *skip* Jump over *skip* bytes from the beginning of the input. The *od* utility shall read or seek past the first *skip* bytes in the concatenated input files. If the combined input is not at least *skip* bytes long, the *od* utility shall write a diagnostic message to standard error and exit with a non-zero exit status.

By default, the *skip* option-argument shall be interpreted as a decimal number. With a leading 0x or 0X, the offset shall be interpreted as a hexadecimal number; otherwise, with a leading `'0'`, the offset shall be interpreted as an octal number. Appending the character `'b'`, `'k'`, or `'m'` to offset shall cause it to be interpreted as a multiple of 512, 1 024, or 1 048 576 bytes, respectively. If the *skip* number is hexadecimal, any appended `'b'` shall be considered to be the final hexadecimal digit.

−N *count* Format no more than *count* bytes of input. By default, *count* shall be interpreted as a decimal number. With a leading 0x or 0X, *count* shall be interpreted as a hexadecimal number; otherwise, with a leading `'0'`, it shall be interpreted as an octal number. If *count* bytes of input (after successfully skipping, if **−j** *skip* is specified) are not available, it shall not be considered an error; the *od* utility shall format the input that is available.

XSI **−o** Interpret *words* (two-byte units) in octal. This shall be equivalent to **−t o2**.

XSI **−s** Interpret *words* (two-byte units) in signed decimal. This shall be equivalent to **−t d2**.

−t *type_string*

Specify one or more output types. See the EXTENDED DESCRIPTION section. The application shall ensure that the *type_string* option-argument is a string specifying the types to be used when writing the input data. The string shall consist of the type specification characters `a`, `c`, `d`, `f`, `o`, `u`, and `x`, specifying named character, character, signed decimal, floating point, octal, unsigned decimal, and hexadecimal, respectively. The type specification characters `d`, `f`, `o`, `u`, and `x` can be followed by an optional unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type. The type specification character `f` can be followed by an optional `F`, `D`, or `L` indicating that the conversion should be applied to an item of type **float**, **double**, or **long double**, respectively. The type specification characters `d`, `o`, `u` and `x` can be followed by an optional `C`, `S`, `I`, or `L` indicating that the conversion should be applied to an item of type **char**, **short**, **int**, or **long**, respectively. Multiple types can be concatenated within the same *type_string* and multiple **−t** options can be specified. Output lines shall be written for each type specified in the order in which the type specification characters are specified.

−v Write all input data. Without the **−v** option, any number of groups of output lines, which would be identical to the immediately preceding group of output lines (except for the byte offsets), shall be replaced with a line containing only an asterisk (`'*'`).

XSI **−x** Interpret *words* (two-byte units) in hexadecimal. This shall be equivalent to **−t x2**.

XSI Multiple types can be specified by using multiple **−bcdostx** options. Output lines are written for each type specified in the order in which the types are specified.

OPERANDS

The following operands shall be supported:

file A pathname of a file to be read. If no *file* operands are specified, the standard input shall be used.

If there are no more than two operands, none of the **−A**, **−j**, **−N**, or **−t** options is specified, and either of the following is true: the first character of the last operand is a plus sign (`'+'`), or there are two operands and the first character of the last operand is numeric; XSI the last operand shall be interpreted as an offset operand on XSI-conformant systems. Under these conditions, the results are unspecified on systems that are not XSI-conformant systems.

XSI **[+]***offset***[.][b]** The *offset* operand specifies the offset in the file where dumping is to commence. This operand is normally interpreted as octal bytes. If `'.'` is appended, the offset shall be interpreted in decimal. If `'b'` is appended, the offset shall be interpreted in units of 512 bytes.

STDIN

The standard input shall be used only if no *file* operands are specified. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *od*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_NUMERIC
Determine the locale for selecting the radix character used when writing floating-point formatted output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the EXTENDED DESCRIPTION section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The *od* utility shall copy sequentially each input file to standard output, transforming the input XSI data according to the output types specified by the −**t** options or the −**bcdosx** options. If no output type is specified, the default output shall be as if −**t oS** had been specified.

The number of bytes transformed by the output type specifier `c` may be variable depending on the *LC_CTYPE* category.

The default number of bytes transformed by output type specifiers `d`, `f`, `o`, `u`, and `x` corresponds to the various C-language types as follows. If the *c99* compiler is present on the system, these specifiers shall correspond to the sizes used by default in that compiler. Otherwise, these sizes may vary among systems that conform to IEEE Std 1003.1-200x.

- For the type specifier characters `d`, `o`, `u`, and `x`, the default number of bytes shall correspond to the size of the underlying implementation's basic integer type. For these specifier characters, the implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types **char**, **short**, **int**, and **long**. These numbers can also be specified by an application as the characters `'C'`, `'S'`, `'I'`, and `'L'`, respectively. The implementation shall also support the values 1, 2, 4, and 8, even if it provides no C-Language types of those sizes. The implementation shall support the decimal value corresponding to the C-language type **long long**. The byte order used when interpreting numeric values is implementation-defined, but shall correspond to the order in which a constant of the corresponding type is stored in memory on the system.

- For the type specifier character `f`, the default number of bytes shall correspond to the number of bytes in the underlying implementation's basic double precision floating-point data type. The implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types **float, double**, and **long double**. These numbers can also be specified by an application as the characters `'F'`, `'D'`, and `'L'`, respectively.

The type specifier character `a` specifies that bytes shall be interpreted as named characters from the International Reference Version (IRV) of the ISO/IEC 646:1991 standard. Only the least significant seven bits of each byte shall be used for this type specification. Bytes with the values listed in the following table shall be written using the corresponding names for those characters.

Table 4-12 Named Characters in *od*

Value	Name	Value	Name	Value	Name	Value	Name
\000	**nul**	\001	**soh**	\002	**stx**	\003	**etx**
\004	**eot**	\005	**enq**	\006	**ack**	\007	**bel**
\010	**bs**	\011	**ht**	\012	**lf** or **nl***	\013	**vt**
\014	**ff**	\015	**cr**	\016	**so**	\017	**si**
\020	**dle**	\021	**dc1**	\022	**dc2**	\023	**dc3**
\024	**dc4**	\025	**nak**	\026	**syn**	\027	**etb**
\030	**can**	\031	**em**	\032	**sub**	\033	**esc**
\034	**fs**	\035	**gs**	\036	**rs**	\037	**us**
\040	**sp**	\177	**del**				

Note: The `"\012"` value may be written either as **lf** or **nl**.

The type specifier character `c` specifies that bytes shall be interpreted as characters specified by the current setting of the *LC_CTYPE* locale category. Characters listed in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`) shall be written as the corresponding escape sequences, except that backslash shall be written as a single backslash and a NUL shall be written as `'\0'`. Other non-printable characters shall be written as one three-digit octal number for each byte in the character. If the size of a byte on the system is greater than nine bits, the format used for non-printable characters is implementation-defined. Printable multi-byte characters shall be written in the area corresponding to the first byte of the character; the two-character sequence `"**"` shall be written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. When either the **−j** *skip* or **−N** *count* option is specified along with the `c` type specifier, and this results in an attempt to start or finish in the middle of a multi-byte character, the result is implementation-defined.

The input data shall be manipulated in blocks, where a block is defined as a multiple of the least common multiple of the number of bytes transformed by the specified output types. If the least common multiple is greater than 16, the results are unspecified. Each input block shall be written as transformed by each output type, one per written line, in the order that the output types were specified. If the input block size is larger than the number of bytes transformed by the output type, the output type shall sequentially transform the parts of the input block, and the output from each of the transformations shall be separated by one or more <blank>s.

If, as a result of the specification of the –**N** option or end-of-file being reached on the last input file, input data only partially satisfies an output type, the input shall be extended sufficiently with null bytes to write the last byte of the input.

Unless –**A n** is specified, the first output line produced for each input block shall be preceded by the input offset, cumulative across input files, of the next byte to be written. The format of the input offset is unspecified; however, it shall not contain any <blank>s, shall start at the first character of the output line, and shall be followed by one or more <blank>s. In addition, the offset of the byte following the last byte written shall be written after all the input data has been processed, but shall not be followed by any <blank>s.

If no –**A** option is specified, the input offset base is unspecified.

EXIT STATUS

The following exit values shall be returned:

0	All input files were processed successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

XSI-conformant applications are warned not to use filenames starting with `'+'` or a first operand starting with a numeric character so that the old functionality can be maintained by implementations, unless they specify one of the –**A**, –**j**, or –**N** options. To guarantee that one of these filenames is always interpreted as a filename, an application could always specify the address base format with the –**A** option.

EXAMPLES

If a file containing 128 bytes with decimal values zero to 127, in increasing order, is supplied as standard input to the command:

```
od –A d –t a
```

on an implementation using an input block size of 16 bytes, the standard output, independent of the current locale setting, would be similar to:

```
0000000 nul soh stx etx eot enq ack bel  bs  ht  nl  vt  ff  cr  so  si
0000016 dle dc1 dc2 dc3 dc4 nak syn etb can  em sub esc  fs  gs  rs  us
0000032  sp   !   "   #   $   %   &   ’   (   )   *   +   ,   –   .   /
0000048   0   1   2   3   4   5   6   7   8   9   :   ;   <   =   >   ?
0000064   @   A   B   C   D   E   F   G   H   I   J   K   L   M   N   O
0000080   P   Q   R   S   T   U   V   W   X   Y   Z   [   \   ]   ^   _
0000096   ‘   a   b   c   d   e   f   g   h   i   j   k   l   m   n   o
0000112   p   q   r   s   t   u   v   w   x   y   z   {   |   }   ~ del
0000128
```

Note that this volume of IEEE Std 1003.1-200x allows **nl** or **lf** to be used as the name for the ISO/IEC 646:1991 standard IRV character with decimal value 10. The IRV names this character **lf** (line feed), but traditional implementations have referred to this character as newline (**nl**) and the POSIX locale character set symbolic name for the corresponding character is a <newline>.

The command:

```
od –A o –t o2x2x –n 18
```

on a system with 32-bit words and an implementation using an input block size of 16 bytes could write 18 bytes in approximately the following format:

```
0000000 032056 031440 041123 042040 052516 044530 020043 031464
            342e    3320    4253    4420    554e    4958    2023    3334
                342e3320        42534420        554e4958        20233334
0000020 032472
            353a
                353a0000
0000022
```

The command:

```
od −A d −t f −t o4 −t x4 −n 24 −j 0x15
```

on a system with 64-bit doubles (for example, IEEE Std 754-1985 double precision floating-point format) would skip 21 bytes of input data and then write 24 bytes in approximately the following format:

```
0000000    1.00000000000000e+00    1.57350000000000e+01
        07774000000 00000000000 10013674121 35341217270
            3ff00000    00000000    402f3851    eb851eb8
0000016    1.40668230000000e+02
        10030312542 04370303230
            40619562    23e18698
0000024
```

RATIONALE

The *od* utility went through several names in early proposals, including *hd*, *xd*, and most recently *hexdump*. There were several objections to all of these based on the following reasons:

- The *hd* and *xd* names conflicted with historical utilities that behaved differently.
- The *hexdump* description was much more complex than needed for a simple dump utility.
- The *od* utility has been available on all historical implementations and there was no need to create a new name for a utility so similar to the historical *od* utility.

The original reasons for not standardizing historical *od* were also fairly widespread. Those reasons are given below along with rationale explaining why the standard developers believe that this version does not suffer from the indicated problem:

- The BSD and System V versions of *od* have diverged, and the intersection of features provided by both does not meet the needs of the user community. In fact, the System V version only provides a mechanism for dumping octal bytes and **short**s, signed and unsigned decimal **short**s, hexadecimal **short**s, and ASCII characters. BSD added the ability to dump **float**s, **double**s, named ASCII characters, and octal, signed decimal, unsigned decimal, and hexadecimal **long**s. The version presented here provides more normalized forms for dumping bytes, **short**s, **int**s, and **long**s in octal, signed decimal, unsigned decimal, and hexadecimal; **float**, **double**, and **long double**; and named ASCII as well as current locale characters.
- It would not be possible to come up with a compatible superset of the BSD and System V flags that met the requirements of the standard developers. The historical default *od* output is the specified default output of this utility. None of the option letters chosen for this version of *od* conflict with any of the options to historical versions of *od*.
- On systems with different sizes for **short**, **int**, and **long**, there was no way to ask for dumps of **int**s, even in the BSD version. Because of the way options are named, the name space could not be extended to solve these problems. This is why the **−t** option was added (with type specifiers more closely matched to the *printf*( ) formats used in the rest of this volume of

IEEE Std 1003.1-200x) and the optional field sizes were added to the `d`, `f`, `o`, `u`, and `x` type specifiers. It is also one of the reasons why the historical practice was not mandated as a required obsolescent form of *od*. (Although the old versions of *od* are not listed as an obsolescent form, implementations are urged to continue to recognize the older forms for several more years.) The `a`, `c`, `f`, `o`, and `x` types match the meaning of the corresponding format characters in the historical implementations of *od* except for the default sizes of the fields converted. The `d` format is signed in this volume of IEEE Std 1003.1-200x to match the *printf*( ) notation. (Historical versions of *od* used `d` as a synonym for `u` in this version. The System V implementation uses `s` for signed decimal; BSD uses `i` for signed decimal and `s` for null-terminated strings.) Other than `d` and `u`, all of the type specifiers match format characters in the historical BSD version of **od**.

The sizes of the C-language types **char**, **short**, **int**, **long**, **float**, **double**, and **long double** are used even though it is recognized that there may be zero or more than one compiler for the C language on an implementation and that they may use different sizes for some of these types. (For example, one compiler might use 2 bytes **short**s, 2 bytes **int**s, and 4 bytes **long**s, while another compiler (or an option to the same compiler) uses 2 bytes **short**s, 4 bytes **int**s, and 4 bytes **long**s.) Nonetheless, there has to be a basic size known by the implementation for these types, corresponding to the values reported by invocations of the *getconf* utility when called with *system_var* operands {UCHAR_MAX}, {USHORT_MAX}, {UINT_MAX}, and {ULONG_MAX} for the types **char**, **short**, **int**, and **long**, respectively. There are similar constants required by the ISO C standard, but not required by the System Interfaces volume of IEEE Std 1003.1-200x or this volume of IEEE Std 1003.1-200x. They are {FLT_MANT_DIG}, {DBL_MANT_DIG}, and {LDBL_MANT_DIG} for the types **float**, **double**, and **long double**, respectively. If the optional *c99* utility is provided by the implementation and used as specified by this volume of IEEE Std 1003.1-200x, these are the sizes that would be provided. If an option is used that specifies different sizes for these types, there is no guarantee that the *od* utility is able to interpret binary data output by such a program correctly.

This volume of IEEE Std 1003.1-200x requires that the numeric values of these lengths be recognized by the *od* utility and that symbolic forms also be recognized. Thus, a conforming application can always look at an array of **unsigned long** data elements using *od* −**t** *uL*.

- The method of specifying the format for the address field based on specifying a starting offset in a file unnecessarily tied the two together. The −**A** option now specifies the address base and the −**S** option specifies a starting offset.
- It would be difficult to break the dependence on U.S. ASCII to achieve an internationalized utility. It does not seem to be any harder for *od* to dump characters in the current locale than it is for the *ed* or *sed* **l** commands. The **c** type specifier does this without difficulty and is completely compatible with the historical implementations of the **c** format character when the current locale uses a superset of the ISO/IEC 646:1991 standard as a codeset. The **a** type specifier (from the BSD **a** format character) was left as a portable means to dump ASCII (or more correctly ISO/IEC 646:1991 standard (IRV)) so that headers produced by *pax* could be deciphered even on systems that do not use the ISO/IEC 646:1991 standard as a subset of their base codeset.

The use of `"**"` as an indication of continuation of a multi-byte character in **c** specifier output was chosen based on seeing an implementation that uses this method. The continuation bytes have to be marked in a way that is not ambiguous with another single-byte or multi-byte character.

An early proposal used −**S** and −**n**, respectively, for the −**j** and −**N** options eventually selected. These were changed to avoid conflicts with historical implementations.

The original standard specified **−t o2** as the default when no output type was given. This was changed to **−t oS** (the length of a **short**) to accommodate a supercomputer implementation that historically used 64 bits as its default (and that defined shorts as 64 bits). This change should not affect conforming applications. The requirement to support lengths of 1, 2, and 4 was added at the same time to address an historical implementation that had no two-byte data types in its C compiler.

The use of a basic integer data type is intended to allow the implementation to choose a word size commonly used by applications on that architecture.

FUTURE DIRECTIONS

All option and operand interfaces marked as extensions may be withdrawn in a future issue.

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the description of the **−c** option, the phrase ''This is equivalent to **−t c**.'' is deleted.

The FUTURE DIRECTIONS section has been modified.

Issue 6

The *od* utility is changed to remove the assumption that **short** was a two-byte entity, as per the revisions in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ''must'' for application requirements.

NAME

paste — merge corresponding or subsequent lines of files

SYNOPSIS

```
paste [−s][−d list] file...
```

DESCRIPTION

The *paste* utility shall concatenate the corresponding lines of the given input files, and writes the resulting lines to standard output.

The default operation of *paste* shall concatenate the corresponding lines of the input files. The <newline> of every line except the line from the last input file shall be replaced with a <tab>.

If an end-of-file condition is detected on one or more input files, but not all input files, *paste* shall behave as though empty lines were read from the files on which end-of-file was detected, unless the −**s** option is specified.

OPTIONS

The *paste* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−**d** *list* Unless a backslash character appears in *list*, each character in *list* is an element specifying a delimiter character. If a backslash character appears in *list*, the backslash character and one or more characters following it are an element specifying a delimiter character as described below. These elements specify one or more delimiters to use, instead of the default <tab>, to replace the <newline> of the input lines. The elements in *list* shall be used circularly; that is, when the list is exhausted the first element from the list is reused. When the −**s** option is specified:

- The last <newline> in a file shall not be modified.
- The delimiter shall be reset to the first element of list after each *file* operand is processed.

When the −**s** option is not specified:

- The <newline>s in the file specified by the last *file* operand shall not be modified.
- The delimiter shall be reset to the first element of list each time a line is processed from each file.

If a backslash character appears in *list*, it and the character following it shall be used to represent the following delimiter characters:

`\n` <newline>.

`\t` <tab>.

`\\` Backslash character.

`\0` Empty string (not a null character). If `'\0'` is immediately followed by the character `'x'`, the character `'X'`, or any character defined by the *LC_CTYPE* **digit** keyword (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale), the results are unspecified.

If any other characters follow the backslash, the results are unspecified.

−**s** Concatenate all of the lines of each separate input file in command line order. The <newline> of every line except the last line in each input file shall be replaced with the <tab>, unless otherwise specified by the **−d** option.

OPERANDS

The following operand shall be supported:

file	A pathname of an input file. If ′−′ is specified for one or more of the *file*s, the standard input shall be used; the standard input shall be read one line at a time, circularly, for each instance of ′−′. Implementations shall support pasting of at least 12 *file* operands.

STDIN

The standard input shall be used only if one or more *file* operands is ′−′. See the INPUT FILES section.

INPUT FILES

The input files shall be text files, except that line lengths shall be unlimited.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *paste*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Concatenated lines of input files shall be separated by the <tab> (or other characters under the control of the **−d** option) and terminated by a <newline>.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

If one or more input files cannot be opened when the **-s** option is not specified, a diagnostic message shall be written to standard error, but no output is written to standard output. If the **-s** option is specified, the *paste* utility shall provide the default behavior described in Section 1.11 (on page 2221).

APPLICATION USAGE

When the escape sequences of the *list* option-argument are used in a shell script, they must be quoted; otherwise, the shell treats the `'\\'` as a special character.

Conforming applications should only use the specific backslash escaped delimiters presented in this volume of IEEE Std 1003.1-200x. Historical implementations treat `'\x'`, where `'x'` is not in this list, as `'x'`, but future implementations are free to expand this list to recognize other common escapes similar to those accepted by *printf* and other standard utilities.

Most of the standard utilities work on text files. The *cut* utility can be used to turn files with arbitrary line lengths into a set of text files containing the same data. The *paste* utility can be used to create (or recreate) files with arbitrary line lengths. For example, if *file* contains long lines:

```
cut -b 1-500 -n file > file1
cut -b 501- -n file > file2
```

creates **file1** (a text file) with lines no longer than 500 bytes (plus the <newline>) and **file2** that contains the remainder of the data from *file*. Note that **file2** is not a text file if there are lines in *file* that are longer than 500 + {LINE_MAX} bytes. The original file can be recreated from **file1** and **file2** using the command:

```
paste -d "\0" file1 file2 > file
```

The commands:

```
paste -d "\0" ...
paste -d "" ...
```

are not necessarily equivalent; the latter is not specified by this volume of IEEE Std 1003.1-200x and may result in an error. The construct `'\0'` is used to mean ‘‘no separator’’ because historical versions of *paste* did not follow the syntax guidelines, and the command:

```
paste -d"" ...
```

could not be handled properly by *getopt*( ).

EXAMPLES

1. Write out a directory in four columns:

   ```
   ls | paste - - - -
   ```

2. Combine pairs of lines from a file into single lines:

   ```
   paste -s -d "\t\n" file
   ```

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

patch — apply changes to files

SYNOPSIS

UP

```
patch [−blNR][ −c| −e| −n][−d dir][−D define][−i patchfile]
    [−o outfile][−p num][−r rejectfile][file]
```

DESCRIPTION

The *patch* utility shall read a source (patch) file containing any of the three forms of difference (diff) listings produced by the *diff* utility (normal, context or in the style of *ed*) and apply those differences to a file. By default, *patch* shall read from the standard input.

The *patch* utility shall attempt to determine the type of the *diff* listing, unless overruled by a **−c**, **−e**, or **−n** option.

If the patch file contains more than one patch, *patch* shall attempt to apply each of them as if they came from separate patch files. (In this case, the application shall ensure that the name of the patch file is determinable for each *diff* listing.)

OPTIONS

The *patch* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−b Save a copy of the original contents of each modified file, before the differences are applied, in a file of the same name with the suffix **.orig** appended to it. If the file already exists, it shall be overwritten; if multiple patches are applied to the same file, the **.orig** file shall be written only for the first patch. When the **−o** *outfile* option is also specified, *file***.orig** shall not be created but, if *outfile* already exists, *outfile***.orig** shall be created.

−c Interpret the patch file as a context difference (the output of the utility *diff* when the **−c** or **−C** options are specified).

−d *dir* Change the current directory to *dir* before processing as described in the EXTENDED DESCRIPTION section.

−D *define* Mark changes with one of the following C preprocessor constructs:

```
#ifdef define
...
#endif

#ifndef define
...
#endif
```

optionally combined with the C preprocessor construct **#else**.

−e Interpret the patch file as an *ed* script, rather than a *diff* script.

−i *patchfile* Read the patch information from the file named by the pathname *patchfile*, rather than the standard input.

−l (The letter ell.) Cause any sequence of <blank>s in the difference script to match any sequence of <blank>s in the input file. Other characters shall be matched exactly.

−n	Interpret the script as a normal difference.
−N	Ignore patches where the differences have already been applied to the file; by default, already-applied patches shall be rejected.
−o *outfile*	Instead of modifying the files (specified by the *file* operand or the difference listings) directly, write a copy of the file referenced by each patch, with the appropriate differences applied, to *outfile*. Multiple patches for a single file shall be applied to the intermediate versions of the file created by any previous patches, and shall result in multiple, concatenated versions of the file being written to *outfile*.
−p *num*	For all pathnames in the patch file that indicate the names of files to be patched, delete *num* pathname components from the beginning of each pathname. If the pathname in the patch file is absolute, any leading slashes shall be considered the first component (that is, **−p 1** shall remove the leading slashes). Specifying **−p 0** shall cause the full pathname to be used. If **−p** is not specified, only the basename (the final pathname component) shall be used.
−R	Reverse the sense of the patch script; that is, assume that the difference script was created from the new version to the old version. The **−R** option cannot be used with *ed* scripts. The *patch* utility shall attempt to reverse each portion of the script before applying it. Rejected differences shall be saved in swapped format. If this option is not specified, and until a portion of the patch file is successfully applied, *patch* attempts to apply each portion in its reversed sense as well as in its normal sense. If the attempt is successful, the user shall be prompted to determine whether the **−R** option should be set.
−r *rejectfile*	Override the default reject filename. In the default case, the reject file shall have the same name as the output file, with the suffix **.rej** appended to it; see **Patch Application** (on page 2893).

OPERANDS

The following operand shall be supported:

file	A pathname of a file to patch.

STDIN

See the INPUT FILES section.

INPUT FILES

Input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *patch*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

LC_TIME Determine the locale for recognizing the format of file timestamps written by the *diff* utility in a context-difference input file.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used for diagnostic and informational messages.

OUTPUT FILES

The output of the *patch* utility, the save files (**.orig** suffixes) and the reject files (**.rej** suffixes) shall be text files.

EXTENDED DESCRIPTION

A patchfile may contain patching instructions for more than one file; filenames shall be determined as specified in **Filename Determination** (on page 2893). When the **–b** option is specified, for each patched file, the original shall be saved in a file of the same name with the suffix **.orig** appended to it.

For each patched file, a reject file may also be created as noted in **Patch Application** (on page 2893). In the absence of a **–r** option, the name of this file shall be formed by appending the suffix **.rej** to the original filename.

Patchfile Format

The patch file shall contain zero or more lines of header information followed by one or more patches. Each patch shall contain zero or more lines of filename identification in the format produced by *diff* **–c**, and one or more sets of *diff* output, which are customarily called *hunks.*

The *patch* utility shall recognize the following expression in the header information:

Index: *pathname*
The file to be patched is named *pathname*.

If all lines (including headers) within a patch begin with the same leading sequence of <blank>s, the *patch* utility shall remove this sequence before proceeding. Within each patch, if the type of difference is context, the *patch* utility shall recognize the following expressions:

*** *filename timestamp*
The patches arose from *filename*.

– – – *filename timestamp*
The patches should be applied to *filename*.

Each hunk within a patch shall be the *diff* output to change a line range within the original file. The line numbers for successive hunks within a patch shall occur in ascending order.

Filename Determination

If no *file* operand is specified, *patch* shall perform the following steps to determine the filename to use:

1. If the type of *diff* is context, the *patch* utility shall delete pathname components (as specified by the −**p** option) from the filename on the line beginning with `"***"`, then test for the existence of this file relative to the current directory (or the directory specified with the −**d** option). If the file exists, the *patch* utility shall use this filename.
2. If the type of *diff* is context, the *patch* utility shall delete the pathname components (as specified by the −**p** option) from the filename on the line beginning with "−−−", then test for the existence of this file relative to the current directory (or the directory specified with the −**d** option). If the file exists, the *patch* utility shall use this filename.
3. If the header information contains a line beginning with the string **Index:**, the *patch* utility shall delete pathname components (as specified by the −**p** option) from this line, then test for the existence of this file relative to the current directory (or the directory specified with the −**d** option). If the file exists, the *patch* utility shall use this filename.
4. XSI If an **SCCS** directory exists in the current directory, *patch* shall attempt to perform a *get* −**e** **SCCS/s.***filename* command to retrieve an editable version of the file. If the file exists, the *patch* utility shall use this filename.
5. The *patch* utility shall write a prompt to standard output and request a filename interactively from the controlling terminal (for example, **/dev/tty**).

Patch Application

If the −**c**, −**e**, or −**n** option is present, the *patch* utility shall interpret information within each hunk as a context difference, an *ed* difference or a normal difference, respectively. In the absence of any of these options, the *patch* utility shall determine the type of difference based on the format of information within the hunk.

For each hunk, the *patch* utility shall begin to search for the place to apply the patch at the line number at the beginning of the hunk, plus or minus any offset used in applying the previous hunk. If lines matching the hunk context are not found, *patch* shall scan both forwards and backwards at least 1 000 bytes for a set of lines that match the hunk context.

If no such place is found and it is a context difference, then another scan shall take place, ignoring the first and last line of context. If that fails, the first two and last two lines of context shall be ignored and another scan shall be made. Implementations may search more extensively for installation locations.

If no location can be found, the *patch* utility shall append the hunk to the reject file. The rejected hunk shall be written in context-difference format regardless of the format of the patch file. If the input was a normal or *ed–style* difference, the reject file may contain differences with zero lines of context. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file since they shall reflect the approximate locations for the failed hunks in the new file rather than the old one.

If the type of patch is an *ed* diff, the implementation may accomplish the patching by invoking the *ed* utility.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

1 One or more lines were written to a reject file.

>1 An error occurred.

CONSEQUENCES OF ERRORS

Patches that cannot be correctly placed in the file shall be written to a reject file.

APPLICATION USAGE

The −**R** option does not work with *ed* scripts because there is too little information to reconstruct the reverse operation.

The −**p** option makes it possible to customize a patchfile to local user directory structures without manually editing the patchfile. For example, if the filename in the patch file was:

```
/curds/whey/src/blurfl/blurfl.c
```

Setting −**p 0** gives the entire pathname unmodified; −**p 1** gives:

```
curds/whey/src/blurfl/blurfl.c
```

without the leading slash, −**p 4** gives:

```
blurfl/blurfl.c
```

and not specifying −**p** at all gives:

```
blurfl.c .
```

EXAMPLES

None.

RATIONALE

Some of the functionality in historical *patch* implementations was not specified. The following documents those features present in historical implementations that have not been specified.

A deleted piece of functionality was the `'+'` pseudo-option allowing an additional set of options and a patch file operand to be given. This was seen as being insufficiently useful to standardize.

In historical implementations, if the string `"Prereq:"` appeared in the header, the *patch* utility would search for the corresponding version information (the string specified in the header, delimited by <blank>s or the beginning or end of a line or the file) anywhere in the original file. This was deleted as too simplistic and insufficiently trustworthy a mechanism to standardize. For example, if:

```
Prereq: 1.2
```

were in the header, the presence of a delimited 1.2 anywhere in the file would satisfy the prerequisite.

The following options were dropped from historical implementations of *patch* as insufficiently useful to standardize:

−**b** The −**b** option historically provided a method for changing the name extension of the backup file from the default **.orig**. This option has been modified and retained in this volume of IEEE Std 1003.1-200x.

−**F** The −**F** option specified the number of lines of a context diff to ignore when searching for a place to install a patch.

−**f** The −**f** option historically caused *patch* not to request additional information from the user.

−r	The −**r** option historically provided a method of overriding the extension of the reject file from the default **.rej**.
−s	The −**s** option historically caused *patch* to work silently unless an error occurred.
−x	The −**x** option historically set internal debugging flags.

In some file system implementations, the saving of a **.orig** file may produce unwanted results. In the case of 12, 13, or 14-character filenames (on file systems supporting 14-character maximum filenames), the **.orig** file overwrites the new file. The reject file may also exceed this filename limit. It was suggested, due to some historical practice, that a tilde (′˜′) suffix be used instead of **.orig** and some other character instead of the **.rej** suffix. This was rejected because it is not obvious to the user which file is which. The suffixes **.orig** and **.rej** are clearer and more understandable.

The −**b** option has the opposite sense in some historical implementations—do not save the **.orig** file. The default case here is not to save the files, making *patch* behave more consistently with the other standard utilities.

The −**w** option in early proposals was changed to −**l** to match historical practice.

The −**N** option was included because without it, a non-interactive application cannot reject previously applied patches. For example, if a user is piping the output of *diff* into the *patch* utility, and the user only wants to patch a file to a newer version non-interactively, the −**N** option is required.

Changes to the −**l** option description were proposed to allow matching across <newline>s in addition to just <blank>s. Since this is not historical practice, and since some ambiguities could result, it is suggested that future developments in this area utilize another option letter, such as −**L**.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The description of the −**D** option and the steps in **Filename Determination** (on page 2893) are changed to match historical practice as defined in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

pathchk — check pathnames

SYNOPSIS

`pathchk [−p] pathname...`

DESCRIPTION

The *pathchk* utility shall check that one or more pathnames are valid (that is, they could be used to access or create a file without causing syntax errors) and portable (that is, no filename truncation results). More extensive portability checks are provided by the **−p** option.

By default, the *pathchk* utility shall check each component of each *pathname* operand based on the underlying file system. A diagnostic shall be written for each *pathname* operand that:

- Is longer than {PATH_MAX} bytes (see **Pathname Variable Values** in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers, **<limits.h>**)
- Contains any component longer than {NAME_MAX} bytes in its containing directory
- Contains any component in a directory that is not searchable
- Contains any character in any component that is not valid in its containing directory

The format of the diagnostic message is not specified, but shall indicate the error detected and the corresponding *pathname* operand.

It shall not be considered an error if one or more components of a *pathname* operand do not exist as long as a file matching the pathname specified by the missing components could be created that does not violate any of the checks specified above.

OPTIONS

The *pathchk* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−p Instead of performing checks based on the underlying file system, write a diagnostic for each *pathname* operand that:

- Is longer than {_POSIX_PATH_MAX} bytes (see **Minimum Values** in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers, **<limits.h>**)
- Contains any component longer than {_POSIX_NAME_MAX} bytes
- Contains any character in any component that is not in the portable filename character set

OPERANDS

The following operand shall be supported:

pathname A pathname to be checked.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pathchk*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All *pathname* operands passed all of the checks.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *test* utility can be used to determine whether a given pathname names an existing file; it does not, however, give any indication of whether or not any component of the pathname was truncated in a directory where the _POSIX_NO_TRUNC feature is not in effect. The *pathchk* utility does not check for file existence; it performs checks to determine whether a pathname does exist or could be created with no pathname component truncation.

The *noclobber* option in the shell (see the *set* (on page 2287) special built-in) can be used to atomically create a file. As with all file creation semantics in the System Interfaces volume of IEEE Std 1003.1-200x, it guarantees atomic creation, but still depends on applications to agree on conventions and cooperate on the use of files after they have been created.

EXAMPLES

To verify that all pathnames in an imported data interchange archive are legitimate and unambiguous on the current system:

```
pax −f archive | sed −e ′/ == .*/s///′ | xargs pathchk
if [ $? −eq 0 ]
then
    pax −r −f archive
```

```
else
    echo Investigate problems before importing files.
    exit 1
fi
```

To verify that all files in the current directory hierarchy could be moved to any system conforming to the System Interfaces volume of IEEE Std 1003.1-200x that also supports the *pax* utility:

```
find . −print | xargs pathchk −p
if [ $? −eq 0 ]
then
    pax −w −f archive .
else
    echo Portable archive cannot be created.
    exit 1
fi
```

To verify that a user-supplied pathname names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file:

```
case $− in
    *C*)    reset="";;
    *)      reset="set +C"
            set −C;;
esac
test −r "$path" && pathchk "$path.out" &&
    rm "$path.out" > "$path.out"
if [ $? −ne 0 ]; then
    printf "%s: %s not found or %s.out fails \
creation checks.\n" $0 "$path" "$path"
    $reset    # Reset the noclobber option in case a trap
              # on EXIT depends on it.
    exit 1
fi
$reset
PROCESSING < "$path" > "$path.out"
```

The following assumptions are made in this example:

1. **PROCESSING** represents the code that is used by the application to use **$path** once it is verified that **$path.out** works as intended.

2. The state of the *noclobber* option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The **reset** variable is used in this example to restore the initial state.)

3. Note the usage of:

   ```
   rm "$path.out" > "$path.out"
   ```

   a. The *pathchk* command has already verified, at this point, that **$path.out** is not truncated.

   b. With the *noclobber* option set, the shell verifies that **$path.out** does not already exist before invoking *rm*.

c. If the shell succeeded in creating **$path.out**, *rm* removes it so that the application can create the file again in the **PROCESSING** step.

d. If the **PROCESSING** step wants the file to exist already when it is invoked, the:

```
rm "$path.out" > "$path.out"
```

should be replaced with:

```
> "$path.out"
```

which verifies that the file did not already exist, but leaves **$path.out** in place for use by **PROCESSING**.

RATIONALE

The *pathchk* utility is new, commissioned for this volume of IEEE Std 1003.1-200x. It, along with the *set* −**C**(*noclobber*) option added to the shell, replaces the *mktemp*, *validfnam*, and *create* utilities that appeared in early proposals. All of these utilities were attempts to solve several common problems:

- Verify the validity (for several different definitions of ‘‘valid’’) of a pathname supplied by a user, generated by an application, or imported from an external source.
- Atomically create a file.
- Perform various string handling functions to generate a temporary filename.

The *create* utility, included in an early proposal, provided checking and atomic creation in a single invocation of the utility; these are orthogonal issues and need not be grouped into a single utility. Note that the *noclobber* option also provides a way of creating a lock for process synchronization; since it provides an atomic *create*, there is no race between a test for existence and the following creation if it did not exist.

Having a function like *tmpnam*( ) in the ISO C standard is important in many high-level languages. The shell programming language, however, has built-in string manipulation facilities, making it very easy to construct temporary filenames. The names needed obviously depend on the application, but are frequently of a form similar to:

`$TMPDIR/``application_abbreviation`**`$$.`**`suffix`

In cases where there is likely to be contention for a given suffix, a simple shell *for* or *while* loop can be used with the shell *noclobber* option to create a file without risk of collisions, as long as applications trying to use the same filename name space are cooperating on the use of files after they have been created.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

NAME

pax — portable archive interchange

SYNOPSIS

```
pax [−cdnv][−H|−L][−f archive][−s replstr]...[pattern...]

pax −r[−cdiknuv][−H|−L][−f archive][−o options]...[−p string]...
    [−s replstr]...[pattern...]

pax −w[−dituvX][−H|−L][−b blocksize][[−a][−f archive][−o options]...
    [−s replstr]...[−x format][file...]

pax −r −w[−diklntuvX][−H|−L][−p string]...[−s replstr]...
    [file...] directory
```

DESCRIPTION

The *pax* utility shall read, write, and write lists of the members of archive files and copy directory hierarchies. A variety of archive formats shall be supported; see the **−x** *format* option.

The action to be taken depends on the presence of the **−r** and **−w** options. The four combinations of **−r** and **−w** are referred to as the four modes of operation: **list**, **read**, **write**, and **copy** modes, corresponding respectively to the four forms shown in the SYNOPSIS section.

list In **list** mode (when neither **−r** nor **−w** are specified), *pax* shall write the names of the members of the archive file read from the standard input, with pathnames matching the specified patterns, to standard output. If a named file is of type directory, the file hierarchy rooted at that file shall be listed as well.

read In **read** mode (when **−r** is specified, but **−w** is not), *pax* shall extract the members of the archive file read from the standard input, with pathnames matching the specified patterns. If an extracted file is of type directory, the file hierarchy rooted at that file shall be extracted as well. The extracted files shall be created performing pathname resolution with the directory in which *pax* was invoked as the current working directory.

If an attempt is made to extract a directory when the directory already exists, this shall not be considered to be an error. If an attempt is made to extract a FIFO when the FIFO already exists, this shall not be considered to be an error.

The ownership, access, and modification times, and file mode of the restored files are discussed under the **−p** option.

write In **write** mode (when **−w** is specified, but **−r** is not), *pax* shall write the contents of the *file* operands to the standard output in an archive format. If no *file* operands are specified, a list of files to copy, one per line, shall be read from the standard input. A file of type directory shall include all of the files in the file hierarchy rooted at the file.

copy In **copy** mode (when both **−r** and **−w** are specified), *pax* shall copy the *file* operands to the destination directory.

If no *file* operands are specified, a list of files to copy, one per line, shall be read from the standard input. A file of type directory shall include all of the files in the file hierarchy rooted at the file.

The effect of the **copy** shall be as if the copied files were written to an archive file and then subsequently extracted, except that there may be hard links between the original and the copied files. If the destination directory is a subdirectory of one of the files to be copied, the results are unspecified. If the destination directory is a file of a type not defined by the System Interfaces volume of IEEE Std 1003.1-200x, the results are implementation-defined; otherwise, it shall be an error for the file named by the *directory* operand not to exist, not be writable by the user, or not be a file of type directory.

In **read** or **copy** modes, if intermediate directories are necessary to extract an archive member, *pax* shall perform actions equivalent to the *mkdir*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

- The intermediate directory used as the *path* argument
- The value of the bitwise-inclusive OR of S_IRWXU, S_IRWXG, and S_IRWXO as the *mode* argument

If any specified *pattern* or *file* operands are not matched by at least one file or archive member, *pax* shall write a diagnostic message to standard error for each one that did not match and exit with a non-zero exit status.

The archive formats described in the EXTENDED DESCRIPTION section shall be automatically detected on input. The default output archive format shall be implementation-defined.

A single archive can span multiple files. The *pax* utility shall determine, in an implementation-defined manner, what file to read or write as the next file.

If the selected archive format supports the specification of linked files, it shall be an error if these files cannot be linked when the archive is extracted. For archive formats that do not store file contents with each name that causes a hard link, if the file that contains the data is not extracted during this *pax* session, either the data shall be restored from the original file, or a diagnostic message shall be displayed with the name of a file that can be used to extract the data. In traversing directories, *pax* shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file visited. When it detects an infinite loop, *pax* shall write a diagnostic message to standard error and shall terminate.

OPTIONS

The *pax* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of presentation of the −**o**, −**p**, and −**s** options is significant.

The following options shall be supported:

−**r**	Read an archive file from standard input.
−**w**	Write files to the standard output in the specified archive format.
−**a**	Append files to the end of the archive. It is implementation-defined which devices on the system support appending. Additional file formats unspecified by this volume of IEEE Std 1003.1-200x may impose restrictions on appending.
−**b** *blocksize*	Block the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats may impose restrictions on blocking. Blocking shall be automatically determined on input. Conforming applications shall not specify a *blocksize* value larger than 32 256. Default blocking when creating archives depends on the archive format. (See the −**x** option below.)
−**c**	Match all file or archive members except those specified by the *pattern* or *file* operands.
−**d**	Cause files of type directory being copied or archived or archive members of type directory being extracted or listed to match only the file or archive member itself and not the file hierarchy rooted at the file.

−f *archive* Specify the pathname of the input or output archive, overriding the default standard input (in **list** or **read** modes) or standard output (**write** mode).

−H If a symbolic link referencing a file of type directory is specified on the command line, *pax* shall archive the file hierarchy rooted in the file referenced by the link, using the name of the link as the root of the file hierarchy. Otherwise, if a symbolic link referencing a file of any other file type which *pax* can normally archive is specified on the command line, then *pax* shall archive the file referenced by the link, using the name of the link. The default behavior shall be to archive the symbolic link itself.

−i Interactively rename files or archive members. For each archive member matching a *pattern* operand or file matching a *file* operand, a prompt shall be written to the file **/dev/tty**. The prompt shall contain the name of the file or archive member, but the format is otherwise unspecified. A line shall then be read from **/dev/tty**. If this line is blank, the file or archive member shall be skipped. If this line consists of a single period, the file or archive member shall be processed with no modification to its name. Otherwise, its name shall be replaced with the contents of the line. The *pax* utility shall immediately exit with a non-zero exit status if end-of-file is encountered when reading a response or if **/dev/tty** cannot be opened for reading and writing.

The results of extracting a hard link to a file that has been renamed during extraction are unspecified.

−k Prevent the overwriting of existing files.

−l (The letter ell.) In **copy** mode, hard links shall be made between the source and destination file hierarchies whenever possible. If specified in conjunction with **−H** or **−L**, when a symbolic link is encountered, the hard link created in the destination file hierarchy shall be to the file referenced by the symbolic link. If specified when neither **−H** nor **−L** is specified, when a symbolic link is encountered, the implementation shall create a hard link to the symbolic link in the source file hierarchy or copy the symbolic link to the destination.

−L If a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, *pax* shall archive the file hierarchy rooted in the file referenced by the link, using the name of the link as the root of the file hierarchy. Otherwise, if a symbolic link referencing a file of any other file type which *pax* can normally archive is specified on the command line or encountered during the traversal of a file hierarchy, *pax* shall archive the file referenced by the link, using the name of the link. The default behavior shall be to archive the symbolic link itself.

−n Select the first archive member that matches each *pattern* operand. No more than one archive member shall be matched for each pattern (although members of type directory shall still match the file hierarchy rooted at that file).

−o *options* Provide information to the implementation to modify the algorithm for extracting or writing files. The value of *options* shall consist of one or more comma-separated keywords of the form:

```
keyword[[:]=value][,keyword[[:]=value], ...]
```

Some keywords apply only to certain file formats, as indicated with each description. Use of keywords that are inapplicable to the file format being processed produces undefined results.

Keywords in the *options* argument shall be a string that would be a valid portable filename as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.276, Portable Filename Character Set.

Note: Keywords are not expected to be filenames, merely to follow the same character composition rules as portable filenames.

Keywords can be preceded with white space. The *value* field shall consist of zero or more characters; within *value*, the application shall precede any literal comma with a backslash, which shall be ignored, but preserves the comma as part of *value*. A comma as the final character, or a comma followed solely by white space as the final characters, in *options* shall be ignored. Multiple −**o** options can be specified; if keywords given to these multiple −**o** options conflict, the keywords and values appearing later in command line sequence shall take precedence and the earlier shall be silently ignored. The following keyword values of *options* shall be supported for the file formats as indicated:

delete=*pattern*
(Applicable only to the −**x** *pax* format.) When used in **write** or **copy** mode, *pax* shall omit from extended header records that it produces any keywords matching the string pattern. When used in **read** or **list** mode, *pax* shall ignore any keywords matching the string pattern in the extended header records. In both cases, matching shall be performed using the pattern matching notation described in Section 2.13.1 (on page 2264) and Section 2.13.2 (on page 2264). For example:

```
−o delete=security.*
```

would suppress security-related information. See **pax Extended Header** (on page 2913) for extended header record keyword usage.

exthdr.name=*string*
(Applicable only to the −**x** *pax* format.) This keyword allows user control over the name that is written into the **ustar** header blocks for the extended header produced under the circumstances described in **pax Header Block** (on page 2912). The name shall be the contents of *string*, after the following character substitutions have been made:

string **Includes:**	**Replaced By:**
`%d`	The directory name of the file, equivalent to the result of the *dirname* utility on the translated pathname.
`%f`	The filename of the file, equivalent to the result of the *basename* utility on the translated pathname.
`%%`	A `'%'` character.

Any other `'%'` characters in *string* produce undefined results.

If no −**o** **exthdr.name=***string* is specified, *pax* shall use the following default value:

```
%d/PaxHeaders/%f
```

globexthdr.name=*string*
(Applicable only to the −**x** *pax* format.) When used in **write** or **copy** mode with the appropriate options, *pax* shall create global extended header records with **ustar** header blocks that will be treated as regular files by previous versions of

pax. This keyword allows user control over the name that is written into the **ustar** header blocks for global extended header records. The name shall be the contents of string, after the following character substitutions have been made:

string **Includes:**	**Replaced By:**
`%n`	An integer that represents the sequence number of the global extended header record in the archive, starting at 1.
`%%`	A `'%'` character.

Any other `'%'` characters in *string* produce undefined results.

If no −**o globexthdr.name=***string* is specified, *pax* shall use the following default value:

`$TMPDIR/GlobalHead.%n`

where $*TMPDIR* represents the value of the *TMPDIR* environment variable. If *TMPDIR* is not set, *pax* shall use **/tmp**.

invalid=*action*

(Applicable only to the −**x** *pax* format.) This keyword allows user control over the action *pax* takes upon encountering values in an extended header record that, in **read** or **copy** mode, are invalid in the destination hierarchy or, in **list** mode, cannot be written in the codeset and current locale of the implementation. The following are invalid values that shall be recognized by *pax*:

- In **read** or **copy** mode, a filename or link name that contains character encodings invalid in the destination hierarchy. (For example, the name may contain embedded NULs.)
- In **read** or **copy** mode, a filename or link name that is longer than the maximum allowed in the destination hierarchy (for either a pathname component or the entire pathname).
- In **list** mode, any character string value (filename, link name, user name, and so on) that cannot be written in the codeset and current locale of the implementation.

The following mutually-exclusive values of the *action* argument are supported:

bypass	In **read** or **copy** mode, *pax* shall bypass the file, causing no change to the destination hierarchy. In **list** mode, *pax* shall write all requested valid values for the file, but its method for writing invalid values is unspecified.
rename	In **read** or **copy** mode, *pax* shall act as if the −**i** option were in effect for each file with invalid filename or link name values, allowing the user to provide a replacement name interactively. In **list** mode, *pax* shall behave identically to the **bypass** action.
UTF-8	When used in **read**, **copy**, or **list** mode and a filename, link name, owner name, or any other field in an extended header record cannot be translated from the *pax* UTF-8 codeset format to the codeset and current locale of the implementation, *pax* shall use the actual UTF-8 encoding for the name.

write In **read** or **copy** mode, *pax* shall write the file, translating or truncating the name, regardless of whether this may overwrite an existing file with a valid name. In **list** mode, *pax* shall behave identically to the **bypass** action.

If no −**o invalid=** option is specified, *pax* shall act as if −**oinvalid=bypass** were specified. Any overwriting of existing files that may be allowed by the −**oinvalid=** actions shall be subject to permission (−**p**) and modification time (−**u**) restrictions, and shall be suppressed if the −**k** option is also specified.

linkdata
(Applicable only to the −**x** *pax* format.) In **write** mode, *pax* shall write the contents of a file to the archive even when that file is merely a hard link to a file whose contents have already been written to the archive.

listopt=*format*
This keyword specifies the output format of the table of contents produced when the −**v** option is specified in **list** mode. See **List Mode Format Specifications** (on page 2908). To avoid ambiguity, the **listopt=***format* shall be the only or final **keyword=***value* pair in a −**o** option-argument; all characters in the remainder of the option-argument shall be considered part of the format string. When multiple −**olistopt=***format* options are specified, the format strings shall be considered a single, concatenated string, evaluated in command line order.

times
(Applicable only to the −**x** *pax* format.) When used in **write** or **copy** mode, *pax* shall include **atime**, **ctime**, and **mtime** extended header records for each file. See **pax Extended Header File Times** (on page 2916).

In addition to these keywords, if the −**x** *pax* format is specified, any of the keywords and values defined in **pax Extended Header** (on page 2913), including implementation extensions, can be used in −**o** option-arguments, in either of two modes:

keyword=*value*
When used in **write** or **copy** mode, these keyword/value pairs shall be included at the beginning of the archive as **typeflag g** global extended header records. When used in **read** or **list** mode, these keyword/value pairs shall act as if they had been at the beginning of the archive as **typeflag g** global extended header records.

keyword:=*value*
When used in **write** or **copy** mode, these keyword/value pairs shall be included as records at the beginning of a **typeflag x** extended header for each file. (This shall be equivalent to the equal-sign form except that it creates no **typeflag g** global extended header records.) When used in **read** or **list** mode, these keyword/value pairs shall act as if they were included as records at the end of each extended header; thus, they shall override any global or file-specific extended header record keywords of the same names. For example, in the command:

```
pax −r −o "
gname:=mygroup,
" <archive
```

the group name will be forced to a new value for all files read from the archive.

The precedences of **–o** keywords over various fields in the archive are described in **pax Extended Header Keyword Precedence** (on page 2916).

–p *string* Specify one or more file characteristic options (privileges). The *string* option-argument shall be a string specifying file characteristics to be retained or discarded on extraction. The string shall consist of the specification characters `a`, `e`, `m`, `o`, and `p`. Other implementation-defined characters can be included. Multiple characteristics can be concatenated within the same string and multiple **–p** options can be specified. The meaning of the specification characters are as follows:

`a` Do not preserve file access times.

`e` Preserve the user ID, group ID, file mode bits (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.168, File Mode Bits), access time, modification time, and any other implementation-defined file characteristics.

`m` Do not preserve file modification times.

`o` Preserve the user ID and group ID.

`p` Preserve the file mode bits. Other implementation-defined file mode attributes may be preserved.

In the preceding list, ‘‘preserve’’ indicates that an attribute stored in the archive shall be given to the extracted file, subject to the permissions of the invoking process. The access and modification times of the file shall be preserved unless otherwise specified with the **–p** option or not stored in the archive. All attributes that are not preserved shall be determined as part of the normal file creation action (see Section 1.7.1.4 (on page 2204)).

If neither the **e** nor the **o** specification character is specified, or the user ID and group ID are not preserved for any reason, *pax* shall not set the S_ISUID and S_ISGID bits of the file mode.

If the preservation of any of these items fails for any reason, *pax* shall write a diagnostic message to standard error. Failure to preserve these items shall affect the final exit status, but shall not cause the extracted file to be deleted.

If file characteristic letters in any of the *string* option-arguments are duplicated or conflict with each other, the ones given last shall take precedence. For example, if **–p** `eme` is specified, file modification times are preserved.

–s *replstr* Modify file or archive member names named by *pattern* or *file* operands according to the substitution expression *replstr*, using the syntax of the *ed* utility. The concepts of ‘‘address’’ and ‘‘line’’ are meaningless in the context of the *pax* utility, and shall not be supplied. The format shall be:

`–s /old/new/[gp]`

where as in *ed*, *old* is a basic regular expression and *new* can contain an ampersand, `'\n'` (where *n* is a digit) backreferences, or subexpression matching. The *old* string also shall be permitted to contain <newline>s.

Any non-null character can be used as a delimiter (`'/'` shown here). Multiple **–s** expressions can be specified; the expressions shall be applied in the order specified, terminating with the first successful substitution. The optional trailing `'g'` is as defined in the *ed* utility. The optional trailing `'p'` shall cause successful substitutions to be written to standard error. File or archive member names that substitute to the empty string shall be ignored when reading and writing archives.

−t When reading files from the file system, and if the user has the permissions required by *utime*( ) to do so, set the access time of each file read to the access time that it had before being read by *pax*.

−u Ignore files that are older (having a less recent file modification time) than a pre-existing file or archive member with the same name. In **read** mode, an archive member with the same name as a file in the file system shall be extracted if the archive member is newer than the file. In **write** mode, an archive file member with the same name as a file in the file system shall be superseded if the file is newer than the archive member. If −**a** is also specified, this is accomplished by appending to the archive; otherwise, it is unspecified whether this is accomplished by actual replacement in the archive or by appending to the archive. In **copy** mode, the file in the destination hierarchy shall be replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.

−v In **list** mode, produce a verbose table of contents (see the STDOUT section). Otherwise, write archive member pathnames to standard error (see the STDERR section).

−x *format* Specify the output archive format. The *pax* utility shall support the following formats:

cpio The *cpio* interchange format; see the EXTENDED DESCRIPTION section. The default *blocksize* for this format for character special archive files shall be 5 120. Implementations shall support all *blocksize* values less than or equal to 32 256 that are multiples of 512.

pax The *pax* interchange format; see the EXTENDED DESCRIPTION section. The default *blocksize* for this format for character special archive files shall be 5 120. Implementations shall support all *blocksize* values less than or equal to 32 256 that are multiples of 512.

ustar The *tar* interchange format; see the EXTENDED DESCRIPTION section. The default *blocksize* for this format for character special archive files shall be 10 240. Implementations shall support all *blocksize* values less than or equal to 32 256 that are multiples of 512.

Implementation-defined formats shall specify a default block size as well as any other block sizes supported for character special archive files.

Any attempt to append to an archive file in a format different from the existing archive format shall cause *pax* to exit immediately with a non-zero exit status.

In **copy** mode, if no −**x** format is specified, *pax* shall behave as if −**x***pax* were specified.

−X When traversing the file hierarchy specified by a pathname, *pax* shall not descend into directories that have a different device ID (*st_dev*; see the System Interfaces volume of IEEE Std 1003.1-200x, *stat*( )).

The options that operate on the names of files or archive members (−**c**, −**i**, −**n**, −**s**, −**u**, and −**v**) shall interact as follows. In **read** mode, the archive members shall be selected based on the user-specified *pattern* operands as modified by the −**c**, −**n**, and −**u** options. Then, any −**s** and −**i** options shall modify, in that order, the names of the selected files. The −**v** option shall write names resulting from these modifications.

In **write** mode, the files shall be selected based on the user-specified pathnames as modified by the −**n** and −**u** options. Then, any −**s** and −**i** options shall modify, in that order, the names of these selected files. The −**v** option shall write names resulting from these modifications.

If both the −**u** and −**n** options are specified, *pax* shall not consider a file selected unless it is newer than the file to which it is compared.

List Mode Format Specifications

In **list** mode with the −**o listopt=***format* option, the *format* argument shall be applied for each selected file. The *pax* utility shall append a <newline> to the **listopt** output for each selected file. The format argument shall be used as the *format* string described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation, with the exceptions 1. through 5. defined in the EXTENDED DESCRIPTION section of *printf*, plus the following exceptions:

6. The sequence (*keyword*) can occur before a format conversion specifier. The conversion argument is defined by the value of *keyword*. The implementation shall support the following keywords:

   — Any of the Field Name entries in Table 4-13 (on page 2917) and Table 4-15 (on page 2920). The implementation may support the *cpio* keywords without the leading **c_** in addition to the form required by Table 4-16 (on page 2921).

   — Any keyword defined for the extended header in **pax Extended Header** (on page 2913).

   — Any keyword provided as an implementation-defined extension within the extended header defined in **pax Extended Header** (on page 2913).

   For example, the sequence `"%(charset)s"` is the string value of the name of the character set in the extended header.

   The result of the keyword conversion argument shall be the value from the applicable header field or extended header, without any trailing NULs.

   All keyword values used as conversion arguments shall be translated from the UTF-8 encoding to the character set appropriate for the local file system, user database, and so on, as applicable.

7. An additional conversion specifier character, `T`, shall be used to specify time formats. The `T` conversion specifier character can be preceded by the sequence (*keyword*=*subformat*), where *subformat* is a date format as defined by *date* operands. The default *keyword* shall be **mtime** and the default subformat shall be:

   ```
   %b %e %H:%M %Y
   ```

8. An additional conversion specifier character, `M`, shall be used to specify the file mode string as defined in *ls* Standard Output. If (*keyword*) is omitted, the **mode** keyword shall be used. For example, `%.1M` writes the single character corresponding to the <*entry type*> field of the *ls* −**l** command.

9. An additional conversion specifier character, `D`, shall be used to specify the device for block or special files, if applicable, in an implementation-defined format. If not applicable, and (*keyword*) is specified, then this conversion shall be equivalent to `%(`*`keyword`*`)u`. If not applicable, and (*keyword*) is omitted, then this conversion shall be equivalent to <space>.

10. An additional conversion specifier character, `F`, shall be used to specify a pathname. The `F` conversion character can be preceded by a sequence of comma-separated keywords:

    ```
    (keyword[,keyword] ... )
    ```

The values for all the keywords that are non-null shall be concatenated together, each separated by a `'/'`. The default shall be (**path**) if the keyword **path** is defined; otherwise, the default shall be (**prefix**,**name**).

11. An additional conversion specifier character, `L`, shall be used to specify a symbolic line expansion. If the current file is a symbolic link, then `%L` shall expand to:

    `"%s -> %s", <value of keyword>, <contents of link>`

    Otherwise, the `%L` conversion specification shall be the equivalent of `%F`.

OPERANDS

The following operands shall be supported:

directory	The destination directory pathname for **copy** mode.
file	A pathname of a file to be copied or archived.
pattern	A pattern matching one or more pathnames of archive members. A pattern must be given in the name-generating notation of the pattern matching notation in Section 2.13 (on page 2264), including the filename expansion rules in Section 2.13.3 (on page 2265). The default, if no *pattern* is specified, is to select all members in the archive.

STDIN

In **write** mode, the standard input shall be used only if no *file* operands are specified. It shall be a text file containing a list of pathnames, one per line, without leading or trailing <blank>s.

In **list** and **read** modes, if **–f** is not specified, the standard input shall be an archive file.

Otherwise, the standard input shall not be used.

INPUT FILES

The input file named by the *archive* option-argument, or standard input when the archive is read from there, shall be a file formatted according to one of the specifications in the EXTENDED DESCRIPTION section or some other implementation-defined format.

The file **/dev/tty** shall be used to write prompts and read responses.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pax*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes and multi-character collating elements used in the pattern matching expressions for the *pattern* operand, the basic regular expression for the **–s** option, and the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES*

category, and pattern matching.

LC_MESSAGES
Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings when the −**v** option is specified.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TMPDIR Determine the pathname that provides part of the default global extended header record file, as described for the −**o** **globexthdr=** keyword as described in the OPTIONS section.

TZ Determine the timezone used to calculate date and time strings when the −**v** option is specified. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

In **write** mode, if −**f** is not specified, the standard output shall be the archive formatted according to one of the specifications in the EXTENDED DESCRIPTION section, or some other implementation-defined format (see −**x** *format*).

In **list** mode, when the −**olistopt**=*format* has been specified, the selected archive members shall be written to standard output using the format described under **List Mode Format Specifications** (on page 2908). In **list** mode without the −**olistopt**=*format* option, the table of contents of the selected archive members shall be written to standard output using the following format: |

```
"%s\n", <path name>
```

If the −**v** option is specified in **list** mode, the table of contents of the selected archive members shall be written to standard output using the following formats.

For pathnames representing hard links to previous members of the archive:

```
"%sΔ==Δ%s\n", <ls −l listing>, <linkname>
```

For all other pathnames:

```
"%s\n", <ls −l listing>
```

where <*ls* −l *listing*> shall be the format specified by the *ls* utility with the −**l** option. When writing pathnames in this format, it is unspecified what is written for fields for which the underlying archive format does not have the correct information, although the correct number of <blank>-separated fields shall be written.

In **list** mode, standard output shall not be buffered more than a line at a time.

STDERR

If −**v** is specified in **read**, **write**, or **copy** modes, *pax* shall write the pathnames it processes to the standard error output using the following format:

```
"%s\n", <pathname>
```

These pathnames shall be written as soon as processing is begun on the file or archive member, and shall be flushed to standard error. The trailing <newline>, which shall not be buffered, is written when the file has been read or written.

If the −**s** option is specified, and the replacement string has a trailing `'p'`, substitutions shall be written to standard error in the following format:

`"%sΔ>>Δ%s\n", <original pathname>, <new pathname>`

In all operating modes of *pax*, optional messages of unspecified format concerning the input archive format and volume number, the number of files, blocks, volumes, and media parts as well as other diagnostic messages may be written to standard error.

In all formats, for both standard output and standard error, it is unspecified how non-printable characters in pathnames or link names are written.

When *pax* is in **read** mode or **list** mode, using the −**xpax** archive format, and a filename, link name, owner name, or any other field in an extended header record cannot be translated from the *pax* UTF-8 codeset format to the codeset and current locale of the implementation, *pax* shall write a diagnostic message to standard error, shall process the file as described for the −**o invalid**=option, and then shall process the next file in the archive.

OUTPUT FILES

In **read** mode, the extracted output files shall be of the archived file type. In **copy** mode, the copied output files shall be the type of the file being copied. In either mode, existing files in the destination hierarchy shall be overwritten only when all permission (−**p**), modification time (−**u**), and invalid-value (−**oinvalid**=) tests allow it.

In **write** mode, the output file named by the −**f** option-argument shall be a file formatted according to one of the specifications in the EXTENDED DESCRIPTION section, or some other implementation-defined format.

EXTENDED DESCRIPTION

pax Interchange Format

A *pax* archive tape or file produced in the −**x***pax* format shall contain a series of blocks. The physical layout of the archive shall be identical to the **ustar** format described in **ustar Interchange Format** (on page 2916). Each file archived shall be represented by the following sequence:

- An optional header block with extended header records. This header block is of the form described in **pax Header Block** (on page 2912), with a *typeflag* value of **x** or **g**. The extended header records, described in **pax Extended Header** (on page 2913), shall be included as the data for this header block.
- A header block that describes the file. Any fields in the preceding optional extended header shall override the associated fields in this header block for this file.
- Zero or more blocks that contain the contents of the file.

At the end of the archive file there shall be two 512-byte blocks filled with binary zeroes, interpreted as an end-of-archive indicator.

A schematic of an example archive with global extended header records and two actual files is shown in Figure 4-1 (on page 2912). In the example, the second file in the archive has no extended header preceding it, presumably because it has no need for extended attributes.

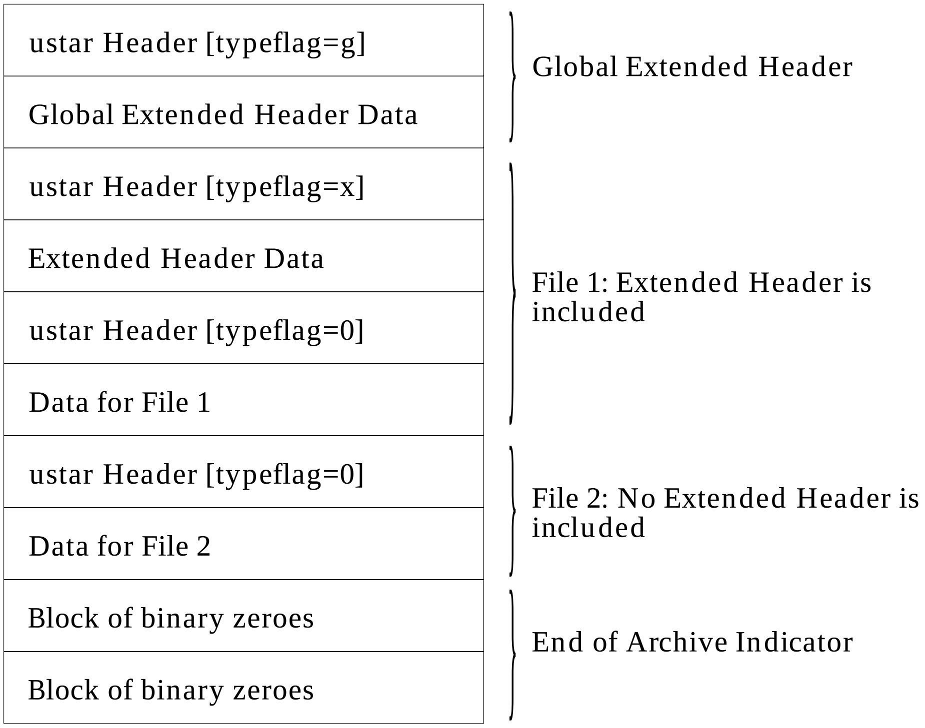

Figure 4-1 pax Format Archive Example

pax Header Block

The *pax* header block shall be identical to the **ustar** header block described in **ustar Interchange Format** (on page 2916), except that two additional *typeflag* values are defined:

x Represents extended header records for the following file in the archive (which shall have its own **ustar** header block). The format of these extended header records shall be as described in **pax Extended Header** (on page 2913).

g Represents global extended header records for the following files in the archive. The format of these extended header records shall be as described in **pax Extended Header** (on page 2913). Each value shall affect all subsequent files that do not override that value in their own extended header record and until another global extended header record is reached that provides another value for the same field. The *typeflag* **g** global headers should not be used with interchange media that could suffer partial data loss in transporting the archive.

For both of these types, the *size* field shall be the size of the extended header records in octets. The other fields in the header block are not meaningful to this version of the *pax* utility. However, if this archive is read by a *pax* utility conforming to a previous version of IEEE Std 1003.1-200x, the header block fields are used to create a regular file that contains the extended header records as data. Therefore, header block field values should be selected to provide reasonable file access to this regular file.

A further difference from the **ustar** header block is that data blocks for files of *typeflag* 1 (the digit one) (hard link) may be included, which means that the size field may be greater than zero. Archives created by **pax –o linkdata** shall include these data blocks with the hard links.

pax Extended Header

A *pax* extended header contains values that are inappropriate for the **ustar** header block because of limitations in that format: fields requiring a character encoding other than that described in the ISO/IEC 646:1991 standard, fields representing file attributes not described in the **ustar** header, and fields whose format or length do not fit the requirements of the **ustar** header. The values in an extended header add attributes to the following file (or files; see the description of the *typeflag* **g** header block) or override values in the following header block(s), as indicated in the following list of keywords.

An extended header shall consist of one or more records, each constructed as follows:

```
"%d %s=%s\n", <length>, <keyword>, <value>
```

The extended header records shall be encoded according to the ISO/IEC 10646-1:2000 standard (UTF-8). The <*length*> field, <blank>, equals sign, and <newline> shown shall be limited to the portable character set, as encoded in UTF-8. The <*keyword*> and <*value*> fields can be any UTF-8 characters. The <*length*> field shall be the decimal length of the extended header record in octets, including the trailing <newline>.

The <*keyword*> field shall be one of the entries from the following list or a keyword provided as an implementation extension. Keywords consisting entirely of lowercase letters, digits, and periods are reserved for future standardization. A keyword shall not include an equals sign. (In the following list, the notations ‘‘file(s)’’ or ‘‘block(s)’’ is used to acknowledge that a keyword affects the following single file after a *typeflag* **x** extended header, but possibly multiple files after *typeflag* **g**. Any requirements in the list for *pax* to include a record when in **write** or **copy** mode shall apply only when such a record has not already been provided through the use of the **−o** option. When used in **copy** mode, *pax* shall behave as if an archive had been created with applicable extended header records and then extracted.)

atime The file access time for the following file(s), equivalent to the value of the *st_atime* member of the **stat** structure for a file, as described by the *stat*( ) function. The access time shall be restored if the process has the appropriate privilege required to do so. The format of the <*value*> shall be as described in **pax Extended Header File Times** (on page 2916).

charset The name of the character set used to encode the data in the following file(s). The entries in the following table are defined to refer to known standards; additional names may be agreed on between the originator and recipient.

<value>	Formal Standard
`ISO-IRΔ646Δ1990`	ISO / IEC 646: 1990
`ISO-IRΔ8859Δ1Δ1998`	ISO / IEC 8859-1: 1998
`ISO-IRΔ8859Δ2Δ1999`	ISO / IEC 8859-2: 1999
`ISO-IRΔ8859Δ3Δ1999`	ISO / IEC 8859-3: 1999
`ISO-IRΔ8859Δ4Δ1998`	ISO / IEC 8859-4: 1998
`ISO-IRΔ8859Δ5Δ1999`	ISO / IEC 8859-5: 1999
`ISO-IRΔ8859Δ6Δ1999`	ISO / IEC 8859-6: 1999
`ISO-IRΔ8859Δ7Δ1987`	ISO / IEC 8859-7: 1987
`ISO-IRΔ8859Δ8Δ1999`	ISO / IEC 8859-8: 1999
`ISO-IRΔ8859Δ9Δ1999`	ISO / IEC 8859-9: 1999
`ISO-IRΔ8859Δ10Δ1998`	ISO / IEC 8859-10: 1998
`ISO-IRΔ8859Δ13Δ1998`	ISO / IEC 8859-13: 1998
`ISO-IRΔ8859Δ14Δ1998`	ISO / IEC 8859-14: 1998
`ISO-IRΔ8859Δ15Δ1999`	ISO / IEC 8859-15: 1999
`ISO-IRΔ10646Δ2000`	ISO / IEC 10646: 2000
`ISO-IRΔ10646Δ2000ΔUTF-8`	ISO / IEC 10646, UTF-8 encoding
`BINARY`	None.

The encoding is included in an extended header for information only; when *pax* is used as described in IEEE Std 1003.1-200x, it shall not translate the file data into any other encoding. The **BINARY** entry indicates unencoded binary data.

When used in **write** or **copy** mode, it is implementation-defined whether *pax* includes a **charset** extended header record for a file.

comment A series of characters used as a comment. All characters in the <*value*> field shall be ignored by *pax*.

ctime The file creation time for the following file(s), equivalent to the value of the *st_ctime* member of the **stat** structure for a file, as described by the *stat*( ) function. The creation time shall be restored if the process has the appropriate privilege required to do so. The format of the <*value*> shall be as described in **pax Extended Header File Times** (on page 2916).

gid The group ID of the group that owns the file, expressed as a decimal number using digits from the ISO / IEC 646: 1991 standard. This record shall override the *gid* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a *gid* extended header record for each file whose group ID is greater than 2 097 151 (octal 7 777 777).

gname The group of the file(s), formatted as a group name in the group database. This record shall override the *gid* and *gname* fields in the following header block(s), and any *gid* extended header record. When used in **read**, **copy**, or **list** mode, *pax* shall translate the name from the UTF-8 encoding in the header record to the character set appropriate for the group database on the receiving system. If any of the UTF-8 characters cannot be translated, and if the −**oinvalid=**UTF-8 option is not specified, the results are implementation-defined. When used in **write** or **copy** mode, *pax* shall include a **gname** extended header record for each file whose group name cannot be represented entirely with the letters and digits of the portable character set.

linkpath The pathname of a link being created to another file, of any type, previously archived. This record shall override the *linkname* field in the following **ustar** header block(s). The following **ustar** header block shall determine the type of link created.

	If *typeflag* of the following header block is 1, it shall be a hard link. If *typeflag* is 2, it shall be a symbolic link and the **linkpath** value shall be the contents of the symbolic link. The *pax* utility shall translate the name of the link (contents of the symbolic link) from the UTF-8 encoding to the character set appropriate for the local file system. When used in **write** or **copy** mode, *pax* shall include a **linkpath** extended header record for each link whose pathname cannot be represented entirely with the members of the portable character set other than NUL.
mtime	The file modification time of the following file(s), equivalent to the value of the *st_mtime* member of the **stat** structure for a file, as described in the *stat*( ) function. This record shall override the *mtime* field in the following header block(s). The modification time shall be restored if the process has the appropriate privilege required to do so. The format of the <*value*> shall be as described in **pax Extended Header File Times** (on page 2916).
path	The pathname of the following file(s). This record shall override the *name* and *prefix* fields in the following header block(s). The *pax* utility shall translate the pathname of the file from the UTF-8 encoding to the character set appropriate for the local file system. When used in **write** or **copy** mode, *pax* shall include a *path* extended header record for each file whose pathname cannot be represented entirely with the members of the portable character set other than NUL.
realtime.*any*	The keywords prefixed by ‘‘realtime.’’ are reserved for future standardization.
security.*any*	The keywords prefixed by ‘‘security.’’ are reserved for future standardization.
size	The size of the file in octets, expressed as a decimal number using digits from the ISO/IEC 646:1991 standard. This record shall override the *size* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a *size* extended header record for each file with a size value greater than 8 589 934 591 (octal 7 777 777 777).
uid	The user ID of the file owner, expressed as a decimal number using digits from the ISO/IEC 646:1991 standard. This record shall override the *uid* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a *uid* extended header record for each file whose owner ID is greater than 2 097 151 (octal 7 777 777).
uname	The owner of the following file(s), formatted as a user name in the user database. This record shall override the *uid* and *uname* fields in the following header block(s), and any *uid* extended header record. When used in **read**, **copy**, or **list** mode, *pax* shall translate the name from the UTF-8 encoding in the header record to the character set appropriate for the user database on the receiving system. If any of the UTF-8 characters cannot be translated, and if the –**oinvalid=** UTF-8 option is not specified, the results are implementation-defined. When used in **write** or **copy** mode, *pax* shall include a **uname** extended header record for each file whose user name cannot be represented entirely with the letters and digits of the portable character set.

If the <*value*> field is zero length, it shall delete any header block field, previously entered extended header value, or global extended header value of the same name.

If a keyword in an extended header record (or in a –**o** option-argument) overrides or deletes a corresponding field in the **ustar** header block, *pax* shall ignore the contents of that header block field.

Unlike the **ustar** header block fields, NULs shall not delimit <*value*>s; all characters within the <*value*> field shall be considered data for the field. None of the length limitations of the **ustar** header block fields in Table 4-13 (on page 2917) shall apply to the extended header records.

pax Extended Header Keyword Precedence

This section describes the precedence in which the various header records and fields and command line options are selected to apply to a file in the archive. When *pax* is used in **read** or **list** modes, it shall determine a file attribute in the following sequence:

1. If −**odelete=***keyword-prefix* is used, the affected attributes shall be determined from step 7., if applicable, or ignored otherwise.
2. If −**o***keyword*:= is used, the affected attributes shall be ignored.
3. If −**o***keyword***:=***value* is used, the affected attribute shall be assigned the value.
4. If there is a *typeflag* **x** extended header record, the affected attribute shall be assigned the <*value*>. When extended header records conflict, the last one given in the header shall take precedence.
5. If −**o***keyword***=***value* is used, the affected attribute shall be assigned the value.
6. If there is a *typeflag* **g** global extended header record, the affected attribute shall be assigned the <*value*>. When global extended header records conflict, the last one given in the global header shall take precedence.
7. Otherwise, the attribute shall be determined from the **ustar** header block.

pax Extended Header File Times

The *pax* utility shall write an **mtime** record for each file in **write** or **copy** modes if the file's modification time cannot be represented exactly in the **ustar** header logical record described in **ustar Interchange Format**. This can occur if the time is out of **ustar** range, or if the file system of the underlying implementation supports non-integer time granularities and the time is not an integer. All of these time records shall be formatted as a decimal representation of the time in seconds since the Epoch. If a period (`'.'`) decimal point character is present, the digits to the right of the point shall represent the units of a subsecond timing granularity, where the first digit is tenths of a second and each subsequent digit is a tenth of the previous digit. In **read** or **copy** mode, the *pax* utility shall truncate the time of a file to the greatest value that is not greater than the input header file time. In **write** or **copy** mode, the *pax* utility shall output a time exactly if it can be represented exactly as a decimal number, and otherwise shall generate only enough digits so that the same time shall be recovered if the file is extracted on a system whose underlying implementation supports the same time granularity.

ustar Interchange Format

A **ustar** archive tape or file shall contain a series of logical records. Each logical record shall be a fixed-size logical record of 512 octets (see below). Although this format may be thought of as being stored on 9-track industry-standard 12.7mm (0.5in) magnetic tape, other types of transportable media are not excluded. Each file archived shall be represented by a header logical record that describes the file, followed by zero or more logical records that give the contents of the file. At the end of the archive file there shall be two 512-octet logical records filled with binary zeros, interpreted as an end-of-archive indicator.

The logical records may be grouped for physical I/O operations, as described under the −**b***blocksize* and −**x** **ustar** options. Each group of logical records may be written with a single operation equivalent to the *write*( ) function. On magnetic tape, the result of this write shall be a single tape physical block. The last physical block shall always be the full size, so logical records after the two zero logical records may contain undefined data.

The header logical record shall be structured as shown in the following table. All lengths and offsets are in decimal.

Table 4-13 ustar Header Block

Field Name	**Octet Offset**	**Length (in Octets)**
name	0	100
mode	100	8
uid	108	8
gid	116	8
size	124	12
mtime	136	12
chksum	148	8
typeflag	156	1
linkname	157	100
magic	257	6
version	263	2
uname	265	32
gname	297	32
devmajor	329	8
devminor	337	8
prefix	345	155

All characters in the header logical record shall be represented in the coded character set of the ISO/IEC 646:1991 standard. For maximum portability between implementations, names should be selected from characters represented by the portable filename character set as octets with the most significant bit zero. If an implementation supports the use of characters outside of slash and the portable filename character set in names for files, users, and groups, one or more implementation-defined encodings of these characters shall be provided for interchange purposes.

However, the *pax* utility shall never create filenames on the local system that cannot be accessed via the procedures described in IEEE Std 1003.1-200x. If a filename is found on the medium that would create an invalid filename, it is implementation-defined whether the data from the file is stored on the file hierarchy and under what name it is stored. The *pax* utility may choose to ignore these files as long as it produces an error indicating that the file is being ignored.

Each field within the header logical record is contiguous; that is, there is no padding used. Each character on the archive medium shall be stored contiguously.

The fields *magic*, *uname*, and *gname* are character strings each terminated by a NUL character. The fields *name*, *linkname*, and *prefix* are NUL-terminated character strings except when all characters in the array contain non-NUL characters including the last character. The *version* field is two octets containing the characters `"00"` (zero-zero). The *typeflag* contains a single character. All other fields are leading zero-filled octal numbers using digits from the ISO/IEC 646:1991 standard IRV. Each numeric field is terminated by one or more <space> or NUL characters.

The *name* and the *prefix* fields shall produce the pathname of the file. A new pathname shall be formed, if *prefix* is not an empty string (its first character is not NUL), by concatenating *prefix* (up to the first NUL character), a slash character, and *name*; otherwise, *name* is used alone. In either case, *name* is terminated at the first NUL character. If *prefix* begins with a NUL character, it shall be ignored. In this manner, pathnames of at most 256 characters can be supported. If a pathname does not fit in the space provided, *pax* shall notify the user of the error, and shall not store any part of the file—header or data—on the medium.

The *linkname* field, described below, shall not use the *prefix* to produce a pathname. As such, a *linkname* is limited to 100 characters. If the name does not fit in the space provided, *pax* shall notify the user of the error, and shall not attempt to store the link on the medium.

The *mode* field provides 12 bits encoded in the ISO/IEC 646: 1991 standard octal digit representation. The encoded bits shall represent the following values:

Table 4-14 ustar *mode* Field

Bit Value	IEEE Std 1003.1-200x Bit	Description
04 000	S_ISUID	Set UID on execution.
02 000	S_ISGID	Set GID on execution.
01 000	<reserved>	Reserved for future standardization.
00 400	S_IRUSR	Read permission for file owner class.
00 200	S_IWUSR	Write permission for file owner class.
00 100	S_IXUSR	Execute/search permission for file owner class.
00 040	S_IRGRP	Read permission for file group class.
00 020	S_IWGRP	Write permission for file group class.
00 010	S_IXGRP	Execute/search permission for file group class.
00 004	S_IROTH	Read permission for file other class.
00 002	S_IWOTH	Write permission for file other class.
00 001	S_IXOTH	Execute/search permission for file other class.

When appropriate privilege is required to set one of these mode bits, and the user restoring the files from the archive does not have the appropriate privilege, the mode bits for which the user does not have appropriate privilege shall be ignored. Some of the mode bits in the archive format are not mentioned elsewhere in this volume of IEEE Std 1003.1-200x. If the implementation does not support those bits, they may be ignored.

The *uid* and *gid* fields are the user and group ID of the owner and group of the file, respectively.

The *size* field is the size of the file in octets. If the *typeflag* field is set to specify a file to be of type 1 (a link) or 2 (a symbolic link), the *size* field shall be specified as zero. If the *typeflag* field is set to specify a file of type 5 (directory), the *size* field shall be interpreted as described under the definition of that record type. No data logical records are stored for types 1, 2, or 5. If the *typeflag* field is set to 3 (character special file), 4 (block special file), or 6 (FIFO), the meaning of the *size* field is unspecified by this volume of IEEE Std 1003.1-200x, and no data logical records shall be stored on the medium. Additionally, for type 6, the *size* field shall be ignored when reading. If the *typeflag* field is set to any other value, the number of logical records written following the header shall be (*size*+511)/512, ignoring any fraction in the result of the division. |

The *mtime* field shall be the modification time of the file at the time it was archived. It is the ISO/IEC 646: 1991 standard representation of the octal value of the modification time obtained from the *stat*( ) function.

The *chksum* field shall be the ISO/IEC 646: 1991 standard IRV representation of the octal value of the simple sum of all octets in the header logical record. Each octet in the header shall be treated as an unsigned value. These values shall be added to an unsigned integer, initialized to zero, the precision of which is not less than 17 bits. When calculating the checksum, the *chksum* field is treated as if it were all spaces.

The *typeflag* field specifies the type of file archived. If a particular implementation does not recognize the type, or the user does not have appropriate privilege to create that type, the file shall be extracted as if it were a regular file if the file type is defined to have a meaning for the *size* field that could cause data logical records to be written on the medium (see the previous description for *size*). If conversion to a regular file occurs, the *pax* utility shall produce an error indicating that the conversion took place. All of the *typeflag* fields shall be coded in the ISO/IEC 646:1991 standard IRV:

`0` Represents a regular file. For backward compatibility, a *typeflag* value of binary zero (`'\0'`) should be recognized as meaning a regular file when extracting files from the archive. Archives written with this version of the archive file format create regular files with a *typeflag* value of the ISO/IEC 646:1991 standard IRV `'0'`.

`1` Represents a file linked to another file, of any type, previously archived. Such files are identified by each file having the same device and file serial number. The linked-to name is specified in the *linkname* field with a NUL-character terminator if it is less than 100 octets in length.

`2` Represents a symbolic link. The contents of the symbolic link shall be stored in the *linkname* field.

`3,4` Represent character special files and block special files respectively. In this case the *devmajor* and *devminor* fields shall contain information defining the device, the format of which is unspecified by this volume of IEEE Std 1003.1-200x. Implementations may map the device specifications to their own local specification or may ignore the entry.

`5` Specifies a directory or subdirectory. On systems where disk allocation is performed on a directory basis, the *size* field shall contain the maximum number of octets (which may be rounded to the nearest disk block allocation unit) that the directory may hold. A *size* field of zero indicates no such limiting. Systems that do not support limiting in this manner should ignore the *size* field.

`6` Specifies a FIFO special file. Note that the archiving of a FIFO file archives the existence of this file and not its contents.

`7` Reserved to represent a file to which an implementation has associated some high-performance attribute. Implementations without such extensions should treat this file as a regular file (type 0).

`A-Z` The letters `'A'` to `'Z'`, inclusive, are reserved for custom implementations. All other values are reserved for future versions of IEEE Std 1003.1-200x.

Attempts to archive a socket using **ustar** interchange format shall produce a diagnostic message. Handling of other file types is implementation-defined.

The *magic* field is the specification that this archive was output in this archive format. If this field contains **ustar** (the five characters from the ISO/IEC 646:1991 standard IRV shown followed by NUL), the *uname* and *gname* fields shall contain the ISO/IEC 646:1991 standard IRV representation of the owner and group of the file, respectively (truncated to fit, if necessary). When the file is restored by a privileged, protection-preserving version of the utility, the user and group databases shall be scanned for these names. If found, the user and group IDs contained within these files shall be used rather than the values contained within the *uid* and *gid* fields.

cpio Interchange Format

The octet-oriented *cpio* archive format shall be a series of entries, each comprising a header that describes the file, the name of the file, and then the contents of the file.

An archive may be recorded as a series of fixed-size blocks of octets. This blocking shall be used only to make physical I/O more efficient. The last group of blocks shall be always at the full size.

For the octet-oriented *cpio* archive format, the individual entry information shall be in the order indicated and described by the following table; see also the **<cpio.h>** header.

Table 4-15 Octet-Oriented *cpio* Archive Entry

Header Field Name	**Length (in Octets)**	**Interpreted as**
c_magic	6	Octal number
c_dev	6	Octal number
c_ino	6	Octal number
c_mode	6	Octal number
c_uid	6	Octal number
c_gid	6	Octal number
c_nlink	6	Octal number
c_rdev	6	Octal number
c_mtime	11	Octal number
c_namesize	6	Octal number
c_filesize	11	Octal number
Filename Field Name	**Length**	**Interpreted as**
c_name	*c_namesize*	Pathname string
File Data Field Name	**Length**	**Interpreted as**
c_filedata	*c_filesize*	Data

cpio Header

For each file in the archive, a header as defined previously shall be written. The information in the header fields is written as streams of the ISO/IEC 646:1991 standard characters interpreted as octal numbers. The octal numbers shall be extended to the necessary length by appending the ISO/IEC 646:1991 standard IRV zeros at the most-significant-digit end of the number; the result is written to the most-significant digit of the stream of octets first. The fields shall be interpreted as follows:

c_magic Identify the archive as being a transportable archive by containing the identifying value `"070707"`.

c_dev, *c_ino* Contains values that uniquely identify the file within the archive (that is, no files contain the same pair of *c_dev* and *c_ino* values unless they are links to the same file). The values shall be determined in an unspecified manner.

c_mode Contains the file type and access permissions as defined in the following table.

Table 4-16 Values for *cpio c_mode* Field

File Permissions Name	Value	Indicates
C_IRUSR	000 400	Read by owner
C_IWUSR	000 200	Write by owner
C_IXUSR	000 100	Execute by owner
C_IRGRP	000 040	Read by group
C_IWGRP	000 020	Write by group
C_IXGRP	000 010	Execute by group
C_IROTH	000 004	Read by others
C_IWOTH	000 002	Write by others
C_IXOTH	000 001	Execute by others
C_ISUID	004 000	Set *uid*
C_ISGID	002 000	Set *gid*
C_ISVTX	001 000	Reserved
File Type Name	**Value**	**Indicates**
C_ISDIR	040 000	Directory
C_ISFIFO	010 000	FIFO
C_ISREG	0100 000	Regular file
C_ISLNK	0120 000	Symbolic link
C_ISBLK	060 000	Block special file
C_ISCHR	020 000	Character special file
C_ISSOCK	0140 000	Socket
C_ISCTG	0110 000	Reserved

Directories, FIFOs, symbolic links, and regular files shall be supported on a system conforming to this volume of IEEE Std 1003.1-200x; additional values defined previously are reserved for compatibility with existing systems. Additional file types may be supported; however, such files should not be written to archives intended to be transported to other systems.

c_uid	Contains the user ID of the owner.
c_gid	Contains the group ID of the group.
c_nlink	Contains the number of links referencing the file at the time the archive was created.
c_rdev	Contains implementation-defined information for character or block special files.
c_mtime	Contains the latest time of modification of the file at the time the archive was created.
c_namesize	Contains the length of the pathname, including the terminating NUL character.
c_filesize	Contains the length of the file in octets. This shall be the length of the data section following the header structure.

cpio Filename

The *c_name* field shall contain the pathname of the file. The length of this field in octets is the value of *c_namesize*.

If a filename is found on the medium that would create an invalid pathname, it is implementation-defined whether the data from the file is stored on the file hierarchy and under what name it is stored.

All characters shall be represented in the ISO/IEC 646:1991 standard IRV. For maximum portability between implementations, names should be selected from characters represented by the portable filename character set as octets with the most significant bit zero. If an implementation supports the use of characters outside the portable filename character set in names for files, users, and groups, one or more implementation-defined encodings of these characters shall be provided for interchange purposes. However, the *pax* utility shall never create filenames on the local system that cannot be accessed via the procedures described previously in this volume of IEEE Std 1003.1-200x. If a filename is found on the medium that would create an invalid filename, it is implementation-defined whether the data from the file is stored on the local file system and under what name it is stored. The *pax* utility may choose to ignore these files as long as it produces an error indicating that the file is being ignored.

cpio File Data

Following *c_name*, there shall be *c_filesize* octets of data. Interpretation of such data occurs in a manner dependent on the file. If *c_filesize* is zero, no data shall be contained in *c_filedata*.

When restoring from an archive:

- If the user does not have the appropriate privilege to create a file of the specified type, *pax* shall ignore the entry and write an error message to standard error.
- Only regular files have data to be restored. Presuming a regular file meets any selection criteria that might be imposed on the format-reading utility by the user, such data shall be restored.
- If a user does not have appropriate privilege to set a particular mode flag, the flag shall be ignored. Some of the mode flags in the archive format are not mentioned elsewhere in this volume of IEEE Std 1003.1-200x. If the implementation does not support those flags, they may be ignored.

cpio Special Entries

FIFO special files, directories, and the trailer shall be recorded with *c_filesize* equal to zero. For other special files, *c_filesize* is unspecified by this volume of IEEE Std 1003.1-200x. The header for the next file entry in the archive shall be written directly after the last octet of the file entry preceding it. A header denoting the filename **TRAILER!!!** shall indicate the end of the archive; the contents of octets in the last block of the archive following such a header are undefined. |

EXIT STATUS

The following exit values shall be returned:

0	All files were processed successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

If *pax* cannot create a file or a link when reading an archive or cannot find a file when writing an archive, or cannot preserve the user ID, group ID, or file mode when the −**p** option is specified, a diagnostic message shall be written to standard error and a non-zero exit status shall be returned, but processing shall continue. In the case where *pax* cannot create a link to a file, *pax* shall not, by default, create a second copy of the file.

If the extraction of a file from an archive is prematurely terminated by a signal or error, *pax* may have only partially extracted the file or (if the −**n** option was not specified) may have extracted a file of the same name as that specified by the user, but which is not the file the user wanted. Additionally, the file modes of extracted directories may have additional bits from the S_IRWXU mask set as well as incorrect modification and access times.

APPLICATION USAGE

The −**p** (privileges) option was invented to reconcile differences between historical *tar* and *cpio* implementations. In particular, the two utilities use −**m** in diametrically opposed ways. The −**p** option also provides a consistent means of extending the ways in which future file attributes can be addressed, such as for enhanced security systems or high-performance files. Although it may seem complex, there are really two modes that are most commonly used:

−**p e**	''Preserve everything''. This would be used by the historical superuser, someone with all the appropriate privileges, to preserve all aspects of the files as they are recorded in the archive. The **e** flag is the sum of **o** and **p**, and other implementation-defined attributes.
−**p p**	''Preserve'' the file mode bits. This would be used by the user with regular privileges who wished to preserve aspects of the file other than the ownership. The file times are preserved by default, but two other flags are offered to disable these and use the time of extraction.

The one pathname per line format of standard input precludes pathnames containing <newline>s. Although such pathnames violate the portable filename guidelines, they may exist and their presence may inhibit usage of *pax* within shell scripts. This problem is inherited from historical archive programs. The problem can be avoided by listing filename arguments on the command line instead of on standard input.

It is almost certain that appropriate privileges are required for *pax* to accomplish parts of this volume of IEEE Std 1003.1-200x. Specifically, creating files of type block special or character special, restoring file access times unless the files are owned by the user (the −**t** option), or preserving file owner, group, and mode (the −**p** option) all probably require appropriate privileges.

In **read** mode, implementations are permitted to overwrite files when the archive has multiple members with the same name. This may fail if permissions on the first version of the file do not permit it to be overwritten.

The **cpio** and **ustar** formats can only support files up to 8589934592 bytes (8 ∗ 2ˆ30) in size.

EXAMPLES

The following command:

```
pax −w −f /dev/rmt/1m .
```

copies the contents of the current directory to tape drive 1, medium density (assuming historical System V device naming procedures. The historical BSD device name would be **/dev/rmt9**).

The following commands:

```
mkdir newdir
pax –rw olddir newdir
```

copy the *olddir* directory hierarchy to *newdir*.

```
pax –r –s ',ˆ//*usr//*,,' –f a.pax
```

reads the archive **a.pax**, with all files rooted in **/usr** in the archive extracted relative to the current directory.

Using the option:

```
–o listopt="%M %(atime)T %(size)D %(name)s"
```

overrides the default output description in Standard Output and instead writes:

```
–rw–rw––– Jan 12 15:53 1492 /usr/foo/bar
```

Using the options:

```
–o listopt='%L\t%(size)D\n%.7' \
–o listopt='(name)s\n%(ctime)T\n%T'
```

overrides the default output description in Standard Output and instead writes:

```
/usr/foo/bar –> /tmp   1492
/usr/fo
Jan 12 1991
Jan 31 15:53
```

RATIONALE

The *pax* utility was new, commissioned for the ISO POSIX-2: 1993 standard. It represents a peaceful compromise between advocates of the historical *tar* and *cpio* utilities.

A fundamental difference between *cpio* and *tar* was in the way directories were treated. The *cpio* utility did not treat directories differently from other files, and to select a directory and its contents required that each file in the hierarchy be explicitly specified. For *tar*, a directory matched every file in the file hierarchy it rooted.

The *pax* utility offers both interfaces; by default, directories map into the file hierarchy they root. The **–d** option causes *pax* to skip any file not explicitly referenced, as *cpio* historically did. The *tar –style* behavior was chosen as the default because it was believed that this was the more common usage and because *tar* is the more commonly available interface, as it was historically provided on both System V and BSD implementations.

The data interchange format specification in this volume of IEEE Std 1003.1-200x requires that processes with ''appropriate privileges'' shall always restore the ownership and permissions of extracted files exactly as archived. If viewed from the historic equivalence between superuser and ''appropriate privileges'', there are two problems with this requirement. First, users running as superusers may unknowingly set dangerous permissions on extracted files. Second, it is needlessly limiting, in that superusers cannot extract files and own them as superuser unless the archive was created by the superuser. (It should be noted that restoration of ownerships and permissions for the superuser, by default, is historical practice in *cpio*, but not in *tar*.) In order to avoid these two problems, the *pax* specification has an additional ''privilege'' mechanism, the **–p** option. Only a *pax* invocation with the privileges needed, and which has the **–p** option set using the **e** specification character, has the ''appropriate privilege'' to restore full ownership and permission information.

Note also that this volume of IEEE Std 1003.1-200x requires that the file ownership and access permissions shall be set, on extraction, in the same fashion as the *creat*( ) function when provided the mode stored in the archive. This means that the file creation mask of the user is applied to the file permissions.

Users should note that directories may be created by *pax* while extracting files with permissions that are different from those that existed at the time the archive was created. When extracting sensitive information into a directory hierarchy that no longer exists, users are encouraged to set their file creation mask appropriately to protect these files during extraction.

The table of contents output is written to standard output to facilitate pipeline processing.

An early proposal had hard links displaying for all pathnames. This was removed because it complicates the output of the case where −**v** is not specified and does not match historical *cpio* usage. The hard-link information is available in the −**v** display.

The description of the −**l** option allows implementations to make hard links to symbolic links. IEEE Std 1003.1-200x does not specify any way to create a hard link to a symbolic link, but many implementations provide this capability as an extension. If there are hard links to symbolic links when an archive is created, the implementation is required to archive the hard link in the archive (unless −**H** or −**L** is specified). When in **read** mode and in **copy** mode, implementations supporting hard links to symbolic links should use them when appropriate.

The archive formats inherited from the POSIX.1-1990 standard have certain restrictions that have been brought along from historical usage. For example, there are restrictions on the length of pathnames stored in the archive. When *pax* is used in **copy**(−**rw**) mode (copying directory hierarchies), the ability to use extensions from the −**x***pax* format overcomes these restrictions.

The default *blocksize* value of 5 120 bytes for *cpio* was selected because it is one of the standard block-size values for *cpio*, set when the −**B** option is specified. (The other default block-size value for *cpio* is 512 bytes, and this was considered to be too small.) The default block value of 10 240 bytes for *tar* was selected because that is the standard block-size value for BSD *tar*. The maximum block size of 32 256 bytes (2^{15}−512 bytes) is the largest multiple of 512 bytes that fits into a signed 16-bit tape controller transfer register. There are known limitations in some historical systems that would prevent larger blocks from being accepted. Historical values were chosen to improve compatibility with historical scripts using *dd* or similar utilities to manipulate archives. Also, default block sizes for any file type other than character special file has been deleted from this volume of IEEE Std 1003.1-200x as unimportant and not likely to affect the structure of the resulting archive.

Implementations are permitted to modify the block-size value based on the archive format or the device to which the archive is being written. This is to provide implementations with the opportunity to take advantage of special types of devices, and it should not be used without a great deal of consideration as it almost certainly decreases archive portability.

The intended use of the −**n** option was to permit extraction of one or more files from the archive without processing the entire archive. This was viewed by the standard developers as offering significant performance advantages over historical implementations. The −**n** option in early proposals had three effects; the first was to cause special characters in patterns to not be treated specially. The second was to cause only the first file that matched a pattern to be extracted. The third was to cause *pax* to write a diagnostic message to standard error when no file was found matching a specified pattern. Only the second behavior is retained by this volume of IEEE Std 1003.1-200x, for many reasons. First, it is in general not acceptable for a single option to have multiple effects. Second, the ability to make pattern matching characters act as normal characters is useful for parts of *pax* other than file extraction. Third, a finer degree of control over the special characters is useful because users may wish to normalize only a single special character in a single filename. Fourth, given a more general escape mechanism, the previous behavior of the −**n** option can be easily obtained using the −**s** option or a *sed* script. Finally, writing a diagnostic message when a pattern specified by the user is unmatched by any file is useful behavior in all cases.

In this version, the −**n** was removed from the **copy** mode synopsis of *pax*; it is inapplicable because there are no pattern operands specified in this mode.

There is another method than *pax* for copying subtrees in IEEE Std 1003.1-200x described as part of the *cp* utility. Both methods are historical practice: *cp* provides a simpler, more intuitive interface, while *pax* offers a finer granularity of control. Each provides additional functionality to the other; in particular, *pax* maintains the hard-link structure of the hierarchy while *cp* does not. It is the intention of the standard developers that the results be similar (using appropriate option combinations in both utilities). The results are not required to be identical; there seemed insufficient gain to applications to balance the difficulty of implementations having to guarantee that the results would be exactly identical.

A single archive may span more than one file. It is suggested that implementations provide informative messages to the user on standard error whenever the archive file is changed.

The −**d** option (do not create intermediate directories not listed in the archive) found in early proposals was originally provided as a complement to the historic −**d** option of *cpio*. It has been deleted.

The −**s** option in early proposals specified a subset of the substitution command from the *ed* utility. As there was no reason for only a subset to be supported, the −**s** option is now compatible with the current *ed* specification. Since the delimiter can be any non-null character, the following usage with single spaces is valid:

```
pax −s " foo bar " ...
```

The −**t** description is worded so as to note that this may cause the access time update caused by some other activity (which occurs while the file is being read) to be overwritten.

The default behavior of *pax* with regard to file modification times is the same as historical implementations of *tar*. It is not the historical behavior of *cpio*.

Because the −**i** option uses **/dev/tty**, utilities without a controlling terminal are not able to use this option.

The −**y** option, found in early proposals, has been deleted because a line containing a single period for the −**i** option has equivalent functionality. The special lines for the −**i** option (a single period and the empty line) are historical practice in *cpio*.

In early drafts, an −**e***charmap* option was included to increase portability of files between systems using different coded character sets. This option was omitted because it was apparent that consensus could not be formed for it. In this version, the use of UTF-8 should be an adequate substitute.

The −**k** option was added to address international concerns about the dangers involved in the character set transformations of −**e** (if the target character set were different from the source, the filenames might be transformed into names matching existing files) and also was made more general to protect files transferred between file systems with different {NAME_MAX} values (truncating a filename on a smaller system might also inadvertently overwrite existing files). As stated, it prevents any overwriting, even if the target file is older than the source. This version adds more granularity of options to solve this problem by introducing the −**oinvalid=** option—specifically the UTF-8 action. (Note that an existing file that is named with a UTF-8 encoding is still subject to overwriting in this case. The −**k** option closes that loophole.)

Some of the file characteristics referenced in this volume of IEEE Std 1003.1-200x might not be supported by some archive formats. For example, neither the *tar* nor *cpio* formats contain the file access time. For this reason, the **e** specification character has been provided, intended to cause all file characteristics specified in the archive to be retained.

It is required that extracted directories, by default, have their access and modification times and permissions set to the values specified in the archive. This has obvious problems in that the directories are almost certainly modified after being extracted and that directory permissions may not permit file creation. One possible solution is to create directories with the mode specified in the archive, as modified by the *umask* of the user, with sufficient permissions to allow file creation. After all files have been extracted, *pax* would then reset the access and modification times and permissions as necessary.

The list-mode formatting description borrows heavily from the one defined by the *printf* utility. However, since there is no separate operand list to get conversion arguments, the format was extended to allow specifying the name of the conversion argument as part of the conversion specification.

The `T` conversion specifier allows time fields to be displayed in any of the date formats. Unlike the *ls* utility, *pax* does not adjust the format when the date is less than six months in the past. This makes parsing the output more predictable.

The `D` conversion specifier handles the ability to display the major/minor or file size, as with *ls*, by using `%−8(`*`size`*`)D`.

The `L` conversion specifier handles the *ls* display for symbolic links.

Conversion specifiers were added to generate existing known types used for *ls*.

pax Interchange Format

The new POSIX data interchange format was developed primarily to satisfy international concerns that the **ustar** and *cpio* formats did not provide for file, user, and group names encoded in characters outside a subset of the ISO/IEC 646:1991 standard. The standard developers realized that this new POSIX data interchange format should be very extensible because there were other requirements they foresaw in the near future:

- Support international character encodings and locale information
- Support security information (ACLs, and so on)
- Support future file types, such as realtime or contiguous files
- Include data areas for implementation use
- Support systems with words larger than 32 bits and timers with subsecond granularity

The following were not goals for this format because these are better handled by separate utilities or are inappropriate for a portable format:

- Encryption
- Compression
- Data translation between locales and codesets
- *inode* storage

The format chosen to support the goals is an extension of the **ustar** format. Of the two formats previously available, only the **ustar** format was selected for extensions because:

- It was easier to extend in an upward-compatible way. It offered version flags and header block type fields with room for future standardization. The *cpio* format, while possessing a more flexible file naming methodology, could not be extended without breaking some theoretical implementation or using a dummy filename that could be a legitimate filename.

- Industry experience since the original ''tar wars'' fought in developing the ISO POSIX-1 standard has clearly been in favor of the **ustar** format, which is generally the default output format selected for *pax* implementations on new systems.

The new format was designed with one additional goal in mind: reasonable behavior when an older *tar* or *pax* utility happened to read an archive. Since the POSIX.1-1990 standard mandated that a ''format-reading utility'' had to treat unrecognized *typeflag* values as regular files, this allowed the format to include all the extended information in a pseudo-regular file that preceded each real file. An option is given that allows the archive creator to set up reasonable names for these files on the older systems. Also, the normative text suggests that reasonable file access values be used for this **ustar** header block. Making these header files inaccessible for convenient reading and deleting would not be reasonable. File permissions of 600 or 700 are suggested.

The **ustar** *typeflag* field was used to accommodate the additional functionality of the new format rather than magic or version because the POSIX.1-1990 standard (and, by reference, the previous version of *pax*), mandated the behavior of the format-reading utility when it encountered an unknown *typeflag*, but was silent about the other two fields.

Early proposals of the first revision to IEEE Std 1003.1-200x contained a proposed archive format that was based on compatibility with the standard for tape files (ISO 1001, similar to the format used historically on many mainframes and minicomputers). This format was overly complex and required considerable overhead in volume and header records. Furthermore, the standard developers felt that it would not be acceptable to the community of POSIX developers, so it was later changed to be a format more closely related to historical practice on POSIX systems.

The prefix and name split of pathnames in **ustar** was replaced by the single path extended header record for simplicity.

The concept of a global extended header (*typeflag* **g**) was controversial. If this were applied to an archive being recorded on magnetic tape, a few unreadable blocks at the beginning of the tape could be a serious problem; a utility attempting to extract as many files as possible from a damaged archive could lose a large percentage of file header information in this case. However, if the archive were on a reliable medium, such as a CD-ROM, the global extended header offers considerable potential size reductions by eliminating redundant information. Thus, the text warns against using the global method for unreliable media and provides a method for implanting global information in the extended header for each file, rather than in the *typeflag* **g** records.

No facility for data translation or filtering on a per-file basis is included because the standard developers could not invent an interface that would allow this in an efficient manner. If a filter, such as encryption or compression, is to be applied to all the files, it is more efficient to apply the filter to the entire archive as a single file. The standard developers considered interfaces that would invoke a shell script for each file going into or out of the archive, but the system overhead in this approach was considered to be too high.

One such approach would be to have **filter=** records that give a pathname for an executable. When the program is invoked, the file and archive would be open for standard input/output and all the header fields would be available as environment variables or command-line arguments. The standard developers did discuss such schemes, but they were omitted from IEEE Std 1003.1-200x due to concerns about excessive overhead. Also, the program itself would need to be in the archive if it were to be used portably.

There is currently no portable means of identifying the character set(s) used for a file in the file system. Therefore, *pax* has not been given a mechanism to generate charset records automatically. The only portable means of doing this is for the user to write the archive using the

−ocharset=*string* command line option. This assumes that all of the files in the archive use the same encoding. The ''implementation-defined'' text is included to allow for a system that can identify the encodings used for each of its files.

The table of standards that accompanies the charset record description is acknowledged to be very limited. Only a limited number of character set standards is reasonable for maximal interchange. Any character set is, of course, possible by prior agreement. It was suggested that EBCDIC be listed, but it was omitted because it is not defined by a formal standard. Formal standards, and then only those with reasonably large followings, can be included here, simply as a matter of practicality. The <*value*>s represent names of officially registered character sets in the format required by the ISO 2375: 1985 standard.

The normal comma or <blank>-separated list rules are not followed in the case of keyword options to allow ease of argument parsing for *getopts*.

Further information on character encodings is in **pax Archive Character Set Encoding/Decoding** (on page 2931).

The standard developers have reserved keyword name space for vendor extensions. It is suggested that the format to be used is:

```
VENDOR.keyword
```

where *VENDOR* is the name of the vendor or organization in all uppercase letters. It is further suggested that the keyword following the period be named differently than any of the standard keywords so that it could be used for future standardization, if appropriate, by omitting the *VENDOR* prefix.

The <*length*> field in the extended header record was included to make it simpler to step through the records, even if a record contains an unknown format (to a particular *pax*) with complex interactions of special characters. It also provides a minor integrity checkpoint within the records to aid a program attempting to recover files from a damaged archive.

There are no extended header versions of the *devmajor* and *devminor* fields because the unspecified format **ustar** header field should be sufficient. If they are not, vendor-specific extended keywords (such as *VENDOR.devmajor*) should be used.

Device and *i*-number labeling of files was not adopted from *cpio*; files are interchanged strictly on a symbolic name basis, as in **ustar**.

Just as with the **ustar** format descriptions, the new format makes no special arrangements for multi-volume archives. Each of the *pax* archive types is assumed to be inside a single POSIX file and splitting that file over multiple volumes (diskettes, tape cartridges, and so on), processing their labels, and mounting each in the proper sequence are considered to be implementation details that cannot be described portably.

The *pax* format is intended for interchange, not only for backup on a single (family of) systems. It is not as densely packed as might be possible for backup:

- It contains information as coded characters that could be coded in binary.
- It identifies extended records with name fields that could be omitted in favor of a fixed-field layout.
- It translates names into a portable character set and identifies locale-related information, both of which are probably unnecessary for backup.

The requirements on restoring from an archive are slightly different from the historical wording, allowing for non-monolithic privilege to bring forward as much as possible. In particular, attributes such as ''high performance file'' might be broadly but not universally granted while set-user-ID or *chown*() might be much more restricted. There is no implication in IEEE Std 1003.1-200x that the security information be honored after it is restored to the file hierarchy, in spite of what might be improperly inferred by the silence on that topic. That is a topic for another standard.

Links are recorded in the fashion described here because a link can be to any file type. It is desirable in general to be able to restore part of an archive selectively and restore all of those files completely. If the data is not associated with each link, it is not possible to do this. However, the data associated with a file can be large, and when selective restoration is not needed, this can be a significant burden. The archive is structured so that files that have no associated data can always be restored by the name of any link name of any link, and the user may choose whether data is recorded with each instance of a file that contains data. The format permits mixing of both types of links in a single archive; this can be done for special needs, and *pax* is expected to interpret such archives on input properly, despite the fact that there is no *pax* option that would force this mixed case on output. (When **−o linkdata** is used, the output must contain the duplicate data, but the implementation is free to include it or omit it when **−o linkdata** is not used.)

The time values are included as extended header records for those implementations needing more than the eleven octal digits allowed by the **ustar** format. Portable file timestamps cannot be negative. If *pax* encounters a file with a negative timestamp in **copy** or **write** mode, it can reject the file, substitute a non-negative timestamp, or generate a non-portable timestamp with a leading `'-'`. Even though some implementations can support finer file-time granularities than seconds, the normative text requires support only for seconds since the Epoch because the ISO POSIX-1 standard states them that way. The **ustar** format includes only *mtime*; the new format adds *atime* and *ctime* for symmetry. The *atime* access time restored to the file system will be affected by the **−p a** and **−p e** options. The *ctime* creation time (actually *inode* modification time) is described with ‘‘appropriate privilege’’ so that it can be ignored when writing to the file system. POSIX does not provide a portable means to change file creation time. Nothing is intended to prevent a non-portable implementation of *pax* from restoring the value.

The *gid*, *size*, and *uid* extended header records were included to allow expansion beyond the sizes specified in the regular *tar* header. New file system architectures are emerging that will exhaust the 12-digit size field. There are probably not many systems requiring more than 8 digits for user and group IDs, but the extended header values were included for completeness, allowing overrides for all of the decimal values in the *tar* header.

The standard developers intended to describe the effective results of *pax* with regard to file ownerships and permissions; implementations are not restricted in timing or sequencing the restoration of such, provided the results are as specified.

Much of the text describing the extended headers refers to use in ‘‘**write** or **copy** modes’’. The **copy** mode references are due to the normative text: ‘‘The effect of the copy shall be as if the copied files were written to an archive file and then subsequently extracted ...’’. There is certainly no way to test whether *pax* is actually generating the extended headers in **copy** mode, but the effects must be as if it had.

pax Archive Character Set Encoding/Decoding

There is a need to exchange archives of files between systems of different native codesets. Filenames, group names, and user names must be preserved to the fullest extent possible when an archive is read on the receiving platform. Translation of the contents of files is not within the scope of the *pax* utility.

There will also be the need to represent characters that are not available on the receiving platform. These unsupported characters cannot be automatically folded to the local set of characters due to the chance of collisions. This could result in overwriting previous extracted files from the archive or pre-existing files on the system.

For these reasons, the codeset used to represent characters within the extended header records of the *pax* archive must be sufficiently rich to handle all commonly used character sets. The fields requiring translation include, at a minimum, filenames, user names, group names, and link pathnames. Implementations may wish to have localized extended keywords that use non-portable characters.

The standard developers considered the following options:

- The archive creator specifies the well-defined name of the source codeset. The receiver must then recognize the codeset name and perform the appropriate translations to the destination codeset.
- The archive creator includes within the archive the character mapping table for the source codeset used to encode extended header records. The receiver must then read the character mapping table and perform the appropriate translations to the destination codeset.
- The archive creator translates the extended header records in the source codeset into a canonical form. The receiver must then perform the appropriate translations to the destination codeset.

The approach that incorporates the name of the source codeset poses the problem of codeset name registration, and makes the archive useless to *pax* archive decoders that do not recognize that codeset.

Because parts of an archive may be corrupted, the standard developers felt that including the character map of the source codeset was too fragile. The loss of this one key component could result in making the entire archive useless. (The difference between this and the global extended header decision was that the latter has a workaround—duplicating extended header records on unreliable media—but this would be too burdensome for large character set maps.)

Both of the above approaches also put an undue burden on the *pax* archive receiver to handle the cross-product of all source and destination codesets.

To simplify the translation from the source codeset to the canonical form and from the canonical form to the destination codeset, the standard developers decided that the internal representation should be a stateless encoding. A stateless encoding is one where each codepoint has the same meaning, without regard to the decoder being in a specific state. An example of a stateful encoding would be the Japanese Shift-JIS; an example of a stateless encoding would be the ISO/IEC 646:1991 standard (equivalent to 7-bit ASCII).

For these reasons, the standard developers decided to adopt a canonical format for the representation of file information strings. The obvious, well-endorsed candidate is the ISO/IEC 10646-1:2000 standard (based in part on Unicode), which can be used to represent the characters of virtually all standardized character sets. The standard developers initially agreed upon using UCS2 (16-bit Unicode) as the internal representation. This repertoire of characters provides a sufficiently rich set to represent all commonly-used codesets.

However, the standard developers found that the 16-bit Unicode representation had some problems. It forced the issue of standardizing byte ordering. The 2-byte length of each character made the extended header records twice as long for the case of strings coded entirely from historical 7-bit ASCII. For these reasons, the standard developers chose the UTF-8 defined in the ISO/IEC 10646-1:2000 standard. This multi-byte representation encodes UCS2 or UCS4 characters reliably and deterministically, eliminating the need for a canonical byte ordering. In addition, NUL octets and other characters possibly confusing to POSIX file systems do not appear, except to represent themselves. It was realized that certain national codesets take up more space after the encoding, due to their placement within the UCS range; it was felt that the usefulness of the encoding of the names outweighs the disadvantage of size increase for file, user, and group names.

The encoding of UTF-8 is as follows:

```
UCS4 Hex Encoding  UTF-8 Binary Encoding

00000000-0000007F  0xxxxxxx
00000080-000007FF  110xxxxx 10xxxxxx
00000800-0000FFFF  1110xxxx 10xxxxxx 10xxxxxx
00010000-001FFFFF  11110xxx 10xxxxxx 10xxxxxx 10xxxxxx
00200000-03FFFFFF  111110xx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
04000000-7FFFFFFF  1111110x 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
```

where each `'x'` represents a bit value from the character being translated.

ustar Interchange Format

The description of the **ustar** format reflects numerous enhancements over pre-1988 versions of the historical *tar* utility. The goal of these changes was not only to provide the functional enhancements desired, but also to retain compatibility between new and old versions. This compatibility has been retained. Archives written using the old archive format are compatible with the new format.

Implementors should be aware that the previous file format did not include a mechanism to archive directory type files. For this reason, the convention of using a filename ending with slash was adopted to specify a directory on the archive.

The total size of the *name* and *prefix* fields have been set to meet the minimum requirements for {PATH_MAX}. If a pathname will fit within the *name* field, it is recommended that the pathname be stored there without the use of the *prefix* field. Although the name field is known to be too small to contain {PATH_MAX} characters, the value was not changed in this version of the archive file format to retain backward compatibility, and instead the prefix was introduced. Also, because of the earlier version of the format, there is no way to remove the restriction on the *linkname* field being limited in size to just that of the *name* field.

The *size* field is required to be meaningful in all implementation extensions, although it could be zero. This is required so that the data blocks can always be properly counted.

It is suggested that if device special files need to be represented that cannot be represented in the standard format that one of the extension types (**A-Z**) be used, and that the additional information for the special file be represented as data and be reflected in the *size* field.

Attempting to restore a special file type, where it is converted to ordinary data and conflicts with an existing filename, need not be specially detected by the utility. If run as an ordinary user, *pax* should not be able to overwrite the entries in, for example, **/dev** in any case (whether the file is converted to another type or not). If run as a privileged user, it should be able to do so, and it would be considered a bug if it did not. The same is true of ordinary data files and similarly named special files; it is impossible to anticipate the needs of the user (who could really intend to overwrite the file), so the behavior should be predictable (and thus regular) and rely on the protection system as required.

The value 7 in the *typeflag* field is intended to define how contiguous files can be stored in a **ustar** archive. IEEE Std 1003.1-200x does not require the contiguous file extension, but does define a standard way of archiving such files so that all conforming systems can interpret these file types in a meaningful and consistent manner. On a system that does not support extended file types, the *pax* utility should do the best it can with the file and go on to the next.

The file protection modes are those conventionally used by the *ls* utility. This is extended beyond the usage in the ISO POSIX-2 standard to support the ‘‘shared text’’ or ‘‘sticky’’ bit. It is intended that the conformance document should not document anything beyond the existence of and support of such a mode. Further extensions are expected to these bits, particularly with overloading the set-user-ID and set-group-ID flags.

cpio Interchange Format

The reference to appropriate privilege in the *cpio* format refers to an error on standard output; the **ustar** format does not make comparable statements.

The model for this format was the historical System V *cpio*–**c** data interchange format. This model documents the portable version of the *cpio* format and not the binary version. It has the flexibility to transfer data of any type described within IEEE Std 1003.1-200x, yet is extensible to transfer data types specific to extensions beyond IEEE Std 1003.1-200x (for example, contiguous files). Because it describes existing practice, there is no question of maintaining upward compatibility.

cpio Header

There has been some concern that the size of the *c_ino* field of the header is too small to handle those systems that have very large *inode* numbers. However, the *c_ino* field in the header is used strictly as a hard-link resolution mechanism for archives. It is not necessarily the same value as the *inode* number of the file in the location from which that file is extracted.

The name *c_magic* is based on historical usage.

cpio Filename

For most historical implementations of the *cpio* utility, {PATH_MAX} octets can be used to describe the pathname without the addition of any other header fields (the NUL character would be included in this count). {PATH_MAX} is the minimum value for pathname size, documented as 256 bytes. However, an implementation may use *c_namesize* to determine the exact length of the pathname. With the current description of the **<cpio.h>** header, this pathname size can be as large as a number that is described in six octal digits.

Two values are documented under the *c_mode* field values to provide for extensibility for known file types:

0110 000 Reserved for contiguous files. The implementation may treat the rest of the information for this archive like a regular file. If this file type is undefined, the implementation may create the file as a regular file.

This provides for extensibility of the *cpio* format while allowing for the ability to read old archives. Files of an unknown type may be read as ‘‘regular files’’ on some implementations. On a system that does not support extended file types, the *pax* utility should do the best it can with the file and go on to the next.

FUTURE DIRECTIONS

None.

SEE ALSO

cp, *ed*, *getopts*, *printf*, the Base Definitions volume of IEEE Std 1003.1-200x, **<cpio.h>**, the System Interfaces volume of IEEE Std 1003.1-200x, *chown*( ), *creat*( ), *mkdir*( ), *stat*( ), *write*( )

CHANGE HISTORY

First released in Issue 4.

Issue 5

A note is added to the APPLICATION USAGE indicating that the *cpio* and *tar* formats can only support files up to 8 gigabytes in size.

Issue 6

The *pax* utility is aligned with the IEEE P1003.2b draft standard:

- Support has been added for symbolic links in the options and interchange formats.
- A new format has been devised, based on extensions to ustar.
- References to the ''extended'' *tar* and *cpio* formats derived from the POSIX.1-1990 standard have been changed to remove the ''extended'' adjective because this could cause confusion with the extended *tar* header added in this revision. (All references to *tar* are actually to **ustar**).

IEEE PASC Interpretation 1003.2 #168 is applied clarifying that *mkdir*( ) and *mkfifo*( ) calls can ignore an [EEXIST] error when extracting an archive.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

IEEE PASC Interpretation 1003.2 #180 is applied, clarifying how extracted files are created when in **read** mode.

IEEE PASC Interpretation 1003.2 #181 is applied, clarifying the description of the −**t** option. |

IEEE PASC Interpretation 1003.2 #195 is applied. |

IEEE PASC Interpretation 1003.2 #206 is applied, clarifying the handling of links for the −**H**, −**L**, and −**l** options. |

NAME

pr — print files

SYNOPSIS

```
pr [+page][−column][−adFmrt][−e[char][gap]][−h header][−i[char][gap]]
    [−l lines][−n[char][width]][−o offset][−s[char]][−w width][−fp]
    [file...]
```

XSI

DESCRIPTION

The *pr* utility is a printing and pagination filter. If multiple input files are specified, each shall be read, formatted, and written to standard output. By default, the input shall be separated into 66-line pages, each with:

- A 5-line header that includes the page number, date, time, and the pathname of the file
- A 5-line trailer consisting of blank lines

If standard output is associated with a terminal, diagnostic messages shall be deferred until the *pr* utility has completed processing.

When options specifying multi-column output are specified, output text columns shall be of equal width; input lines that do not fit into a text column shall be truncated. By default, text columns shall be separated with at least one <blank>.

OPTIONS

The *pr* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that: the *page* option has a `'+'` delimiter; *page* and *column* can be multi-digit numbers; some of the option-arguments are optional; and some of the option-arguments cannot be specified as separate arguments from the preceding option letter. In particular, the **−s** option does not allow the option letter to be separated from its argument, and the options **−e**, **−i**, and **−n** require that both arguments, if present, not be separated from the option letter.

The following options shall be supported. In the following option descriptions, *column*, *lines*, *offset*, *page*, and *width* are positive decimal integers; *gap* is a non-negative decimal integer.

+*page*	Begin output at page number *page* of the formatted input.
−*column*	Produce multi-column output that is arranged in *column* columns (the default shall be 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with **−m**. The options **−e** and **−i** shall be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column shall never exceed the length of the page (see the **−l** option). When used with **−t**, use the minimum number of lines to write the output.
−a	Modify the effect of the **−***column* option so that the columns are filled across the page in a round-robin order (for example, when *column* is 2, the first input line heads column 1, the second heads column 2, the third is the second line in column 1, and so on).
−d	Produce output that is double-spaced; append an extra <newline> following every <newline> found in the input.
−e[*char***][***gap***]**	Expand each input <tab> to the next greater column position specified by the formula $n*gap+1$, where *n* is an integer > 0. If *gap* is zero or is omitted, it shall default to 8. All <tab>s in the input shall be expanded into the appropriate number of <space>s. If any non-digit character, *char*, is specified, it shall be used as the

input <tab>.

XSI **−f**	Use a <form-feed> for new pages, instead of the default behavior that uses a sequence of <newline>s. Pause before beginning the first page if the standard output is associated with a terminal.
−F	Use a <form-feed> for new pages, instead of the default behavior that uses a sequence of <newline>s.
−h *header*	Use the string *header* to replace the contents of the *file* operand in the page header.
−i[*char***][***gap***]**	In output, replace multiple <space>s with <tab>s wherever two or more adjacent <space>s reach column positions *gap*+1, 2* *gap*+1, 3* *gap*+1, and so on. If *gap* is zero or is omitted, default tab settings at every eighth column position shall be assumed. If any non-digit character, *char*, is specified, it shall be used as the output <tab>.
−l *lines*	Override the 66-line default and reset the page length to *lines*. If *lines* is not greater than the sum of both the header and trailer depths (in lines), the *pr* utility shall suppress both the header and trailer, as if the **−t** option were in effect.
−m	Merge files. Standard output shall be formatted so the *pr* utility writes one line from each file specified by a *file* operand, side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementations shall support merging of at least nine *file* operands.
−n[*char***][***width***]**	Provide *width*-digit line numbering (default for *width* shall be 5). The number shall occupy the first *width* column positions of each text column of default output or each line of **−m** output. If *char* (any non-digit character) is given, it shall be appended to the line number to separate it from whatever follows (default for *char* is a <tab>).
−o *offset*	Each line of output shall be preceded by offset <space>s. If the **−o** option is not specified, the default offset shall be zero. The space taken is in addition to the output line width (see the **−w** option below).
−p	Pause before beginning each page if the standard output is directed to a terminal (*pr* shall write an <alert> to standard error and wait for a <carriage-return> to be read on **/dev/tty**).
−r	Write no diagnostic reports on failure to open files.
−s[*char***]**	Separate text columns by the single character *char* instead of by the appropriate number of <space>s (default for *char* shall be <tab>).
−t	Write neither the five-line identifying header nor the five-line trailer usually supplied for each page. Quit writing after the last line of each file without spacing to the end of the page.
−w *width*	Set the width of the line to *width* column positions for multiple text-column output only. If the **−w** option is not specified and the **−s** option is not specified, the default width shall be 72. If the **−w** option is not specified and the **−s** option is specified, the default width shall be 512. For single column output, input lines shall not be truncated.

OPERANDS

The following operand shall be supported:

file	A pathname of a file to be written. If no *file* operands are specified, or if a *file* operand is `'−'`, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

The file **/dev/tty** shall be used to read responses required by the −**p** option.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pr*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and which characters are defined as printable (character class **print**). Non-printable characters are still written to standard output, but are not counted for the purpose for column-width and line-length calculations.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_TIME	Determine the format of the date and time for use in writing header lines.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
TZ	Determine the timezone used to calculate date and time strings written in header lines. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

If *pr* receives an interrupt while writing to a terminal, it shall flush all accumulated error messages to the screen before terminating.

STDOUT

The *pr* utility output shall be a paginated version of the original file (or files). This pagination shall be accomplished using either <form-feed>s or a sequence of <newline>s, as controlled by XSI the −**F** or −**f** option. Page headers shall be generated unless the −**t** option is specified. The page headers shall be of the form:

```
"\n\n%s %s Page %d\n\n\n", <output of date>, <file>, <page number>
```

In the POSIX locale, the <*output of date*> field, representing the date and time of last modification of the input file (or the current date and time if the input file is standard input), shall be equivalent to the output of the following command as it would appear if executed at the given time:

```
date "+%b %e %H:%M %Y"
```

without the trailing <newline>, if the page being written is from standard input. If the page being written is not from standard input, in the POSIX locale, the same format shall be used, but the time used shall be the modification time of the file corresponding to *file* instead of the current time. When the *LC_TIME* locale category is not set to the POSIX locale, a different format and order of presentation of this field may be used.

If the standard input is used instead of a *file* operand, the <*file*> field shall be replaced by a null string.

If the −**h** option is specified, the <*file*> field shall be replaced by the *header* argument.

STDERR

The standard error shall be used for diagnostic messages and for alerting the terminal when −**p** is specified. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. Print a numbered list of all files in the current directory:

   ```
   ls −a | pr −n −h "Files in $(pwd)."
   ```

2. Print **file1** and **file2** as a double-spaced, three-column listing headed by ‘‘file list’’:

   ```
   pr −3d −h "file list" file1 file2
   ```

3. Write **file1** on **file2**, expanding tabs to columns 10, 19, 28, . . .:

   ```
   pr −e9 −t <file1 >file2
   ```

RATIONALE

This utility is one of those that does not follow the Utility Syntax Guidelines because of its historical origins. The standard developers could have added new options that obeyed the guidelines (and marked the old options *obsolescent*) or devised an entirely new utility; there are examples of both actions in this volume of IEEE Std 1003.1-200x. Because of its widespread use by historical applications, the standard developers decided to exempt this version of *pr* from many of the guidelines.

Implementations are required to accept option-arguments to the −**h**, −**l**, −**o**, and −**w** options whether presented as part of the same argument or as a separate argument to *pr*, as suggested by the Utility Syntax Guidelines. The −**n** and −**s** options, however, are specified as in historical practice because they are frequently specified without their optional arguments. If a <blank>

were allowed before the option-argument in these cases, a *file* operand could mistakenly be interpreted as an option-argument in historical applications.

The text about the minimum number of lines in multi-column output was included to ensure that a best effort is made in balancing the length of the columns. There are known historical implementations in which, for example, 60-line files are listed by *pr* –2 as one column of 56 lines and a second of 4. Although this is not a problem when a full page with headers and trailers is produced, it would be relatively useless when used with **–t**.

Historical implementations of the *pr* utility have differed in the action taken for the **–f** option. BSD uses it as described here for the **–F** option; System V uses it to change trailing <newline>s on each page to a <form-feed> and, if standard output is a TTY device, sends an <alert> to standard error and reads a line from **/dev/tty** before the first page. There were strong arguments from both sides of this issue concerning historical practice and as a result the **–F** option was added. XSI-conformant systems support the System V historical actions for the **–f** option.

The <*output of date*> field in the **–l** format is specified only for the POSIX locale. As noted, the format can be different in other locales. No mechanism for defining this is present in this volume of IEEE Std 1003.1-200x, as the appropriate vehicle is a message catalog; that is, the format should be specified as a ‘‘message’’.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **–p** option is added.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

printf — write formatted output

SYNOPSIS

```
printf format[argument...]
```

DESCRIPTION

The *printf* utility shall write formatted operands to the standard output. The *argument* operands shall be formatted under control of the *format* operand.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

format	A string describing the format to use to write the remaining operands. See the EXTENDED DESCRIPTION section.
argument	The strings to be written to standard output, under the control of *format*. See the EXTENDED DESCRIPTION section.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *printf*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_NUMERIC	Determine the locale for numeric formatting. It shall affect the format of numbers written using the `e`, `E`, `f`, `g`, and `G` conversion specifier characters (if supported).
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the EXTENDED DESCRIPTION section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The *format* operand shall be used as the *format* string described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation with the following exceptions:

1. A <space> in the format string, in any context other than a flag of a conversion specification, shall be treated as an ordinary character that is copied to the output.
2. A `'Δ'` character in the format string shall be treated as a `'Δ'` character, not as a <space>.
3. In addition to the escape sequences shown in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`), `"\ddd"`, where *ddd* is a one, two, or three-digit octal number, shall be written as a byte with the numeric value specified by the octal number.
4. The implementation shall not precede or follow output from the `d` or `u` conversion specifiers with <blank>s not specified by the *format* operand.
5. The implementation shall not precede output from the `o` conversion specifier with zeros not specified by the *format* operand.
6. The `e`, `E`, `f`, `g`, and `G` conversion specifiers need not be supported.
7. An additional conversion specifier character, `b`, shall be supported as follows. The argument shall be taken to be a string that may contain backslash-escape sequences. The following backslash-escape sequences shall be supported:

   — The escape sequences listed in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`), which shall be converted to the characters they represent

   — `"\0ddd"`, where *ddd* is a zero, one, two, or three-digit octal number that shall be converted to a byte with the numeric value specified by the octal number

   — `'\c'`, which shall not be written and shall cause *printf* to ignore any remaining characters in the string operand containing it, any remaining string operands, and any additional characters in the *format* operand

   The interpretation of a backslash followed by any other sequence of characters is unspecified.

   Bytes from the converted string shall be written until the end of the string or the number of bytes indicated by the precision specification is reached. If the precision is omitted, it shall be taken to be infinite, so all bytes up to the end of the converted string shall be written.
8. For each conversion specification that consumes an argument, the next argument operand shall be evaluated and converted to the appropriate type for the conversion as specified below.
9. The *format* operand shall be reused as often as necessary to satisfy the argument operands. Any extra `c` or `s` conversion specifiers shall be evaluated as if a null string argument were supplied; other extra conversion specifications shall be evaluated as if a zero argument were supplied. If the *format* operand contains no conversion specifications and *argument* operands are present, the results are unspecified.

10. If a character sequence in the *format* operand begins with a `'%'` character, but does not form a valid conversion specification, the behavior is unspecified.

The *argument* operands shall be treated as strings if the corresponding conversion specifier is `b`, `c`, or `s`; otherwise, it shall be evaluated as a C constant, as described by the ISO C standard, with the following extensions:

- A leading plus or minus sign shall be allowed.
- If the leading character is a single-quote or double-quote, the value shall be the numeric value in the underlying codeset of the character following the single-quote or double-quote.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message shall be written to standard error and the utility shall not exit with a zero exit status, but shall continue processing any remaining operands and shall write the value accumulated at the time the error was detected to standard output.

It is not considered an error if an argument operand is not completely used for a `c` or `s` conversion or if a string operand's first or second character is used to get the numeric value of a character.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The floating-point formatting conversion specifications of *printf*() are not required because all arithmetic in the shell is integer arithmetic. The *awk* utility performs floating-point calculations and provides its own **printf** function. The *bc* utility can perform arbitrary-precision floating-point arithmetic, but does not provide extensive formatting capabilities. (This *printf* utility cannot really be used to format *bc* output; it does not support arbitrary precision.) Implementations are encouraged to support the floating-point conversions as an extension.

Note that this *printf* utility, like the *printf*() function defined in the System Interfaces volume of IEEE Std 1003.1-200x on which it is based, makes no special provision for dealing with multi-byte characters when using the `%c` conversion specification or when a precision is specified in a `%b` or `%s` conversion specification. Applications should be extremely cautious using either of these features when there are multi-byte characters in the character set.

No provision is made in this volume of IEEE Std 1003.1-200x which allows field widths and precisions to be specified as `'*'` since the `'*'` can be replaced directly in the *format* operand using shell variable substitution. Implementations can also provide this feature as an extension if they so choose.

Hexadecimal character constants as defined in the ISO C standard are not recognized in the *format* operand because there is no consistent way to detect the end of the constant. Octal character constants are limited to, at most, three octal digits, but hexadecimal character constants are only terminated by a non-hex-digit character. In the ISO C standard, the `"##"` concatenation operator can be used to terminate a constant and follow it with a hexadecimal character to be written. In the shell, concatenation occurs before the *printf* utility has a chance to parse the end of the hexadecimal constant.

The `%b` conversion specification is not part of the ISO C standard; it has been added here as a portable way to process backslash escapes expanded in string operands as provided by the *echo* utility. See also the APPLICATION USAGE section of *echo* (on page 2534) for ways to use *printf* as a replacement for all of the traditional versions of the *echo* utility.

If an argument cannot be parsed correctly for the corresponding conversion specification, the *printf* utility is required to report an error. Thus, overflow and extraneous characters at the end of an argument being used for a numeric conversion shall be reported as errors.

EXAMPLES

To alert the user and then print and read a series of prompts:

```
printf "\aPlease fill in the following: \nName: "
read name
printf "Phone number: "
read phone
```

To read out a list of right and wrong answers from a file, calculate the percentage correctly, and print them out. The numbers are right-justified and separated by a single <tab>. The percentage is written to one decimal place of accuracy:

```
while read right wrong ; do
    percent=$(echo "scale=1;($right*100)/($right+$wrong)" | bc)
    printf "%2d right\t%2d wrong\t(%s%%)\n" \
        $right $wrong $percent
done < database_file
```

The command:

```
printf "%5d%4d\n" 1 21 321 4321 54321
```

produces:

```
    1  21
  3214321
54321   0
```

Note that the *format* operand is used three times to print all of the given strings and that a `'0'` was supplied by *printf* to satisfy the last `%4d` conversion specification.

The *printf* utility is required to notify the user when conversion errors are detected while producing numeric output; thus, the following results would be expected on an implementation with 32-bit twos-complement integers when `%d` is specified as the *format* operand:

Argument	Standard Output	Diagnostic Output
5a	5	**printf: "5a" not completely converted**
9999999999	2147483647	**printf: "9999999999" arithmetic overflow**
−9999999999	−2147483648	**printf: "−9999999999" arithmetic overflow**
ABC	0	**printf: "ABC" expected numeric value**

The diagnostic message format is not specified, but these examples convey the type of information that should be reported. Note that the value shown on standard output is what would be expected as the return value from the *strtol*( ) function as defined in the System Interfaces volume of IEEE Std 1003.1-200x. A similar correspondence exists between `%u` and *strtoul*( ) and `%e`, `%f`, and `%g` (if the implementation supports floating-point conversions) and *strtod*( ).

In a locale using the ISO/IEC 646:1991 standard as the underlying codeset, the command:

```
printf "%d\n" 3 +3 -3 \'3 \"+3 "'-3"
```

produces:

3	Numeric value of constant 3
3	Numeric value of constant 3
−3	Numeric value of constant −3
51	Numeric value of the character `'3'` in the ISO/IEC 646:1991 standard codeset
43	Numeric value of the character `'+'` in the ISO/IEC 646:1991 standard codeset
45	Numeric value of the character `'-'` in the ISO/IEC 646:1991 standard codeset

Note that in a locale with multi-byte characters, the value of a character is intended to be the value of the equivalent of the **wchar_t** representation of the character as described in the System Interfaces volume of IEEE Std 1003.1-200x.

RATIONALE

The *printf* utility was added to provide functionality that has historically been provided by *echo*. However, due to irreconcilable differences in the various versions of *echo* extant, the version has few special features, leaving those to this new *printf* utility, which is based on one in the Ninth Edition system.

The EXTENDED DESCRIPTION section almost exactly matches the *printf*( ) function in the ISO C standard, although it is described in terms of the file format notation in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

NAME

prs — print an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI
```
prs [−a][−d dataspec][−r[SID]] file...
prs [ −e| −l] −c cutoff [−d dataspec] file...
prs [ −e| −l] −r[SID][−d dataspec]file...
```

DESCRIPTION

The *prs* utility shall write to standard output parts or all of an SCCS file in a user-supplied format.

OPTIONS

The *prs* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the **−r** option has an optional option-argument. This optional option-argument cannot be presented as a separate argument. The following options shall be supported:

−d *dataspec*	Specify the output data specification. The *dataspec* shall be a string consisting of SCCS file *data keywords* (see **Data Keywords** (on page 2946)) interspersed with optional user-supplied text.
−r[*SID***]**	Specify the SCCS identification string (SID) of a delta for which information is desired. If no *SID* option-argument is specified, the SID of the most recently created delta shall be assumed.
−e	Request information for all deltas created earlier than and including the delta designated via the **−r** option or the date-time given by the **−c** option.
−l	Request information for all deltas created later than and including the delta designated via the **−r** option or the date-time given by the **−c** option.
−c *cutoff*	Indicate the *cutoff* date-time, in the form: `YY[MM[DD[HH[MM[SS]]]]]` For the *YY* component, values in the range [69,99] shall refer to years 1969 to 1999 inclusive, and values in the range [00,68] shall refer to years 2000 to 2068 inclusive. **Note:** It is expected that in a future version of IEEE Std 1003.1-200x the default century inferred from a 2-digit year will change. (This would apply to all commands accepting a 2-digit year as input.) No changes (deltas) to the SCCS file that were created after the specified *cutoff* date-time shall be included in the output. Units omitted from the date-time default to their maximum possible values; for example, **−c 7502** is equivalent to **−c 750228235959**.
−a	Request writing of information for both removed, that is, *delta type*=*R* (see *rmdel* (on page 3027)) and existing, that is, *delta type*=*D*, deltas. If the **−a** option is not specified, information for existing deltas only shall be provided.

OPERANDS

The following operand shall be supported:

file	A pathname of an existing SCCS file or a directory. If *file* is a directory, the *prs* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin

with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only when the *file* operand is specified as `'−'`. Each line of the text file shall be interpreted as an SCCS pathname.

INPUT FILES

Any SCCS files displayed are files of an unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *prs*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be a text file whose format is dependent on the data keywords specified with the −**d** option.

Data Keywords

Data keywords specify which parts of an SCCS file shall be retrieved and output. All parts of an SCCS file have an associated data keyword. A data keyword may appear in a *dataspec* multiple times.

The information written by *prs* shall consist of:

1. The user-supplied text
2. Appropriate values (extracted from the SCCS file) substituted for the recognized data keywords in the order of appearance in the *dataspec*

The format of a data keyword value shall either be simple (`'S'`), in which keyword substitution is direct, or multi-line (`'M'`).

User-supplied text shall be any text other than recognized data keywords. A <tab> shall be specified by `'\t'` and <newline> by `'\n'`. When the −**r** option is not specified, the default *dataspec* shall be:

```
:PN::\n\n
```

and the following *dataspec* shall be used for each selected delta:

```
:Dt:\t:DL:\nMRs:\n:MR:COMMENTS:\n:C:
```

*** The line statistics are capped at 99 999. For example, if 100 000 lines were unchanged in a certain revision, **:Lu:** shall produce the value 99 999.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. The following example:

```
prs −d "User Names for :F: are:\n:UN:" s.file
```

might write to standard output:

```
User Names for s.file are:
xyz
131
abc
```

2. The following example:

```
prs −d "Delta for pgm :M:: :I: − :D: By :P:" −r s.file
```

might write to standard output:

```
Delta for pgm main.c: 3.7 − 77/12/01 By cas
```

3. As a special case:

```
prs s.file
```

might write to standard output:

```
s.file:
<blank line>
D 1.1 77/12/01 00:00:00 cas 1 000000/00000/00000
MRs:
bl78−12345
bl79−54321
COMMENTS:
this is the comment line for s.file initial delta
<blank line>
```

for each delta table entry of the **D** type. The only option allowed to be used with this special case is the −**a** option.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The phrase ''in which keyword substitution is followed by a <newline>'' is deleted from the end of the second paragraph of **Data Keywords** (on page 2946).

The interpretation of the *YY* component of the −**c** *cutoff* argument is noted.

Issue 6

The normative text is reworded to emphasize the term ''shall'' for implementation requirements.

The Open Group Base Resolution bwg2001-007 is applied, updating the table in STDOUT with a note that line statistics are capped at 99 999 for the **:Li:**, **:Ld:**, **:Lu:**, and **:DL:** keywords.

The Open Group Interpretation PIN4C.00009 is applied.

NAME

ps — report process status

SYNOPSIS

UP XSI

```
ps [−aA][−defl][−G grouplist][−o format]...[−p proclist][−t termlist]
   [−U userlist][−g grouplist][−n namelist][−u userlist]
```

DESCRIPTION

The *ps* utility shall write information about processes, subject to having the appropriate privileges to obtain information about those processes.

By default, *ps* shall select all processes with the same effective user ID as the current user and the same controlling terminal as the invoker.

OPTIONS

The *ps* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

	−a	Write information for all processes associated with terminals. Implementations may omit session leaders from this list.
	−A	Write information for all processes.
XSI	**−d**	Write information for all processes, except session leaders.
XSI	**−e**	Write information for all processes. (Equivalent to −**A**.)
XSI	**−f**	Generate a **full** listing. (See the STDOUT section for the contents of a **full** listing.)
XSI	**−g** *grouplist*	Write information for processes whose session leaders are given in *grouplist*. The application shall ensure that the *grouplist* is a single argument in the form of a <blank> or comma-separated list.
	−G *grouplist*	Write information for processes whose real group ID numbers are given in *grouplist*. The application shall ensure that the *grouplist* is a single argument in the form of a <blank> or comma-separated list.
XSI	**−l**	Generate a **long** listing. (See STDOUT for the contents of a **long** listing.)
XSI	**−n** *namelist*	Specify the name of an alternative system *namelist* file in place of the default. The name of the default file and the format of a *namelist* file are unspecified.
	−o *format*	Write information according to the format specification given in *format*. This is fully described in the STDOUT section. Multiple −**o** options can be specified; the format specification shall be interpreted as the <space>-separated concatenation of all the *format* option-arguments.
	−p *proclist*	Write information for processes whose process ID numbers are given in *proclist*. The application shall ensure that the *proclist* is a single argument in the form of a <blank> or comma-separated list.
XSI	**−t** *termlist*	Write information for processes associated with terminals given in *termlist*. The application shall ensure that the *termlist* is a single argument in the form of a <blank> or comma-separated list. Terminal identifiers shall be given in an implementation-defined format. On XSI-conformant systems, they shall be given in one of two forms: the device's filename (for example, **tty04**) or, if the device's filename starts with **tty**, just the identifier following the characters **tty** (for

example, `"04"`).

XSI **−u** *userlist*	Write information for processes whose user ID numbers or login names are given in *userlist*. The application shall ensure that the *userlist* is a single argument in the form of a <blank> or comma-separated list. In the listing, the numerical user ID shall be written unless the **−f** option is used, in which case the login name shall be written.
−U *userlist*	Write information for processes whose real user ID numbers or login names are given in *userlist*. The application shall ensure that the *userlist* is a single argument in the form of a <blank> or comma-separated list.

With the exception of **−o** *format*, all of the options shown are used to select processes. If any are specified, the default list shall be ignored and *ps* shall select the processes represented by the inclusive OR of all the selection-criteria options.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ps*:

COLUMNS	Override the system-selected horizontal display line size, used to determine the number of text columns to display. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
LC_TIME	Determine the format and contents of the date and time strings displayed.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
TZ	Determine the timezone used to calculate date and time strings displayed. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the −**o** option is not specified, the standard output format is unspecified.

XSI On XSI-conformant systems, the output format shall be as follows. The column headings and descriptions of the columns in a *ps* listing are given below. The precise meanings of these fields are implementation-defined. The letters `'f'` and `'l'` (below) indicate the option (**full** or **long**) that shall cause the corresponding heading to appear; **all** means that the heading always appears. Note that these two options determine only what information is provided for a process; they do not determine which processes are listed.

F	(l)	Flags (octal and additive) associated with the process.
S	(l)	The state of the process.
UID	(f,l)	The user ID number of the process owner; the login name is printed under the −**f** option.
PID	(all)	The process ID of the process; it is possible to kill a process if this datum is known.
PPID	(f,l)	The process ID of the parent process.
C	(f,l)	Processor utilization for scheduling.
PRI	(l)	The priority of the process; higher numbers mean lower priority.
NI	(l)	Nice value; used in priority computation.
ADDR	(l)	The address of the process.
SZ	(l)	The size in blocks of the core image of the process.
WCHAN	(l)	The event for which the process is waiting or sleeping; if blank, the process is running.
STIME	(f)	Starting time of the process.
TTY	(all)	The controlling terminal for the process.
TIME	(all)	The cumulative execution time for the process.
CMD	(all)	The command name; the full command name and its arguments are written under the −**f** option.

A process that has exited and has a parent, but has not yet been waited for by the parent, shall be marked **defunct**.

Under the option −**f**, *ps* tries to determine the command name and arguments given when the process was created by examining memory or the swap area. Failing this, the command name, as it would appear without the option −**f**, is written in square brackets.

The −**o** option allows the output format to be specified under user control.

The application shall ensure that the format specification is a list of names presented as a single argument, <blank> or comma-separated. Each variable has a default header. The default header can be overridden by appending an equals sign and the new text of the header. The rest of the characters in the argument shall be used as the header text. The fields specified shall be written in the order specified on the command line, and should be arranged in columns in the output. The field widths shall be selected by the system to be at least as wide as the header text (default or overridden value). If the header text is null, such as −**o** *user*=, the field width shall be at least as wide as the default header text. If all header text fields are null, no header line shall be written.

The following names are recognized in the POSIX locale:

ruser	The real user ID of the process. This shall be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
user	The effective user ID of the process. This shall be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
rgroup	The real group ID of the process. This shall be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
group	The effective group ID of the process. This shall be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
pid	The decimal value of the process ID.
ppid	The decimal value of the parent process ID.
pgid	The decimal value of the process group ID.
pcpu	The ratio of CPU time used recently to CPU time available in the same period, expressed as a percentage. The meaning of ‘‘recently’’ in this context is unspecified. The CPU time available is determined in an unspecified manner.
vsz	The size of the process in (virtual) memory in 1 024 byte units as a decimal integer.
nice	The decimal value of the nice value of the process; see *nice* (on page 2863).
etime	In the POSIX locale, the elapsed time since the process was started, in the form: `[[dd–]hh:]mm:ss` where *dd* shall represent the number of days, *hh* the number of hours, *mm* the number of minutes, and *ss* the number of seconds. The *dd* field shall be a decimal integer. The *hh*, *mm*, and *ss* fields shall be two-digit decimal integers padded on the left with zeros.
time	In the POSIX locale, the cumulative CPU time of the process in the form: `[dd–]hh:mm:ss` The *dd*, *hh*, *mm*, and *ss* fields shall be as described in the **etime** specifier.
tty	The name of the controlling terminal of the process (if any) in the same format used by the *who* utility.
comm	The name of the command being executed (*argv*[0] value) as a string.
args	The command with all its arguments as a string. The implementation may truncate this value to the field width; it is implementation-defined whether any further truncation occurs. It is unspecified whether the string represented is a version of the argument list as it was passed to the command when it started, or is a version of the arguments as they may have been modified by the application. Applications cannot depend on being able to modify their argument list and having that modification be reflected in the output of *ps*.

Any field need not be meaningful in all implementations. In such a case a hyphen (`'−'`) should be output in place of the field value.

Only **comm** and **args** shall be allowed to contain <blank>s; all others shall not. Any implementation-defined variables shall be specified in the system documentation along with the default header and indicating if the field may contain <blank>s.

The following table specifies the default header to be used in the POSIX locale corresponding to each format specifier.

Table 4-17 Variable Names and Default Headers in *ps*

Format Specifier	Default Header	Format Specifier	Default Header
args	**COMMAND**	**ppid**	**PPID**
comm	**COMMAND**	**rgroup**	**RGROUP**
etime	**ELAPSED**	**ruser**	**RUSER**
group	**GROUP**	**time**	**TIME**
nice	**NI**	**tty**	**TT**
pcpu	**%CPU**	**user**	**USER**
pgid	**PGID**	**vsz**	**VSZ**
pid	**PID**		

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Things can change while *ps* is running; the snapshot it gives is only true for an instant, and might not be accurate by the time it is displayed.

The **args** format specifier is allowed to produce a truncated version of the command arguments. In some implementations, this information is no longer available when the *ps* utility is executed.

If the field width is too narrow to display a textual ID, the system may use a numeric version. Normally, the system would be expected to choose large enough field widths, but if a large number of fields were selected to write, it might squeeze fields to their minimum sizes to fit on one line. One way to ensure adequate width for the textual IDs is to override the default header for a field to make it larger than most or all user or group names.

There is no special quoting mechanism for header text. The header text is the rest of the argument. If multiple header changes are needed, multiple −**o** options can be used, such as:

```
ps −o "user=User Name" −o pid=Process\ ID
```

On some implementations, especially multi-level secure systems, *ps* may be severely restricted and produce information only about child processes owned by the user.

EXAMPLES

The command:

```
ps −o user,pid,ppid=MOM −o args
```

writes at least the following in the POSIX locale:

```
  USER   PID   MOM   COMMAND
helene    34    12   ps −o uid,pid,ppid=MOM −o args
```

The contents of the **COMMAND** field need not be the same in all implementations, due to possible truncation.

RATIONALE

There is very little commonality between BSD and System V implementations of *ps*. Many options conflict or have subtly different usages. The standard developers attempted to select a set of options for the base standard that were useful on a wide range of systems and selected options that either can be implemented on both BSD and System V-based systems without breaking the current implementations or where the options are sufficiently similar that any changes would not be unduly problematic for users or implementors.

It is recognized that on some implementations, especially multi-level secure systems, *ps* may be nearly useless. The default output has therefore been chosen such that it does not break historical implementations and also is likely to provide at least some useful information on most systems.

The major change is the addition of the format specification capability. The motivation for this invention is to provide a mechanism for users to access a wider range of system information, if the system permits it, in a portable manner. The fields chosen to appear in this volume of IEEE Std 1003.1-200x were arrived at after considering what concepts were likely to be both reasonably useful to the ‘‘average’’ user and had a reasonable chance of being implemented on a wide range of systems. Again it is recognized that not all systems are able to provide all the information and, conversely, some may wish to provide more. It is hoped that the approach adopted will be sufficiently flexible and extensible to accommodate most systems. Implementations may be expected to introduce new format specifiers.

The default output should consist of a short listing containing the process ID, terminal name, cumulative execution time, and command name of each process.

The preference of the standard developers would have been to make the format specification an operand of the *ps* command. Unfortunately, BSD usage precluded this.

At one time a format was included to display the environment array of the process. This was deleted because there is no portable way to display it.

The −**A** option is equivalent to the BSD −**g** and the SVID −**e**. Because the two systems differed, a mnemonic compromise was selected.

The −**a** option is described with some optional behavior because the SVID omits session leaders, but BSD does not.

In an early proposal, format specifiers appeared for priority and start time. The former was not defined adequately in this volume of IEEE Std 1003.1-200x and was removed in deference to the defined nice value; the latter because elapsed time was considered to be more useful.

In a new BSD version of *ps*, a −**O** option can be used to write all of the default information, followed by additional format specifiers. This was not adopted because the default output is implementation-defined. Nevertheless, this is a useful option that should be reserved for that purpose. In the −**o** option for the POSIX Shell and Utilities *ps*, the format is the concatenation of each −**o**. Therefore, the user can have an alias or function that defines the beginning of their desired format and add more fields to the end of the output in certain cases where that would be useful.

The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, *who*, and *write* require that they all use the same format.

The **pcpu** field indicates that the CPU time available is determined in an unspecified manner. This is because it is difficult to express an algorithm that is useful across all possible machine architectures. Historical counterparts to this value have attempted to show percentage of use in the recent past, such as the preceding minute. Frequently, these values for all processes did not add up to 100%. Implementations are encouraged to provide data in this field to users that will help them identify processes currently affecting the performance of the system.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

NAME

pwd — return working directory name

SYNOPSIS

```
pwd [−L | −P ]
```

DESCRIPTION

The *pwd* utility shall write to standard output an absolute pathname of the current working directory, which does not contain the filenames dot or dot-dot.

OPTIONS

The *pwd* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

−L	If the *PWD* environment variable contains an absolute pathname of the current directory that does not contain the filenames dot or dot-dot, *pwd* shall write this pathname to standard output. Otherwise, the **−L** option shall behave as the **−P** option.
−P	The absolute pathname written shall not contain filenames that, in the context of the pathname, refer to files of type symbolic link.

If both **−L** and **−P** are specified, the last one shall apply. If neither **−L** nor **−P** is specified, the *pwd* utility shall behave as if **−L** had been specified.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pwd*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PWD	If the **−P** option is in effect, this variable shall be set to an absolute pathname of the current working directory that does not contain any components that specify symbolic links, does not contain any components that are dot, and does not contain any components that are dot-dot. If an application sets or unsets the value of *PWD*, the behavior of *pwd* is unspecified.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *pwd* utility output is an absolute pathname of the current working directory:

`"%s\n", <directory pathname>`

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If an error is detected, output shall not be written to standard output, a diagnostic message shall be written to standard error, and the exit status is not zero.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

Some implementations have historically provided *pwd* as a shell special built-in command.

In most utilities, if an error occurs, partial output may be written to standard output. This does not happen in historical implementations of *pwd*. Because *pwd* is frequently used in historical shell scripts without checking the exit status, it is important that the historical behavior is required here; therefore, the CONSEQUENCES OF ERRORS section specifically disallows any partial output being written to standard output.

FUTURE DIRECTIONS

None.

cd, the System Interfaces volume of IEEE Std 1003.1-200x, *getcwd*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

The –**P** and –**L** options are added to describe actions relating to symbolic links as specified in the IEEE P1003.2b draft standard.

NAME

qalter — alter batch job

SYNOPSIS

BE

```
qalter [−a date_time][−A account_string][−c interval][−e path_name]
    [−h hold_list][−j join_list][−k keep_list][−l resource_list]
    [−m mail_options][−M mail_list][−N name][−o path_name]
    [−p priority][−r y|n][−S path_name_list][−u user_list]
    job_identifier ...
```

DESCRIPTION

The attributes of a batch job are altered by a request to the batch server that manages the batch job. The *qalter* utility is a user-accessible batch client that requests the alteration of the attributes of one or more batch jobs.

The *qalter* utility shall alter the attributes of those batch jobs, and only those batch jobs, for which a batch *job_identifier* is presented to the utility.

The *qalter* utility shall alter the attributes of batch jobs in the order in which the batch *job_identifier*s are presented to the utility.

If the *qalter* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

For each batch *job_identifier* for which the *qalter* utility succeeds, each attribute of the identified batch job shall be altered as indicated by all the options presented to the utility.

For each identified batch job for which the *qalter* utility fails, the utility shall not alter any attribute of the batch job.

For each batch job that the *qalter* utility processes, the utility shall not modify any attribute other than those required by the options and option-arguments presented to the utility.

The *qalter* utility shall alter batch jobs by sending a *Modify Job Request* to the batch server that manages each batch job. At the time the *qalter* utility exits, it shall have modified the batch job corresponding to each successfully processed batch *job_identifier*. An attempt to alter the attributes of a batch job in the RUNNING state is implementation-defined.

OPTIONS

The *qalter* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

−a *date_time* Redefine the time at which the batch job becomes eligible for execution.

The *date_time* argument shall be in the same form and represent the same time as for the *touch* utility. The time so represented shall be set into the *Execution_Time* attribute of the batch job. If the time specified is earlier than the current time, the **−a** option shall have no effect.

−A *account_string*

Redefine the account to which the resource consumption of the batch job should be charged.

The syntax of the *account_string* option-argument is unspecified.

The *qalter* utility shall set the *Account_Name* attribute of the batch job to the value of the *account_string* option-argument.

–**c** *interval* Redefine whether the batch job should be checkpointed, and if so, how often.

The *qalter* utility shall accept a value for the interval option-argument that is one of the following:

`n`	No checkpointing is to be performed on the batch batch job (NO_CHECKPOINT).
`s`	Checkpointing is to be performed only when the batch server is shut down (CHECKPOINT_AT_SHUTDOWN).
`c`	Automatic periodic checkpointing is to be performed at the *Minimum_Cpu_Interval* attribute of the batch queue, in units of CPU minutes (CHECKPOINT_AT_MIN_CPU_INTERVAL).
`c`=*minutes*	Automatic periodic checkpointing is to be performed every *minutes* of CPU time, or every *Minimum_Cpu_Interval* minutes, whichever is greater. The *minutes* argument shall conform to the syntax for unsigned integers and shall be greater than zero.

An implementation may define other checkpoint intervals. The conformance document for an implementation shall describe any alternative checkpoint intervals, how they are specified, their internal behavior, and how they affect the behavior of the utility.

The *qalter* utility shall set the *Checkpoint* attribute of the batch job to the value of the *interval* option-argument.

–**e** *path_name* Redefine the path to be used for the standard error stream of the batch job.

The *qalter* utility shall accept a *path_name* option-argument that conforms to the syntax of the *path_name* element defined in the System Interfaces volume of IEEE Std 1003.1-200x, which can be preceded by a host name element of the form *hostname*:.

If the *path_name* option-argument constitutes an absolute pathname, the *qalter* utility shall set the *Error_Path* attribute of the batch job to the value of the *path_name* option-argument, including the host name element, if present.

If the *path_name* option-argument constitutes a relative pathname and no host name element is specified, the *qalter* utility shall set the *Error_Path* attribute of the batch job to the value of the absolute pathname derived by expanding the *path_name* option-argument relative to the current directory of the process that executes the *qalter* utility.

If the *path_name* option-argument constitutes a relative pathname and a host name element is specified, the *qalter* utility shall set the *Error_Path* attribute of the batch job to the value of the option-argument without expansion.

If the *path_name* option-argument does not include a host name element, the *qalter* utility shall prefix the pathname in the *Error_Path* attribute with *hostname*:, where *hostname* is the name of the host upon which the *qalter* utility is being executed.

–**h** *hold_list* Redefine the types of holds, if any, on the batch job. The *qalter* –**h** option shall accept a value for the *hold_list* option-argument that is a string of alphanumeric characters in the portable character set.

The *qalter* utility shall accept a value for the *hold_list* option-argument that is a string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character `'n'`. For each unique character in the *hold_list* option-argument, the *qalter* utility shall add a value to the *Hold_Types* attribute of the batch job as follows, each representing a different hold type:

`u` USER

`s` SYSTEM

`o` OPERATOR

If any of these characters are duplicated in the *hold_list* option-argument, the duplicates shall be ignored. An existing *Hold_Types* attribute can be cleared by the hold type:

`n` NO_HOLD

The *qalter* utility shall consider it an error if any hold type other than `'n'` is combined with hold type `'n'`. Strictly conforming applications shall not repeat any of the characters `'u'`, `'s'`, `'o'`, or `'n'` within the *hold_list* option-argument. The *qalter* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters. An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

−**j** *join_list* Redefine which streams of the batch job are to be merged. The *qalter* −**j** option shall accept a value for the *join_list* option-argument that is a string of alphanumeric characters in the portable character set.

The *qalter* utility shall accept a *join_list* option-argument that consists of one or more of the characters `'e'` and `'o'`, or the single character `'n'`.

All of the other batch job output streams specified shall be merged into the output stream represented by the character listed first in the *join_list* option-argument.

For each unique character in the *join_list* option-argument, the *qalter* utility shall add a value to the *Join_Path* attribute of the batch job as follows, each representing a different batch job stream to join:

`e` The standard error of the batch batch job (JOIN_STD_ERROR).

`o` The standard output of the batch batch job (JOIN_STD_OUTPUT).

An existing *Join_Path* attribute can be cleared by the join type:

`n` NO_JOIN

If `'n'` is specified, then no files are joined. The *qalter* utility shall consider it an error if any join type other than `'n'` is combined with join type `'n'`.

Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or `'n'` within the *join_list* option-argument. The *qalter* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other join types. The conformance document for an implementation shall describe any additional batch job streams, how they are specified, their internal behavior, and how they affect the behavior of the utility.

−**k** *keep_list* Redefine which output of the batch job to retain on the execution host.

The *qalter* −**k** option shall accept a value for the *keep_list* option-argument that is a string of alphanumeric characters in the portable character set.

The *qalter* utility shall accept a *keep_list* option-argument that consists of one or more of the characters `'e'` and `'o'` or the single character `'n'`.

For each unique character in the *keep_list* option-argument, the *qalter* utility shall add a value to the *Keep_Files* attribute of the batch job as follows, each representing a different batch job stream to keep:

`e` The standard error of the batch batch job (KEEP_STD_ERROR).

`o` The standard output of the batch batch job (KEEP_STD_OUTPUT).

If both `'e'` and `'o'` are specified, then both files are retained. An existing *Keep_Files* attribute can be cleared by the keep type:

`n` NO_KEEP

If `'n'` is specified, then no files are retained. The *qalter* utility shall consider it an error if any keep type other than `'n'` is combined with keep type `'n'`.

Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or `'n'` within the *keep_list* option-argument. The *qalter* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters. An implementation may define other keep types. The conformance document for an implementation shall describe any additional keep types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

−l *resource_list*

Redefine the resources that are allowed or required by the batch job.

The *qalter* utility shall accept a *resource_list* option-argument that conforms to the following syntax:

```
resource=value[,,resource=value,,...]
```

The *qalter* utility shall set one entry in the value of the *Resource_List* attribute of the batch job for each resource listed in the *resource_list* option-argument.

Because the list of supported resource names might vary by batch server, the *qalter* utility shall rely on the batch server to validate the resource names and associated values. See Section 3.3.3 (on page 2325) for a means of removing *keyword=value* (and *value@keyword*) pairs and other general rules for list-oriented batch job attributes.

−m *mail_options*

Redefine the points in the execution of the batch job at which the batch server is to send mail about a change in the state of the batch job.

The *qalter* **−m** option shall accept a value for the *mail_options* option-argument that is a string of alphanumeric characters in the portable character set.

The *qalter* utility shall accept a value for the *mail_options* option-argument that is a string of one or more of the characters `'e'`, `'b'`, and `'a'`, or the single character `'n'`. For each unique character in the *mail_options* option-argument, the *qalter* utility shall add a value to the *Mail_Users* attribute of the batch job as follows, each representing a different time during the life of a batch job at which to send mail:

`e` MAIL_AT_EXIT

`b` MAIL_AT_BEGINNING

`a` MAIL_AT_ABORT

If any of these characters are duplicated in the *mail_options* option-argument, the duplicates shall be ignored.

An existing *Mail_Points* attribute can be cleared by the mail type:

`n` NO_MAIL

If `'n'` is specified, then mail is not sent. The *qalter* utility shall consider it an error if any mail type other than `'n'` is combined with mail type `'n'`. Strictly conforming applications shall not repeat any of the characters `'e'`, `'b'`, `'a'`, or `'n'` within the *mail_options* option-argument. The *qalter* utility shall permit the repetition of characters but shall not assign additional meaning to the repeated characters.

An implementation may define other mail types. The conformance document for an implementation shall describe any additional mail types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

−**M** *mail_list* Redefine the list of users to which the batch server that executes the batch job is to send mail, if the batch server sends mail about the batch job.

The syntax of the *mail_list* option-argument is unspecified. If the implementation of the *qalter* utility uses a name service to locate users, the utility shall accept the syntax used by the name service.

If the implementation of the *qalter* utility does not use a name service to locate users, the implementation shall accept the following syntax for user names:

```
mail_address[,,mail_address,,...]
```

The interpretation of *mail_address* is implementation-defined.

The *qalter* utility shall set the *Mail_Users* attribute of the batch job to the value of the *mail_list* option-argument.

−**N** *name* Redefine the name of the batch job.

The *qalter* −**N** option shall accept a value for the *name* option-argument that is a string of up to 15 alphanumeric characters in the portable character set where the first character is alphabetic.

The syntax of the *name* option-argument is unspecified.

The *qalter* utility shall set the *Job_Name* attribute of the batch job to the value of the *name* option-argument.

−**o** *path_name* Redefine the path for the standard output of the batch job.

The *qalter* utility shall accept a *path_name* option-argument that conforms to the syntax of the *path_name* element defined in the System Interfaces volume of IEEE Std 1003.1-200x, which can be preceded by a host name element of the form *hostname*:.

If the *path_name* option-argument constitutes an absolute pathname, the *qalter* utility shall set the *Output_Path* attribute of the batch job to the value of the *path_name* option-argument.

If the *path_name* option-argument constitutes a relative pathname and no host name element is specified, the *qalter* utility shall set the *Output_Path* attribute of the batch job to the absolute pathname derived by expanding the *path_name* option-argument relative to the current directory of the process that executes the *qalter* utility.

If the *path_name* option-argument constitutes a relative pathname and a host name element is specified, the *qalter* utility shall set the *Output_Path* attribute of the batch job to option-argument without any expansion of the pathname.

If the *path_name* option-argument does not include a host name element, the *qalter* utility shall prefix the pathname in the *Output_Path* attribute with *hostname*:, where *hostname* is the name of the host upon which the *qalter* utility is being executed.

−**p** *priority* Redefine the priority of the batch job.

The *qalter* utility shall accept a value for the priority option-argument that conforms to the syntax for signed decimal integers, and which is not less than −1 024 and not greater than 1 023.

The *qalter* utility shall set the *Priority* attribute of the batch job to the value of the *priority* option-argument.

−**r** `y|n` Redefine whether the batch job is rerunable.

If the value of the option-argument is `'y'`, the *qalter* utility shall set the *Rerunable* attribute of the batch job to TRUE.

If the value of the option-argument is `'n'`, the *qalter* utility shall set the *Rerunable* attribute of the batch job to FALSE.

The *qalter* utility shall consider it an error if any character other than `'y'` or `'n'` is specified in the option-argument.

−**S** *path_name_list*

Redefine the shell that interprets the script at the destination system.

The *qalter* utility shall accept a *path_name_list* option-argument that conforms to the following syntax:

```
pathname[@host][,pathname[@host],...]
```

The *qalter* utility shall accept only one pathname that is missing a corresponding host name. The *qalter* utility shall allow only one pathname per named host.

The *qalter* utility shall add a value to the *Shell_Path_List* attribute of the batch job for each entry in the *path_name_list* option-argument. See Section 3.3.3 (on page 2325) for a means of removing *keyword*=*value* (and *value*@*keyword*) pairs and other general rules for list-oriented batch job attributes.

−**u** *user_list* Redefine the user name under which the batch job is to run at the destination system.

The *qalter* utility shall accept a *user_list* option-argument that conforms to the following syntax:

```
username[@host][,,username[@host],,...]
```

The *qalter* utility shall accept only one user name that is missing a corresponding host name. The *qalter* utility shall accept only one user name per named host.

The *qalter* utility shall add a value to the *User_List* attribute of the batch job for each entry in the *user_list* option-argument. See Section 3.3.3 (on page 2325) for a means of removing *keyword*=*value* (and *value*@*keyword*) pairs and other general rules for list-oriented batch job attributes.

OPERANDS

The *qalter* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2324)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qalter*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME	Determine the login name of the user.
TZ	Determine the timezone used to interpret the *date-time* option-argument. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qalter* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qalter* utility attempts to locate the batch job on other batch servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qalter* utility allows users to change the attributes of a batch job.

As a means of altering a queued job, the *qalter* utility is superior to deleting and requeuing the batch job insofar as an altered job retains its place in the queue with some traditional selection algorithms. In addition, the *qalter* utility is both shorter and simpler than a sequence of *qdel* and *qsub* utilities.

The result of an attempt on the part of a user to alter a batch job in a RUNNING state is implementation-defined because a batch job in the RUNNING state will already have opened its output files and otherwise performed any actions indicated by the options in effect at the time the batch job began execution.

The options processed by the *qalter* utility are identical to those of the *qsub* utility, with a few exceptions: −**V**, −**v**, and −**q**. The −**V** and −**v** are inappropriate for the *qalter* utility, since they capture potentially transient environment information from the submitting process. The −**q** option would specify a new queue, which would largely negate the previously stated advantage of using *qalter*; furthermore, the *qmove* utility provides a superior means of moving jobs.

Each of the following paragraphs provides the rationale for a *qalter* option.

Additional rationale concerning these options can be found in the rationale for the *qsub* utility.

The −**a** option allows users to alter the date and time at which a batch job becomes eligible to run.

The −**A** option allows users to change the account that will be charged for the resources consumed by the batch job. Support for the −**A** option is mandatory for conforming implementations of *qalter*, even though support of accounting is optional for servers. Whether or not to support accounting is left to the implementor of the server, but mandatory support of the −**A** option assures users of a consistent interface and allows them to control accounting on servers that support accounting.

The −**c** option allows users to alter the checkpointing interval of a batch job. A checkpointing system, which is not defined by IEEE Std 1003.1-200x, allows recovery of a batch job at the most recent checkpoint in the event of a crash. Checkpointing is typically used for jobs that consume expensive computing time or must meet a critical schedule. Users should be allowed to make the tradeoff between the overhead of checkpointing and the risk to the timely completion of the batch job; therefore, this volume of IEEE Std 1003.1-200x provides the checkpointing interval option. Support for checkpointing is optional for servers.

The −**e** option allows users to alter the name and location of the standard error stream written by a batch job. However, the path of the standard error stream is meaningless if the value of the *Join_Path* attribute of the batch job is TRUE.

The −**h** option allows users to set the hold type in the *Hold_Types* attribute of a batch job. The *qhold* and *qrls* utilities add or remove hold types to the *Hold_Types* attribute, respectively. The −**h** option has been modified to allow for implementation-defined hold types.

The −**j** option allows users to alter the decision to join (merge) the standard error stream of the batch job with the standard output stream of the batch job.

The –**l** option allows users to change the resource limits imposed on a batch job.

The –**m** option allows users to modify the list of points in the life of a batch job at which the designated users will receive mail notification.

The –**M** option allows users to alter the list of users who will receive notification about events in the life of a batch job.

The –**N** option allows users to change the name of a batch job.

The –**o** option allows users to alter the name and path to which the standard output stream of the batch job will be written.

The –**P** option allows users to modify the priority of a batch job. Support for priority is optional for batch servers.

The –**r** option allows users to alter the rerunability status of a batch job.

The –**S** option allows users to change the name and location of the shell image that will be invoked to interpret the script of the batch job. This option has been modified to allow a list of shell name and locations associated with different host.

The –**u** option allows users to change the user identifier under which the batch job will execute.

The *job_identifier* operand syntax is provided so that the user can differentiate between the originating and destination (or executing) batch server. These may or may not be the same. The *.server_name* portion identifies the originating batch server, while the *@server* portion identifies the destination batch server.

Historically, the *qalter* utility has been a component of the Network Queuing System (NQS), the existing practice from which this utility has been derived.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

Issue 6

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

IEEE PASC Interpretation 1003.2 #182 is applied, clarifying the description of the –**a** option.

NAME

qdel — delete batch jobs

SYNOPSIS

BE
```
qdel job_identifier ...
```

DESCRIPTION

A batch job is deleted by sending a request to the batch server that manages the batch job. A batch job that has been deleted is no longer subject to management by batch services.

The *qdel* utility is a user-accessible client of batch services that requests the deletion of one or more batch jobs.

The *qdel* utility shall request a batch server to delete those batch jobs for which a batch *job_identifier* is presented to the utility.

The *qdel* utility shall delete batch jobs in the order in which their batch *job_identifier*s are presented to the utility.

If the *qdel* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qdel* utility shall delete each batch job by sending a *Delete Job Request* to the batch server that manages the batch job.

The *qdel* utility shall not exit until the batch job corresponding to each successfully processed batch *job_identifier* has been deleted.

OPTIONS

None.

OPERANDS

The *qdel* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2324)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qdel*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LOGNAME Determine the login name of the user.

ASYNCHRONOUS EVENTS

Default.

STDOUT

An implementation of the *qdel* utility may write informative messages to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qdel* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qdel* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qdel* utility allows users and administrators to delete jobs.

The *qdel* utility provides functionality that is not otherwise available. For example, the *kill* utility of the operating system does not suffice. First, to use the *kill* utility, the user might have to log in on a remote node, because the *kill* utility does not operate across the network. Second, unlike *qdel*, *kill* cannot remove jobs from queues. Lastly, the arguments of the *qdel* utility are job identifiers rather than process identifiers, and so this utility can be passed the output of the *qselect* utility, thus providing users with a means of deleting a list of jobs.

Because a set of jobs can be selected using the *qselect* utility, the *qdel* utility has not been complicated with options that provide for selection of jobs. Instead, the batch jobs to be deleted are identified individually by their job identifiers.

Historically, the *qdel* utility has been a component of NQS, the existing practice on which it is based. However, the *qdel* utility defined in this volume of IEEE Std 1003.1-200x does not provide an option for specifying a signal number to send to the batch job prior to the killing of the process; that capability has been subsumed by the *qsig* utility.

A discussion was held about the delays of networking and the possibility that the batch server may never respond, due to a down router, down batch server, or other network mishap. The DESCRIPTION records this under the words ‘‘fails to process any job identifier’’. In the broad sense, the network problem is also an error, which causes the failure to process the batch job identifier.

FUTURE DIRECTIONS

None.

Issue 6

The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

NAME

qhold — hold batch jobs

SYNOPSIS

BE
```
qhold [−h hold_list] job_identifier ...
```

DESCRIPTION

A hold is placed on a batch job by a request to the batch server that manages the batch job. A batch job that has one or more holds is not eligible for execution. The *qhold* utility is a user-accessible client of batch services that requests one or more types of hold to be placed on one or more batch jobs.

The *qhold* utility shall place holds on those batch jobs for which a batch *job_identifier* is presented to the utility.

The *qhold* utility shall place holds on batch jobs in the order in which their batch *job_identifier*s are presented to the utility. If the *qhold* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qhold* utility shall place holds on each batch job by sending a *Hold Job Request* to the batch server that manages the batch job.

The *qhold* utility shall not exit until holds have been placed on the batch job corresponding to each successfully processed batch *job_identifier*.

OPTIONS

The *qhold* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:

−**h** *hold_list* Define the types of holds to be placed on the batch job.

The *qhold* −**h** option shall accept a value for the *hold_list* option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).

The *qhold* utility shall accept a value for the *hold_list* option-argument that is a string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character `'n'`.

For each unique character in the *hold_list* option-argument, the *qhold* utility shall add a value to the *Hold_Types* attribute of the batch job as follows, each representing a different hold type:

`u`	USER
`s`	SYSTEM
`o`	OPERATOR

If any of these characters are duplicated in the *hold_list* option-argument, the duplicates shall be ignored.

An existing *Hold_Types* attribute can be cleared by the following hold type:

`n` NO_HOLD

The *qhold* utility shall consider it an error if any hold type other than `'n'` is combined with hold type `'n'`.

Strictly conforming applications shall not repeat any of the characters `'u'`, `'s'`, `'o'`, or `'n'` within the *hold_list* option-argument. The *qhold* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

If the −**h** option is not presented to the *qhold* utility, the implementation shall set the *Hold_Types* attribute to USER.

OPERANDS

The *qhold* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2324)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qhold*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME	Determine the login name of the user.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qhold* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qhold* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qhold* utility allows users to place a hold on one or more jobs. A hold makes a batch job ineligible for execution.

The *qhold* utility has options that allow the user to specify the type of hold. Should the user wish to place a hold on a set of jobs that meet a selection criteria, such a list of jobs can be acquired using the *qselect* utility.

The −**h** option allows the user to specify the type of hold that is to be placed on the job. This option allows for USER, SYSTEM, OPERATOR, and implementation-defined hold types. The USER and OPERATOR holds are distinct. The batch server that manages the batch job will verify that the user is authorized to set the specified hold for the batch job.

Mail is not required on hold because the administrator has the tools and libraries to build this option if he or she wishes.

Historically, the *qhold* utility has been a part of some existing batch systems, although it has not traditionally been a part of the NQS.

FUTURE DIRECTIONS

None.

NAME

qmove — move batch jobs

SYNOPSIS

BE `qmove destination job_identifier ...`

DESCRIPTION

To move a batch job is to remove the batch job from the batch queue in which it resides and instantiate the batch job in another batch queue. A batch job is moved by a request to the batch server that manages the batch job. The *qmove* utility is a user-accessible batch client that requests the movement of one or more batch jobs.

The *qmove* utility shall move those batch jobs, and only those batch jobs, for which a batch *job_identifier* is presented to the utility.

The *qmove* utility shall move batch jobs in the order in which the corresponding batch *job_identifier*s are presented to the utility.

If the *qmove* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qmove* utility shall move batch jobs by sending a *Move Job Request* to the batch server that manages each batch job. The *qmove* utility shall not exit before the batch jobs corresponding to all successfully processed batch *job_identifier*s have been moved.

OPTIONS

None.

OPERANDS

The *qmove* utility shall accept one operand that conforms to the syntax for a *destination* (see Section 3.3.2 (on page 2325)).

The *qmove* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2324)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qmove*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LOGNAME	Determine the login name of the user.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qmove* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qmove* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qmove* utility allows users to move jobs between queues.

The alternative to using the *qmove* utility—deleting the batch job and requeuing it—entails considerably more typing.

Since the means of selecting jobs based on attributes has been encapsulated in the *qselect* utility, the only option of the *qmove* utility concerns authorization. The −**u** option provides the user with the convenience of changing the user identifier under which the batch job will execute. Minimalism and consistency has taken precedence over convenience; the −**u** option has been deleted because the equivalent capability exists with the −**u** option of the *qalter* utility.

FUTURE DIRECTIONS

None.

qalter, *qselect*, Chapter 3 (on page 2303)

CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

Issue 6

The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

NAME

qmsg — send message to batch jobs

SYNOPSIS

BE `qmsg [−E][−O] message_string job_identifier ...`

DESCRIPTION

To send a message to a batch job is to request that a server write a message string into one or more output files of the batch job. A message is sent to a batch job by a request to the batch server that manages the batch job. The *qmsg* utility is a user-accessible batch client that requests the sending of messages to one or more batch jobs.

The *qmsg* utility shall write messages into the files of batch jobs by sending a *Job Message Request* to the batch server that manages the batch job. The *qmsg* utility shall not directly write the message into the files of the batch job.

The *qmsg* utility shall send a *Job Message Request* for those batch jobs, and only those batch jobs, for which a batch *job_identifier* is presented to the utility.

The *qmsg* utility shall send *Job Message Request*s for batch jobs in the order in which their batch *job_identifier*s are presented to the utility.

If the *qmsg* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qmsg* utility shall not exit before a *Job Message Request* has been sent to the server that manages the batch job that corresponds to each successfully processed batch *job_identifier*.

OPTIONS

The *qmsg* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

−E Specify that the message is written to the standard error of each batch job.

The *qmsg* utility shall write the message into the standard error of the batch job.

−O Specify that the message is written to the standard output of each batch job.

The *qmsg* utility shall write the message into the standard output of the batch job.

If neither the −**O** nor the −**E** option is presented to the *qmsg* utility, the utility shall write the message into an implementation-defined file. The conformance document for the implementation shall describe the name and location of the implementation-defined file. If both the −**O** and the −**E** options are presented to the *qmsg* utility, then the utility shall write the messages to both standard output and standard error.

OPERANDS

The *qmsg* utility shall accept a minimum of two operands, *message_string* and one or more batch *job_identifier*s.

The *message_string* operand shall be the string to be written to one or more output files of the batch job followed by a <newline>. If the string contains <blank>s, then the application shall ensure that the string is quoted. The *message_string* shall be encoded in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).

All remaining operands are batch *job_identifier*s that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2324)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qmsg*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME	Determine the login name of the user.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qmsg* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qmsg* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qmsg* utility allows users to write messages into the output files of running jobs. Users, including operators and administrators, have a number of occasions when they want to place messages in the output files of a batch job. For example, if a disk that is being used by a batch job is showing errors, the operator might note this in the standard error stream of the batch job.

The options of the *qmsg* utility provide users with the means of placing the message in the output stream of their choice. The default output stream for the message—if the user does not designate an output stream—is implementation-defined, since many implementations will provide, as an extension to this volume of IEEE Std 1003.1-200x, a log file that shows the history of utility execution.

If users wish to send a message to a set of jobs that meet a selection criteria, the *qselect* utility can be used to acquire the appropriate list of job identifiers.

The −**E** option allows users to place the message in the standard error stream of the batch job.

The −**O** option allows users to place the message in the standard output stream of the batch job.

Historically, the *qmsg* utility is an existing practice in the offerings of one or more implementors of an NQS-derived batch system. The utility has been found to be useful enough that it deserves to be included in this volume of IEEE Std 1003.1-200x.

FUTURE DIRECTIONS

None.

NAME

qrerun — rerun batch jobs

SYNOPSIS

BE

```
qrerun job_identifier ...
```

DESCRIPTION

To rerun a batch job is to terminate the session leader of the batch job, delete any associated checkpoint files, and return the batch job to the batch queued state. A batch job is rerun by a request to the batch server that manages the batch job. The *qrerun* utility is a user-accessible batch client that requests the rerunning of one or more batch jobs.

The *qrerun* utility shall rerun those batch jobs for which a batch *job_identifier* is presented to the utility.

The *qrerun* utility shall rerun batch jobs in the order in which their batch *job_identifier*s are presented to the utility.

If the *qrerun* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qrerun* utility shall rerun batch jobs by sending a *Rerun Job Request* to the batch server that manages each batch job.

For each successfully processed batch *job_identifier*, the *qrerun* utility shall have rerun the corresponding batch batch job at the time the utility exits.

OPTIONS

None.

OPERANDS

The *qrerun* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2324)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qrerun*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LOGNAME Determine the login name of the user.

ASYNCHRONOUS EVENTS

Issue 6

The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

NAME

qrls — release batch jobs

SYNOPSIS

BE

```
qrls [−h hold_list] job_identifier ...
```

DESCRIPTION

A batch job might have one or more holds, which prevent the batch job from executing. A batch job from which all the holds have been removed becomes eligible for execution and is said to have been released. A batch job hold is removed by sending a request to the batch server that manages the batch job. The *qrls* utility is a user-accessible client of batch services that requests holds be removed from one or more batch jobs.

The *qrls* utility shall remove one or more holds from those batch jobs for which a batch *job_identifier* is presented to the utility.

The *qrls* utility shall remove holds from batch jobs in the order in which their batch *job_identifier*s are presented to the utility.

If the *qrls* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qrls* utility shall remove holds on each batch job by sending a *Release Job Request* to the batch server that manages the batch job.

The *qrls* utility shall not exit until the holds have been removed from the batch job corresponding to each successfully processed batch *job_identifier*.

OPTIONS

The *qrls* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:

−**h** *hold_list* Define the types of holds to be removed from the batch job.

The *qrls* −**h** option shall accept a value for the *hold_list* option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).

The *qrls* utility shall accept a value for the *hold_list* option-argument that is a string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character `'n'`.

For each unique character in the *hold_list* option-argument, the *qrls* utility shall add a value to the *Hold_Types* attribute of the batch job as follows, each representing a different hold type:

`u`	USER
`s`	SYSTEM
`o`	OPERATOR

If any of these characters are duplicated in the *hold_list* option-argument, the duplicates shall be ignored.

An existing *Hold_Types* attribute can be cleared by the following hold type:

`n`	NO_HOLD

The *qrls* utility shall consider it an error if any hold type other than `'n'` is combined with hold type `'n'`.

Strictly conforming applications shall not repeat any of the characters `'u'`, `'s'`, `'o'`, or `'n'` within the *hold_list* option-argument. The *qrls* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

If the **−h** option is not presented to the *qrls* utility, the implementation shall remove the USER hold in the *Hold_Types* attribute.

OPERANDS

The *qrls* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2324)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qrls*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME	Determine the login name of the user.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qrls* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qrls* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qrls* utility allows users, operators, and administrators to remove holds from jobs.

The *qrls* utility does not support any job selection options or wildcard arguments. Users may acquire a list of jobs selected by attributes using the *qselect* utility. For example, a user could select all of their held jobs.

The −**h** option allows the user to specify the type of hold that is to be removed. This option allows for USER, SYSTEM, OPERATOR, and implementation-defined hold types. The batch server that manages the batch job will verify whether the user is authorized to remove the specified hold for the batch job. If more than one type of hold has been placed on the batch job, a user may wish to remove only some of them.

Mail is not required on release because the administrator has the tools and libraries to build this option if required.

The *qrls* utility is a new utility *vis-a-vis* existing practice; it has been defined in this volume of IEEE Std 1003.1-200x as the natural complement to the *qhold* utility.

FUTURE DIRECTIONS

None.

SEE ALSO

qhold, *qselect*, Chapter 3 (on page 2303)

CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

Issue 6

The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

NAME

qselect — select batch jobs

SYNOPSIS

BE

```
qselect [−a [op]date_time][−A account_string][−c [op]interval]
    [−h hold_list][−l resource_list][−N name][−p [op]priority]
    [−q destination][−r y|n][−s states][−u user_list]
```

DESCRIPTION

To select a set of batch jobs is to return the batch *job_identifier*s for each batch job that meets a list of selection criteria. A set of batch jobs is selected by a request to a batch server. The *qselect* utility is a user-accessible batch client that requests the selection of batch jobs.

Upon successful completion, the *qselect* utility shall have returned a list of zero or more batch *job_identifier*s that meet the criteria specified by the options and option-arguments presented to the utility.

The *qselect* utility shall select batch jobs by sending a *Select Jobs Request* to a batch server. The *qselect* utility shall not exit until the server replies to each request generated.

For each option presented to the *qselect* utility, the utility shall restrict the set of selected batch jobs as described in the OPTIONS section.

The *qselect* utility shall not restrict selection of batch jobs except by authorization and as required by the options presented to the utility.

When an option is specified with a mandatory or optional *op* component to the option-argument, then *op* shall specify a relation between the value of a certain batch job attribute and the *value* component of the option-argument. If an *op* is allowable on an option, then the description of the option letter indicates the *op* as either mandatory or optional. Acceptable strings for the *op* component, and the relation the string indicates, are shown in the following list:

`.eq.`	The value represented by the attribute of the batch job is equal to the value represented by the option-argument.
`.ge.`	The value represented by the attribute of the batch job is greater than or equal to the value represented by the option-argument.
`.gt.`	The value represented by the attribute of the batch job is greater than the value represented by the option-argument.
`.lt.`	The value represented by the attribute of the batch job is less than the value represented by the option-argument.
`.le.`	The value represented by the attribute of the batch job is less than or equal to the value represented by the option-argument.
`.ne.`	The value represented by the attribute of the batch job is not equal to the value represented by the option-argument.

OPTIONS

The *qselect* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

−a [*op***]***date_time*

Restrict selection to a specific time, or a range of times.

The *qselect* utility shall select only batch jobs for which the value of the *Execution_Time* attribute is related to the Epoch equivalent of the local time expressed by the value of the *date_time* component of the option-argument in the manner indicated by the value of the *op* component of the option-argument.

The *qselect* utility shall accept a *date_time* component of the option-argument that conforms to the syntax of the *time* operand of the *touch* utility.

If the *op* component of the option-argument is not presented to the *qselect* utility, the utility shall select batch jobs for which the *Execution_Time* attribute is equal to the *date_time* component of the option-argument.

When comparing times, the *qselect* utility shall use the following definitions for the *op* component of the option-argument:

`.eq.` The time represented by value of the *Execution_Time* attribute of the batch job is equal the time represented by the *date_time* component of the option-argument.

`.ge.` The time represented by value of the *Execution_Time* attribute of the batch job is after or equal to the time represented by the *date_time* component of the option-argument.

`.gt.` The time represented by value of the *Execution_Time* attribute of the batch job is after the time represented by the *date_time* component of the option-argument.

`.lt.` The time represented by value of the *Execution_Time* attribute of the batch job is before the time represented by the *date_time* component of the option-argument.

`.le.` The time represented by value of the *Execution_Time* attribute of the batch job is before or equal to the time represented by the *date_time* component of the option-argument.

`.ne.` The time represented by value of the *Execution_Time* attribute of the batch job is not equal to the time represented by the *date_time* component of the option-argument.

The *qselect* utility shall accept the defined character strings for the *op* component of the option-argument.

−**A** *account_string*

Restrict selection to the batch jobs charging a specified account.

The *qselect* utility shall select only batch jobs for which the value of the *Account_Name* attribute of the batch job matchs the value of the *account_string* option-argument.

The syntax of the *account_string* option-argument is unspecified.

−**c** **[***op***]***interval*

Restrict selection to batch jobs within a range of checkpoint intervals.

The *qselect* utility shall select only batch jobs for which the value of the *Checkpoint* attribute relates to the value of the *interval* component of the option-argument in the manner indicated by the value of the *op* component of the option-argument.

If the *op* component of the option-argument is omitted, the *qselect* utility shall select batch jobs for which the value of the *Checkpoint* attribute is equal to the value of the *interval* component of the option-argument.

When comparing checkpoint intervals, the *qselect* utility shall use the following definitions for the *op* component of the option-argument:

`.eq.` The value of the *Checkpoint* attribute of the batch job equals the value of the *interval* component of the option-argument.

`.ge.` The value of the *Checkpoint* attribute of the batch job is greater than or equal to the value of the *interval* component option-argument.

`.gt.` The value of the *Checkpoint* attribute of the batch job is greater than the value of the *interval* component option-argument.

`.lt.` The value of the *Checkpoint* attribute of the batch job is less than the value of the *interval* component option-argument.

`.le.` The value of the *Checkpoint* attribute of the batch job is less than or equal to the value of the *interval* component option-argument.

`.ne.` The value of the *Checkpoint* attribute of the batch job does not equal the value of the *interval* component option-argument.

The *qselect* utility shall accept the defined character strings for the *op* component of the option-argument.

The ordering relationship for the values of the interval option-argument is defined to be:

`'n' .gt. 's' .gt. 'c=`*`minutes`*`' .ge. 'c'`

When comparing *Checkpoint* attributes with an interval having the value of the single character `'u'`, only equality or inequality are valid comparisons.

–h *hold_list* Restrict selection to batch jobs that have a specific type of hold.

The *qselect* utility shall select only batch jobs for which the value of the *Hold_Types* attribute matches the value of the *hold_list* option-argument.

The *qselect* **–h** option shall accept a value for the *hold_list* option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).

The *qselect* utility shall accept a value for the *hold_list* option-argument that is a string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character `'n'`.

Each unique character in the *hold_list* option-argument of the *qselect* utility is defined as follows, each representing a different hold type:

`u` USER

`s` SYSTEM

`o` OPERATOR

If any of these characters are duplicated in the *hold_list* option-argument, the duplicates shall be ignored.

The *qselect* utility shall consider it an error if any hold type other than `'n'` is combined with hold type `'n'`.

Strictly conforming applications shall not repeat any of the characters `'u'`, `'s'`, `'o'`, or `'n'` within the *hold_list* option-argument. The *qselect* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

−l *resource_list*

Restrict selection to batch jobs with specified resource limits and attributes.

The *qselect* utility shall accept a *resource_list* option-argument with the following syntax:

`resource_name op value [,,resource_name op value,, ...]`

When comparing resource values, the *qselect* utility shall use the following definitions for the *op* component of the option-argument:

`.eq.`	The value of the resource of the same name in the *Resource_List* attribute of the batch job equals the value of the value component of the option-argument.
`.ge.`	The value of the resource of the same name in the *Resource_List* attribute of the batch job is greater than or equal to the value of the *value* component of the option-argument.
`.gt.`	The value of the resource of the same name in the *Resource_List* attribute of the batch job is greater than the value of the value component of the option-argument.
`.lt.`	The value of the resource of the same name in the *Resource_List* attribute of the batch job is less than the value of the value component of the option-argument.
`.ne.`	The value of the resource of the same name in the *Resource_List* attribute of the batch job does not equal the value of the value component of the option-argument.
`.le.`	The value of the resource of the same name in the *Resource_List* attribute of the batch job is less than or equal to the value of the *value* component of the option-argument.

When comparing the limit of a *Resource_List* attribute with the *value* component of the option-argument, if the limit, the value, or both are non-numeric, only equality or inequality are valid comparisons.

The *qselect* utility shall select only batch jobs for which the values of the *resource_names* listed in the *resource_list* option-argument match the corresponding limits of the *Resource_List* attribute of the batch job.

Limits of *resource_names* present in the *Resource_List* attribute of the batch job that have no corresponding values in the *resource_list* option-argument shall not be considered when selecting batch jobs.

−N *name* Restrict selection to batch jobs with a specified name.

The *qselect* utility shall select only batch jobs for which the value of the *Job_Name* attribute matches the value of the *name* option-argument. The string specified in the *name* option-argument shall be passed, uninterpreted, to the server. This allows an implementation to match ‘‘wildcard’’ patterns against batch job names.

An implementation shall describe in the conformance document the format it supports for matching against the *Job_Name* attribute.

−p [*op***]***priority*

Restrict selection to batch jobs of the specified priority or range of priorities.

The *qselect* utility shall select only batch jobs for which the value of the *Priority* attribute of the batch job relates to the value of the *priority* component of the option-argument in the manner indicated by the value of the *op* component of the option-argument.

If the *op* component of the option-argument is omitted, the *qselect* utility shall select batch jobs for which the value of the *Priority* attribute of the batch job is equal to the value of the *priority* component of the option-argument.

When comparing priority values, the *qselect* utility shall use the following definitions for the *op* component of the option-argument:

`.eq.` The value of the *Priority* attribute of the batch job equals the value of the *priority* component of the option-argument.

`.ge.` The value of the *Priority* attribute of the batch job is greater than or equal to the value of the *priority* component option-argument.

`.gt.` The value of the *Priority* attribute of the batch job is greater than the value of the *priority* component option-argument.

`.lt.` The value of the *Priority* attribute of the batch job is less than the value of the *priority* component option-argument.

`.lt.` The value of the *Priority* attribute of the batch job is less than or equal to the value of the *priority* component option-argument.

`.ne.` The value of the *Priority* attribute of the batch job does not equal the value of the *priority* component option-argument.

−q *destination*

Restrict selection to the specified batch queue or server, or both.

The *qselect* utility shall select only batch jobs that are located at the destination indicated by the value of the *destination* option-argument.

The destination defines a batch queue, a server, or a batch queue at a server.

The *qselect* utility shall accept an option-argument for the **−q** option that conforms to the syntax for a destination. If the **−q** option is not presented to the *qselect* utility, the utility shall select batch jobs from all batch queues at the default batch server.

If the option-argument describes only a batch queue, the *qselect* utility shall select only batch jobs from the batch queue of the specified name at the default batch server. The means by which *qselect* determines the default server is implementation-defined.

If the option-argument describes only a batch server, the *qselect* utility shall select batch jobs from all the batch queues at that batch server.

If the option-argument describes both a batch queue and a batch server, the *qselect* utility shall select only batch jobs from the specified batch queue at the specified server.

−r `y|n` Restrict selection to batch jobs with the specified rerunability status.

The *qselect* utility shall select only batch jobs for which the value of the *Rerunable* attribute of the batch job matches the value of the option-argument.

The *qselect* utility shall accept a value for the option-argument that consists of either the single character `'y'` or the single character `'n'`. The character `'y'` represents the value TRUE, and the character `'n'` represents the value FALSE.

−s *states* Restrict selection to batch jobs in the specified states.

The *qselect* utility shall accept an option-argument that consists of any combination of the characters `'e'`, `'q'`, `'r'`, `'w'`, `'h'`, and `'t'`.

Conforming applications shall not repeat any character in the option-argument. The *qselect* utility shall permit the repetition of characters in the option-argument, but shall not assign additional meaning to repeated characters.

The *qselect* utility shall interpret the characters in the *states* option-argument as follows:

`e`	Represents the EXITING state.
`q`	Represents the QUEUED state.
`r`	Represents the RUNNING state.
`t`	Represents the TRANSITING state.
`h`	Represents the HELD state.
`w`	Represents the WAITING state.

For each character in the *states* option-argument, the *qselect* utility shall select batch jobs in the corresponding state.

−u *user_list* Restrict selection to batch jobs owned by the specified user names.

The *qselect* utility shall select only the batch jobs of those users specified in the *user_list* option-argument.

The *qselect* utility shall accept a *user_list* option-argument that conforms to the following syntax:

```
username[@host][,,username[@host],, ...]
```

The *qselect* utility shall accept only one user name that is missing a corresponding host name. The *qselect* utility shall accept only one user name per named host.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qselect*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME	Determine the login name of the user.
TZ	Determine the timezone used to interpret the *date-time* option-argument. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *qselect* utility shall write zero or more batch *job_identifier*s to standard output.

The *qselect* utility shall separate the batch *job_identifier*s written to standard output by white space.

The *qselect* utility shall write batch *job_identifier*s in the following format:

```
sequence_number.server_name@server
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

The following example shows how a user might use the *qselect* utility in conjunction with the *qdel* utility to delete all of his or her jobs in the queued state without affecting any jobs that are already running:

```
qdel $(qselect −s q)
```

or:

```
qselect −s q || xargs qdel
```

RATIONALE

The *qselect* utility allows users to acquire a list of job identifiers that match user-specified selection criteria. The list of identifiers returned by the *qselect* utility conforms to the syntax of the batch job identifier list processed by a utility such as *qmove*, *qdel*, and *qrls*.The *qselect* utility is thus a powerful tool for causing another batch system utility to act upon a set of jobs that match a list of selection criteria.

The options of the *qselect* utility let the user apply a number of useful filters for selecting jobs. Each option further restricts the selection of jobs. Many of the selection options allow the specification of a relational operator. The FORTRAN-like syntax of the operator—that is, `".lt."`, was chosen rather than the C-like "<=" meta-characters.

The −**a** option allows users to restrict the selected jobs to those that have been submitted (or altered) to wait until a particular time. The time period is determined by the argument of this option, which includes both a time and an operator—it is thus possible to select jobs waiting until a specific time, jobs waiting until after a certain time, or those waiting for a time before the specified time.

The −**A** option allows users to restrict the selected jobs to those that have been submitted (or altered) to charge a particular account.

The −**c** option allows users to restrict the selected jobs to those whose checkpointing interval falls within the specified range.

The −**l** option allows users to select those jobs whose resource limits fall within the range indicated by the value of the option. For example, a user could select those jobs for which the CPU time limit is greater than two hours.

The −**N** option allows users to select jobs by job name. For instance, all the parts of a task that have been divided in parallel jobs might be given the same name, and thus manipulated as a group by means of this option.

The −**q** option allows users to select jobs in a specified queue.

The −**r** option allows users to select only those jobs with a specified rerun criteria. For instance, a user might select only those jobs that can be rerun for use with the *qrerun* utility.

The −**s** option allows users to select only those jobs that are in a certain state.

The −**u** option allows users to select jobs that have been submitted to execute under a particular account.

The selection criteria provided by the options of the *qselect* utility allow users to select jobs based on all the appropriate attributes that can be assigned to jobs by the *qsub* utility.

Historically, the *qselect* utility has not been a part of existing practice; it is an improvement that has been introduced in this volume of IEEE Std 1003.1-200x.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

NAME

qsig — signal batch jobs

SYNOPSIS

BE

```
qsig [−s signal] job_identifier ...
```

DESCRIPTION

To signal a batch job is to send a signal to the session leader of the batch job. A batch job is signaled by sending a request to the batch server that manages the batch job. The *qsig* utility is a user-accessible batch client that requests the signaling of a batch job.

The *qsig* utility shall signal those batch jobs for which a batch *job_identifier* is presented to the utility. The *qsig* utility shall not signal any batch jobs whose batch *job_identifier*s are not presented to the utility.

The *qsig* utility shall signal batch jobs in the order in which the corresponding batch *job_identifier*s are presented to the utility. If the *qsig* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qsig* utility shall signal batch jobs by sending a *Signal Job Request* to the batch server that manages the batch job.

For each successfully processed batch *job_identifier*, the *qsig* utility shall have received a completion reply to each *Signal Job Request* sent to a batch server at the time the utility exits.

OPTIONS

The *qsig* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:

−**s** *signal* Define the signal to be sent to the batch job.

The *qsig* utility shall accept a *signal* option-argument that is either a symbolic signal name or an unsigned integer signal number (see the POSIX.1-1990 standard, Section 3.3.1.1). The *qsig* utility shall accept signal names for which the SIG prefix has been omitted.

If the *signal* option-argument is a signal name, the *qsig* utility shall send that name.

If the *signal* option-argument is a number, the *qsig* utility shall send the signal value represented by the number.

If the −**s** option is not presented to the *qsig* utility, the utility shall send the signal SIGTERM to each signaled batch job.

OPERANDS

The *qsig* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2324)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qsig*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME	Determine the login name of the user.

ASYNCHRONOUS EVENTS

Default.

STDOUT

An implementation of the *qsig* utility may write informative messages to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qsig* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qsig* utility waits to output the diagnostic message while attempting to locate the batch job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qsig* utility allows users to signal batch jobs.

A user may be unable to signal a batch job with the *kill* utility of the operating system for a number of reasons. First, the process ID of the batch job may be unknown to the user. Second, the processes of the batch job may be on a remote node. However, by virtue of communication between batch nodes, the *qsig* utility can arrange for the signaling of a process.

Because a batch job that is not running cannot be signaled, and because the signal may not terminate the batch job, the *qsig* utility is not a substitute for the *qdel* utility.

The options of the *qsig* utility allow the user to specify the signal that is to be sent to the batch job.

The −**s** option allows users to specify a signal by name or by number, and thus override the default signal. The POSIX.1-1990 standard defines signals by both name and number.

The *qsig* utility is a new utility, *vis-a-vis* existing practice; it has been defined in this volume of IEEE Std 1003.1-200x in response to user-perceived shortcomings in existing practice.

FUTURE DIRECTIONS

None.

kill, *qdel*, Chapter 3 (on page 2303)

CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

Issue 6

The *LC_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

NAME

qstat — show status of batch jobs

SYNOPSIS

BE

```
qstat [−f] job_identifier ...

qstat −Q [−f] destination ...

qstat −B [−f] server_name ...
```

DESCRIPTION

The status of a batch job, batch queue, or batch server is obtained by a request to the server. The *qstat* utility is a user-accessible batch client that requests the status of one or more batch jobs, batch queues, or servers, and writes the status information to standard output.

For each successfully processed batch *job_identifier*, the *qstat* utility shall display information about the corresponding batch job.

For each successfully processed destination, the *qstat* utility shall display information about the corresponding batch queue.

For each successfully processed server name, the *qstat* utility shall display information about the corresponding server.

The *qstat* utility shall acquire batch job status information by sending a *Job Status Request* to a batch server. The *qstat* utility shall acquire batch queue status information by sending a *Queue Status Request* to a batch server. The *qstat* utility shall acquire server status information by sending a *Server Status Request* to a batch server.

OPTIONS

The *qstat* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

−f Specify that a full display is produced.

The minimum contents of a full display are specified in the STDOUT section.

Additional contents and format of a full display are implementation-defined.

−Q Specify that the operand is a destination.

The *qstat* utility shall display information about each batch queue at each destination identified as an operand.

−B Specify that the operand is a server name.

The *qstat* utility shall display information about each server identified as an operand.

OPERANDS

If the **−Q** option is presented to the *qstat* utility, the utility shall accept one or more operands that conform to the syntax for a destination (see Section 3.3.2 (on page 2325)).

If the **−B** option is presented to the *qstat* utility, the utility shall accept one or more *server_name* operands.

If neither the **−B** nor the **−Q** option is presented to the *qstat* utility, the utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2324)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qstat*:

HOME	Determine the pathname of the user's home directory.
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes and multi-character collating elements within regular expressions.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_NUMERIC	Determine the locale for selecting the radix character used when writing floating-point formatted output.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If an operand presented to the *qstat* utility is a batch *job_identifier* and the −**f** option is not specified, the *qstat* utility shall display the following items on a single line, in the stated order, with white space between each item, for each successfully processed operand:

- The batch *job_identifier*
- The batch job name
- The *Job_Owner* attribute
- The CPU time used by the batch job
- The batch job state
- The batch job location

If an operand presented to the *qstat* utility is a batch *job_identifier* and the −**f** option is specified, the *qstat* utility shall display the following items for each success fully processed operand:

- The batch *job_identifier*
- The batch job name

- The *Job_Owner* attribute
- The execution user ID
- The CPU time used by the batch job
- The batch job state
- The batch job location
- Additional implementation-defined information, if any, about the batch job or batch queue

If an operand presented to the *qstat* utility is a destination, the −**Q** option is specified, and the −**f** option is not specified, the *qstat* utility shall display the following items on a single line, in the stated order, with white space between each item, for each successfully processed operand:

- The batch queue name
- The maximum number of batch jobs that shall be run in the batch queue concurrently
- The total number of batch jobs in the batch queue
- The status of the batch queue
- For each state, the number of batch jobs in that state in the batch queue and the name of the state
- The type of batch queue (execution or routing)

If the operands presented to the *qstat* utility are destinations, the −**Q** option is specified, and the −**f** option is specified, the *qstat* utility shall display the following items for each successfully processed operand:

- The batch queue name
- The maximum number of batch jobs that shall be run in the batch queue concurrently
- The total number of batch jobs in the batch queue
- The status of the batch queue
- For each state, the number of batch jobs in that state in the batch queue and the name of the state
- The type of batch queue (execution or routing)
- Additional implementation-defined information, if any, about the batch queue

If the operands presented to the *qstat* utility are batch server names, the −**B** option is specified, and the −**f** option is not specified, the *qstat* utility shall display the following items on a single line, in the stated order, with white space between each item, for each successfully processed operand:

- The batch server name
- The maximum number of batch jobs that shall be run in the batch queue concurrently
- The total number of batch jobs managed by the batch server
- The status of the batch server
- For each state, the number of batch jobs in that state and the name of the state

If the operands presented to the *qstat* utility are server names, the −**B** option is specified, and the −**f** option is specified, the *qstat* utility shall display the following items for each successfully processed operand:

- The server name
- The maximum number of batch jobs that shall be run in the batch queue concurrently
- The total number of batch jobs managed by the server
- The status of the server
- For each state, the number of batch jobs in that state and the name of the state
- Additional implementation-defined information, if any, about the server

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qstat* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qstat* utility waits to output the diagnostic message while attempting to locate the batch job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qstat* utility allows users to display the status of jobs and listing the batch jobs in queues.

The operands of the *qstat* utility may be either job identifiers, queues (specified as destination identifiers), or batch server names. The **–Q** and **–B** options, or absence thereof, indicate the nature of the operands.

The other options of the *qstat* utility allow the user to control the amount of information displayed and the format in which it is displayed. Should a user wish to display the status of a set of jobs that match a selection criteria, the *qselect* utility may be used to acquire such a list.

The **–f** option allows users to request a ‘‘full’’ display in an implementation-defined format.

Historically, the *qstat* utility has been a part of the NQS and its derivatives, the existing practice on which it is based.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

Issue 6

IEEE PASC Interpretation 1003.2 #191 is applied, removing the following ENVIRONMENT VARIABLES listed as affecting *qstat*: *COLUMNS*, *LINES*, *LOGNAME*, *TERM*, and *TZ*.

The *LC_TIME* entry is also removed from the ENVIRONMENT VARIABLES section.

NAME

qsub — submit a script

SYNOPSIS

BE
```
qsub [−a date_time][−A account_string][−c interval]
    [−C directive_prefix][−e path_name][−h][−j join_list][−k keep_list]
    [−m mail_options][−M mail_list][−N name]
    [−o path_name][−p priority][−q destination][−r y|n]
    [−S path_name_list][−u user_list][−v variable_list][−V]
    [−z][script]
```

DESCRIPTION

To submit a script is to create a batch job that executes the script. A script is submitted by a request to a batch server. The *qsub* utility is a user-accessible batch client that submits a script.

Upon successful completion, the *qsub* utility shall have created a batch job that will execute the submitted script.

The *qsub* utility shall submit a script by sending a *Queue Job Request* to a batch server.

The *qsub* utility shall place the value of the following environment variables in the *Variable_List* attribute of the batch job: *HOME*, *LANG*, *LOGNAME*, *PATH*, *MAIL*, *SHELL*, and *TZ*. The name of the environment variable shall be the current name prefixed with the string PBS_O_.

Note: If the current value of the *HOME* variable in the environment space of the *qsub* utility is **/aa/bb/cc**, then *qsub* shall place *PBS_O_HOME*=**/aa/bb/cc** in the *Variable_List* attribute of the batch job.

In addition to the variables described above, the *qsub* utility shall add the following variables with the indicated values to the variable list:

PBS_O_WORKDIR	The absolute path of the current working directory of the *qsub* utility process.
PBS_O_HOST	The name of the host on which the *qsub* utility is running.

OPTIONS

The *qsub* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

−**a** *date_time* Define the time at which a batch job becomes eligible for execution.

The *qsub* utility shall accept an option-argument that conforms to the syntax of the *time* operand of the *touch* utility.

Table 4-18 Environment Variable Values (Utilities)

Variable Name	Value at qsub Time
PBS_O_HOME	*HOME*
PBS_O_HOST	Client host name
PBS_O_LANG	*LANG*
PBS_O_LOGNAME	*LOGNAME*
PBS_O_PATH	*PATH*
PBS_O_MAIL	*MAIL*
PBS_O_SHELL	*SHELL*
PBS_O_TZ	*TZ*
PBS_O_WORKDIR	Current working directory

Note: The server that initiates execution of the batch job will add other variables to the batch job's environment; see Section 3.2.2.1 (on page 2308).

The *qsub* utility shall set the *Execution_Time* attribute of the batch job to the number of seconds since the Epoch that is equivalent to the local time expressed by the value of the *date_time* option-argument. The Epoch is defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.149, Epoch.

If the −**a** option is not presented to the *qsub* utility, the utility shall set the *Execution_Time* attribute of the batch job to a time (number of seconds since the Epoch) that is earlier than the time at which the utility exits.

−**A** *account_string*

Define the account to which the resource consumption of the batch job should be charged.

The syntax of the *account_string* option-argument is unspecified.

The *qsub* utility shall set the *Account_Name* attribute of the batch job to the value of the *account_string* option-argument.

If the −**A** option is not presented to the *qsub* utility, the utility shall omit the *Account_Name* attribute from the attributes of the batch job.

−**c** *interval* Define whether the batch job should be checkpointed, and if so, how often.

The *qsub* utility shall accept a value for the interval option-argument that is one of the following:

`n` No checkpointing shall be performed on the batch batch job (NO_CHECKPOINT).

`s` Checkpointing shall be performed only when the batch server is shut down (CHECKPOINT_AT_SHUTDOWN).

`c` Automatic periodic checkpointing shall be performed at the *Minimum_Cpu_Interval* attribute of the batch queue, in units of CPU minutes (CHECKPOINT_AT_MIN_CPU_INTERVAL).

`c=`*minutes* Automatic periodic checkpointing shall be performed every minutes of CPU time, or every *Minimum_Cpu_Interval* minutes, whichever is greater. The *minutes* argument shall conform to the syntax for unsigned integers and shall be greater than zero.

The *qsub* utility shall set the *Checkpoint* attribute of the batch job to the value of the *interval* option-argument.

If the **–c** option is not presented to the *qsub* utility, the utility shall set the *Checkpoint* attribute of the batch job to the single character `'u'` (CHECKPOINT_UNSPECIFIED).

–C *directive_prefix*
Define the prefix that declares a directive to the *qsub* utility within the script.

The *directive_prefix* is not a batch job attribute; it affects the behavior of the *qsub* utility.

If the **–C** option is presented to the *qsub* utility, and the value of the *directive_prefix* option-argument is the null string, the utility shall not scan the script file for directives. If the **–C** option is not presented to the *qsub* utility, then the value of the *PBS_DPREFIX* environment variable is used. If the environment variable is not defined, then #PBS encoded in the portable character set is the default.

–e *path_name* Define the path to be used for the standard error stream of the batch job.

The *qsub* utility shall accept a *path_name* option-argument which can be preceded by a host name element of the form *hostname*:.

If the *path_name* option-argument constitutes an absolute pathname, the *qsub* utility shall set the *Error_Path* attribute of the batch job to the value of the *path_name* option-argument.

If the *path_name* option-argument constitutes a relative pathname and no host name element is specified, the *qsub* utility shall set the *Error_Path* attribute of the batch job to the value of the absolute pathname derived by expanding the *path_name* option-argument relative to the current directory of the process executing *qsub*.

If the *path_name* option-argument constitutes a relative pathname and a host name element is specified, the *qsub* utility shall set the *Error_Path* attribute of the batch job to the value of the *path_name* option-argument without expansion. The host name element shall be included.

If the *path_name* option-argument does not include a host name element, the *qsub* utility shall prefix the pathname with *hostname*:, where *hostname* is the name of the host upon which the *qsub* utility is being executed.

If the **–e** option is not presented to the *qsub* utility, the utility shall set the *Error_Path* attribute of the batch job to the host name and path of the current directory of the submitting process and the default filename.

The default filename for standard error has the following format:

`job_name.esequence_number`

–h Specify that a USER hold is applied to the batch job.

The *qsub* utility shall set the value of the *Hold_Types* attribute of the batch job to the value USER.

If the **–h** option is not presented to the *qsub* utility, the utility shall set the *Hold_Types* attribute of the batch job to the value NO_HOLD.

–j *join_list* Define which streams of the batch job are to be merged. The *qsub* **–j** option shall accept a value for the *join_list* option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).

The *qsub* utility shall accept a *join_list* option-argument that consists of one or more of the characters `'e'` and `'o'` or the single character `'n'`.

All of the other batch job output streams specified will be merged into the output stream represented by the character listed first in the *join_list* option-argument.

For each unique character in the *join_list* option-argument, the *qsub* utility shall add a value to the *Join_Path* attribute of the batch job as follows, each representing a different batch job stream to join:

`e` The standard error of the batch batch job (JOIN_STD_ERROR).

`o` The standard output of the batch batch job (JOIN_STD_OUTPUT).

An existing *Join_Path* attribute can be cleared by the following join type:

`n` NO_JOIN

If `'n'` is specified, then no files are joined. The *qsub* utility shall consider it an error if any join type other than `'n'` is combined with join type `'n'`.

Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or `'n'` within the *join_list* option-argument. The *qsub* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other join types. The conformance document for an implementation shall describe any additional batch job streams, how they are specified, their internal behavior, and how they affect the behavior of the utility.

If the −**j** option is not presented to the *qsub* utility, the utility shall set the value of the *Join_Path* attribute of the batch job to NO_JOIN.

−**k** *keep_list* Define which output of the batch job to retain on the execution host.

The *qsub* −**k** option shall accept a value for the *keep_list* option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).

The *qsub* utility shall accept a *keep_list* option-argument that consists of one or more of the characters `'e'` and `'o'` or the single character `'n'`.

For each unique character in the *keep_list* option-argument, the *qsub* utility shall add a value to the *Keep_Files* attribute of the batch job as follows, each representing a different batch job stream to keep:

`e` The standard error of the batch batch job (KEEP_STD_ERROR).

`o` The standard output of the batch batch job (KEEP_STD_OUTPUT).

If both `'e'` and `'o'` are specified, then both files are retained. An existing *Keep_Files* attribute can be cleared by the following keep type:

`n` NO_KEEP

If `'n'` is specified, then no files are retained. The *qsub* utility shall consider it an error if any keep type other than `'n'` is combined with keep type `'n'`.

Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or `'n'` within the *keep_list* option-argument. The *qsub* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other keep types. The conformance document for an implementation shall describe any additional keep types, how they are specified, their internal behavior, and how they affect the behavior of the utility. If the −**k** option is not presented to the *qsub* utility, the utility shall set the *Keep_Files* attribute of the batch job to the value NO_KEEP.

−**m** *mail_options*

Define the points in the execution of the batch job at which the batch server that manages the batch job shall send mail about a change in the state of the batch job.

The *qsub* −**m** option shall accept a value for the *mail_options* option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).

The *qsub* utility shall accept a value for the *mail_options* option-argument that is a string of one or more of the characters `'e'`, `'b'`, and `'a'`, or the single character `'n'`.

For each unique character in the *mail_options* option-argument, the *qsub* utility shall add a value to the *Mail_Users* attribute of the batch job as follows, each representing a different time during the life of a batch job at which to send mail:

`e`	MAIL_AT_EXIT
`b`	MAIL_AT_BEGINNING
`a`	MAIL_AT_ABORT

If any of these characters are duplicated in the *mail_options* option-argument, the duplicates shall be ignored.

An existing *Mail_Points* attribute can be cleared by the following mail type:

`n`	NO_MAIL

If `'n'` is specified, then mail is not sent. The *qsub* utility shall consider it an error if any mail type other than `'n'` is combined with mail type `'n'`.

Strictly conforming applications shall not repeat any of the characters `'e'`, `'b'`, `'a'`, or `'n'` within the *mail_options* option-argument.

The *qsub* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters. An implementation may define other mail types. The conformance document for an implementation shall describe any additional mail types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

If the −**m** option is not presented to the *qsub* utility, the utility shall set the *Mail_Points* attribute to the value MAIL_AT_ABORT.

−**M** *mail_list* Define the list of users to which a batch server that executes the batch job shall send mail, if the server sends mail about the batch job.

The syntax of the *mail_list* option-argument is unspecified.

If the implementation of the *qsub* utility uses a name service to locate users, the utility should accept the syntax used by the name service.

If the implementation of the *qsub* utility does not use a name service to locate users, the implementation should accept the following syntax for user names:

`mail_address[,,mail_address,, ...]`

The interpretation of *mail_address* is implementation-defined.

The *qsub* utility shall set the *Mail_Users* attribute of the batch job to the value of the *mail_list* option-argument.

If the −**M** option is not presented to the *qsub* utility, the utility shall place only the user name and host name for the current process in the *Mail_Users* attribute of the batch job.

−**N** *name* Define the name of the batch job.

The *qsub* −**N** option shall accept a value for the *name* option-argument that is a string of up to 15 alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set) where the first character is alphabetic.

The *qsub* utility shall set the value of the *Job_Name* attribute of the batch job to the value of the *name* option-argument.

If the −**N** option is not presented to the *qsub* utility, the utility shall set the *Job_Name* attribute of the batch job to the name of the *script* argument from which the directory specification if any, has been removed.

If the −**N** option is not presented to the *qsub* utility, and the script is read from standard input, the utility shall set the *Job_Name* attribute of the batch job to the value STDIN.

−**o** *path_name* Define the path for the standard output of the batch job.

The *qsub* utility shall accept a *path_name* option-argument that conforms to the syntax of the *path_name* element defined in the System Interfaces volume of IEEE Std 1003.1-200x, which can be preceded by a host name element of the form *hostname*:.

If the *path_name* option-argument constitutes an absolute pathname, the *qsub* utility shall set the *Output_Path* attribute of the batch job to the value of the *path_name* option-argument without expansion.

If the *path_name* option-argument constitutes a relative pathname and no host name element is specified, the *qsub* utility shall set the *Output_Path* attribute of the batch job to the pathname derived by expanding the value of the *path_name* option-argument relative to the current directory of the process executing the *qsub*.

If the *path_name* option-argument constitutes a relative pathname and a host name element is specified, the *qsub* utility shall set the *Output_Path* attribute of the batch job to the value of the *path_name* option-argument without expansion.

If the *path_name* option-argument does not specify a host name element, the *qsub* utility shall prefix the pathname with *hostname*:, where *hostname* is the name of the host upon which the *qsub* utility is executing.

If the −**o** option is not presented to the *qsub* utility, the utility shall set the *Output_Path* attribute of the batch job to the host name and path of the current directory of the submitting process and the default filename.

The default filename for standard output has the following format:

`job_name.osequence_number`

−p *priority* Define the priority the batch job should have relative to other batch jobs owned by the batch server.

The *qsub* utility shall set the *Priority* attribute of the batch job to the value of the *priority* option-argument.

If the **−p** option is not presented to the *qsub* utility, the value of the *Priority* attribute is implementation-defined.

The *qsub* utility shall accept a value for the *priority* option-argument that conforms to the syntax for signed decimal integers, and which is not less than −1 024 and not greater than 1 023.

−q *destination*

Define the destination of the batch job.

The destination is not a batch job attribute; it determines the batch server, and possibly the batch queue, to which the *qsub* utility batch queues the batch job.

The *qsub* utility shall submit the script to the batch server named by the *destination* option-argument or the server that owns the batch queue named in the *destination* option-argument.

The *qsub* utility shall accept an option-argument for the **−q** option that conforms to the syntax for a destination (see Section 3.3.2 (on page 2325)).

If the **−q** option is not presented to the *qsub* utility, the *qsub* utility shall submit the batch job to the default destination. The mechanism for determining the default destination is implementation-defined.

−r *y* | *n* Define whether the batch job is rerunable.

If the value of the option-argument is *y*, the *qsub* utility shall set the *Rerunable* attribute of the batch job to TRUE.

If the value of the option-argument is *n*, the *qsub* utility shall set the *Rerunable* attribute of the batch job to FALSE.

If the **−r** option is not presented to the *qsub* utility, the utility shall set the *Rerunable* attribute of the batch job to TRUE.

−S *path_name_list*

Define the pathname to the shell under which the batch job is to execute.

The *qsub* utility shall accept a *path_name_list* option-argument that conforms to the following syntax:

```
pathname[@host][,,pathname[@host],, ...]
```

The *qsub* utility shall allow only one pathname for a given host name. The *qsub* utility shall allow only one pathname that is missing a corresponding host name.

The *qsub* utility shall add a value to the *Shell_Path_List* attribute of the batch job for each entry in the *path_name_list* option-argument.

If the **−S** option is not presented to the *qsub* utility, the utility shall set the *Shell_Path_List* attribute of the batch job to the null string.

The conformance document for an implementation shall describe the mechanism used to set the default shell and determine the current value of the default shell. An implementation shall provide a means for the installation to set the default shell to the login shell of the user under which the batch job is to execute. See

Section 3.3.3 (on page 2325) for a means of removing *keyword*=*value* (and *value*@*keyword*) pairs and other general rules for list-oriented batch job attributes.

−u *user_list* Define the user name under which the batch job is to execute.

The *qsub* utility shall accept a *user_list* option-argument that conforms to the following syntax:

`username[@host][,,username[@host],, ...]`

The *qsub* utility shall accept only one user name that is missing a corresponding host name. The *qsub* utility shall accept only one user name per named host.

The *qsub* utility shall add a value to the *User_List* attribute of the batch job for each entry in the *user_list* option-argument.

If the **−u** option is not presented to the *qsub* utility, the utility shall set the *User_List* attribute of the batch job to the user name from which the utility is executing. See Section 3.3.3 (on page 2325) for a means of removing *keyword*=*value* (and *value*@*keyword*) pairs and other general rules for list-oriented batch job attributes.

−v *variable_list*

Add to the list of variables that are exported to the session leader of the batch job.

A *variable_list* is a set of strings of either the form <*variable*> or <*variable*=*value*>, delimited by commas.

If the **−v** option is presented to the *qsub* utility, the utility shall also add, to the environment *Variable_List* attribute of the batch job, every variable named in the environment *variable_list* option-argument and, optionally, values of specified variables.

If a value is not provided on the command line, the *qsub* utility shall set the value of each variable in the environment *Variable_List* attribute of the batch job to the value of the corresponding environment variable for the process in which the utility is executing; see Table 4-18 (on page 3003).

A conforming application shall not repeat a variable in the environment *variable_list* option-argument.

The *qsub* utility shall not repeat a variable in the environment *Variable_List* attribute of the batch job. See Section 3.3.3 (on page 2325) for a means of removing *keyword*=*value* (and *value*@*keyword*) pairs and other general rules for list-oriented batch job attributes.

−V Specify that all of the environment variables of the process are exported to the context of the batch job.

The *qsub* utility shall place every environment variable in the process in which the utility is executing in the list and shall set the value of each variable in the attribute to the value of that variable in the process.

−z Specify that the utility does not write the batch *job_identifier* of the created batch job to standard output.

If the **−z** option is presented to the *qsub* utility, the utility shall not write the batch *job_identifier* of the created batch job to standard output.

If the **−z** option is not presented to the *qsub* utility, the utility shall write the identifier of the created batch job to standard output.

OPERANDS

The *qsub* utility shall accept a *script* operand that indicates the path to the script of the batch job.

If the *script* operand is not presented to the *qsub* utility, or if the operand is the single-character string `'-'`, the utility shall read the script from standard input.

If the script represents a partial path, the *qsub* utility shall expand the path relative to the current directory of the process executing the utility.

STDIN

The *qsub* utility reads the script of the batch job from standard input if the script operand is omitted or is the single character `'-'`.

INPUT FILES

In addition to binding the file indicated by the *script* operand to the batch job, the *qsub* utility reads the script file and acts on directives in the script.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qsub*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME	Determine the login name of the user.
PBS_DPREFIX	Determine the default prefix for directives within the script.
SHELL	Determine the pathname of the preferred command language interpreter of the user.
TZ	Determine the timezone used to interpret the *date-time* option-argument. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Once created, a batch job exists until it exits, aborts, or is deleted.

After a batch job is created by the *qsub* utility, batch servers might route, execute, modify, or delete the batch job.

STDOUT

The *qsub* utility writes the batch *job_identifier* assigned to the batch job to standard output, unless the **−z** option is specified.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

Script Preservation

The *qsub* utility shall make the script available to the server executing the batch job in such a way that the server executes the script as it exists at the time of submission.

The *qsub* utility can send a copy of the script to the server with the *Queue Job Request* or store a temporary copy of the script in a location specified to the server.

Option Specification

A script can contain directives to the *qsub* utility.

The *qsub* utility shall scan the lines of the script for directives, skipping blank lines, until the first line that begins with a string other than the directive string; if directives occur on subsequent lines, the utility shall ignore those directives.

Lines are separated by a <newline>. If the first line of the script begins with `"#!"` or a colon (`':'`), then it is skipped. The *qsub* utility shall process a line in the script as a directive if and only if the string of characters from the first non-white-space character on the line until the first <space> or <tab> on the line match the directive prefix. If a line in the script contains a directive and the final characters of the line are backslash (`'\'`) and <newline>, then the next line shall be interpreted as a continuation of that directive.

The *qsub* utility shall process the options and option-arguments contained on the directive prefix line using the same syntax as if the options were input on the *qsub* utility.

The *qsub* utility shall continue to process a directive prefix line until after a <newline> is encountered. An implementation may ignore lines which, according to the syntax of the shell that will interpret the script, are comments. An implementation shall describe in the conformance document the format of any shell comments that it will recognize.

If an option is present in both a directive and the arguments to the *qsub* utility, the utility shall ignore the option and the corresponding option-argument, if any, in the directive.

If an option that is present in the directive is not present in the arguments to the *qsub* utility, the utility shall process the option and the option-argument, if any.

In order of preference, the *qsub* utility shall select the directive prefix from one of the following sources:

- If the **–C** option is presented to the utility, the value of the *directive_prefix* option-argument
- If the environment variable *PBS_DPREFIX* is defined, the value of that variable
- The four-character string `"#PBS"` encoded in the portable character set

If the **–C** option is present in the script file it shall be ignored.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qsub* utility allows users to create a batch job that will process the script specified as the operand of the utility.

The options of the *qsub* utility allow users to control many aspects of the queuing and execution of a batch job.

The −**a** option allows users to designate the time after which the batch job will become eligible to run. By specifying an execution time, users can take advantage of resources at off-peak hours, synchronize jobs with chronologically predictable events, and perhaps take advantage of off-peak pricing of computing time. For these reasons and others, a timing option is existing practice on the part of almost every batch system, including NQS.

The −**A** option allows users to specify the account that will be charged for the batch job. Support for account is not mandatory for conforming batch servers.

The −**C** option allows users to prescribe the prefix for directives within the script file. The default prefix `"#PBS"` may be inappropriate if the script will be interpreted with an alternate shell, as specified by the −**S** option.

The −**c** option allows users to establish the checkpointing interval for their jobs. A checkpointing system, which is not defined by this volume of IEEE Std 1003.1-200x, allows recovery of a batch job at the most recent checkpoint in the event of a crash. Checkpointing is typically used for jobs that consume expensive computing time or must meet a critical schedule. Users should be allowed to make the tradeoff between the overhead of checkpointing and the risk to the timely completion of the batch job; therefore, this volume of IEEE Std 1003.1-200x provides the checkpointing interval option. Support for checkpointing is optional for batch servers.

The −**e** option allows users to redirect the standard error streams of their jobs to a non-default path. For example, if the submitted script generally produces a great deal of useless error output, a user might redirect the standard error output to the null device. Or, if the file system holding the default location (the home directory of the user) has too little free space, the user might redirect the standard error stream to a file in another file system.

The −**h** option allows users to create a batch job that is held until explicitly released. The ability to create a held job is useful when some external event must complete before the batch job can execute. For example, the user might submit a held job and release it when the system load has dropped.

The −**j** option allows users to merge the standard error of a batch job into its standard output stream, which has the advantage of showing the sequential relationship between output and error messages.

The −**m** option allows users to designate those points in the execution of a batch job at which mail will be sent to the submitting user, or to the account(s) indicated by the −**M** option. By requesting mail notification at points of interest in the life of a job, the submitting user, or other designated users, can track the progress of a batch job.

The –**N** option allows users to associate a name with the batch job. The job name in no way affects the processing of the batch job, but rather serves as a mnemonic handle for users. For example, the batch job name can help the user distinguish between multiple jobs listed by the *qstat* utility.

The –**o** option allows users to redirect the standard output stream. A user might, for example, wish to redirect to the null device the standard output stream of a job that produces copious yet superfluous output.

The –**P** option allows users to designate the relative priority of a batch job for selection from a queue.

The –**q** option allows users to specify an initial queue for the batch job. If the user specifies a routing queue, the batch batch server routes the batch job to another queue for execution or further routing. If the user specifies a non-routing queue, the batch server of the queue eventually executes the batch job.

The –**r** option allows users to control whether the submitted job will be rerun if the controlling batch node fails during execution of the batch job. The –**r** option likewise allows users to indicate whether or not the batch job is eligible to be rerun by the *qrerun* utility. Some jobs cannot be correctly rerun because of changes they make in the state of databases or other aspects of their environment. This volume of IEEE Std 1003.1-200x specifies that the default, if the –**r** option is not presented to the utility, will be that the batch job cannot be rerun, since the result of rerunning a non-rerunable job might be catastrophic.

The –**S** option allows users to specify the program (usually a shell) that will be invoked to process the script of the batch job. This option has been modified to allow a list of shell names and locations associated with different hosts.

The –**u** option is useful when the submitting user is authorized to use more than one account on a given host, in which case the –**u** option allows the user to select from among those accounts. The option-argument is a list of user-host pairs, so that the submitting user can provide different user identifiers for different nodes in the event the batch job is routed. The –**u** option provides a lot of flexibility to accommodate sites with complex account structures. Users that have the same user identifier on all the hosts they are authorized to use will not need to use the –**u** option.

The –**V** option allows users to export all their current environment variables, as of the time the batch job is submitted, to the context of the processes of the batch job.

The –**v** option allows users to export specific environment variables from their current process to the processes of the batch job.

The –**z** option allows users to suppress the writing of the batch job identifier to standard output. The –**z** option is an existing NQS practice that has been standardized.

Historically, the *qsub* utility has served the batch job-submission function in the NQS system, the existing practice on which it is based. Some changes and additions have been made to the *qsub* utility in this volume of IEEE Std 1003.1-200x, *vis-a-vis* NQS, as a result of the growing pool of experience with distributed batch systems.

The set of features of the *qsub* utility as defined in this volume of IEEE Std 1003.1-200x appears to incorporate all the common existing practice on potentially POSIX-conformant platforms.

FUTURE DIRECTIONS

None.

SEE ALSO

qrerun, *qstat*, *touch*, Chapter 3 (on page 2303)

CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

Issue 6

The **–l** option has been removed as there is no portable description of the resources that are allowed or required by the batch job.

NAME

read — read a line from standard input

SYNOPSIS

```
read [−r] var...
```

DESCRIPTION

The *read* utility shall read a single line from standard input.

By default, unless the **−r** option is specified, backslash (`'\'`) shall act as an escape character, as described in Section 2.2.1 (on page 2232). If standard input is a terminal device and the invoking shell is interactive, *read* shall prompt for a continuation line when:

- The shell reads an input line ending with a backslash, unless the **−r** option is specified.
- A here-document is not terminated after a <newline> is entered.

The line shall be split into fields as in the shell (see Section 2.6.5 (on page 2243)); the first field shall be assigned to the first variable *var*, the second field to the second variable *var*, and so on. If there are fewer *var* operands specified than there are fields, the leftover fields and their intervening separators shall be assigned to the last *var*. If there are fewer fields than *var*s, the remaining *var*s shall be set to empty strings.

The setting of variables specified by the *var* operands shall affect the current shell execution environment; see Section 2.12 (on page 2263). If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(read foo)
nohup read ...
find . −exec read ... \;
```

it shall not affect the shell variables in the caller's environment.

OPTIONS

The *read* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option is supported:

−r	Do not treat a backslash character in any special way. Consider each backslash to be part of the input line.

OPERANDS

The following operand shall be supported:

var	The name of an existing or nonexisting shell variable.

STDIN

The standard input shall be a text file.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *read*:

IFS	Determine the internal field separators used to delimit fields; see Section 2.5.3 (on page 2236).
LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables

	used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
PS2	Provide the prompt string that an interactive shell shall write to standard error when a line ending with a backslash is read and the **–r** option was not specified, or if a here-document is not terminated after a <newline> is entered.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used for diagnostic messages and prompts for continued input.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	End-of-file was detected or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The **–r** option is included to enable *read* to subsume the purpose of the *line* utility, which is not included in IEEE Std 1003.1-200x.

The results are undefined if an end-of-file is detected following a backslash at the end of a line when **–r** is not specified.

EXAMPLES

The following command:

```
while read –r xx yy
do
    printf "%s %s\n" "$yy" "$xx"
done < input_file
```

prints a file with the first field of each line moved to the end of the line.

RATIONALE

The *read* utility historically has been a shell built-in. It was separated off into its own utility to take advantage of the richer description of functionality introduced by this volume of IEEE Std 1003.1-200x.

Since *read* affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(read foo)
nohup read ...
find . −exec read ... \;
```

it does not affect the shell variables in the environment of the caller.

FUTURE DIRECTIONS

None.

SEE ALSO

None.

CHANGE HISTORY

First released in Issue 2.

NAME

renice — set nice values of running processes

SYNOPSIS

UP

```
renice -n increment [-g | -p | -u] ID ...
```

DESCRIPTION

The *renice* utility shall request that the nice values (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.239, Nice Value) of one or more running processes be changed. By default, the applicable processes are specified by their process IDs. When a process group is specified (see **−g**), the request shall apply to all processes in the process group.

The nice value shall be bounded in an implementation-defined manner. If the requested *increment* would raise or lower the nice value of the executed utility beyond implementation-defined limits, then the limit whose value was exceeded shall be used.

When a user is *renice*d, the request applies to all processes whose saved set-user-ID matches the user ID corresponding to the user.

Regardless of which options are supplied or any other factor, *renice* shall not alter the nice values of any process unless the user requesting such a change has appropriate privileges to do so for the specified process. If the user lacks appropriate privileges to perform the requested action, the utility shall return an error status.

The saved set-user-ID of the user's process shall be checked instead of its effective user ID when *renice* attempts to determine the user ID of the process in order to determine whether the user has appropriate privileges.

OPTIONS

The *renice* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−g	Interpret all operands as unsigned decimal integer process group IDs.
−n *increment*	Specify how the nice value of the specified process or processes is to be adjusted. The *increment* option-argument is a positive or negative decimal integer that shall be used to modify the nice value of the specified process or processes. Positive *increment* values shall cause a lower nice value. Negative *increment* values may require appropriate privileges and shall cause a higher nice value.
−p	Interpret all operands as unsigned decimal integer process IDs. The **−p** option is the default if no options are specified.
−u	Interpret all operands as users. If a user exists with a user name equal to the operand, then the user ID of that user is used in further processing. Otherwise, if the operand represents an unsigned decimal integer, it shall be used as the numeric user ID of the user.

OPERANDS

The following operands shall be supported:

ID	A process ID, process group ID, or user name/user ID, depending on the option selected.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *renice*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. Adjust the nice value so that process IDs 987 and 32 would have a lower nice value:

   ```
   renice −n 5 −p 987 32
   ```

2. Adjust the nice value so that group IDs 324 and 76 would have a higher nice value, if the user has the appropriate privileges to do so:

   ```
   renice −n −4 −g 324 76
   ```

3. Adjust the nice value so that numeric user ID 8 and user **sas** would have a lower nice value:

   ```
   renice −n 4 −u 8 sas
   ```

Useful nice value increments on historical systems include 19 or 20 (the affected processes run only when nothing else in the system attempts to run) and any negative number (to make processes run faster).

RATIONALE

The *gid*, *pid*, and *user* specifications do not fit either the definition of operand or option-argument. However, for clarity, they have been included in the OPTIONS section, rather than the OPERANDS section.

The definition of nice value is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions such as the realtime priorities in the System Interfaces volume of IEEE Std 1003.1-200x make the notion of a single underlying priority for all scheduling policies problematic. Some implementations may implement the *nice*-related features to affect all processes on the system, others to affect just the general time-sharing activities implied by this volume of IEEE Std 1003.1-200x, and others may have no effect at all. Because of the use of ‘‘implementation-defined’’ in *nice* and *renice*, a wide range of implementation strategies are possible.

Originally, this utility was written in the historical manner, using the term ‘‘nice value’’. This was always a point of concern with users because it was never intuitively obvious what this meant. With a newer version of *renice*, which used the term ‘‘system scheduling priority’’, it was hoped that novice users could better understand what this utility was meant to do. Also, it would be easier to document what the utility was meant to do. Unfortunately, the addition of the POSIX realtime scheduling capabilities introduced the concepts of process and thread scheduling priorities that were totally unaffected by the *nice*/*renice* utilities or the *nice*( )/*setpriority*( ) functions. Continuing to use the term ‘‘system scheduling priority’’ would have incorrectly suggested that these utilities and functions were indeed affecting these realtime priorities. It was decided to revert to the historical term ‘‘nice value’’ to reference this unrelated process attribute.

Although this utility has use by system administrators (and in fact appears in the system administration portion of the BSD documentation), the standard developers considered that it was very useful for individual end users to control their own processes.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

In the SYNOPSIS, an ellipsis is added to the **–u** option in all three obsolescent forms.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent forms of the SYNOPSIS are removed.

Text previously conditional on POSIX_SAVED_IDS is mandatory in this issue. This is a FIPS requirement.

NAME

rm — remove directory entries

SYNOPSIS

```
rm [−fiRr] file...
```

DESCRIPTION

The *rm* utility shall remove the directory entry specified by each *file* argument.

If either of the files dot or dot-dot are specified as the basename portion of an operand (that is, the final pathname component), *rm* shall write a diagnostic message to standard error and do nothing more with such operands.

For each *file* the following steps shall be taken:

1. If the *file* does not exist:
   a. If the **−f** option is not specified, *rm* shall write a diagnostic message to standard error.
   b. Go on to any remaining *files*.
2. If *file* is of type directory, the following steps shall be taken:
   a. If neither the **−R** option nor the **−r** option is specified, *rm* shall write a diagnostic message to standard error, do nothing more with *file*, and go on to any remaining files.
   b. If the **−f** option is not specified, and either the permissions of *file* do not permit writing and the standard input is a terminal or the **−i** option is specified, *rm* shall write a prompt to standard error and read a line from the standard input. If the response is not affirmative, *rm* shall do nothing more with the current file and go on to any remaining files.
   c. For each entry contained in *file*, other than dot or dot-dot, the four steps listed here (1 to 4) shall be taken with the entry as if it were a *file* operand. The *rm* utility shall not traverse directories by following symbolic links into other parts of the hierarchy, but shall remove the links themselves.
   d. If the **−i** option is specified, *rm* shall write a prompt to standard error and read a line from the standard input. If the response is not affirmative, *rm* shall do nothing more with the current file, and go on to any remaining files.
3. If *file* is not of type directory, the **−f** option is not specified, and either the permissions of *file* do not permit writing and the standard input is a terminal or the **−i** option is specified, *rm* shall write a prompt to the standard error and read a line from the standard input. If the response is not affirmative, *rm* shall do nothing more with the current file and go on to any remaining files.
4. If the current file is a directory, *rm* shall perform actions equivalent to the *rmdir*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x called with a pathname of the current file used as the *path* argument. If the current file is not a directory, *rm* shall perform actions equivalent to the *unlink*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x called with a pathname of the current file used as the *path* argument.

   If this fails for any reason, *rm* shall write a diagnostic message to standard error, do nothing more with the current file, and go on to any remaining files.

The *rm* utility shall be able to descend to arbitrary depths in a file hierarchy, and shall not fail due to path length limitations (unless an operand specified by the user exceeds system limitations).

OPTIONS

The *rm* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–f	Do not prompt for confirmation. Do not write diagnostic messages or modify the exit status in the case of nonexistent operands. Any previous occurrences of the **–i** option shall be ignored.
–i	Prompt for confirmation as described previously. Any previous occurrences of the **–f** option shall be ignored.
–R	Remove file hierarchies. See the DESCRIPTION.
–r	Equivalent to **–R**.

OPERANDS

The following operand shall be supported:

file	A pathname of a directory entry to be removed.

STDIN

The standard input shall be used to read an input line in response to each prompt specified in the STDOUT section. Otherwise, the standard input shall not be used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *rm*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and the behavior of character classes within regular expressions used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.
LC_MESSAGES	Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Prompts shall be written to standard error under the conditions specified in the DESCRIPTION and OPTIONS sections. The prompts shall contain the *file* pathname, but their format is otherwise unspecified. The standard error also shall be used for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All of the named directory entries for which *rm* performed actions equivalent to *rmdir*( ) or *unlink*( ) functions were removed.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *rm* utility is forbidden to remove the names dot and dot-dot in order to avoid the consequences of inadvertently doing something like:

```
rm −r .*
```

Some implementations do not permit the removal of the last link to an executable binary file that is being executed; see the [EBUSY] error in the *unlink*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x. Thus, the *rm* utility can fail to remove such files. |

The −**i** option causes *rm* to prompt and read the standard input even if the standard input is not a terminal, but in the absence of −**i** the mode prompting is not done when the standard input is not a terminal.

EXAMPLES

1. The following command:

   ```
   rm a.out core
   ```

   removes the directory entries: **a.out** and **core**.

2. The following command:

   ```
   rm −Rf junk
   ```

   removes the directory **junk** and all its contents, without prompting.

RATIONALE

For absolute clarity, paragraphs (2b) and (3) in the DESCRIPTION of *rm* describing the behavior when prompting for confirmation, should be interpreted in the following manner:

```
if ((NOT f_option) AND
    ((not_writable AND input_is_terminal) OR i_option))
```

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application not using the −**f** option, or using the −**i** option, relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

The −**r** option is historical practice on all known systems. The synonym −**R** option is provided for consistency with the other utilities in this volume of IEEE Std 1003.1-200x that provide options requesting recursive descent through the file hierarchy.

The behavior of the −**f** option in historical versions of *rm* is inconsistent. In general, along with ''forcing'' the unlink without prompting for permission, it always causes diagnostic messages to be suppressed and the exit status to be unmodified for nonexistent operands and files that cannot be unlinked. In some versions, however, the −**f** option suppresses usage messages and system errors as well. Suppressing such messages is not a service to either shell scripts or users.

It is less clear that error messages regarding files that cannot be unlinked (removed) should be suppressed. Although this is historical practice, this volume of IEEE Std 1003.1-200x does not permit the −**f** option to suppress such messages.

When given the −**r** and −**i** options, historical versions of *rm* prompt the user twice for each directory, once before removing its contents and once before actually attempting to delete the directory entry that names it. This allows the user to ''prune'' the file hierarchy walk. Historical versions of *rm* were inconsistent in that some did not do the former prompt for directories named on the command line and others had obscure prompting behavior when the −**i** option was specified and the permissions of the file did not permit writing. The POSIX Shell and Utilities *rm* differs little from historic practice, but does require that prompts be consistent. Historical versions of *rm* were also inconsistent in that prompts were done to both standard output and standard error. This volume of IEEE Std 1003.1-200x requires that prompts be done to standard error, for consistency with *cp* and *mv*, and to allow historical extensions to *rm* that provide an option to list deleted files on standard output.

The *rm* utility is required to descend to arbitrary depths so that any file hierarchy may be deleted. This means, for example, that the *rm* utility cannot run out of file descriptors during its descent (that is, if the number of file descriptors is limited, *rm* cannot be implemented in the historical fashion where one file descriptor is used per directory level). Also, *rm* is not permitted to fail because of path length restrictions, unless an operand specified by the user is longer than {PATH_MAX}.

The *rm* utility removes symbolic links themselves, not the files they refer to, as a consequence of the dependence on the *unlink*( ) functionality, per the DESCRIPTION. When removing hierarchies with −**r** or −**R**, the prohibition on following symbolic links has to be made explicit.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

Text is added to clarify actions relating to symbolic links as specified in the IEEE P1003.2b draft standard.

NAME

rmdel — remove a delta from an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI
```
rmdel −r SID file...
```

DESCRIPTION

The *rmdel* utility shall remove the delta specified by the SID from each named SCCS file. The delta to be removed shall be the most recent delta in its branch in the delta chain of each named SCCS file. In addition, the application shall ensure that the SID specified is not that of a version being edited for the purpose of making a delta; that is, if a *p-file* (see *get* (on page 2675)) exists for the named SCCS file, the SID specified shall not appear in any entry of the *p-file*.

Removal of a delta shall be restricted to:

1. The user who made the delta
2. The owner of the SCCS file
3. The owner of the directory containing the SCCS file

OPTIONS

The *rmdel* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−r *SID* Specify the SCCS identification string (*SID*) of the delta to be deleted.

OPERANDS

The following operand shall be supported:

file A pathname of an existing SCCS file or a directory. If *file* is a directory, the *rmdel* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input is taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only when the *file* operand is specified as `'−'`. Each line of the text file shall be interpreted as an SCCS pathname.

INPUT FILES

The SCCS files shall be files of unspecified format. |

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *rmdel*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The SCCS files shall be files of unspecified format. During processing of a *file*, a temporary *x-file*, as described in *admin* (on page 2328), may be created and deleted; a locking *z-file*, as described in *get* (on page 2675), may be created and deleted.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The normative text is reworded to emphasize the term ‘‘shall’’ for implementation requirements.

NAME

rmdir — remove directories

SYNOPSIS

`rmdir [−p] dir...`

DESCRIPTION

The *rmdir* utility shall remove the directory entry specified by each *dir* operand, which, in order to succeed, the application shall ensure refers to an empty directory.

Directories shall be processed in the order specified. If a directory and a subdirectory of that directory are specified in a single invocation of the *rmdir* utility, the application shall specify the subdirectory before the parent directory so that the parent directory will be empty when the *rmdir* utility tries to remove it.

OPTIONS

The *rmdir* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−p Remove all directories in a pathname. For each *dir* operand:

1. The directory entry it names shall be removed.
2. If the *dir* operand includes more than one pathname component, effects equivalent to the following command shall occur:

```
rmdir −p $(dirname dir)
```

OPERANDS

The following operand shall be supported:

dir A pathname of an empty directory to be removed.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *rmdir*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Each directory entry specified by a *dir* operand was removed successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The definition of an empty directory is one that contains, at most, directory entries for dot and dot-dot.

EXAMPLES

If a directory **a** in the current directory is empty except it contains a directory **b** and **a/b** is empty except it contains a directory **c**:

```
rmdir −p a/b/c
```

removes all three directories.

RATIONALE

On historical System V systems, the −**p** option also caused a message to be written to the standard output. The message indicated whether the whole path was removed or whether part of the path remained for some reason. The STDERR section requires this diagnostic when the entire path specified by a *dir* operand is not removed, but does not allow the status message reporting success to be written as a diagnostic.

The *rmdir* utility on System V also included an −**s** option that suppressed the informational message output by the −**p** option. This option has been omitted because the informational message is not specified by this volume of IEEE Std 1003.1-200x.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

sact — print current SCCS file-editing activity (**DEVELOPMENT**)

SYNOPSIS

XSI

```
sact file...
```

DESCRIPTION

The *sact* utility shall inform the user of any impending deltas to a named SCCS file by writing a list to standard output. This situation occurs when *get* −**e** has been executed previously without a subsequent execution of *delta*, *unget*, or *sccs* **unedit**.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file	A pathname of an existing SCCS file or a directory. If *file* is a directory, the *sact* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored. If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only when the *file* operand is specified as `'−'`. Each line of the text file shall be interpreted as an SCCS pathname.

INPUT FILES

Any SCCS files interrogated are files of an unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sact*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The output for each named file shall consist of a line in the following format:

`"%sΔ%sΔ%sΔ%sΔ%s\n", <SID>, <new SID>, <login>, <date>, <time>`

<SID>	Specifies the SID of a delta that currently exists in the SCCS file to which changes are made to make the new delta.
<new SID>	Specifies the SID for the new delta to be created.
<login>	Contains the login name of the user who makes the delta (that is, who executed a *get* for editing).
<date>	Contains the date that *get* −**e** was executed, in the format used by the *prs* **:D:** data keyword.
<time>	Contains the time that *get* −**e** was executed, in the format used by the *prs* **:T:** data keyword.

If there is more than one named file or if a directory or standard input is named, each pathname shall be written before each of the preceding lines:

`"\n%s:\n", <pathname>`

STDERR

The standard error shall be used only for optional informative messages concerning SCCS files with no impending deltas, and for diagnostic messages.

OUTPUT FILES

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to emphasize the term ‘‘shall’’ for implementation requirements.

NAME

sccs — front end for the SCCS subsystem (**DEVELOPMENT**)

SYNOPSIS

XSI

```
sccs [−r][−d path][−p path] command [options...][operands...]
```

DESCRIPTION

The *sccs* utility is a front end to the SCCS programs. It also includes the capability to run set-user-id to another user to provide additional protection.

The *sccs* utility shall invoke the specified *command* with the specified *options* and *operands*. By default, each of the *operands* shall be modified by prefixing it with the string `"SCCS/s."`.

The *command* can be the name of one of the SCCS utilities in this volume of IEEE Std 1003.1-200x (*admin*, *delta*, *get*, *prs*, *rmdel*, *sact*, *unget*, *val*, or *what*) or one of the pseudo-utilities listed in the EXTENDED DESCRIPTION section.

OPTIONS

The *sccs* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that *options* operands are actually options to be passed to the utility named by *command*. When the portion of the command:

```
command [options ... ] [operands ... ]
```

is considered, all of the pseudo-utilities used as *command* shall support the Utility Syntax Guidelines. Any of the other SCCS utilities that can be invoked in this manner support the Guidelines to the extent indicated by their individual OPTIONS sections.

The following options shall be supported preceding the *command* operand:

−d *path* A pathname of a directory to be used as a root directory for the SCCS files. The default shall be the current directory. The **−d** option shall take precedence over the *PROJECTDIR* variable. See **−p**.

−p *path* A pathname of a directory in which the SCCS files are located. The default shall be the **SCCS** directory.

The **−p** option differs from the **−d** option in that the **−d** option-argument shall be prefixed to the entire pathname and the **−p** option-argument shall be inserted before the final component of the pathname. For example:

```
sccs −d /x −p y get a/b
```

converts to:

```
get /x/a/y/s.b
```

This allows the creation of aliases such as:

```
alias syssccs="sccs −d /usr/src"
```

which is used as:

```
syssccs get cmd/who.c
```

−r Invoke *command* with the real user ID of the process, not any effective user ID that the *sccs* utility is set to. Certain commands (*admin*, **check**, **clean**, **diffs**, **info**, *rmdel*, and **tell**) cannot be run set-user-ID by all users, since this would allow anyone to change the authorizations. These commands are always run as the real user.

OPERANDS

The following operands shall be supported:

command	An SCCS utility name or the name of one of the pseudo-utilities listed in the EXTENDED DESCRIPTION section.
options	An option or option-argument to be passed to *command*.
operands	An operand to be passed to *command*.

STDIN

See the utility description for the specified *command*.

INPUT FILES

See the utility description for the specified *command*.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sccs*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PROJECTDIR	Provide a default value for the **−d** *path* option. If the value of *PROJECTDIR* begins with a slash, it shall be considered an absolute pathname; otherwise, the value of *PROJECTDIR* is treated as a user name and that user's initial working directory shall be examined for a subdirectory **src** or **source**. If such a directory is found, it shall be used. Otherwise, the value shall be used as a relative pathname.

Additional environment variable effects may be found in the utility description for the specified *command*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the utility description for the specified *command*.

STDERR

See the utility description for the specified *command*.

OUTPUT FILES

See the utility description for the specified *command*.

EXTENDED DESCRIPTION

The following pseudo-utilities shall be supported as *command* operands. All options referred to in the following list are values given in the *options* operands following *command*.

check	Equivalent to **info**, except that nothing shall be printed if nothing is being edited, and a non-zero exit status shall be returned if anything is being edited. The intent is to have this included in an ‘‘install’’ entry in a makefile to ensure that everything is included into the SCCS file before a version is installed.
clean	Remove everything from the current directory that can be recreated from SCCS files, but do not remove any files being edited. If the −**b** option is given, branches shall be ignored in the determination of whether they are being edited; this is dangerous if branches are kept in the same directory.
create	Create an SCCS file, taking the initial contents from the file of the same name. Any options to *admin* are accepted. If the creation is successful, the original files shall be renamed by prefixing the basenames with a comma. These renamed files should be removed after it has been verified that the SCCS files have been created successfully.
delget	Perform a *delta* on the named files and then *get* new versions. The new versions shall have ID keywords expanded and shall not be editable. Any −**m**, −**p**, −**r**, −**s**, and −**y** options shall be passed to *delta*, and any −**b**, −**c**, −**e**, −**i**, −**k**, −**l**, −**s**, and −**x** options shall be passed to *get*.
deledit	Equivalent to **delget**, except that the *get* phase shall include the −**e** option. This option is useful for making a checkpoint of the current editing phase. The same options shall be passed to *delta* as described above, and all the options listed for *get* above except −**e** shall be passed to **edit**.
diffs	Write a difference listing between the current version of the files checked out for editing and the versions in SCCS format. Any −**r**, −**c**, −**i**, −**x**, and −**t** options shall be passed to *get*; any −**l**, −**s**, −**e**, −**f**, −**h**, and −**b** options shall be passed to *diff*. A −**C** option shall be passed to *diff* as −**c**.
edit	Equivalent to *get* −**e**.
fix	Remove the named delta, but leave a copy of the delta with the changes that were in it. It is useful for fixing small compiler bugs, and so on. The application shall ensure that it is followed by a −**r** *SID* option. Since **fix** does not leave audit trails, it should be used carefully.
info	Write a listing of all files being edited. If the −**b** option is given, branches (that is, SIDs with two or fewer components) shall be ignored. If a −**u** *user* option is given, then only files being edited by the named user shall be listed. A −**U** option shall be equivalent to −**u**<*current user*>.
print	Write out verbose information about the named files, equivalent to *sccs prs*.
tell	Write a <newline>-separated list of the files being edited to standard output. Takes the −**b**, −**u**, and −**U** options like **info** and **check**.
unedit	This is the opposite of an **edit** or a *get* −**e**. It should be used with caution, since any changes made since the *get* are lost.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Many of the SCCS utilities take directory names as operands as well as specific filenames. The pseudo-utilities supported by *sccs* are not described as having this capability, but are not prohibited from doing so.

EXAMPLES

1. To get a file for editing, edit it and produce a new delta:

```
sccs get −e file.c
ex file.c
sccs delta file.c
```

2. To get a file from another directory:

```
sccs −p /usr/src/sccs/s. get cc.c
```

or:

```
sccs get /usr/src/sccs/s.cc.c
```

3. To make a delta of a large number of files in the current directory:

```
sccs delta *.c
```

4. To get a list of files being edited that are not on branches:

```
sccs info −b
```

5. To delta everything being edited by the current user:

```
sccs delta $(sccs tell −U)
```

6. In a makefile, to get source files from an SCCS file if it does not already exist:

```
SRCS = <list of source files>
$(SRCS):
    sccs get $(REL) $@
```

RATIONALE

SCCS and its associated utilities are part of the XSI Development Utilities option within the XSI extension.

SCCS is an abbreviation for Source Code Control System. It is a maintenance and enhancement tracking tool. When a file is put under SCCS, the source code control system maintains the file and, when changes are made, identifies and stores them in the file with the original source code and/or documentation. As other changes are made, they too are identified and retained in the file.

Retrieval of the original and any set of changes is possible. Any version of the file as it develops can be reconstructed for inspection or additional modification. History data can be stored with each version, documenting why the changes were made, who made them, and when they were made.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

In the ENVIRONMENT VARIABLES section, the *PROJECTDIR* description is updated from ‘‘otherwise, the home directory of a user of that name is examined’’ to ‘‘otherwise, the value of *PROJECTDIR* is treated as a user name and that user’s initial working directory is examined’’.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The normative text is reworded to emphasize the term ‘‘shall’’ for implementation requirements.

NAME

sed — stream editor

SYNOPSIS

```
sed [−n] script[file...]
sed [−n][−e script]...[−f script_file]...[file...]
```

DESCRIPTION

The *sed* utility is a stream editor that shall read one or more text files, make editing changes according to a script of editing commands, and write the results to standard output. The script shall be obtained from either the *script* operand string or a combination of the option-arguments from the −**e** *script* and −**f** *script_file* options.

OPTIONS

The *sed* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of presentation of the −**e** and −**f** options is significant.

The following options shall be supported:

−**e** *script*	Add the editing commands specified by the *script* option-argument to the end of the script of editing commands. The *script* option-argument shall have the same properties as the *script* operand, described in the OPERANDS section.
−**f** *script_file*	Add the editing commands in the file *script_file* to the end of the script.
−**n**	Suppress the default output (in which each line, after it is examined for editing, is written to standard output). Only lines explicitly selected for output are written.

Multiple −**e** and −**f** options may be specified. All commands shall be added to the script in the order specified, regardless of their origin.

OPERANDS

The following operands shall be supported:

file	A pathname of a file whose contents are read and edited. If multiple *file* operands are specified, the named files shall be read in the order specified and the concatenation shall be edited. If no *file* operands are specified, the standard input shall be used.
script	A string to be used as the script of editing commands. The application shall not present a *script* that violates the restrictions of a text file except that the final character need not be a <newline>.

STDIN

The standard input shall be used only if no *file* operands are specified. See the INPUT FILES section.

INPUT FILES

The input files shall be text files. The *script_file*s named by the −**f** option shall consist of editing commands.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sed*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), and the behavior of character classes within regular expressions.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The input files shall be written to standard output, with the editing commands specified in the script applied. If the −**n** option is specified, only those input lines selected by the script shall be written to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files shall be text files whose formats are dependent on the editing commands given.

EXTENDED DESCRIPTION

The *script* shall consist of editing commands of the following form:

```
[address[,address]]function
```

where *function* represents a single-character command verb from the list in **Editing Commands in sed** (on page 3041), followed by any applicable arguments.

The command can be preceded by <blank>s and/or semicolons. The function can be preceded by <blank>s. These optional characters shall have no effect.

In default operation, *sed* cyclically shall append a line of input, less its terminating <newline>, into the pattern space. Normally the pattern space will be empty, unless a **D** command terminated the last cycle. The *sed* utility shall then apply in sequence all commands whose addresses select that pattern space, and at the end of the script copy the pattern space to standard output (except when −**n** is specified) and delete the pattern space. Whenever the pattern space is written to standard output or a named file, *sed* shall immediately follow it with a <newline>.

Some of the editing commands use a hold space to save all or part of the pattern space for subsequent retrieval. The pattern and hold spaces shall each be able to hold at least 8 192 bytes.

Addresses in sed

An address is either a decimal number that counts input lines cumulatively across files, a `'$'` character that addresses the last line of input, or a context address (which consists of a BRE, as described in **Regular Expressions in sed**, preceded and followed by a delimiter, usually a slash).

An editing command with no addresses shall select every pattern space.

An editing command with one address shall select each pattern space that matches the address.

An editing command with two addresses shall select the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second. (If the second address is a number less than or equal to the line number first selected, only one line shall be selected.) Starting at the first line following the selected range, *sed* shall look again for the first address. Thereafter, the process shall be repeated. Omitting either or both of the address components in the following form produces undefined results:

`[`*`address`*`[,`*`address`*`]]`

Regular Expressions in sed

The *sed* utility shall support the BREs described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions, with the following additions:

- In a context address, the construction `"\cBREc"`, where *c* is any character other than backslash or <newline>, shall be identical to `"/BRE/"`. If the character designated by *c* appears following a backslash, then it shall be considered to be that literal character, which shall not terminate the BRE. For example, in the context address `"\xabc\xdefx"`, the second *x* stands for itself, so that the BRE is `"abcxdef"`.
- The escape sequence `'\n'` shall match a <newline> embedded in the pattern space. A literal <newline> shall not be used in the BRE of a context address or in the substitute function.
- If an RE is empty (that is, no pattern is specified) *sed* shall behave as if the last RE used in the last command applied (either as an address or as part of a substitute command) was specified.

Editing Commands in sed

In the following list of editing commands, the maximum number of permissible addresses for each function is indicated by [*0addr*], [*1addr*], or [*2addr*], representing zero, one, or two addresses.

The argument *text* shall consist of one or more lines. Each embedded <newline> in the text shall be preceded by a backslash. Other backslashes in text shall be removed, and the following character shall be treated literally.

The **r** and **w** command verbs, and the *w* flag to the **s** command, take an optional *rfile* (or *wfile*) parameter, separated from the command verb letter or flag by one or more <blank>s; implementations may allow zero separation as an extension.

The argument *rfile* or the argument *wfile* shall terminate the editing command. Each *wfile* shall be created before processing begins. Implementations shall support at least ten *wfile* arguments in the script; the actual number (greater than or equal to 10) that is supported by the implementation is unspecified. The use of the *wfile* parameter shall cause that file to be initially created, if it does not exist, or shall replace the contents of an existing file.

The **b**, **r**, **s**, **t**, **w**, **y**, and **:** command verbs shall accept additional arguments. The following synopses indicate which arguments shall be separated from the command verbs by a single

<space>.

The **a** and **r** commands schedule text for later output. The text specified for the **a** command, and the contents of the file specified for the **r** command, shall be written to standard output just before the next attempt to fetch a line of input when executing the **N** or **n** commands, or when reaching the end of the script. If written when reaching the end of the script, and the −**n** option was not specified, the text shall be written after copying the pattern space to standard output. The contents of the file specified for the **r** command shall be as of the time the output is written, not the time the **r** command is applied. The text shall be output in the order in which the **a** and **r** commands were applied to the input.

Command verbs other than **{**, **a**, **b**, **c**, **i**, **r**, **t**, **w**, **:**, and **#** can be followed by a semicolon, optional <blank>s, and another command verb. However, when the **s** command verb is used with the *w* flag, following it with another command in this manner produces undefined results.

A function can be preceded by one or more ′!′ characters, in which case the function shall be applied if the addresses do not select the pattern space. Zero or more <blank>s shall be accepted before the first ′!′ character. It is unspecified whether <blank>s can follow a ′!′ character, and conforming applications shall not follow a ′!′ character with <blank>s.

[_2addr_**] {**_function_ _function_ . . . **}**	Execute a list of *sed* functions only when the pattern space is selected. The list of *sed* functions shall be surrounded by braces and separated by <newline>s, and conform to the following rules. The braces can be preceded or followed by <blank>s. The functions can be preceded by <blank>s, but shall not be followed by <blank>s. The <right-brace> shall be preceded by a <newline> and can be preceded or followed by <blank>s.
[_1addr_**]a** _text_	Write text to standard output as described previously.
[_2addr_**]b [**_label_**]**	Branch to the **:** function bearing the *label*. If *label* is not specified, branch to the end of the script. The implementation shall support *label*s recognized as unique up to at least 8 characters; the actual length (greater than or equal to 8) that shall be supported by the implementation is unspecified. It is unspecified whether exceeding a label length causes an error or a silent truncation.
[_2addr_**]c** _text_	Delete the pattern space. With a 0 or 1 address or at the end of a 2-address range, place *text* on the output and start the next cycle.
[_2addr_**]d**	Delete the pattern space and start the next cycle.
[_2addr_**]D**	Delete the initial segment of the pattern space through the first <newline> and start the next cycle.
[_2addr_**]g**	Replace the contents of the pattern space by the contents of the hold space.
[_2addr_**]G**	Append to the pattern space a <newline> followed by the contents of the hold space.
[_2addr_**]h**	Replace the contents of the hold space with the contents of the pattern space.
[_2addr_**]H**	Append to the hold space a <newline> followed by the contents of the pattern space.

[_1addr_**]i**\
text Write *text* to standard output.

[_2addr_**]l** (The letter ell.) Write the pattern space to standard output in a visually unambiguous form. The characters listed in the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\r'`, `'\t'`, `'\v'`) shall be written as the corresponding escape sequence; the `'\n'` in that table is not applicable. Non-printable characters not in that table shall be written as one three-digit octal number (with a preceding backslash) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than 9 bits, the format used for non-printable characters is implementation-defined.

Long lines shall be folded, with the point of folding indicated by writing a backslash followed by a <newline>; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line shall be marked with a `'$'`.

[_2addr_**]n** Write the pattern space to standard output if the default output has not been suppressed, and replace the pattern space with the next line of input, less its terminating <newline>.

If no next line of input is available, the **n** command verb shall branch to the end of the script and quit without starting a new cycle.

[_2addr_**]N** Append the next line of input, less its terminating <newline>, to the pattern space, using an embedded <newline> to separate the appended material from the original material. Note that the current line number changes.

If no next line of input is available, the **N** command verb shall branch to the end of the script and quit without starting a new cycle or copying the pattern space to standard output.

[_2addr_**]p** Write the pattern space to standard output.

[_2addr_**]P** Write the pattern space, up to the first <newline>, to standard output.

[_1addr_**]q** Branch to the end of the script and quit without starting a new cycle.

[_1addr_**]r** *rfile* Copy the contents of *rfile* to standard output as described previously. If *rfile* does not exist or cannot be read, it shall be treated as if it were an empty file, causing no error condition.

[_2addr_**]s**/*BRE*/*replacement*/*flags*

Substitute the replacement string for instances of the BRE in the pattern space. Any character other than backslash or <newline> can be used instead of a slash to delimit the BRE and the replacement. Within the BRE and the replacement, the BRE delimiter itself can be used as a literal character if it is preceded by a backslash.

The replacement string shall be scanned from beginning to end. An ampersand (`'&'`) appearing in the replacement shall be replaced by the string matching the BRE. The special meaning of `'&'` in this context can be suppressed by preceding it by a backslash. The characters `"\n"`, where *n* is a digit, shall be replaced by the text matched by the corresponding backreference expression. The special meaning of `"\n"` where *n* is a digit in this context, can be suppressed by preceding it by a backslash. For each other backslash (`'\'`) encountered, the following character shall lose its special meaning (if any). The meaning of a `'\'` immediately followed by any character other than '&', '\', a digit, or the delimiter character used for this command, is unspecified.

A line can be split by substituting a <newline> into it. The application shall escape the <newline> in the replacement by preceding it by a backslash. A substitution shall be considered to have been performed even if the replacement string is identical to the string that it replaces. Any backslash used to alter the default meaning of a subsequent character shall be discarded from the BRE or the replacement before evaluating the BRE or using the replacement.

The value of *flags* shall be zero or more of:

n Substitute for the *n*th occurrence only of the BRE found within the pattern space.

g Globally substitute for all non-overlapping instances of the BRE rather than just the first one. If both **g** and **n** are specified, the results are unspecified.

p Write the pattern space to standard output if a replacement was made.

w *wfile* Write. Append the pattern space to *wfile* if a replacement was made. A conforming application shall precede the *wfile* argument with one or more <blank>s. If the *w* flag is not the last flag value given in a concatenation of multiple flag values, the results are undefined.

[*2addr***]t [***label***]**

Test. Branch to the **:** command verb bearing the *label* if any substitutions have been made since the most recent reading of an input line or execution of a **t**. If *label* is not specified, branch to the end of the script.

[*2addr***]w** *wfile*

Append (write) the pattern space to *wfile*.

[*2addr***]x** Exchange the contents of the pattern and hold spaces.

[*2addr***]y/***string1***/***string2***/**

Replace all occurrences of characters in *string1* with the corresponding characters in *string2*. If a backslash followed by an 'n' appear in *string1* or *string2*, the two characters shall be handled as a single <newline>. If the number of characters in *string1* and *string2* are not equal, or if any of the characters in *string1* appear more than once, the results are undefined. Any character other than backslash or <newline> can be used instead of slash to delimit the strings. If the delimiter is not *n*, within *string1* and *string2*, the delimiter itself can be used as a literal character if it is preceded by a backslash. If a backslash character is immediately followed by a backslash character in *string1* or *string2*, the two backslash characters shall be counted as a single literal backslash character. The meaning of a backslash followed by any character that is not 'n', a backslash, or the delimiter character is undefined.

[*0addr***]:***label* Do nothing. This command bears a *label* to which the **b** and **t** commands branch.

[*1addr***]=** Write the following to standard output:

```
"%d\n", <current line number>
```

[*0addr***]** Ignore this empty command.

[*0addr*]# Ignore the `'#'` and the remainder of the line (treat them as a comment), with the single exception that if the first two characters in the script are `"#n"`, the default output shall be suppressed; this shall be the equivalent of specifying −**n** on the command line.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Regular expressions match entire strings, not just individual lines, but a <newline> is matched by `'\n'` in a *sed* RE; a <newline> is not allowed by the general definition of regular expression in IEEE Std 1003.1-200x. Also note that `'\n'` cannot be used to match a <newline> at the end of an arbitrary input line; <newline>s appear in the pattern space as a result of the **N** editing command.

EXAMPLES

This *sed* script simulates the BSD *cat* −**s** command, squeezing excess blank lines from standard input.

```
sed −n '
# Write non-empty lines.
/./ {
    p
    d
    }
# Write a single empty line, then look for more empty lines.
/ˆ$/    p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/ˆ$/    {
    N
    s/.//
    b Empty
    }
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
    p
'

RATIONALE

This volume of IEEE Std 1003.1-200x requires implementations to support at least ten distinct *wfile*s, matching historical practice on many implementations. Implementations are encouraged to support more, but conforming applications should not exceed this limit.

The exit status codes specified here are different from those in System V. System V returns 2 for garbled *sed* commands, but returns zero with its usage message or if the input file could not be opened. The standard developers considered this to be a bug.

The manner in which the **l** command writes non-printable characters was changed to avoid the historical backspace-overstrike method, and other requirements to achieve unambiguous output were added. See the RATIONALE for *ed* (on page 2537) for details of the format chosen, which is the same as that chosen for *sed*.

This volume of IEEE Std 1003.1-200x requires implementations to provide pattern and hold spaces of at least 8 192 bytes, larger than the 4 000 bytes spaces used by some historical implementations, but less than the 20 480 bytes limit used in an early proposal. Implementations are encouraged to allocate dynamically larger pattern and hold spaces as needed.

The requirements for acceptance of <blank>s and <space>s in command lines has been made more explicit than in early proposals to describe clearly the historical practice and to remove confusion about the phrase ‘‘protect initial blanks [*sic*] and tabs from the stripping that is done on every script line’’ that appears in much of the historical documentation of the *sed* utility description of text. (Not all implementations are known to have stripped <blank>s from text lines, although they all have allowed leading <blank>s preceding the address on a command line.)

The treatment of `'#'` comments differs from the SVID which only allows a comment as the first line of the script, but matches BSD-derived implementations. The comment character is treated as a command, and it has the same properties in terms of being accepted with leading <blank>s; the BSD implementation has historically supported this.

Early proposals required that a *script_file* have at least one non-comment line. Some historical implementations have behaved in unexpected ways if this were not the case. The standard developers considered that this was incorrect behavior and that application developers should not have to avoid this feature. A correct implementation of this volume of IEEE Std 1003.1-200x shall permit *script_file*s that consist only of comment lines.

Early proposals indicated that if −**e** and −**f** options were intermixed, all −**e** options were processed before any −**f** options. This has been changed to process them in the order presented because it matches historical practice and is more intuitive.

The treatment of the **p** flag to the **s** command differs between System V and BSD-based systems when the default output is suppressed. In the two examples:

```
echo a | sed    's/a/A/p'
echo a | sed −n 's/a/A/p'
```

This volume of IEEE Std 1003.1-200x, BSD, System V documentation, and the SVID indicate that the first example should write two lines with **A**, whereas the second should write one. Some System V systems write the **A** only once in both examples because the **p** flag is ignored if the −**n** option is not specified.

This is a case of a diametrical difference between systems that could not be reconciled through the compromise of declaring the behavior to be unspecified. The SVID/BSD/System V documentation behavior was adopted for this volume of IEEE Std 1003.1-200x because:

- No known documentation for any historic system describes the interaction between the **p** flag and the −**n** option.
- The selected behavior is more correct as there is no technical justification for any interaction between the **p** flag and the −**n** option. A relationship between −**n** and the **p** flag might imply that they are only used together, but this ignores valid scripts that interrupt the cyclical nature of the processing through the use of the **D**, **d**, **q**, or branching commands. Such scripts rely on the **p** suffix to write the pattern space because they do not make use of the default output at the ‘‘bottom’’ of the script.

- Because the −**n** option makes the **p** flag unnecessary, any interaction would only be useful if *sed* scripts were written to run both with and without the −**n** option. This is believed to be unlikely. It is even more unlikely that programmers have coded the **p** flag expecting it to be unnecessary. Because the interaction was not documented, the likelihood of a programmer discovering the interaction and depending on it is further decreased.

- Finally, scripts that break under the specified behavior produce too much output instead of too little, which is easier to diagnose and correct.

The form of the substitute command that uses the **n** suffix was limited to the first 512 matches in an early proposal. This limit has been removed because there is no reason an editor processing lines of {LINE_MAX} length should have this restriction. The command **s/a/A/2047** should be able to substitute the 2 047th occurrence of **a** on a line.

The **b**, **t**, and **:** commands are documented to ignore leading white space, but no mention is made of trailing white space. Historical implementations of *sed* assigned different locations to the labels `'x'` and `"x "`. This is not useful, and leads to subtle programming errors, but it is historical practice, and changing it could theoretically break working scripts. Implementors are encouraged to provide warning messages about labels that are never used or jumps to labels that do not exist.

Historically, the *sed* **!** and **}** editing commands did not permit multiple commands on a single line using a semicolon as a command delimiter. Implementations are permitted, but not required, to support this extension.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Implementations are required to support at least ten *wfile* arguments in an editing command.

The EXTENDED DESCRIPTION is changed to align with the IEEE P1003.2b draft standard.

IEEE PASC Interpretation 1003.2 #190 is applied.

IEEE PASC Interpretation 1003.2 #203 is applied, clarifying the meaning of the backslash escape sequences in a replacement string for a BRE.

NAME

sh — shell, the standard command language interpreter

SYNOPSIS

```
sh [−abCefhimnuvx][−o option][+abCefhmnuvx][+o option]
    [command_file [argument...]]

sh −c[−abCefhimnuvx][−o option][+abCefhimnuvx][+o option]command_string
    [command_name [argument...]]

sh −s[−abCefhimnuvx][−o option][+abCefhimnuvx][+o option][argument]
```

DESCRIPTION

The *sh* utility is a command language interpreter that shall execute commands read from a command line string, the standard input, or a specified file. The application shall ensure that the commands to be executed are expressed in the language described in Chapter 2 (on page 2231).

Pathname expansion shall not fail due to the size of a file.

Shell input and output redirections have an implementation-defined offset maximum that is established in the open file description.

OPTIONS

The *sh* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, with an extension for support of a leading plus sign (`'+'`) as noted below.

The **−a**, **−b**, **−C**, **−e**, **−f**, **−m**, **−n**, **−o** *option*, **−u**, **−v**, and **−x** options are described as part of the *set* utility in Section 2.14 (on page 2266). The option letters derived from the *set* special built-in shall also be accepted with a leading plus sign (`'+'`) instead of a leading hyphen (meaning the reverse case of the option as described in this volume of IEEE Std 1003.1-200x).

The following additional options shall be supported:

−c	Read commands from the *command_string* operand. Set the value of special parameter 0 (see Section 2.5.2 (on page 2235)) from the value of the *command_name* operand and the positional parameters ($1, $2, and so on) in sequence from the remaining *argument* operands. No commands shall be read from the standard input.
−i	Specify that the shell is *interactive*; see below. An implementation may treat specifying the **−i** option as an error if the real user ID of the calling process does not equal the effective user ID or if the real group ID does not equal the effective group ID.
−s	Read commands from the standard input.

If there are no operands and the **−c** option is not specified, the **−s** option shall be assumed.

If the **−i** option is present, or if there are no operands and the shell's standard input and standard error are attached to a terminal, the shell is considered to be *interactive*.

OPERANDS

The following operands shall be supported:

−	A single hyphen shall be treated as the first operand and then ignored. If both `'−'` and `"−−"` are given as arguments, or if other operands precede the single hyphen, the results are undefined.
argument	The positional parameters ($1, $2, and so on) shall be set to *arguments*, if any.

command_file The pathname of a file containing commands. If the pathname contains one or more slash characters, the implementation attempts to read that file; the file need not be executable. If the pathname does not contain a slash character:

- The implementation shall attempt to read that file from the current working directory; the file need not be executable.
- If the file is not in the current working directory, the implementation may perform a search for an executable file using the value of *PATH*, as described in Section 2.9.1.1 (on page 2249).

Special parameter 0 (see Section 2.5.2 (on page 2235)) shall be set to the value of *command_file*. If *sh* is called using a synopsis form that omits *command_file*, special parameter 0 shall be set to the value of the first argument passed to *sh* from its parent (for example, *argv*[0] for a C program), which is normally a pathname used to execute the *sh* utility.

command_name

A string assigned to special parameter 0 when executing the commands in *command_string*. If *command_name* is not specified, special parameter 0 shall be set to the value of the first argument passed to *sh* from its parent (for example, *argv*[0] for a C program), which is normally a pathname used to execute the *sh* utility.

command_string

A string that shall be interpreted by the shell as one or more commands, as if the string were the argument to the *system*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x. If the *command_string* operand is an empty string, *sh* shall exit with a zero exit status.

STDIN

The standard input shall be used only if one of the following is true:

- The −**s** option is specified.
- The −**c** option is not specified and no operands are specified.
- The script executes one or more commands that require input from standard input (such as a *read* command that does not redirect its input).

See the INPUT FILES section.

When the shell is using standard input and it invokes a command that also uses standard input, the shell shall ensure that the standard input file pointer points directly after the command it has read when the command begins execution. It shall not read ahead in such a manner that any characters intended to be read by the invoked command are consumed by the shell (whether interpreted by the shell or not) or that characters that are not read by the invoked command are not seen by the shell. When the command expecting to read standard input is started asynchronously by an interactive shell, it is unspecified whether characters are read by the command or interpreted by the shell.

If the standard input to *sh* is a FIFO or terminal device and is set to non-blocking reads, then *sh* shall enable blocking reads on standard input. This shall remain in effect when the command completes.

INPUT FILES

The input file shall be a text file, except that line lengths shall be unlimited. If the input file is empty or consists solely of blank lines or comments, or both, *sh* shall exit with a zero exit status.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sh*:

ENV	This variable, when and only when an interactive shell is invoked, shall be subjected to parameter expansion (see Section 2.6.2 (on page 2239)) by the shell, and the resulting value shall be used as a pathname of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of *ENV* is not an absolute pathname, the results are unspecified. *ENV* shall be ignored if the real and effective user IDs or real and effective group IDs of the process are different.
FCEDIT	This variable, when expanded by the shell, shall determine the default value for the −**e** *editor* option's *editor* option-argument. If *FCEDIT* is null or unset, *ed* shall be used as the editor. This volume of IEEE Std 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.
HISTFILE	Determine a pathname naming a command history file. If the *HISTFILE* variable is not set, the shell may attempt to access or create a file **.sh_history** in the directory referred to by the *HOME* environment variable. If the shell cannot obtain both read and write access to, or create, the history file, it shall use an unspecified mechanism that allows the history to operate properly. (References to history ''file'' in this section shall be understood to mean this unspecified mechanism in such cases.) An implementation may choose to access this variable only when initializing the history file; this initialization shall occur when *fc* or *sh* first attempt to retrieve entries from, or add entries to, the file, as the result of commands issued by the user, the file named by the *ENV* variable, or implementation-defined system start-up files. Implementations may choose to disable the history list mechanism for users with appropriate privileges who do not set *HISTFILE*; the specific circumstances under which this occurs are implementation-defined. If more than one instance of the shell is using the same history file, it is unspecified how updates to the history file from those shells interact. As entries are deleted from the history file, they shall be deleted oldest first. It is unspecified when history file entries are physically removed from the history file. This volume of IEEE Std 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.
HISTSIZE	Determine a decimal number representing the limit to the number of previous commands that are accessible. If this variable is unset, an unspecified default greater than or equal to 128 shall be used. The maximum number of commands in the history list is unspecified, but shall be at least 128. An implementation may choose to access this variable only when initializing the history file, as described under *HISTFILE*. Therefore, it is unspecified whether changes made to *HISTSIZE* after the history file has been initialized are effective.
HOME	Determine the pathname of the user's home directory. The contents of *HOME* are used in Tilde Expansion as described in Section 2.6.1 (on page 2239). This volume of IEEE Std 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.
IFS	*Input field separators*: a string treated as a list of characters that shall be used for field splitting and to split lines into words with the *read* command. See Section 2.6.5 (on page 2243). If *IFS* is not set, the shell shall behave as if the value of *IFS* were <space>, <tab>, and <newline>. Implementations may ignore the value of *IFS* in the environment at the time *sh* is invoked, treating *IFS* as if it were not set.

	LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
	LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
	LC_COLLATE	Determine the behavior of range expressions, equivalence classes and multi-character collating elements within pattern matching.
	LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), which characters are defined as letters (character class **alpha**), and the behavior of character classes within pattern matching.
	LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
	MAIL	Determine a pathname of the user's mailbox file for purposes of incoming mail notification. If this variable is set, the shell shall inform the user if the file named by the variable is created or if its modification time has changed. Informing the user shall be accomplished by writing a string of unspecified format to standard error prior to the writing of the next primary prompt string. Such check shall be performed only after the completion of the interval defined by the *MAILCHECK* variable after the last such check. The user shall be informed only if *MAIL* is set and *MAILPATH* is not set. This volume of IEEE Std 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.
	MAILCHECK	Establish a decimal integer value that specifies how often (in seconds) the shell shall check for the arrival of mail in the files specified by the *MAILPATH* or *MAIL* variables. The default value shall be 600 seconds. If set to zero, the shell shall check before issuing each primary prompt. This volume of IEEE Std 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.
	MAILPATH	Provide a list of pathnames and optional messages separated by colons. If this variable is set, the shell shall inform the user if any of the files named by the variable are created or if any of their modification times change. (See the preceding entry for *MAIL* for descriptions of mail arrival and user informing.) Each pathname can be followed by `'%'` and a string that shall be subjected to parameter expansion and written to standard error when the modification time changes. If a `'%'` character in the pathname is preceded by a backslash, it shall be treated as a literal `'%'` in the pathname. The default message is unspecified. The *MAILPATH* environment variable takes precedence over the *MAIL* variable. This volume of IEEE Std 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.
XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
	PATH	Establish a string formatted as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables, used to effect command interpretation; see Section 2.9.1.1 (on page 2249).

PWD This variable shall represent an absolute pathname of the current working directory. Assignments to this variable may be ignored unless the value is an absolute pathname of the current working directory and there are no filename components of dot or dot-dot.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the STDERR section.

STDERR

Except as otherwise stated (by the descriptions of any invoked utilities or in interactive mode), standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

See Chapter 2. The following additional capabilities are supported on systems supporting the User Portability Utilities option.

Command History List

When the *sh* utility is being used interactively, it shall maintain a list of commands previously entered from the terminal in the file named by the *HISTFILE* environment variable. The type, size, and internal format of this file are unspecified. Multiple *sh* processes can share access to the file for a user, if file access permissions allow this; see the description of the *HISTFILE* environment variable.

Command Line Editing

When *sh* is being used interactively from a terminal, the current command and the command history (see *fc* (on page 2637)) can be edited using *vi*-mode command line editing. This mode uses commands, described below, similar to a subset of those described in the *vi* utility. Implementations may offer other command line editing modes corresponding to other editing utilities.

The command *set* −**o** *vi* shall enable *vi*-mode editing and place *sh* into *vi* insert mode (see **Command Line Editing (vi-mode)** (on page 3053)). This command also shall disable any other editing mode that the implementation may provide. The command *set* **+o** *vi* disables *vi*-mode editing.

Certain block-mode terminals may be unable to support shell command line editing. If a terminal is unable to provide either edit mode, it need not be possible to *set* −**o** *vi* when using the shell on this terminal.

In the following sections, the characters *erase*, *interrupt*, *kill*, and *end-of-file* are those set by the *stty* utility.

Command Line Editing (vi-mode)

In *vi* editing mode, there shall be a distinguished line, the edit line. All the editing operations which modify a line affect the edit line. The edit line is always the newest line in the command history buffer.

With *vi*-mode enabled, *sh* can be switched between insert mode and command mode.

When in insert mode, an entered character shall be inserted into the command line, except as noted in **vi Line Editing Insert Mode**. Upon entering *sh* and after termination of the previous command, *sh* shall be in insert mode.

Typing an escape character shall switch *sh* into command mode (see **vi Line Editing Command Mode** (on page 3054)). In command mode, an entered character shall either invoke a defined operation, is used as part of a multi-character operation, or is treated as an error. A character that is not recognized as part of an editing command shall terminate any specific editing command and shall alert the terminal. Typing the *interrupt* character in command mode shall cause *sh* to terminate command line editing on the current command line, reissue the prompt on the next line of the terminal, and reset the command history (see *fc* (on page 2637)) so that the most recently executed command is the previous command (that is, the command that was being edited when it was interrupted is not reentered into the history).

In the following sections, the phrase ‘‘move the cursor to the beginning of the word’’ shall mean ‘‘move the cursor to the first character of the current word’’ and the phrase ‘‘move the cursor to the end of the word’’ shall mean ‘‘move the cursor to the last character of the current word’’. The phrase ‘‘beginning of the command line’’ indicates the point between the end of the prompt string issued by the shell (or the beginning of the terminal line, if there is no prompt string) and the first character of the command text.

vi Line Editing Insert Mode

While in insert mode, any character typed shall be inserted in the current command line, unless it is from the following set.

<newline>	Execute the current command line. If the current command line is not empty, this line shall be entered into the command history (see *fc*).
erase	Delete the character previous to the current cursor position and move the current cursor position back one character. In insert mode, characters shall be erased from both the screen and the buffer when backspacing.
interrupt	Terminate command line editing with the same effects as described for interrupting command mode; see **Command Line Editing (vi-mode)**.
kill	Clear all the characters from the input line.
<control>-V	Insert the next character input, even if the character is otherwise a special insert mode character.
<control>-W	Delete the characters from the one preceding the cursor to the preceding word boundary. The word boundary in this case is the closer to the cursor of either the beginning of the line or a character that is in neither the **blank** nor **punct** character classification of the current locale.
end-of-file	Interpreted as the end of input in *sh*. This interpretation shall occur only at the beginning of an input line. If *end-of-file* is entered other than at the beginning of the line, the results are unspecified.

<ESC> Place *sh* into command mode.

vi Line Editing Command Mode

In command mode for the command line editing feature, decimal digits not beginning with 0 that precede a command letter shall be remembered. Some commands use these decimal digits as a count number that affects the operation.

The term *motion command* represents one of the commands:

`<space>  0  b  F  l  W  ˆ  $  ;  E  f  T  w  |  ,  B  e  h  t`

If the current line is not the edit line, any command that modifies the current line shall cause the content of the current line to replace the content of the edit line, and the current line shall become the edit line. This replacement cannot be undone (see the **u** and **U** commands below). The modification requested shall then be performed to the edit line. When the current line is the edit line, the modification shall be done directly to the edit line.

Any command that is preceded by *count* shall take a count (the numeric value of any preceding decimal digits). Unless otherwise noted, this count shall cause the specified operation to repeat by the number of times specified by the count. Also unless otherwise noted, a *count* that is out of range is considered an error condition and shall alert the terminal, but neither the cursor position, nor the command line, shall change.

The terms *word* and *bigword* are used as defined in the *vi* description. The term *save buffer* corresponds to the term *unnamed buffer* in *vi*.

The following commands shall be recognized in command mode:

<newline> Execute the current command line. If the current command line is not empty, this line shall be entered into the command history (see *fc*).

<control>-L Redraw the current command line. Position the cursor at the same location on the redrawn line.

Insert the character '#' at the beginning of the current command line and treat the resulting edit line as a comment. This line shall be entered into the command history; see *fc* (on page 2637).

= Display the possible shell word expansions (see Section 2.6 (on page 2238)) of the bigword at the current command line position.

> **Note:** This does not modify the content of the current line, and therefore does not cause the current line to become the edit line.

These expansions shall be displayed on subsequent terminal lines. If the bigword contains none of the characters '?', '*', or '[', an asterisk ('*') shall be implicitly assumed at the end. If any directories are matched, these expansions shall have a '/' character appended. After the expansion, the line shall be redrawn, the cursor is repositioned at the current cursor position, and *sh* shall be placed in command mode.

**** Perform pathname expansion (see Section 2.6.6 (on page 2244)) on the current bigword, up to the largest set of characters that can be matched uniquely. If the bigword contains none of the characters '?', '*', or '[', an asterisk ('*') shall be implicitly assumed at the end. This maximal expansion then shall replace the original bigword in the command line, and the cursor shall be placed after this expansion. If the resulting bigword completely and uniquely matches a directory, a '/' character shall be inserted directly after the bigword. If some other file is completely matched, a single <space> shall be inserted after the bigword. After this operation, *sh* shall be placed in insert mode.

*****
Perform pathname expansion on the current bigword and insert all expansions into the command to replace the current bigword, with each expansion separated by a single <space>. If at the end of the line, the current cursor position shall be moved to the first column position following the expansions and *sh* shall be placed in insert mode. Otherwise, the current cursor position shall be the last column position of the first character after the expansions and *sh* shall be placed in insert mode. If the current bigword contains none of the characters '?', '*', or '[', before the operation, an asterisk shall be implicitly assumed at the end.

@*letter*
Insert the value of the alias named _*letter*. The symbol *letter* represents a single alphabetic character from the portable character set; implementations may support additional characters as an extension. If the alias _*letter* contains other editing commands, these commands shall be performed as part of the insertion. If no alias _*letter* is enabled, this command shall have no effect.

[*count*]~
Convert, if the current character is a lowercase letter, to the equivalent uppercase letter and *vice versa*, as prescribed by the current locale. The current cursor position then shall be advanced by one character. If the cursor was positioned on the last character of the line, the case conversion shall occur, but the cursor shall not advance. If the '~' command is preceded by a *count*, that number of characters shall be converted, and the cursor shall be advanced to the character position after the last character converted. If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count*].
Repeat the most recent non-motion command, even if it was executed on an earlier command line. If the previous command was preceded by a *count*, and no count is given on the '.' command, the count from the previous command shall be included as part of the repeated command. If the '.' command is preceded by a *count*, this shall override any *count* argument to the previous command. The *count* specified in the '.' command shall become the count for subsequent '.' commands issued without a count.

[*number*]v
Invoke the *vi* editor to edit the current command line in a temporary file. When the editor exits, the commands in the temporary file shall be executed and placed in the command history. If a *number* is included, it specifies the command number in the command history to be edited, rather than the current command line.

[*count*]l (ell)
[*count*]<space>
Move the current cursor position to the next character position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count*]h
Move the current cursor position to the *count*th (default 1) previous character position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the count is larger than the number of characters before the cursor, this shall not be considered an error; the cursor shall move to the first character on the line.

[*count*]w
Move to the start of the next word. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be

	advanced. If the *count* is larger than the number of words after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.
[*count*]**W**	Move to the start of the next bigword. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of bigwords after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.
[*count*]**e**	Move to the end of the current word. If at the end of a word, move to the end of the next word. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of words after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.
[*count*]**E**	Move to the end of the current bigword. If at the end of a bigword, move to the end of the next bigword. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of bigwords after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.
[*count*]**b**	Move to the beginning of the current word. If at the beginning of a word, move to the beginning of the previous word. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the *count* is larger than the number of words preceding the cursor, this shall not be considered an error; the cursor shall return to the first character on the line.
[*count*]**B**	Move to the beginning of the current bigword. If at the beginning of a bigword, move to the beginning of the previous bigword. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the *count* is larger than the number of bigwords preceding the cursor, this shall not be considered an error; the cursor shall return to the first character on the line.
^	Move the current cursor position to the first character on the input line that is not a <blank>.
$	Move to the last character position on the current command line.
0	(Zero.) Move to the first character position on the current command line.
[*count*] **|**	Move to the *count*th character position on the current command line. If no number is specified, move to the first position. The first character position shall be numbered 1. If the count is larger than the number of characters on the line, this shall not be considered an error; the cursor shall be placed on the last character on the line.
[*count*]**f***c*	Move to the first occurrence of the character `'c'` that occurs after the current cursor position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the character `'c'` does not occur in the line after the current cursor position, the terminal shall be alerted and the cursor shall not be moved.
[*count*]**F***c*	Move to the first occurrence of the character `'c'` that occurs before the current cursor position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the character `'c'`

does not occur in the line before the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***]t***c* Move to the character before the first occurrence of the character `'c'` that occurs after the current cursor position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the character `'c'` does not occur in the line after the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***]T***c* Move to the character after the first occurrence of the character `'c'` that occurs before the current cursor position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the character `'c'` does not occur in the line before the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***];** Repeat the most recent **f**, **F**, **t**, or **T** command. Any number argument on that previous command shall be ignored. Errors are those described for the repeated command.

[*count***],** Repeat the most recent **f**, **F**, **t**, or **T** command. Any number argument on that previous command shall be ignored. However, reverse the direction of that command.

a Enter insert mode after the current cursor position. Characters that are entered shall be inserted before the next character.

A Enter insert mode after the end of the current command line.

i Enter insert mode at the current cursor position. Characters that are entered shall be inserted before the current character. |

I Enter insert mode at the beginning of the current command line.

R Enter insert mode, replacing characters from the command line beginning at the current cursor position.

[*count***]c***motion*

Delete the characters between the current cursor position and the cursor position that would result from the specified *motion* command. Then enter insert mode before the first character following any deleted characters. If *count* is specified, it shall be applied to the motion command. A *count* shall be ignored for the following motion commands:

```
0    ^    $    c
```

If the *motion* command is the character `'c'`, the current command line shall be cleared and insert mode shall be entered. If the *motion* command would move the current cursor position toward the beginning of the command line, the character under the current cursor position shall not be deleted. If the motion command would move the current cursor position toward the end of the command line, the character under the current cursor position shall be deleted. If the *count* is larger than the number of characters between the current cursor position and the end of the command line toward which the motion command would move the cursor, this shall not be considered an error; all of the remaining characters in the aforementioned range shall be deleted and insert mode shall be entered. If the motion command is invalid, the terminal shall be alerted, the cursor shall not be moved, and no text shall be deleted.

C Delete from the current character to the end of the line and enter insert mode at the new end-of-line.

S Clear the entire edit line and enter insert mode.

[*count***]r***c* Replace the current character with the character `'c'`. With a number *count*, replace the current and the following *count*−1 characters. After this command, the current cursor position shall be on the last character that was changed. If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; all of the remaining characters shall be changed.

[*count***]_** Append a <space> after the current character position and then append the last bigword in the previous input line after the <space>. Then enter insert mode after the last character just appended. With a number *count*, append the *count*th bigword in the previous line.

[*count***]x** Delete the character at the current cursor position and place the deleted characters in the save buffer. If the cursor was positioned on the last character of the line, the character shall be deleted and the cursor position shall be moved to the previous character (the new last character). If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; all the characters from the cursor to the end of the line shall be deleted.

[*count***]X** Delete the character before the current cursor position and place the deleted characters in the save buffer. The character under the current cursor position shall not change. If the cursor was positioned on the first character of the line, the terminal shall be alerted, and the **X** command shall have no effect. If the line contained a single character, the **X** command shall have no effect. If the line contained no characters, the terminal shall be alerted and the cursor shall not be moved. If the *count* is larger than the number of characters before the cursor, this shall not be considered an error; all the characters from before the cursor to the beginning of the line shall be deleted.

[*count***]d***motion*

Delete the characters between the current cursor position and the character position that would result from the *motion* command. A number *count* repeats the *motion* command *count* times. If the *motion* command would move toward the beginning of the command line, the character under the current cursor position shall not be deleted. If the *motion* command is **d**, the entire current command line shall be cleared. If the *count* is larger than the number of characters between the current cursor position and the end of the command line toward which the motion command would move the cursor, this shall not be considered an error; all of the remaining characters in the aforementioned range shall be deleted. The deleted characters shall be placed in the save buffer.

D Delete all characters from the current cursor position to the end of the line. The deleted characters shall be placed in the save buffer.

[*count***]y***motion*

Yank (that is, copy) the characters from the current cursor position to the position resulting from the *motion* command into the save buffer. A number *count* shall be applied to the *motion* command. If the *motion* command would move toward the beginning of the command line, the character under the current cursor position shall not be included in the set of yanked characters. If the *motion* command is **y**, the entire current command line shall be yanked into the save buffer. The current cursor position shall be unchanged. If the *count* is larger than the number of

	characters between the current cursor position and the end of the command line toward which the motion command would move the cursor, this shall not be considered an error; all of the remaining characters in the aforementioned range shall be yanked.
Y	Yank the characters from the current cursor position to the end of the line into the save buffer. The current character position shall be unchanged.
[*count***]p**	Put a copy of the current contents of the save buffer after the current cursor position. The current cursor position shall be advanced to the last character put from the save buffer. A *count* shall indicate how many copies of the save buffer shall be put.
[*count***]P**	Put a copy of the current contents of the save buffer before the current cursor position. The current cursor position shall be moved to the last character put from the save buffer. A *count* shall indicate how many copies of the save buffer shall be put.
u	Undo the last command that change the edit line. This operation shall not undo the copy of any command line to the edit line.
U	Undo all changes made to the edit line. This operation shall not undo the copy of any command line to the edit line.
[*count***]k** **[***count***]–**	Set the current command line to be the *count*th previous command line in the shell command history. If *count* is not specified, it shall default to 1. The cursor shall be positioned on the first character of the new command. If a **k** or – command would retreat past the maximum number of commands in effect for this shell (affected by the *HISTSIZE* environment variable), the terminal shall be alerted, and the command shall have no effect.
[*count***]j** **[***count***]+**	Set the current command line to be the *count*th next command line in the shell command history. If *count* is not specified, it shall default to 1. The cursor shall be positioned on the first character of the new command. If a **j** or **+** command advances past the edit line, the current command line shall be restored to the edit line and terminal shall be alerted.
[*number***]G**	Set the current command line to be the oldest command line stored in the shell command history. With a number *number*, set the current command line to be the command line *number* in the history. If command line *number* does not exist, the terminal shall be alerted and the command line shall not be changed.
/*pattern*<newline>	Move backwards through the command history, searching for the specified pattern, beginning with the previous command line. Patterns use the pattern matching notation described in Section 2.13 (on page 2264), except that the '^' character shall have special meaning when it appears as the first character of *pattern*. In this case, the '^' is discarded and the characters after the '^' shall be matched only at the beginning of a line. Commands in the command history shall be treated as strings, not as filenames. If the pattern is not found, the current command line shall be unchanged and the terminal is alerted. If it is found in a previous line, the current command line shall be set to that line and the cursor shall be set to the first character of the new command line.

If *pattern* is empty, the last non-empty pattern provided to **/** or **?** shall be used. If there is no previous non-empty pattern, the terminal shall be alerted and the current command line shall remain unchanged.

?*pattern*<newline>
Move forwards through the command history, searching for the specified pattern, beginning with the next command line. Patterns use the pattern matching notation described in Section 2.13 (on page 2264), except that the '^' character shall have special meaning when it appears as the first character of *pattern*. In this case, the '^' is discarded and the characters after the '^' shall be matched only at the beginning of a line. Commands in the command history shall be treated as strings, not as filenames. If the pattern is not found, the current command line shall be unchanged and the terminal alerted. If it is found in a following line, the current command line shall be set to that line and the cursor shall be set to the fist character of the new command line.

If *pattern* is empty, the last non-empty pattern provided to **/** or **?** shall be used. If there is no previous non-empty pattern, the terminal shall be alerted and the current command line shall remain unchanged.

n Repeat the most recent **/** or **?** command. If there is no previous **/** or **?**, the terminal shall be alerted and the current command line shall remain unchanged.

N Repeat the most recent **/** or **?** command, reversing the direction of the search. If there is no previous **/** or **?**, the terminal shall be alerted and the current command line shall remain unchanged.

EXIT STATUS

The following exit values shall be returned:

0	The script to be executed consisted solely of zero or more blank lines or comments, or both.
1-125	A non-interactive shell detected a syntax, redirection or variable assignment error.
127	A specified *command_file* could not be found by a non-interactive shell.

Otherwise, the shell shall return the exit status of the last command it invoked or attempted to invoke (see also the *exit* utility in Section 2.14 (on page 2266)).

CONSEQUENCES OF ERRORS

See Section 2.8.1 (on page 2247).

APPLICATION USAGE

Standard input and standard error are the files that determine whether a shell is interactive when **−i** is not specified. For example:

```
sh > file
```

and:

```
sh 2> file
```

create interactive and non-interactive shells, respectively. Although both accept terminal input, the results of error conditions are different, as described in Section 2.8.1 (on page 2247); in the second example a redirection error encountered by a special built-in utility aborts the shell.

A conforming application must protect its first operand, if it starts with a plus sign, by preceding it with the "−−" argument that denotes the end of the options.

Applications should note that the standard *PATH* to the shell cannot be assumed to be either **/bin/sh** or **/usr/bin/sh**, and should be determined by interrogation of the *PATH* returned by *getconf PATH*, ensuring that the returned pathname is an absolute pathname and not a shell built in.

For example, to determine the location of the standard *sh* utility:

```
command −v sh
```

On some implementations this might return:

```
/usr/xpg4/bin/sh
```

Furthermore, on systems that support executable scripts (the "#!" construct), it is recommended that applications using executable scripts install them using *getconf* **−v** to determine the shell pathname and update the "#!" script appropriately as it is being installed (for example, with *sed*). For example:

```
#
# Installation time script to install correct POSIX shell pathname
#
# Get list of paths to check
#
Sifs=$IFS
IFS=:
set $(getconf PATH)
IFS=$Sifs
#
# Check each path for ’sh’
#
for i in $@
do
    if [ −f ${i}/sh ];
    then
        Pshell=${i}/sh
    fi
done
#
# This is the list of scripts to update. They should be of the
# form ’${name}.source’ and will be transformed to ’${name}’.
# Each script should begin:
#
# !INSTALLSHELLPATH −p
#
scripts="a b c"
#
# Transform each script
#
for i in ${scripts}
do
    sed −e "s|INSTALLSHELLPATH|${Pshell}|" < ${i}.source > ${i}
done
```

EXAMPLES

1. Execute a shell command from a string:

   ```
   sh −c "cat myfile"
   ```

2. Execute a shell script from a file in the current directory:

```
sh my_shell_cmds
```

RATIONALE

The *sh* utility and the *set* special built-in utility share a common set of options.

The KornShell ignores the contents of *IFS* upon entry to the script. A conforming application cannot rely on importing *IFS*. One justification for this, beyond security considerations, is to assist possible future shell compilers. Allowing *IFS* to be imported from the environment prevents many optimizations that might otherwise be performed via dataflow analysis of the script itself.

The text in the STDIN section about non-blocking reads concerns an instance of *sh* that has been invoked, probably by a C-language program, with standard input that has been opened using the O_NONBLOCK flag; see *open*( ) in the System Interfaces volume of IEEE Std 1003.1-200x. If the shell did not reset this flag, it would immediately terminate because no input data would be available yet and that would be considered the same as end-of-file.

The options associated with a *restricted shell* (command name *rsh* and the **−r** option) were excluded because the standard developers considered that the implied level of security could not be achieved and they did not want to raise false expectations.

On systems that support set-user-ID scripts, a historical trapdoor has been to link a script to the name **−i**. When it is called by a sequence such as

```
sh −
```

or by:

```
#! usr/bin/sh −
```

the historical systems have assumed that no option letters follow. Thus, this volume of IEEE Std 1003.1-200x allows the single hyphen to mark the end of the options, in addition to the use of the regular "−−" argument, because it was considered that the older practice was so pervasive. An alternative approach is taken by the KornShell, where real and effective user/group IDs must match for an interactive shell; this behavior is specifically allowed by this volume of IEEE Std 1003.1-200x.

Note: There are other problems with set-user-ID scripts that the two approaches described here do not resolve.

The initialization process for the history file can be dependent on the system start-up files, in that they may contain commands that effectively preempt the user's settings of *HISTFILE* and *HISTSIZE*. For example, function definition commands are recorded in the history file, unless the *set* **−o** *nolog* option is set. If the system administrator includes function definitions in some system start-up file called before the *ENV* file, the history file is initialized before the user gets a chance to influence its characteristics.) In some historical shells, the history file is initialized just after the *ENV* file has been processed. Therefore, it is implementation-defined whether changes made to *HISTFILE* after the history file has been initialized are effective.

The default messages for the various *MAIL*-related messages are unspecified because they vary across implementations. Typical messages are:

```
"you have mail\n"
```

or:

```
"you have new mail\n"
```

It is important that the descriptions of command line editing refer to the same shell as that in IEEE Std 1003.1-200x so that interactive users can also be application programmers without having to deal with programmatic differences in their two environments. It is also essential that the utility name *sh* be specified because this explicit utility name is too firmly rooted in historical practice of application programs for it to change.

Consideration was given to mandating a diagnostic message when attempting to set *vi*-mode on terminals that do not support command line editing. However, it is not historical practice for the shell to be cognizant of all terminal types and thus be able to detect inappropriate terminals in all cases. Implementations are encouraged to supply diagnostics in this case whenever possible, rather than leaving the user in a state where editing commands work incorrectly.

In early proposals, the KornShell-derived *emacs* mode of command line editing was included, even though the *emacs* editor itself was not. The community of *emacs* proponents was adamant that the full *emacs* editor not be included in earlier versions of IEEE Std 1003.1 because they were concerned that an attempt to standardize this very powerful environment would encourage vendors to ship versions conforming strictly to earlier versions of IEEE Std 1003.1, but lacking the extensibility required by the community. The author of the original *emacs* program also expressed his desire to omit the program. Furthermore, there were a number of historical systems that did not include *emacs*, or included it without supporting it, but there were very few that did not include and support *vi*. The shell *emacs* command line editing mode was finally omitted from earlier versions of IEEE Std 1003.1 because it became apparent that the KornShell version and the editor being distributed with the GNU system had diverged in some respects. The author of *emacs* requested that the POSIX *emacs* mode either be deleted or have a significant number of unspecified conditions. Although the KornShell author agreed to consider changes to bring the shell into alignment, the standard developers decided to defer specification at this time, rather than attempting to agree on a specific subset of *emacs* late within the development of earlier versions of IEEE Std 1003.1. At the time, it was assumed that convergence on an acceptable definition would occur for a subsequent draft, but that has not happened, and there appears to be no impetus to do so. In any case, implementations are free to offer additional command line editing modes based on the exact models of editors their users are most comfortable with.

Early proposals had the following list entry in **vi Line Editing Insert Mode** (on page 3053):

\	If followed by the *erase* or *kill* character, that character shall be inserted into the input line. Otherwise, the backslash itself shall be inserted into the input line.

However, this is not actually a feature of *sh* command line editing insert mode, but one of some historical terminal line drivers. Some conforming implementations continue to do this when the *stty* **iexten** flag is set.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Text is added to the DESCRIPTION for the Large File Summit proposal.

Issue 6

The Open Group Corrigendum U029/2 is applied, correcting the second SYNOPSIS.

The Open Group Corrigendum U027/3 is applied, correcting a typographical error.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The option letters derived from the set special built-in are also accepted with a leading plus sign (`'+'`).
- Large file extensions are added:
  - Pathname expansion does not fail due to the size of a file.
  - Shell input and output redirections have an implementation-defined offset maximum that is established in the open file description.

In the ENVIRONMENT VARIABLES section, the text ‘‘user’s home directory’’ is updated to ‘‘directory referred to by the *HOME* environment variable’’.

Descriptions for the *ENV* and *PWD* environment variables are included to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

sleep — suspend execution for an interval

SYNOPSIS

`sleep` *`time`*

DESCRIPTION

The *sleep* utility shall suspend execution for at least the integral number of seconds specified by the *time* operand.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

time	A non-negative decimal integer specifying the number of seconds for which to suspend execution.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sleep*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

If the *sleep* utility receives a SIGALRM signal, one of the following actions shall be taken:

1. Terminate normally with a zero exit status.
2. Effectively ignore the signal.
3. Provide the default behavior for signals described in the ASYNCHRONOUS EVENTS section of Section 1.11 (on page 2221). This could include terminating with a non-zero exit status.

The *sleep* utility shall take the standard action for all other signals.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The execution was successfully suspended for at least *time* seconds, or a SIGALRM signal was received. See the ASYNCHRONOUS EVENTS section.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

The *sleep* utility can be used to execute a command after a certain amount of time, as in:

```
(sleep 105; command) &
```

or to execute a command every so often, as in:

```
while true
do
    command
    sleep 37
done
```

RATIONALE

The exit status is allowed to be zero when *sleep* is interrupted by the SIGALRM signal because most implementations of this utility rely on the arrival of that signal to notify them that the requested finishing time has been successfully attained. Such implementations thus do not distinguish this situation from the successful completion case. Other implementations are allowed to catch the signal and go back to sleep until the requested time expires or to provide the normal signal termination procedures.

As with all other utilities that take integral operands and do not specify subranges of allowed values, *sleep* is required by this volume of IEEE Std 1003.1-200x to deal with *time* requests of up to 2 147 483 647 seconds. This may mean that some implementations have to make multiple calls to the delay mechanism of the underlying operating system if its argument range is less than this.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

sort — sort, merge, or sequence check text files

SYNOPSIS

```
sort [−m][−o output][−bdfinru][−t char][−k keydef]... [file...]

sort −c [−bdfinru][−t char][−k keydef][file]
```

DESCRIPTION

The *sort* utility shall perform one of the following functions:

1. Sort lines of all the named files together and write the result to the specified output.
2. Merge lines of all the named (presorted) files together and write the result to the specified output.
3. Check that a single input file is correctly presorted.

Comparisons shall be based on one or more sort keys extracted from each line of input (or, if no sort keys are specified, the entire line up to, but not including, the terminating <newline>), and shall be performed using the collating sequence of the current locale.

OPTIONS

The *sort* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, and the **−k** *keydef* option should follow the **−b**, **−d**, **−f**, **−i**, **−n**, and **−r** options.

The following options shall be supported:

−c	Check that the single input file is ordered as specified by the arguments and the collating sequence of the current locale. No output shall be produced; only the exit code shall be affected.
−m	Merge only; the input file shall be assumed to be already sorted.
−o *output*	Specify the name of an output file to be used instead of the standard output. This file can be the same as one of the input *file*s.
−u	Unique: suppress all but one in each set of lines having equal keys. If used with the **−c** option, check that there are no lines with duplicate keys, in addition to checking that the input file is sorted.

The following options shall override the default ordering rules. When ordering options appear independent of any key field specifications, the requested field ordering rules shall be applied globally to all sort keys. When attached to a specific key (see **−k**), the specified ordering options shall override all global ordering options for that key.

−d	Specify that only <blank>s and alphanumeric characters, according to the current setting of *LC_CTYPE*, shall be significant in comparisons. The behavior is undefined for a sort key to which **−i** or **−n** also applies.
−f	Consider all lowercase characters that have uppercase equivalents, according to the current setting of *LC_CTYPE*, to be the uppercase equivalent for the purposes of comparison.
−i	Ignore all characters that are non-printable, according to the current setting of *LC_CTYPE*.
−n	Restrict the sort key to an initial numeric string, consisting of optional <blank>s, optional minus sign, and zero or more digits with an optional radix character and thousands separators (as defined in the current locale), which shall be sorted by

arithmetic value. An empty digit string shall be treated as zero. Leading zeros and signs on zeros shall not affect ordering.

−r Reverse the sense of comparisons.

The treatment of field separators can be altered using the options:

−b Ignore leading <blank>s when determining the starting and ending positions of a restricted sort key. If the **−b** option is specified before the first **−k** option, it shall be applied to all **−k** options. Otherwise, the **−b** option can be attached independently to each **−k** *field_start* or *field_end* option-argument (see below).

−t *char* Use *char* as the field separator character; *char* shall not be considered to be part of a field (although it can be included in a sort key). Each occurrence of *char* shall be significant (for example, <*char*><*char*> delimits an empty field). If **−t** is not specified, <blank>s shall be used as default field separators; each maximal non-empty sequence of <blank>s that follows a non-<blank> shall be a field separator.

Sort keys can be specified using the options:

−k *keydef* The *keydef* argument is a restricted sort key field definition. The format of this definition is:

`field_start[type][,field_end[type]]`

where *field_start* and *field_end* define a key field restricted to a portion of the line (see the EXTENDED DESCRIPTION section), and *type* is a modifier from the list of characters `'b'`, `'d'`, `'f'`, `'i'`, `'n'`, `'r'`. The `'b'` modifier shall behave like the **−b** option, but shall apply only to the *field_start* or *field_end* to which it is attached. |
The other modifiers shall behave like the corresponding options, but shall apply only to the key field to which they are attached; they shall have this effect if specified with *field_start*, *field_end*, or both. If any modifier is attached to a *field_start* or to a *field_end*, no option shall apply to either. Implementations shall support at least nine occurrences of the **−k** option, which shall be significant in command line order. If no **−k** option is specified, a default sort key of the entire line shall be used.

When there are multiple key fields, later keys shall be compared only after all earlier keys compare equal. Except when the **−u** option is specified, lines that otherwise compare equal shall be ordered as if none of the options **−d**, **−f**, **−i**, **−n**, or **−k** were present (but with **−r** still in effect, if it was specified) and with all bytes in the lines significant to the comparison. The order in which lines that still compare equal are written is unspecified.

OPERANDS

The following operand shall be supported:

file A pathname of a file to be sorted, merged, or checked. If no *file* operands are specified, or if a *file* operand is `'−'`, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files, except that the *sort* utility shall add a <newline> to the end of a file ending with an incomplete last line.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sort*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for ordering rules.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classification for the −**b**, −**d**, −**f**, −**i**, and −**n** options.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_NUMERIC	Determine the locale for the definition of the radix character and thousands separator for the −**n** option.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

Unless the −**o** or −**c** options are in effect, the standard output shall contain the sorted input.

STDERR

The standard error shall be used for diagnostic messages. A warning message about correcting an incomplete last line of an input file may be generated, but need not affect the final exit status.

OUTPUT FILES

If the −**o** option is in effect, the sorted input shall be written to the file *output*.

EXTENDED DESCRIPTION

The notation:

```
−k field_start[type][,field_end[type]]
```

shall define a key field that begins at *field_start* and ends at *field_end* inclusive, unless *field_start* falls beyond the end of the line or after *field_end*, in which case the key field is empty. A missing *field_end* shall mean the last character of the line.

A field comprises a maximal sequence of non-separating characters and, in the absence of option −**t**, any preceding field separator.

The *field_start* portion of the *keydef* option-argument shall have the form:

```
field_number[.first_character]
```

Fields and characters within fields shall be numbered starting with 1. The *field_number* and *first_character* pieces, interpreted as positive decimal integers, shall specify the first character to be used as part of a sort key. If .*first_character* is omitted, it shall refer to the first character of the field.

The *field_end* portion of the *keydef* option-argument shall have the form:

```
field_number[.last_character]
```

The *field_number* shall be as described above for *field_start*. The *last_character* piece, interpreted as a non-negative decimal integer, shall specify the last character to be used as part of the sort key. If *last_character* evaluates to zero or *.last_character* is omitted, it shall refer to the last character of the field specified by *field_number*.

If the −**b** option or **b** type modifier is in effect, characters within a field shall be counted from the first non-<blank> in the field. (This shall apply separately to *first_character* and *last_character*.)

EXIT STATUS

The following exit values shall be returned:

0	All input files were output successfully, or −**c** was specified and the input file was correctly sorted.
1	Under the −**c** option, the file was not ordered as specified, or if the −**c** and −**u** options were both specified, two input lines were found with equal keys.
>1	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The default value for −**t**, <blank>, has different properties from, for example, −**t**"<space>". If a line contains:

```
<space><space>foo
```

the following treatment would occur with default separation as opposed to specifically selecting a <space>:

Field	**Default**	**−t "<space>"**
1	<space><space>foo	*empty*
2	*empty*	*empty*
3	*empty*	foo

The leading field separator itself is included in a field when −**t** is not used. For example, this command returns an exit status of zero, meaning the input was already sorted:

```
sort −c −k 2 <<eof
y<tab>b
x<space>a
eof
```

(assuming that a <tab> precedes the <space> in the current collating sequence). The field separator is not included in a field when it is explicitly set via −**t**. This is historical practice and allows usage such as:

```
sort −t "|" −k 2n <<eof
Atlanta|425022|Georgia
Birmingham|284413|Alabama
Columbia|100385|South Carolina
eof
```

where the second field can be correctly sorted numerically without regard to the non-numeric field separator.

The wording in the OPTIONS section clarifies that the −**b**, −**d**, −**f**, −**i**, −**n**, and −**r** options have to come before the first sort key specified if they are intended to apply to all specified keys. The way it is described in this volume of IEEE Std 1003.1-200x matches historical practice, not historical documentation. The results are unspecified if these options are specified after a −**k** option.

The −**f** option might not work as expected in locales where there is not a one-to-one mapping between an uppercase and a lowercase letter.

EXAMPLES

1. The following command sorts the contents of **infile** with the second field as the sort key:

```
sort −k 2,2 infile
```

2. The following command sorts, in reverse order, the contents of **infile1** and **infile2**, placing the output in **outfile** and using the second character of the second field as the sort key (assuming that the first character of the second field is the field separator):

```
sort −r −o outfile −k 2.2,2.2 infile1 infile2
```

3. The following command sorts the contents of **infile1** and **infile2** using the second non-<blank> of the second field as the sort key:

```
sort −k 2.2b,2.2b infile1 infile2
```

4. The following command prints the System V password file (user database) sorted by the numeric user ID (the third colon-separated field):

```
sort −t : −k 3,3n /etc/passwd
```

5. The following command prints the lines of the already sorted file **infile**, suppressing all but one occurrence of lines having the same third field:

```
sort −um −k 3.1,3.0 infile
```

RATIONALE

Examples in some historical documentation state that options −**um** with one input file keep the first in each set of lines with equal keys. This behavior was deemed to be an implementation artifact and was not standardized.

The −**z** option was omitted; it is not standard practice on most systems and is inconsistent with using *sort* to sort several files individually and then merge them together. The text concerning −**z** in historical documentation appeared to require implementations to determine the proper buffer length during the sort phase of operation, but not during the merge.

The −**y** option was omitted because of non-portability. The −**M** option, present in System V, was omitted because of non-portability in international usage.

An undocumented −**T** option exists in some implementations. It is used to specify a directory for intermediate files. Implementations are encouraged to support the use of the *TMPDIR* environment variable instead of adding an option to support this functionality.

The −**k** option was added to satisfy two objections. First, the zero-based counting used by *sort* is not consistent with other utility conventions. Second, it did not meet syntax guideline requirements.

Historical documentation indicates that ‘‘setting −**n** implies −**b**’’. The description of −**n** already states that optional leading <blank>s are tolerated in doing the comparison. If −**b** is enabled, rather than implied, by **−n**, this has unusual side effects. When a character offset is used in a column of numbers (for example, to sort modulo 100), that offset is measured relative to the most significant digit, not to the column. Based upon a recommendation from the author of the original *sort* utility, the **−b** implication has been omitted from this volume of IEEE Std 1003.1-200x, and an application wishing to achieve the previously mentioned side effects has to code the **−b** flag explicitly.

FUTURE DIRECTIONS

None.

split

NAME

split — split files into pieces

SYNOPSIS

UP
```
split [−l line_count][−a suffix_length][file[name]]

split −b n[k|m][−a suffix_length][file[name]]
```

DESCRIPTION

The *split* utility shall read an input file and write one or more output files. The default size of each output file shall be 1 000 lines. The size of the output files can be modified by specification of the −**b** or −**l** options. Each output file shall be created with a unique suffix. The suffix shall consist of exactly *suffix_length* lowercase letters from the POSIX locale. The letters of the suffix shall be used as if they were a base-26 digit system, with the first suffix to be created consisting of all `'a'` characters, the second with a `'b'` replacing the last `'a'`, and so on, until a name of all `'z'` characters is created. By default, the names of the output files shall be `'x'`, followed by a two-character suffix from the character set as described above, starting with `"aa"`, `"ab"`, `"ac"`, and so on, and continuing until the suffix `"zz"`, for a maximum of 676 files.

If the number of files required exceeds the maximum allowed by the suffix length provided, such that the last allowable file would be larger than the requested size, the *split* utility shall fail after creating the last file with a valid suffix; *split* shall not delete the files it created with valid suffixes. If the file limit is not exceeded, the last file created shall contain the remainder of the input file, and may be smaller than the requested size.

OPTIONS

The *split* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−**a** *suffix_length*	Use *suffix_length* letters to form the suffix portion of the filenames of the split file. If −**a** is not specified, the default suffix length shall be two. If the sum of the *name* operand and the *suffix_length* option-argument would create a filename exceeding {NAME_MAX} bytes, an error shall result; *split* shall exit with a diagnostic message and no files shall be created.
−**b** *n*	Split a file into pieces *n* bytes in size.
−**b** *n***k**	Split a file into pieces *n**1024 bytes in size.
−**b** *n***m**	Split a file into pieces *n**1 048 576 bytes in size.
−**l** *line_count*	Specify the number of lines in each resulting file piece. The *line_count* argument is an unsigned decimal integer. The default is 1 000. If the input does not end with a <newline>, the partial line shall be included in the last output file.

OPERANDS

The following operands shall be supported:

file	The pathname of the ordinary file to be split. If no input file is given or *file* is `'−'`, the standard input shall be used.
name	The prefix to be used for each of the files resulting from the split operation. If no *name* argument is given, `'x'` shall be used as the prefix of the output files. The combined length of the basename of *prefix* and *suffix_length* cannot exceed {NAME_MAX} bytes. See the OPTIONS section.

STDIN

See the INPUT FILES section.

INPUT FILES

Any file can be used as input.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *split*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files contain portions of the original input file; otherwise, unchanged.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

In the following examples **foo** is a text file that contains 5 000 lines.

1. Create five files, **xaa**, **xab**, **xac**, **xad**, and **xae**:

   ```
   split foo
   ```

2. Create five files, but the suffixed portion of the created files consists of three letters, **xaaa**, **xaab**, **xaac**, **xaad**, and **xaae**:

   ```
   split −a 3 foo
   ```

3. Create three files with four-letter suffixes and a supplied prefix, **bar_aaaa**, **bar_aaab**, and **bar_aaac**:

   ```
   split −a 4 −l 2000 foo bar_
   ```

4. Create as many files as are necessary to contain at most 20*1 024 bytes, each with the default prefix of **x** and a five-letter suffix:

   ```
   split −a 5 −b 20k foo
   ```

RATIONALE

The −**b** option was added to provide a mechanism for splitting files other than by lines. While most uses of the −**b** option are for transmitting files over networks, some believed it would have additional uses.

The −**a** option was added to overcome the limitation of being able to create only 676 files.

Consideration was given to deleting this utility, using the rationale that the function provided by this utility is available via the *csplit* utility (see *csplit* (on page 2480)). Upon reconsideration of the purpose of the User Portability Extension, it was decided to retain both this utility and the *csplit* utility because users use both utilities and have historical expectations of their behavior. Furthermore, the splitting on byte boundaries in *split* cannot be duplicated with the historical *csplit*.

The text ''*split* shall not delete the files it created with valid suffixes'' would normally be assumed, but since the related utility, *csplit*, does delete files under some circumstances, the historical behavior of *split* is made explicit to avoid misinterpretation.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent SYNOPSIS is removed.

NAME

strings — find printable strings in files

SYNOPSIS

UP `strings [−a][−t format][−n number][file...]`

DESCRIPTION

The *strings* utility shall look for printable strings in regular files and shall write those strings to standard output. A printable string is any sequence of four (by default) or more printable characters terminated by a <newline> or NUL character. Additional implementation-defined strings may be written; see *localedef*.

OPTIONS

The *strings* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−a	Scan files in their entirety. If **−a** is not specified, it is implementation-defined what portion of each file is scanned for strings.
−n *number*	Specify the minimum string length, where the *number* argument is a positive decimal integer. The default shall be 4.
−t *format*	Write each string preceded by its byte offset from the start of the file. The format shall be dependent on the single character used as the *format* option-argument:

d	The offset shall be written in decimal.
o	The offset shall be written in octal.
x	The offset shall be written in hexadecimal.

OPERANDS

The following operand shall be supported:

file	A pathname of a regular file to be used as input. If no *file* operand is specified, the *strings* utility shall read from the standard input.

STDIN

See the INPUT FILES section.

INPUT FILES

The input files named by the utility arguments or the standard input shall be regular files of any format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *strings*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and to identify printable strings.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Strings found shall be written to the standard output, one per line.

When the **−t** option is not specified, the format of the output shall be:

```
"%s", <string>
```

With the **−t o** option, the format of the output shall be:

```
"%o %s", <byte offset>, <string>
```

With the **−t x** option, the format of the output shall be:

```
"%x %s", <byte offset>, <string>
```

With the **−t d** option, the format of the output shall be:

```
"%d %s", <byte offset>, <string>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

By default the data area (as opposed to the text, ‘‘bss’’ or header areas) of a binary executable file is scanned. Implementations document which areas are scanned.

Some historical implementations do not require NUL or <newline> terminators for strings to permit those languages that do not use NUL as a string terminator to have their strings written.

EXAMPLES

None.

RATIONALE

Apart from rationalizing the option syntax and slight difficulties with object and executable binary files, *strings* is specified to match historical practice closely. The **−a** and **−n** options were introduced to replace the non-conforming – and −*number* options.

The **−o** option historically means different things on different implementations. Some use it to mean ‘‘*offset* in decimal’’, while others use it as ‘‘*offset* in octal’’. Instead of trying to decide which way would be least objectionable, the **−t** option was added. It was originally named **−O** to mean ‘‘offset’’, but was changed to **−t** to be consistent with *od*.

The ISO C standard function *isprint*( ) is restricted to a domain of **unsigned char**. This volume of IEEE Std 1003.1-200x requires implementations to write strings as defined by the current locale.

FUTURE DIRECTIONS

None.

SEE ALSO

nm

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

strip — remove unnecessary information from executable files (**DEVELOPMENT**)

SYNOPSIS

SD
```
strip file...
```

DESCRIPTION

The *strip* utility shall remove from executable files named by the *file* operands any information the implementor deems unnecessary for execution of those files. The nature of that information is unspecified. The effect of *strip* shall be similar to the use of the –**s** option to *c99* or *fort77*.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file	A pathname referring to an executable file.

STDIN

Not used.

INPUT FILES

The input files shall be in the form of executable files successfully produced by any compiler defined by this volume of IEEE Std 1003.1-200x.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *strip*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The *strip* utility shall produce executable files of unspecified format.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

Historically, this utility has been used to remove the symbol table from an executable file. It was included since it is known that the amount of symbolic information can amount to several megabytes; the ability to remove it in a portable manner was deemed important, especially for smaller systems.

The behavior of *strip* is said to be the same as the **–s** option to a compiler. While the end result is essentially the same, it is not required to be identical.

FUTURE DIRECTIONS

None.

ar, *c99*, *fort77*

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the Software Development Utilities option.

NAME

stty — set the options for a terminal

SYNOPSIS

```
stty [ −a| −g]

stty operands
```

DESCRIPTION

The *stty* utility shall set or report on terminal I/O characteristics for the device that is its standard input. Without options or operands specified, it shall report the settings of certain characteristics, usually those that differ from implementation-defined defaults. Otherwise, it shall modify the terminal state according to the specified operands. Detailed information about the modes listed in the first five groups below are described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. Operands in the Combination Modes group (see **Combination Modes** (on page 3087)) are implemented using operands in the previous groups. Some combinations of operands are mutually-exclusive on some terminal types; the results of using such combinations are unspecified.

Typical implementations of this utility require a communications line configured to use the **termios** interface defined in the System Interfaces volume of IEEE Std 1003.1-200x. On systems where none of these lines are available, and on lines not currently configured to support the **termios** interface, some of the operands need not affect terminal characteristics.

OPTIONS

The *stty* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−a	Write to standard output all the current settings for the terminal.
−g	Write to standard output all the current settings in an unspecified form that can be used as arguments to another invocation of the *stty* utility on the same system. The form used shall not contain any characters that would require quoting to avoid word expansion by the shell; see Section 2.6 (on page 2238).

OPERANDS

The following operands shall be supported to set the terminal characteristics.

Control Modes

parenb (**−parenb**)	Enable (disable) parity generation and detection. This shall have the effect of setting (not setting) PARENB in the **termios** *c_cflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
parodd (**−parodd**)	Select odd (even) parity. This shall have the effect of setting (not setting) PARODD in the **termios** *c_cflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
cs5 cs6 cs7 cs8	Select character size, if possible. This shall have the effect of setting CS5, CS6, CS7, and CS8, respectively, in the **termios** *c_cflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
number	Set terminal baud rate to the number given, if possible. If the baud rate is set to zero, the modem control lines shall not be longer asserted. This shall have the effect of setting the input and output **termios** baud rate values as defined

in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

ispeed *number* Set terminal input baud rate to the number given, if possible. If the input baud rate is set to zero, the input baud rate shall be specified by the value of the output baud rate. This shall have the effect of setting the input **termios** baud rate values as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

ospeed *number* Set terminal output baud rate to the number given, if possible. If the output baud rate is set to zero, the modem control lines shall no longer be asserted. This shall have the effect of setting the output **termios** baud rate values as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

hupcl (−**hupcl**) Stop asserting modem control lines (do not stop asserting modem control lines) on last close. This shall have the effect of setting (not setting) HUPCL in the **termios** *c_cflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

hup (−**hup**) Equivalent to **hupcl**(−**hupcl**).

cstopb (−**cstopb**) Use two (one) stop bits per character. This shall have the effect of setting (not setting) CSTOPB in the **termios** *c_cflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

cread (−**cread**) Enable (disable) the receiver. This shall have the effect of setting (not setting) CREAD in the **termios** *c_cflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

clocal (−**clocal**) Assume a line without (with) modem control. This shall have the effect of setting (not setting) CLOCAL in the **termios** *c_cflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

It is unspecified whether *stty* shall report an error if an attempt to set a Control Mode fails.

Input Modes

ignbrk (−**ignbrk**) Ignore (do not ignore) break on input. This shall have the effect of setting (not setting) IGNBRK in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

brkint (−**brkint**) Signal (do not signal) INTR on break. This shall have the effect of setting (not setting) BRKINT in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

ignpar (−**ignpar**) Ignore (do not ignore) bytes with parity errors. This shall have the effect of setting (not setting) IGNPAR in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

parmrk (−**parmrk**)

Mark (do not mark) parity errors. This shall have the effect of setting (not setting) PARMRK in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

inpck (**–inpck**) Enable (disable) input parity checking. This shall have the effect of setting (not setting) INPCK in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

istrip (**–istrip**) Strip (do not strip) input characters to seven bits. This shall have the effect of setting (not setting) ISTRIP in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

inlcr (**–inlcr**) Map (do not map) NL to CR on input. This shall have the effect of setting (not setting) INLCR in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

igncr (–igncr) Ignore (do not ignore) CR on input. This shall have the effect of setting (not setting) IGNCR in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

icrnl (**–icrnl**) Map (do not map) CR to NL on input. This shall have the effect of setting (not setting) ICRNL in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

ixon (**–ixon**) Enable (disable) START/STOP output control. Output from the system is stopped when the system receives STOP and started when the system receives START. This shall have the effect of setting (not setting) IXON in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

XSI **ixany** (**–ixany**) Allow any character to restart output. This shall have the effect of setting (not setting) IXANY in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

ixoff (**–ixoff**) Request that the system send (not send) STOP characters when the input queue is nearly full and START characters to resume data transmission. This shall have the effect of setting (not setting) IXOFF in the **termios** *c_iflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

Output Modes

opost (**–opost**) Post-process output (do not post-process output; ignore all other output modes). This shall have the effect of setting (not setting) OPOST in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

XSI **ocrnl** (**–ocrnl**) Map (do not map) CR to NL on output This shall have the effect of setting (not setting) OCRNL in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

onocr (**–onocr**) Do not (do) output CR at column zero. This shall have the effect of setting (not setting) ONOCR in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

onlret (**–onlret**) The terminal newline key performs (does not perform) the CR function. This shall have the effect of setting (not setting) ONLRET in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

ofill (−**ofill**)	Use fill characters (use timing) for delays. This shall have the effect of setting (not setting) OFILL in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
ofdel (−**ofdel**)	Fill characters are DELs (NULs). This shall have the effect of setting (not setting) OFDEL in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
cr0 cr1 cr2 cr3	Select the style of delay for CRs. This shall have the effect of setting CRDLY to CR0, CR1, CR2, or CR3, respectively, in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
nl0 nl1	Select the style of delay for NL. This has the effect of setting NLDLY to NL0 or NL1, respectively, in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
tab0 tab1 tab2 tab3	Select the style of delay for horizontal tabs. This shall have the effect of setting TABDLY to TAB0, TAB1, TAB2, or TAB3, respectively, in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. Note that TAB3 has the effect of expanding <tab>s to <space>s.
tabs (−**tabs**)	Synonym for **tab0** (**tab3**).
bs0 bs1	Select the style of delay for backspaces. This shall have the effect of setting BSDLY to BS0 or BS1, respectively, in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
ff0 ff1	Select the style of delay for form-feeds. This shall have the effect of setting FFDLY to FF0 or FF1, respectively, in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
vt0 vt1	Select the style of delay for vertical-tabs. This shall have the effect of setting VTDLY to VT0 or VT1, respectively, in the **termios** *c_oflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

Local Modes

isig (−**isig**)	Enable (disable) the checking of characters against the special control characters INTR, QUIT, and SUSP. This shall have the effect of setting (not setting) ISIG in the **termios** *c_lflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
icanon (−**icanon**)	Enable (disable) canonical input (ERASE and KILL processing). This shall have the effect of setting (not setting) ICANON in the **termios** *c_lflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
iexten (−**iexten**)	Enable (disable) any implementation-defined special control characters not currently controlled by **icanon**, **isig**, **ixon**, or **ixoff**. This shall have the effect of setting (not setting) IEXTEN in the **termios** *c_lflag* field, as defined in the Base

Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

echo (−**echo**) Echo back (do not echo back) every character typed. This shall have the effect of setting (not setting) ECHO in the **termios** *c_lflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

echoe (−**echoe**) The ERASE character visually erases (does not erase) the last character in the current line from the display, if possible. This shall have the effect of setting (not setting) ECHOE in the **termios** *c_lflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

echok (−**echok**) Echo (do not echo) NL after KILL character. This shall have the effect of setting (not setting) ECHOK in the **termios** *c_lflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

echonl (−**echonl**) Echo (do not echo) NL, even if **echo** is disabled. This shall have the effect of setting (not setting) ECHONL in the **termios** *c_lflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

noflsh (−**noflsh**) Disable (enable) flush after INTR, QUIT, SUSP. This shall have the effect of setting (not setting) NOFLSH in the **termios** *c_lflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

tostop (−**tostop**) Send SIGTTOU for background output. This shall have the effect of setting (not setting) TOSTOP in the **termios** *c_lflag* field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

Special Control Character Assignments

<control>-character string

Set *<control>-character* to *string*. If *<control>-character* is one of the character sequences in the first column of the following table, the corresponding Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface control character from the second column shall be recognized. This has the effect of setting the corresponding element of the **termios** *c_cc* array (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers, **<termios.h>**).

Table 4-19 Control Character Names in *stty*

Control Character	c_cc Subscript	Description
eof	VEOF	EOF character
eol	VEOL	EOL character
erase	VERASE	ERASE character
intr	VINTR	INTR character
kill	VKILL	KILL character
quit	VQUIT	QUIT character
susp	VSUSP	SUSP character
start	VSTART	START character
stop	VSTOP	STOP character

If *string* is a single character, the control character shall be set to that character. If *string* is the two-character sequence `"^-"` or the string *undef*, the control character shall be set to _POSIX_VDISABLE , if it is in effect for the device; if _POSIX_VDISABLE is not in effect for the device, it shall be treated as an error. In the POSIX locale, if *string* is a two-character sequence beginning with circumflex (`'^'`), and the second character is one of those listed in the `"^c"` column of the following table, the control character shall be set to the corresponding character value in the Value column of the table.

Table 4-20 Circumflex Control Characters in *stty*

^c	Value	^c	Value	^c	Value
`a, A`	<SOH>	`l, L`	<FF>	`w, W`	<ETB>
`b, B`	<STX>	`m, M`	<CR>	`x, X`	<CAN>
`c, C`	<ETX>	`n, N`	<SO>	`y, Y`	<EM>
`d, D`	<EOT>	`o, O`	<SI>	`z, Z`	<SUB>
`e, E`	<ENQ>	`p, P`	<DLE>	`[`	<ESC>
`f, F`	<ACK>	`q, Q`	<DC1>	`\`	<FS>
`g, G`	<BEL>	`r, R`	<DC2>	`]`	<GS>
`h, H`	<BS>	`s, S`	<DC3>	`^`	<RS>
`i, I`	<HT>	`t, T`	<DC4>	`_`	<US>
`j, J`	<LF>	`u, U`	<NAK>	`?`	<DEL>
`k, K`	<VT>	`v, V`	<SYN>		

min *number*

Set the value of MIN to *number*. MIN is used in non-canonical mode input processing (**icanon**).

time *number*

Set the value of TIME to *number*. TIME is used in non-canonical mode input processing (**icanon**).

Combination Modes

saved settings

Set the current terminal characteristics to the saved settings produced by the **−g** option.

evenp or **parity**

Enable **parenb** and **cs7**; disable **parodd**.

oddp

Enable **parenb**, **cs7**, and **parodd**.

−**parity**, −**evenp**, or −**oddp**
Disable **parenb**, and set **cs8**.

XSI **raw** (−**raw** or **cooked**)
Enable (disable) raw input and output. Raw mode shall be equivalent to setting:

```
stty cs8 erase ^- kill ^- intr ^- \
    quit ^- eof ^- eol ^- -post -inpck
```

nl (−**nl**)
Enable (disable) **icrnl**. In addition, −**nl** unsets **inlcr** and **igncr**.

ek Reset ERASE and KILL characters back to system defaults.

sane Reset all modes to some reasonable, unspecified, values.

STDIN

Although no input is read from standard input, standard input shall be used to get the current terminal I/O characteristics and to set new terminal I/O characteristics.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *stty*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE This variable determines the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and which characters are in the class **print**.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If operands are specified, no output shall be produced.

If the −**g** option is specified, *stty* shall write to standard output the current settings in a form that can be used as arguments to another instance of *stty* on the same system.

If the −**a** option is specified, all of the information as described in the OPERANDS section shall be written to standard output. Unless otherwise specified, this information shall be written as <space>-separated tokens in an unspecified format, on one or more lines, with an unspecified number of tokens per line. Additional information may be written.

If no options or operands are specified, an unspecified subset of the information written for the −**a** option shall be written.

If speed information is written as part of the default output, or if the −**a** option is specified and if the terminal input speed and output speed are the same, the speed information shall be written as follows:

```
"speed %d baud;", <speed>
```

Otherwise, speeds shall be written as:

```
"ispeed %d baud; ospeed %d baud;", <ispeed>, <ospeed>
```

In locales other than the POSIX locale, the word **baud** may be changed to something more appropriate in those locales.

If control characters are written as part of the default output, or if the −**a** option is specified, control characters shall be written as:

```
"%s = %s;", <control-character name>, <value>
```

where <*value*> is either the character, or some visual representation of the character if it is non-printable, or the string *undef* if the character is disabled.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The terminal options were read or set successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The −**g** flag is designed to facilitate the saving and restoring of terminal state from the shell level. For example, a program may:

```
saveterm="$(stty −g)"       # save terminal state
stty (new settings)         # set new state
...                        # ...
stty $saveterm              # restore terminal state
```

Since the format is unspecified, the saved value is not portable across systems.

Since the −**a** format is so loosely specified, scripts that save and restore terminal settings should use the −**g** option.

EXAMPLES

None.

RATIONALE

The original *stty* description was taken directly from System V and reflected the System V terminal driver **termio**. It has been modified to correspond to the terminal driver **termios**.

Output modes are specified only for XSI-conformant systems. All implementations are expected to provide *stty* operands corresponding to all of the output modes they support.

The *stty* utility is primarily used to tailor the user interface of the terminal, such as selecting the preferred ERASE and KILL characters. As an application programming utility, *stty* can be used within shell scripts to alter the terminal settings for the duration of the script.

The **termios** section states that individual disabling of control characters is possible through the option _POSIX_VDISABLE. If enabled, two conventions currently exist for specifying this: System V uses `"^−"`, and BSD uses *undef*. Both are accepted by *stty* in this volume of IEEE Std 1003.1-200x. The other BSD convention of using the letter `'u'` was rejected because it conflicts with the actual letter `'u'`, which is an acceptable value for a control character.

Early proposals did not specify the mapping of `"^c"` to control characters because the control characters were not specified in the POSIX locale character set description file requirements. The control character set is now specified in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 3, Definitions so the historical mapping is specified. Note that although the mapping corresponds to control-character key assignments on many terminals that use the ISO/IEC 646:1991 standard (or ASCII) character encodings, the mapping specified here is to the control characters, not their keyboard encodings.

Since **termios** supports separate speeds for input and output, two new options were added to specify each distinctly.

Some historical implementations use standard input to get and set terminal characteristics; others use standard output. Since input from a login TTY is usually restricted to the owner while output to a TTY is frequently open to anyone, using standard input provides fewer chances of accidentally (or maliciously) altering the terminal settings of other users. Using standard input also allows *stty* −**a** and *stty* −**g** output to be redirected for later use. Therefore, usage of standard input is required by this volume of IEEE Std 1003.1-200x.

FUTURE DIRECTIONS

NAME

tabs — set terminal tabs

SYNOPSIS

```
tabs [ −n| −a| −a2| −c| −c2| −c3| −f| −p| −s| −u][+m[n]] [−T type]

tabs [−T type][ +[n]] n1[,n2,...]
```

DESCRIPTION

The *tabs* utility shall display a series of characters that first clears the hardware terminal tab settings and then initializes the tab stops at the specified positions and optionally adjusts the margin.

The phrase ‘‘tab-stop position *N*’’ shall be taken to mean that, from the start of a line of output, tabbing to position *N* shall cause the next character output to be in the (*N*+1)th column position on that line. The maximum number of tab stops allowed is terminal-dependent.

It need not be possible to implement *tabs* on certain terminals. If the terminal type obtained from the *TERM* environment variable or **−T** option represents such a terminal, an appropriate diagnostic message shall be written to standard error and *tabs* shall exit with a status greater than zero.

OPTIONS

The *tabs* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for various extensions: the options **−a2**, **−c2**, and **−c3** are multi-character.

The following options shall be supported:

−*n*	Specify repetitive tab stops separated by a uniform number of column positions, *n*, where *n* is a single-digit decimal number. The default usage of *tabs* with no arguments shall be equivalent to **tabs**−8. When **−0** is used, the tab stops shall be cleared and no new ones set.
−a	1,10,16,36,72 Assembler, applicable to some mainframes.
−a2	1,10,16,40,72 Assembler, applicable to some mainframes.
−c	1,8,12,16,20,55 COBOL, normal format.
−c2	1,6,10,14,49 COBOL, compact format (columns 1 to 6 omitted).
−c3	1,6,10,14,18,22,26,30,34,38,42,46,50,54,58,62,67 COBOL compact format (columns 1 to 6 omitted), with more tabs than **−c2**.
−f	1,7,11,15,19,23 FORTRAN
−p	1,5,9,13,17,21,25,29,33,37,41,45,49,53,57,61 PL/1
−s	1,10,55 SNOBOL
−u	1,12,20,44 Assembler, applicable to some mainframes.

–T *type*	Indicate the type of terminal. If this option is not supplied and the *TERM* variable is unset or null, an unspecified default terminal type shall be used. The setting of *type* shall take precedence over the value in *TERM*.

OPERANDS

The following operand shall be supported:

*n1***[**,*n2*,. . .**]**	A single command line argument that consists of tab-stop values separated using either commas or <blank>s. The application shall ensure that the tab-stop values are positive decimal integers in strictly ascending order. If any number (except the first one) is preceded by a plus sign, it is taken as an increment to be added to the previous value. For example, the tab lists 1,10,20,30 and 1,10,+10,+10 are considered to be identical.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *tabs*:

	LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
	LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
	LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
	LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
	TERM	Determine the terminal type. If this variable is unset or null, and if the **–T** option is not specified, an unspecified default terminal type shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If standard output is a terminal, the appropriate sequence to clear and set the tab stops may be written to standard output in an unspecified format. If standard output is not a terminal, undefined results occur.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

This utility makes use of the terminal's hardware tabs and the *stty tabs* option.

This utility is not recommended for application use.

Some integrated display units might not have escape sequences to set tab stops, but may be set by internal system calls. On these terminals, *tabs* works if standard output is directed to the terminal; if output is directed to another file, however, *tabs* fails.

EXAMPLES

None.

RATIONALE

Consideration was given to having the *tput* utility handle all of the functions described in *tabs*. However, the separate *tabs* utility was retained because it seems more intuitive to use a command named *tabs* than *tput* with a new option. The POSIX Shell and Utilities *tput* does not support setting or clearing tabs, and no known historical version of *tabs* supports the capability of setting arbitrary tab stops.

The System V *tabs* interface is very complex; the version in this volume of IEEE Std 1003.1-200x has a reduced feature list, but many of the features omitted were restored as XSI extensions even though the supported languages and coding styles are primarily historical.

There was considerable sentiment for specifying only a means of resetting the tabs back to a known state—presumably the ''standard'' of tabs every eight positions. The following features were omitted:

- Setting tab stops via the first line in a file, using −−*file*. Since even the SVID has no complete explanation of this feature, it is doubtful that it is in widespread use.

In an early proposal, a **−t** *tablist* option was added for consistency with *expand*; this was later removed when inconsistencies with the historical list of tabs were identified.

Consideration was given to adding a **−p** option that would output the current tab settings so that they could be saved and then later restored. This was not accepted because querying the tab stops of the terminal is not a capability in historical *terminfo* or *termcap* facilities and might not be supported on a wide range of terminals.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

tail — copy the last part of a file

SYNOPSIS

`tail [−f][ −c number| −n number][file]`

DESCRIPTION

The *tail* utility shall copy its input file to the standard output beginning at a designated place.

Copying shall begin at the point in the file indicated by the −**c** *number* or −**n** *number* options. The option-argument *number* shall be counted in units of lines or bytes, according to the options −**n** and −**c**. Both line and byte counts start from 1.

Tails relative to the end of the file may be saved in an internal buffer, and thus may be limited in length. Such a buffer, if any, shall be no smaller than {LINE_MAX}*10 bytes.

OPTIONS

The *tail* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−**c** *number* The application shall ensure that the *number* option-argument is a decimal integer whose sign affects the location in the file, measured in bytes, to begin the copying:

Sign	Copying Starts
+	Relative to the beginning of the file.
−	Relative to the end of the file.
none	Relative to the end of the file.

The origin for counting shall be 1; that is, −**c** +1 represents the first byte of the file, −**c** −1 the last.

−**f** If the input file is a regular file or if the *file* operand specifies a FIFO, do not terminate after the last line of the input file has been copied, but read and copy further bytes from the input file when they become available. If no *file* operand is specified and standard input is a pipe, the −**f** option shall be ignored. If the input file is not a FIFO, pipe, or regular file, it is unspecified whether or not the −**f** option shall be ignored.

−**n** *number* This option shall be equivalent to −**c** *number*, except the starting location in the file shall be measured in lines instead of bytes. The origin for counting shall be 1; that is, −**n** +1 represents the first line of the file, −**n** −1 the last.

If neither −**c** nor −**n** is specified, −**n** 10 shall be assumed.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified. See the INPUT FILES section.

INPUT FILES

If the −**c** option is specified, the input file can contain arbitrary data; otherwise, the input file shall be a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *tail*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The designated portion of the input file shall be written to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The −**c** option should be used with caution when the input is a text file containing multi-byte characters; it may produce output that does not start on a character boundary.

Although the input file to *tail* can be any type, the results might not be what would be expected on some character special device files or on file types not described by the System Interfaces volume of IEEE Std 1003.1-200x. Since this volume of IEEE Std 1003.1-200x does not specify the block size used when doing input, *tail* need not read all of the data from devices that only perform block transfers.

EXAMPLES

The –**f** option can be used to monitor the growth of a file that is being written by some other process. For example, the command:

```
tail –f fred
```

prints the last ten lines of the file **fred**, followed by any lines that are appended to **fred** between the time *tail* is initiated and killed. As another example, the command:

```
tail –f –c 15 fred
```

prints the last 15 bytes of the file **fred**, followed by any bytes that are appended to **fred** between the time *tail* is initiated and killed.

RATIONALE

This version of *tail* was created to allow conformance to the Utility Syntax Guidelines. The historical –**b** option was omitted because of the general non-portability of block-sized units of text. The –**c** option historically meant ''characters'', but this volume of IEEE Std 1003.1-200x indicates that it means ''bytes''. This was selected to allow reasonable implementations when multi-byte characters are possible; it was not named –**b** to avoid confusion with the historical –**b**.

The origin of counting both lines and bytes is 1, matching all widespread historical implementations.

The restriction on the internal buffer is a compromise between the historical System V implementation of 4 096 bytes and the BSD 32 768 bytes.

The –**f** option has been implemented as a loop that sleeps for 1 second and copies any bytes that are available. This is sufficient, but if more efficient methods of determining when new data are available are developed, implementations are encouraged to use them.

Historical documentation indicates that *tail* ignores the –**f** option if the input file is a pipe (pipe and FIFO on systems that support FIFOs). On BSD-based systems, this has been true; on System V-based systems, this was true when input was taken from standard input, but it did not ignore the –**f** flag if a FIFO was named as the *file* operand. Since the –**f** option is not useful on pipes and all historical implementations ignore –**f** if no *file* operand is specified and standard input is a pipe, this volume of IEEE Std 1003.1-200x requires this behavior. However, since the –**f** option is useful on a FIFO, this volume of IEEE Std 1003.1-200x also requires that if standard input is a FIFO or a FIFO is named, the –**f** option shall not be ignored. Although historical behavior does not ignore the –**f** option for other file types, this is unspecified so that implementations are allowed to ignore the –**f** option if it is known that the file cannot be extended.

This was changed to the current form based on comments noting that –**c** was almost never used without specifying a number and that there was no need to specify –**l** if –**n** *number* was given.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent SYNOPSIS lines and associated text are removed.

The normative text is reworded to avoid use of the term ''must'' for application requirements.

NAME

talk — talk to another user

SYNOPSIS

UP

```
talk address [terminal]
```

DESCRIPTION

The *talk* utility is a two-way, screen-oriented communication program.

When first invoked, *talk* shall send a message similar to:

```
Message from <unspecified string>
talk: connection requested by your_address
talk: respond with: talk your_address
```

to the specified *address*. At this point, the recipient of the message can reply by typing:

```
talk your_address
```

Once communication is established, the two parties can type simultaneously, with their output displayed in separate regions of the screen. Characters shall be processed as follows:

- Typing the alert character shall alert the recipient's terminal.
- Typing <control>-L shall cause the sender's screen regions to be refreshed.
- Typing the erase and kill characters shall affect the sender's terminal in the manner described by the **termios** interface in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
- Typing the interrupt or end-of-file characters shall terminate the local *talk* utility. Once the *talk* session has been terminated on one side, the other side of the *talk* session shall be notified that the *talk* session has been terminated and shall be able to do nothing except exit.
- Typing characters from *LC_CTYPE* classifications **print** or **space** shall cause those characters to be sent to the recipient's terminal.
- When and only when the *stty* **iexten** local mode is enabled, the existence and processing of additional special control characters and multi-byte or single-byte functions shall be implementation-defined.
- Typing other non-printable characters shall cause implementation-defined sequences of printable characters to be sent to the recipient's terminal.

Permission to be a recipient of a *talk* message can be denied or granted by use of the *mesg* utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The *talk* utility shall fail when the user lacks the appropriate privileges to perform the requested action.

Certain block-mode terminals do not have all the capabilities necessary to support the simultaneous exchange of messages required for *talk*. When this type of exchange cannot be supported on such terminals, the implementation may support an exchange with reduced levels of simultaneous interaction or it may report an error describing the terminal-related deficiency.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

address	The recipient of the *talk* session. One form of *address* is the <*user name*>, as returned by the *who* utility. Other address formats and how they are handled are unspecified.
terminal	If the recipient is logged in more than once, the *terminal* argument can be used to indicate the appropriate terminal name. If *terminal* is not specified, the *talk* message shall be displayed on one or more accessible terminals in use by the recipient. The format of *terminal* shall be the same as that returned by the *who* utility.

STDIN

Characters read from standard input shall be copied to the recipient's terminal in an unspecified manner. If standard input is not a terminal, talk shall write a diagnostic message and exit with a non-zero status.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *talk*:

	LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
	LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
	LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). If the recipient's locale does not use an *LC_CTYPE* equivalent to the sender's, the results are undefined.
	LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
	TERM	Determine the name of the invoker's terminal type. If this variable is unset or null, an unspecified default terminal type shall be used.

ASYNCHRONOUS EVENTS

When the *talk* utility receives a SIGINT signal, the utility shall terminate and exit with a zero status. It shall take the standard action for all other signals.

STDOUT

If standard output is a terminal, characters copied from the recipient's standard input may be written to standard output. Standard output also may be used for diagnostic messages. If standard output is not a terminal, *talk* shall exit with a non-zero status.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred or *talk* was invoked on a terminal incapable of supporting it.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Because the handling of non-printable, non-<space>s is tied to the *stty* description of **iexten**, implementation extensions within the terminal driver can be accessed. For example, some implementations provide line editing functions with certain control character sequences.

EXAMPLES

None.

RATIONALE

The *write* utility was included in this volume of IEEE Std 1003.1-200x since it can be implemented on all terminal types. The *talk* utility, which cannot be implemented on certain terminals, was considered to be a ''better'' communications interface. Both of these programs are in widespread use on historical implementations. Therefore, both utilities have been specified.

All references to networking abilities (*talk*ing to a user on another system) were removed as being outside the scope of this volume of IEEE Std 1003.1-200x.

Historical BSD and System V versions of *talk* terminate both of the conversations when either user breaks out of the session. This can lead to adverse consequences if a user unwittingly continues to enter text that is interpreted by the shell when the other terminates the session. Therefore, the version of *talk* specified by this volume of IEEE Std 1003.1-200x requires both users to terminate their end of the session explicitly.

Only messages sent to the terminal of the invoking user can be internationalized in any way:

- The original ''Message from <*unspecified string*> ...'' message sent to the terminal of the recipient cannot be internationalized because the environment of the recipient is as yet inaccessible to the *talk* utility. The environment of the invoking party is irrelevant.
- Subsequent communication between the two parties cannot be internationalized because the two parties may specify different languages in their environment (and non-portable characters cannot be mapped from one language to another).
- Neither party can be required to communicate in a language other than C and/or the one specified by their environment because unavailable terminal hardware support (for example, fonts) may be required.

The text in the STDOUT section reflects the usage of the verb ''display'' in this section; some *talk* implementations actually use standard output to write to the terminal, but this volume of IEEE Std 1003.1-200x does not require that to be the case.

The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, *who*, and *write* require that they all use or accept the same format.

The handling of non-printable characters is partially implementation-defined because the details of mapping them to printable sequences is not needed by the user. Historical implementations, for security reasons, disallow the transmission of non-printable characters that may send commands to the other terminal.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

NAME

tee — duplicate standard input

SYNOPSIS

```
tee [−ai][file...]
```

DESCRIPTION

The *tee* utility shall copy standard input to standard output, making a copy in zero or more files. The *tee* utility shall not buffer output.

If the **−a** option is not specified, output files shall be written (see Section 1.7.1.4 (on page 2204).

OPTIONS

The *tee* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−a	Append the output to the files.
−i	Ignore the SIGINT signal.

OPERANDS

The following operands shall be supported:

file	A pathname of an output file. Processing of at least 13 *file* operands shall be supported.

STDIN

The standard input can be of any type.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *tee*:

	LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
	LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
	LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
	LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default, except that if the **−i** option was specified, SIGINT shall be ignored.

STDOUT

The standard output shall be a copy of the standard input.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

If any *file* operands are specified, the standard input shall be copied to each named file.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The standard input was successfully copied to all output files.
>0	An error occurred.

CONSEQUENCES OF ERRORS

If a write to any successfully opened *file* operand fails, writes to other successfully opened *file* operands and standard output shall continue, but the exit status shall be non-zero. Otherwise, the default actions specified in Section 1.11 (on page 2221) apply.

APPLICATION USAGE

The *tee* utility is usually used in a pipeline, to make a copy of the output of some utility.

The *file* operand is technically optional, but *tee* is no more useful than *cat* when none is specified.

EXAMPLES

Save an unsorted intermediate form of the data in a pipeline:

```
... | tee unsorted | sort > sorted
```

RATIONALE

The buffering requirement means that *tee* is not allowed to use ISO C standard fully buffered or line-buffered writes. It does not mean that *tee* has to do 1-byte reads followed by 1-byte writes.

It should be noted that early versions of BSD ignore any invalid options and accept a single '–' as an alternative to **–i**. They also print a message if unable to open a file:

```
"tee: cannot access %s\n", <pathname>
```

Historical implementations ignore write errors. This is explicitly not permitted by this volume of IEEE Std 1003.1-200x.

Some historical implementations use O_APPEND when providing append mode; others use the *lseek*( ) function to seek to the end of file after opening the file without O_APPEND. This volume of IEEE Std 1003.1-200x requires functionality equivalent to using O_APPEND; see Section 1.7.1.4 (on page 2204).

FUTURE DIRECTIONS

None.

Issue 6

IEEE PASC Interpretation 1003.2 #168 is applied.

NAME

test — evaluate expression

SYNOPSIS

```
test [expression]

[ [expression] ]
```

DESCRIPTION

The *test* utility shall evaluate the *expression* and indicates the result of the evaluation by its exit status. An exit status of zero indicates that the expression evaluated as true and an exit status of 1 indicates that the expression evaluated as false.

In the second form of the utility, which uses `"[]"` rather than *test*, the application shall ensure that the square brackets are separate arguments.

OPTIONS

The *test* utility shall not recognize the `"−−"` argument in the manner specified by guideline 10 in the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

No options shall be supported.

OPERANDS

The application shall ensure that all operators and elements of primaries are presented as separate arguments to the *test* utility.

The following primaries can be used to construct *expression*:

−**b** *file*	True if *file* exists and is a block special file.
−**c** *file*	True if *file* exists and is a character special file.
−**d** *file*	True if *file* exists and is a directory.
−**e** *file*	True if *file* exists.
−**f** *file*	True if *file* exists and is a regular file.
−**g** *file*	True if *file* exists and its set-group-ID flag is set.
−**h** *file*	True if *file* exists and is a symbolic link.
−**L** *file*	True if *file* exists and is a symbolic link.
−**n** *string*	True if the length of *string* is non-zero.
−**p** *file*	True if *file* is a FIFO.
−**r** *file*	True if *file* exists and is readable. True shall indicate that permission to read from *file* will be granted, as defined in Section 1.7.1.4 (on page 2204).
−**S** *file*	True if *file* exists and is a socket.
−**s** *file*	True if *file* exists and has a size greater than zero.
−**t** *file_descriptor*	True if the file whose file descriptor number is *file_descriptor* is open and is associated with a terminal.
−**u** *file*	True if *file* exists and its set-user-ID flag is set.
−**w** *file*	True if *file* exists and is writable. True shall indicate that permission to write from *file* will be granted, as defined in Section 1.7.1.4 (on page 2204).

	−x *file*	True if *file* exists and is executable. True shall indicate that permission to execute *file* will be granted, as defined in Section 1.7.1.4 (on page 2204). If *file* is a directory, true shall indicate that permission to search *file* will be granted.
	−z *string*	True if the length of string *string* is zero.
	string	True if the string *string* is not the null string.
	s1 **=** *s2*	True if the strings *s1* and *s2* are identical.
	s1 **!=** *s2*	True if the strings *s1* and *s2* are not identical.
	n1 **−eq** *n2*	True if the integers *n1* and *n2* are algebraically equal.
	n1 **−ne** *n2*	True if the integers *n1* and *n2* are not algebraically equal.
	n1 **−gt** *n2*	True if the integer *n1* is algebraically greater than the integer *n2*.
	n1 **−ge** *n2*	True if the integer *n1* is algebraically greater than or equal to the integer *n2*.
	n1 **−lt** *n2*	True if the integer *n1* is algebraically less than the integer *n2*.
	n1 **−le** *n2*	True if the integer *n1* is algebraically less than or equal to the integer *n2*.
XSI	*expression1* **−a** *expression2*	True if both *expression1* and *expression2* are true. The **−a** binary primary is left associative. It has a higher precedence than **−o**.
XSI	*expression1* **−o** *expression2*	True if either *expression1* or *expression2* is true. The **−o** binary primary is left associative.

With the exception of the **−h** *file* primary, if a *file* argument is a symbolic link, *test* shall evaluate the expression by resolving the symbolic link and using the file referenced by the link.

These primaries can be combined with the following operators:

	! *expression*	True if *expression* is false.
XSI	**(** *expression* **)**	True if *expression* is true. The parentheses can be used to alter the normal precedence and associativity.

The primaries with two elements of the form:

```
−primary_operator primary_operand
```

are known as *unary primaries*. The primaries with three elements in either of the two forms:

```
primary_operand −primary_operator primary_operand
primary_operand primary_operator primary_operand
```

are known as *binary primaries*. Additional implementation-defined operators and *primary_operator*s may be provided by implementations. They shall be of the form −*operator* where the first character of *operator* is not a digit.

The algorithm for determining the precedence of the operators and the return value that shall be generated is based on the number of arguments presented to *test*. (However, when using the `"[...]"` form, the right-bracket final argument shall not be counted in this algorithm.)

In the following list, $1, $2, $3, and $4 represent the arguments presented to *test*:

0 arguments: Exit false (1).

1 argument:	Exit true (0) if $1 is not null; otherwise, exit false.
2 arguments:	• If $1 is `'!'`, exit true if $2 is null, false if $2 is not null. • If $1 is a unary primary, exit true if the unary test is true, false if the unary test is false. • Otherwise, produce unspecified results.
3 arguments:	• If $2 is a binary primary, perform the binary test of $1 and $3. • If $1 is `'!'`, negate the two-argument test of $2 and $3. • If $1 is `'('` and $3 is `')'`, perform the unary test of $2. • Otherwise, produce unspecified results.
4 arguments:	• If $1 is `'!'`, negate the three-argument test of $2, $3, and $4. XSI • If $1 is `'('` and $4 is `')'`, perform the two-argument test of $2 and $3. • Otherwise, the results are unspecified.
>4 arguments:	The results are unspecified. XSI On XSI-conformant systems, combinations of primaries and operators shall be evaluated using the precedence and associativity rules described previously. In addition, the string comparison binary primaries `'='` and `"!="` shall have a higher precedence than any unary primary.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *test*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	*expression* evaluated to true.
1	*expression* evaluated to false or *expression* was missing.
>1	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Scripts should be careful when dealing with user-supplied input that could be confused with primaries and operators. Unless the application writer knows all the cases that produce input to the script, invocations like:

```
test "$1" −a "$2"
```

should be written as:

```
test "$1" && test "$2"
```

to avoid problems if a user supplied values such as $1 set to '!' and $2 set to the null string. That is, in cases where maximal portability is of concern, replace:

```
test expr1 −a expr2
```

with:

```
test expr1 && test expr2
```

and replace:

```
test expr1 −o expr2
```

with:

```
test expr1 || test expr2
```

but note that, in *test*, **−a** has higher precedence than **−o** while "&&" and "||" have equal precedence in the shell.

Parentheses or braces can be used in the shell command language to effect grouping.

Parentheses must be escaped when using *sh*; for example:

```
test \( expr1 −a expr2 \) −o expr3
```

This command is not always portable outside XSI-conformant systems. The following form can be used instead:

```
( test expr1 && test expr2 ) || test expr3
```

The two commands:

```
test "$1"
test ! "$1"
```

could not be used reliably on some historical systems. Unexpected results would occur if such a *string* expression were used and $1 expanded to '!', '(', or a known unary primary. Better constructs are:

```
test -n "$1"
test -z "$1"
```

respectively.

Historical systems have also been unreliable given the common construct:

```
test "$response" = "expected string"
```

One of the following is a more reliable form:

```
test "X$response" = "Xexpected string"
test "expected string" = "$response"
```

Note that the second form assumes that *expected string* could not be confused with any unary primary. If *expected string* starts with '-', '(', '!', or even '=', the first form should be used instead. Using the preceding rules without the XSI marked extensions, any of the three comparison forms is reliable, given any input. (However, note that the strings are quoted in all cases.)

Because the string comparison binary primaries, '=' and "!=", have a higher precedence than any unary primary in the greater than 4 argument case, unexpected results can occur if arguments are not properly prepared. For example, in:

```
test -d $1 -o -d $2
```

If $1 evaluates to a possible directory name of '=', the first three arguments are considered a string comparison, which shall cause a syntax error when the second -**d** is encountered. One of the following forms prevents this; the second is preferred:

```
test \( -d "$1" \) -o \( -d "$2" \)
test -d "$1" || test -d "$2"
```

Also in the greater than 4 argument case:

```
test "$1" = "bat" -a "$2" = "ball"
```

Syntax errors occur if $1 evaluates to '(' or '!'. One of the following forms prevents this; the third is preferred:

```
test "X$1" = "Xbat" -a "X$2" = "Xball"
test "$1" = "bat" && test "$2" = "ball"
test "X$1" = "Xbat" && test "X$2" = "Xball"
```

EXAMPLES

1. Exit if there are not two or three arguments (two variations):

   ```
   if [ $# -ne 2 -a $# -ne 3 ]; then exit 1; fi
   if [ $# -lt 2 -o $# -gt 3 ]; then exit 1; fi
   ```

2. Perform a *mkdir* if a directory does not exist:

```
test ! −d tempdir && mkdir tempdir
```

3. Wait for a file to become non-readable:

```
while test −r thefile
do
    sleep 30
done
echo '"thefile" is no longer readable'
```

4. Perform a command if the argument is one of three strings (two variations):

```
if [ "$1" = "pear" ] || [ "$1" = "grape" ] || [ "$1" = "apple" ]
then
    command
fi

case "$1" in
    pear|grape|apple) command ;;
esac
```

RATIONALE

The KornShell-derived conditional command (double bracket **[[ ]]**) was removed from the shell command language description in an early proposal. Objections were raised that the real problem is misuse of the *test* command (**[**), and putting it into the shell is the wrong way to fix the problem. Instead, proper documentation and a new shell reserved word (**!**) are sufficient.

Tests that require multiple *test* operations can be done at the shell level using individual invocations of the *test* command and shell logicals, rather than using the error-prone −**o** flag of *test*.

XSI-conformant systems support more than four arguments.

XSI-conformant systems support the combining of primaries with the following constructs:

expression1 −**a** *expression2*
True if both *expression1* and *expression2* are true.

expression1 −**o** *expression2*
True if at least one of *expression1* and *expression2* are true.

(*expression* **)**
True if *expression* is true.

In evaluating these more complex combined expressions, the following precedence rules are used:

- The unary primaries have higher precedence than the algebraic binary primaries.
- The unary primaries have lower precedence than the string binary primaries.
- The unary and binary primaries have higher precedence than the unary *string* primary.
- The **!** operator has higher precedence than the −**a** operator, and the −**a** operator has higher precedence than the −**o** operator.
- The −**a** and −**o** operators are left associative.
- The parentheses can be used to alter the normal precedence and associativity.

The BSD and System V versions of −**f** are not the same. The BSD definition was:

−**f** *file*	True if *file* exists and is not a directory.

The SVID version (true if the file exists and is a regular file) was chosen for this volume of IEEE Std 1003.1-200x because its use is consistent with the −**b**, −**c**, −**d**, and −**p** operands (*file* exists and is a specific file type).

The −**e** primary, possessing similar functionality to that provided by the C shell, was added because it provides the only way for a shell script to find out if a file exists without trying to open the file. Since implementations are allowed to add additional file types, a portable script cannot use:

```
test −b foo −o −c foo −o −d foo −o −f foo −o −p foo
```

to find out if **foo** is an existing file.) On historical BSD systems, the existence of a file could be determined by:

```
test −f foo −o −d foo
```

but there was no easy way to determine that an existing file was a regular file. An early proposal used the KornShell −**a** primary (with the same meaning), but this was changed to −**e** because there were concerns about the high probability of humans confusing the −**a** primary with the −**a** binary operator.

The following options were not included in this volume of IEEE Std 1003.1-200x, although they are provided by some implementations. These operands should not be used by new implementations for other purposes:

−**k** *file*	True if *file* exists and its sticky bit is set.
−**C** *file*	True if *file* is a contiguous file.
−**V** *file*	True if *file* is a version file.

The following option was not included because it was undocumented in most implementations, has been removed from some implementations (including System V), and the functionality is provided by the shell (see Section 2.6.2 (on page 2239).

−**l** *string*	The length of the string *string*.

The −**b**, −**c**, −**g**, −**p**, −**u**, and −**x** operands are derived from the SVID; historical BSD does not provide them. The −**k** operand is derived from System V; historical BSD does not provide it.

On historical BSD systems, *test* −**w** *directory* always returned false because *test* tried to open the directory for writing, which always fails.

Some additional primaries newly invented or from the KornShell appeared in an early proposal as part of the conditional command (**[[ ]]**): *s1* **>** *s2*, *s1* **<** *s2*, *str* **=** *pattern*, *str* **!=** *pattern*, *f1* −**nt** *f2*, *f1* −**ot** *f2*, and *f1* −**ef** *f2*. They were not carried forward into the *test* utility when the conditional command was removed from the shell because they have not been included in the *test* utility built into historical implementations of the *sh* utility.

The −**t** *file_descriptor* primary is shown with a mandatory argument because the grammar is ambiguous if it can be omitted. Historical implementations have allowed it to be omitted, providing a default of 1.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

The −**h** operand is added for symbolic links, and access permission requirements are clarified for the −**r**, −**w**, and −**x** operands to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The −**L** and −**S** operands are added for symbolic links and sockets.

NAME

time — time a simple command

SYNOPSIS

UP
```
time [−p] utility [argument...]
```

DESCRIPTION

The *time* utility shall invoke the utility named by the *utility* operand with arguments supplied as the *argument* operands and write a message to standard error that lists timing statistics for the utility. The message shall include the following information:

- The elapsed (real) time between invocation of *utility* and its termination.
- The User CPU time, equivalent to the sum of the *tms_utime* and *tms_cutime* fields returned by the *times*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x for the process in which *utility* is executed.
- The System CPU time, equivalent to the sum of the *tms_stime* and *tms_cstime* fields returned by the *times*( ) function for the process in which *utility* is executed.

The precision of the timing shall be no less than the granularity defined for the size of the clock tick unit on the system, but the results shall be reported in terms of standard time units (for example, 0.02 seconds, 00:00:00.02, 1m33.75s, 365.21 seconds), not numbers of clock ticks.

When *time* is used as part of a pipeline, the times reported are unspecified, except when it is the sole command within a grouping command (see Section 2.9.4.1 (on page 2253)) in that pipeline. For example, the commands on the left are unspecified; those on the right report on utilities **a** and **c**, respectively:

```
time a | b | c     { time a } | b | c
a | b | time c     a | b | (time c)
```

OPTIONS

The *time* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−p	Write the timing output to standard error in the format shown in the STDERR section.

OPERANDS

The following operands shall be supported:

utility	The name of a utility that is to be invoked. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2266), the results are undefined.
argument	Any string to be supplied as an argument when invoking the utility named by the *utility* operand.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *time*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic and informative messages written to standard error.
LC_NUMERIC	Determine the locale for numeric formatting.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PATH	Determine the search path that shall be used to locate the utility to be invoked; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used to write the timing statistics. If −**p** is specified, the following format shall be used in the POSIX locale:

```
"real %f\nuser %f\nsys %f\n", <real seconds>, <user seconds>,
    <system seconds>
```

where each floating-point number shall be expressed in seconds. The precision used may be less than the default six digits of `%f`, but shall be sufficiently precise to accommodate the size of the clock tick on the system (for example, if there were 60 clock ticks per second, at least two digits shall follow the radix character). The number of digits following the radix character shall be no less than one, even if this always results in a trailing zero. The implementation may append white space and additional information following the format shown here.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If the *utility* utility is invoked, the exit status of *time* shall be the exit status of *utility*; otherwise, the *time* utility shall exit with one of the following values:

1-125 An error occurred in the *time* utility.

126	The utility specified by *utility* was found but could not be invoked.
127	The utility specified by *utility* could not be found.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ‘‘failure to find a utility’’ from ‘‘invoked utility exited with an error indication’’. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ‘‘normal error conditions’’ and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

EXAMPLES

It is frequently desirable to apply *time* to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the *time* applies to everything in the file.

Alternatively, the following command can be used to apply *time* to a complex command:

```
time sh −c 'complex-command-line'
```

RATIONALE

When the *time* utility was originally proposed to be included in the earlier version of IEEE Std 1003.1, questions were raised about its suitability for inclusion on the grounds that it was not useful for portable applications, specifically:

- The underlying CPU definitions from the System Interfaces volume of IEEE Std 1003.1-200x are vague, so the numeric output could not be compared accurately between systems or even between invocations.
- The creation of portable benchmark programs was outside the scope this volume of IEEE Std 1003.1-200x.

However, *time* does fit in the scope of user portability. Human judgement can be applied to the analysis of the output, and it could be very useful in hands-on debugging of applications or in providing subjective measures of system performance. Hence it has been included in this volume of IEEE Std 1003.1-200x.

The default output format has been left unspecified because historical implementations differ greatly in their style of depicting this numeric output. The **−p** option was invented to provide scripts a common means of obtaining this information.

In the KornShell, *time* is a shell reserved word that can be used to time an entire pipeline, rather than just a simple command. The POSIX definition has been worded to allow this implementation. Consideration was given to invalidating this approach because of the historical model from the C shell and System V shell. However, since the System V *time* utility historically has not produced accurate results in pipeline timing (because the constituent processes are not all owned by the same parent process, as allowed by POSIX), it did not seem worthwhile to break historical KornShell usage.

The term *utility* is used, rather than *command*, to highlight the fact that shell compound commands, pipelines, special built-ins, and so on, cannot be used directly. However, *utility* includes user application programs and shell scripts, not just the standard utilities.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

NAME

touch — change file access and modification times

SYNOPSIS

```
touch [−acm][ −r ref_file| −t time] file...
```

DESCRIPTION

The *touch* utility shall change the modification times, access times, or both of files. The modification time shall be equivalent to the value of the *st_mtime* member of the **stat** structure for a file, as described in the System Interfaces volume of IEEE Std 1003.1-200x; the access time shall be equivalent to the value of *st_atime*.

The time used can be specified by the **−t** *time* option-argument, the corresponding time fields of the file referenced by the **−r** *ref_file* option-argument, or the *date_time* operand, as specified in the following sections. If none of these are specified, *touch* shall use the current time (the value returned by the equivalent of the *time*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x).

For each *file* operand, *touch* shall perform actions equivalent to the following functions defined in the System Interfaces volume of IEEE Std 1003.1-200x:

1. If *file* does not exist, a *creat*( ) function call is made with the *file* operand used as the *path* argument and the value of the bitwise-inclusive OR of S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP, S_IROTH, and S_IWOTH used as the *mode* argument.
2. The *utime*( ) function is called with the following arguments:
   a. The *file* operand is used as the *path* argument.
   b. The **utimbuf** structure members *actime* and *modtime* are determined as described in the OPTIONS section.

OPTIONS

The *touch* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−a	Change the access time of *file*. Do not change the modification time unless **−m** is also specified.
−c	Do not create a specified *file* if it does not exist. Do not write any diagnostic messages concerning this condition.
−m	Change the modification time of *file*. Do not change the access time unless **−a** is also specified.
−r *ref_file*	Use the corresponding time of the file named by the pathname *ref_file* instead of the current time.
−t *time*	Use the specified *time* instead of the current time. The option-argument shall be a decimal number of the form: **[[***CC***]***YY***]***MMDDhhmm***[.***SS***]** where each two digits represents the following: *MM* The month of the year [01,12]. *DD* The day of the month [01,31].

hh	The hour of the day [00,23].
mm	The minute of the hour [00,59].
CC	The first two digits of the year (the century).
YY	The second two digits of the year.
SS	The second of the minute [00,60].

Both *CC* and *YY* shall be optional. If neither is given, the current year shall be assumed. If *YY* is specified, but *CC* is not, *CC* shall be derived as follows:

If *YY* is:	***CC* becomes:**
[69,99]	19
[00,68]	20

Note: It is expected that in a future version of IEEE Std 1003.1-200x the default century inferred from a 2-digit year will change. (This would apply to all commands accepting a 2-digit year as input.)

The resulting time shall be affected by the value of the *TZ* environment variable. If the resulting time value precedes the Epoch, *touch* shall exit immediately with an error status. The range of valid times past the Epoch is implementation-defined, but it shall extend to at least the time 0 hours, 0 minutes, 0 seconds, January 1, 2038, Coordinated Universal Time. Some implementations may not be able to represent dates beyond the January 18, 2038, because they use **signed int** as a time holder.

The range for *SS* is [00,60] rather than [00,59] because of leap seconds. If *SS* is 60, and the resulting time, as affected by the *TZ* environment variable, does not refer to a leap second, the resulting time shall be one second after a time where *SS* is 59. If *SS* is not given a value, it is assumed to be zero.

If neither the −**a** nor −**m** options were specified, *touch* shall behave as if both the −**a** and −**m** options were specified.

OPERANDS

The following operands shall be supported:

file	A pathname of a file whose times shall be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *touch*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in

arguments).

LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
TZ	Determine the timezone to be used for interpreting the *time* option-argument. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The utility executed successfully and all requested changes were made.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The interpretation of time is taken to be *seconds since the Epoch* (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.14, Seconds Since the Epoch). It should be noted that implementations conforming to the System Interfaces volume of IEEE Std 1003.1-200x do not take leap seconds into account when computing seconds since the Epoch. When *SS*=60 is used, the resulting time always refers to 1 plus *seconds since the Epoch* for a time when *SS*=59.

Although the **–t** *time* option-argument specifies values in 1969, the access time and modification time fields are defined in terms of seconds since the Epoch (00:00:00 on 1 January 1970 UTC). Therefore, depending on the value of *TZ* when *touch* is run, there is never more than a few valid hours in 1969 and there need not be any valid times in 1969.

One ambiguous situation occurs if **–t** *time* is not specified, **–r** *ref_file* is not specified, and the first operand is an eight or ten-digit decimal number. A portable script can avoid this problem by using:

```
touch -- file
```

or:

```
touch ./file
```

in this case.

EXAMPLES

None.

RATIONALE

The functionality of *touch* is described almost entirely through references to functions in the System Interfaces volume of IEEE Std 1003.1-200x. In this way, there is no duplication of effort required for describing such side effects as the relationship of user IDs to the user database, permissions, and so on.

There are some significant differences between the *touch* utility in this volume of IEEE Std 1003.1-200x and those in System V and BSD systems. They are upward-compatible for historical applications from both implementations:

1. In System V, an ambiguity exists when a pathname that is a decimal number leads the operands; it is treated as a time value. In BSD, no *time* value is allowed; files may only be *touch*ed to the current time. The −**t** *time* construct solves these problems for future conforming applications (note that the −**t** option is not historical practice).
2. The inclusion of the century digits, *CC*, is also new. Note that a ten-digit *time* value is treated as if *YY*, and not *CC*, were specified. The caveat about the range of dates following the Epoch was included as recognition that some implementations are not able to represent dates beyond 18 January 2038 because they use **signed int** as a time holder.

The −**r** option was added because several comments requested this capability. This option was named −**f** in an early proposal, but was changed because the −**f** option is used in the BSD version of *touch* with a different meaning.

At least one historical implementation of *touch* incremented the exit code if −**c** was specified and the file did not exist. This volume of IEEE Std 1003.1-200x requires exit status zero if no errors occur.

FUTURE DIRECTIONS

Applications should use the −**r** or −**t** options.

SEE ALSO

date, the System Interfaces volume of IEEE Std 1003.1-200x, *creat*( ), *time*( ), **<sys/stat.h>**

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent *date_time* operand is removed.

The Open Group Corrigendum U027/1 is applied. This extends the range of valid time past the Epoch to at least the time 0 hours, 0 minutes, 0 seconds, January 1, 2038, Coordinated Universal Time. This is a new requirement on POSIX implementations.

The range for double leap seconds is changed from [00,61] to [00,60] to align with the ISO/IEC 9899:1999 standard.

NAME

tput — change terminal characteristics

SYNOPSIS

UP
```
tput [−T type] operand...
```

DESCRIPTION

The *tput* utility shall display terminal-dependent information. The manner in which this information is retrieved is unspecified. The information displayed shall clear the terminal screen, initialize the user's terminal, or reset the user's terminal, depending on the operand given. The exact consequences of displaying this information are unspecified.

OPTIONS

The *tput* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−T *type*	Indicate the type of terminal. If this option is not supplied and the *TERM* variable is unset or null, an unspecified default terminal type shall be used. The setting of *type* shall take precedence over the value in *TERM*.

OPERANDS

The following strings shall be supported as operands by the implementation in the POSIX locale:

clear	Display the clear-screen sequence.
init	Display the sequence that initializes the user's terminal in an implementation-defined manner.
reset	Display the sequence that resets the user's terminal in an implementation-defined manner.

If a terminal does not support any of the operations described by these operands, this shall not be considered an error condition.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *tput*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI	*NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
	TERM	Determine the terminal type. If this variable is unset or null, and if the −**T** option is not specified, an unspecified default terminal type shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If standard output is a terminal device, it may be used for writing the appropriate sequence to clear the screen or reset or initialize the terminal. If standard output is not a terminal device, undefined results occur.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The requested string was written successfully.
1	Unspecified.
2	Usage error.
3	No information is available about the specified terminal type.
4	The specified operand is invalid.
>4	An error occurred.

CONSEQUENCES OF ERRORS

If one of the operands is not available for the terminal, *tput* continues processing the remaining operands.

APPLICATION USAGE

The difference between resetting and initializing a terminal is left unspecified, as they vary greatly based on hardware types. In general, resetting is a more severe action.

Some terminals use control characters to perform the stated functions, and on such terminals it might make sense to use *tput* to store the initialization strings in a file or environment variable for later use. However, because other terminals might rely on system calls to do this work, the standard output cannot be used in a portable manner, such as the following non-portable constructs:

```
ClearVar='tput clear'
tput reset | mailx −s "Wake Up" ddg
```

EXAMPLES

1. Initialize the terminal according to the type of terminal in the environmental variable *TERM*. This command can be included in a **.profile** file.

   ```
   tput init
   ```

2. Reset a 450 terminal.

```
tput −T 450 reset
```

RATIONALE

The list of operands was reduced to a minimum for the following reasons:

- The only features chosen were those that were likely to be used by human users interacting with a terminal.
- Specifying the full *terminfo* set was not considered desirable, but the standard developers did not want to select among operands.
- This volume of IEEE Std 1003.1-200x does not attempt to provide applications with sophisticated terminal handling capabilities, as that falls outside of its assigned scope and intersects with the responsibilities of other standards bodies.

The difference between resetting and initializing a terminal is left unspecified as this varies greatly based on hardware types. In general, resetting is a more severe action.

The exit status of 1 is historically reserved for finding out if a Boolean operand is not set. Although the operands were reduced to a minimum, the exit status of 1 should still be reserved for the Boolean operands, for those sites that wish to support them.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

NAME

tr — translate characters

SYNOPSIS

```
tr [−c | −C][−s] string1 string2

tr −s [−c | −C] string1

tr −d [−c | −C] string1

tr −ds [−c | −C] string1 string2
```

DESCRIPTION

The *tr* utility shall copy the standard input to the standard output with substitution or deletion of selected characters. The options specified and the *string1* and *string2* operands shall control translations that occur while copying characters and single-character collating elements.

OPTIONS

The *tr* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c	Complement the set of values specified by *string1*. See the EXTENDED DESCRIPTION section.
−C	Complement the set of characters specified by *string1*. See the EXTENDED DESCRIPTION section.
−d	Delete all occurrences of input characters that are specified by *string1*.
−s	Replace instances of repeated characters with a single character, as described in the EXTENDED DESCRIPTION section.

OPERANDS

The following operands shall be supported:

string1, *string2*

Translation control strings. Each string shall represent a set of characters to be converted into an array of characters used for the translation. For a detailed description of how the strings are interpreted, see the EXTENDED DESCRIPTION section.

STDIN

The standard input can be any type of file.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *tr*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of range expressions and equivalence classes.

LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and the behavior of character classes.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *tr* output shall be identical to the input, with the exception of the specified transformations.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The operands *string1* and *string2* (if specified) define two arrays of characters. The constructs in the following list can be used to specify characters or single-character collating elements. If any of the constructs result in multi-character collating elements, *tr* shall exclude, without a diagnostic, those multi-character elements from the resulting array.

character	Any character not described by one of the conventions below shall represent itself.
octal	Octal sequences can be used to represent characters with specific coded values. An octal sequence shall consist of a backslash followed by the longest sequence of one, two, or three-octal-digit characters (01234567). The sequence shall cause the value whose encoding is represented by the one, two, or three-digit octal integer to be placed into the array. If the size of a byte on the system is greater than nine bits, the valid escape sequence used to represent a byte is implementation-defined. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading `'\'` for each byte.
character	The backslash-escape sequences in the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`) shall be supported. The results of using any other character, other than an octal digit, following the backslash are unspecified.
c−*c*	In the POSIX locale, this construct shall represent the range of collating elements between the range endpoints (as long as neither endpoint is an octal sequence of the form *octal*), inclusive, as defined by the collation sequence. The characters or collating elements in the range shall be placed in the array in ascending collation sequence. If the second endpoint precedes the starting endpoint in the collation sequence, it is unspecified whether the range of collating elements is empty, or this construct is treated as invalid. In locales other than the POSIX locale, this construct has unspecified behavior. If either or both of the range endpoints are octal sequences of the form *octal*, this shall represent the range of specific coded values between the two range endpoints, inclusive.

[:*class*:] Represents all characters belonging to the defined character class, as defined by the current setting of the *LC_CTYPE* locale category. The following character class names shall be accepted when specified in *string1*:

alnum **blank** **digit** **lower** **punct** **upper**
alpha **cntrl** **graph** **print** **space** **xdigit**

XSI In addition, character class expressions of the form [:*name*:] shall be recognized in those locales where the *name* keyword has been given a **charclass** definition in the *LC_CTYPE* category.

When both the **–d** and **–s** options are specified, any of the character class names shall be accepted in *string2*. Otherwise, only character class names **lower** or **upper** are valid in *string2* and then only if the corresponding character class (**upper** and **lower**, respectively) is specified in the same relative position in *string1*. Such a specification shall be interpreted as a request for case conversion. When [: *lower*:] appears in *string1* and [:*upper*:] appears in *string2*, the arrays shall contain the characters from the **toupper** mapping in the *LC_CTYPE* category of the current locale. When [:*upper*:] appears in *string1* and [:*lower*:] appears in *string2*, the arrays shall contain the characters from the **tolower** mapping in the *LC_CTYPE* category of the current locale. The first character from each mapping pair shall be in the array for *string1* and the second character from each mapping pair shall be in the array for *string2* in the same relative position.

Except for case conversion, the characters specified by a character class expression shall be placed in the array in an unspecified order.

If the name specified for *class* does not define a valid character class in the current locale, the behavior is undefined.

[=*equiv*=] Represents all characters or collating elements belonging to the same equivalence class as *equiv*, as defined by the current setting of the *LC_COLLATE* locale category. An equivalence class expression shall be allowed only in *string1*, or in *string2* when it is being used by the combined **–d** and **–s** options. The characters belonging to the equivalence class shall be placed in the array in an unspecified order.

[*x***n*] Represents *n* repeated occurrences of the character *x*. Because this expression is used to map multiple characters to one, it is only valid when it occurs in *string2*. If *n* is omitted or is zero, it shall be interpreted as large enough to extend the *string2*-based sequence to the length of the *string1*-based sequence. If *n* has a leading zero, it shall be interpreted as an octal value. Otherwise, it shall be interpreted as a decimal value.

When the **–d** option is not specified:

- Each input character found in the array specified by *string1* shall be replaced by the character in the same relative position in the array specified by *string2*. When the array specified by *string2* is shorter that the one specified by *string1*, the results are unspecified.
- If the **–C** option is specified, the complements of the characters specified by *string1* (the set of all characters in the current character set, as defined by the current setting of *LC_CTYPE*, except for those actually specified in the *string1* operand) shall be placed in the array in ascending collation sequence, as defined by the current setting of *LC_COLLATE*.
- If the **–c** option is specified, the complement of the values specified by *string1* shall be placed in the array in ascending order by binary value.

- Because the order in which characters specified by character class expressions or equivalence class expressions is undefined, such expressions should only be used if the intent is to map several characters into one. An exception is case conversion, as described previously.

When the −**d** option is specified:

- Input characters found in the array specified by *string1* shall be deleted.
- When the −**C** option is specified with −**d**, all characters except those specified by *string1* shall be deleted. The contents of *string2* are ignored, unless the −**s** option is also specified.
- When the −**c** option is specified with −**d**, all values except those specified by *string1* shall be deleted. The contents of *string2* shall be ignored, unless the −**s** option is also specified.
- The same string cannot be used for both the −**d** and the −**s** option; when both options are specified, both *string1* (used for deletion) and *string2* (used for squeezing) shall be required.

When the −**s** option is specified, after any deletions or translations have taken place, repeated sequences of the same character shall be replaced by one occurrence of the same character, if the character is found in the array specified by the last operand. If the last operand contains a character class, such as the following example:

```
tr −s '[:space:]'
```

the last operand's array shall contain all of the characters in that character class. However, in a case conversion, as described previously, such as:

```
tr −s '[:upper:]' '[:lower:]'
```

the last operand's array shall contain only those characters defined as the second characters in each of the **toupper** or **tolower** character pairs, as appropriate.

An empty string used for *string1* or *string2* produces undefined results.

EXIT STATUS

The following exit values shall be returned:

0	All input was processed successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If necessary, *string1* and *string2* can be quoted to avoid pattern matching by the shell.

If an ordinary digit (representing itself) is to follow an octal sequence, the octal sequence must use the full three digits to avoid ambiguity.

When *string2* is shorter than *string1*, a difference results between historical System V and BSD systems. A BSD system pads *string2* with the last character found in *string2*. Thus, it is possible to do the following:

```
tr 0123456789 d
```

which would translate all digits to the letter `'d'`. Since this area is specifically unspecified in this volume of IEEE Std 1003.1-200x, both the BSD and System V behaviors are allowed, but a conforming application cannot rely on the BSD behavior. It would have to code the example in the following way:

```
tr 0123456789 '[d*]'
```

It should be noted that, despite similarities in appearance, the string operands used by *tr* are not regular expressions.

Unlike some historical implementations, this definition of the *tr* utility correctly processes NUL characters in its input stream. NUL characters can be stripped by using:

```
tr −d '\000'
```

EXAMPLES

1. The following example creates a list of all words in **file1** one per line in **file2**, where a word is taken to be a maximal string of letters.

   ```
   tr −cs "[:alpha:]" "[\n*]" <file1 >file2
   ```

2. The next example translates all lowercase characters in **file1** to uppercase and writes the results to standard output.

   ```
   tr "[:lower:]" "[:upper:]" <file1
   ```

3. This example uses an equivalence class to identify accented variants of the base character `'e'` in **file1**, which are stripped of diacritical marks and written to **file2**.

   ```
   tr "[=e=]" e <file1 >file2
   ```

RATIONALE

In some early proposals, an explicit option −**n** was added to disable the historical behavior of stripping NUL characters from the input. It was considered that automatically stripping NUL characters from the input was not correct functionality. However, the removal of −**n** in a later proposal does not remove the requirement that *tr* correctly process NUL characters in its input stream. NUL characters can be stripped by using *tr* −**d** '\000'.

Historical implementations of *tr* differ widely in syntax and behavior. For example, the BSD version has not needed the bracket characters for the repetition sequence. The POSIX Shell and Utilities *tr* syntax is based more closely on the System V and XPG3 model while attempting to accommodate historical BSD implementations. In the case of the short *string2* padding, the decision was to unspecify the behavior and preserve System V and XPG3 scripts, which might find difficulty with the BSD method. The assumption was made that BSD users of *tr* have to make accommodations to meet the POSIX Shell and Utilities syntax. Since it is possible to use the repetition sequence to duplicate the desired behavior, whereas there is no simple way to achieve the System V method, this was the correct, if not desirable, approach.

The use of octal values to specify control characters, while having historical precedents, is not portable. The introduction of escape sequences for control characters should provide the necessary portability. It is recognized that this may cause some historical scripts to break.

An early proposal included support for multi-character collating elements. It was pointed out that, while *tr* does employ some syntactical elements from REs, the aim of *tr* is quite different; ranges, for example, do not have a similar meaning (‘‘any of the chars in the range matches’’, *versus* ‘‘translate each character in the range to the output counterpart’’). As a result, the previously included support for multi-character collating elements has been removed. What remains are ranges in current collation order (to support, for example, accented characters), character classes, and equivalence classes.

In XPG3 the [:*class*:] and [=*equiv*=] conventions are shown with double brackets, as in RE syntax. However, *tr* does not implement RE principles; it just borrows part of the syntax. Consequently, [:*class*:] and [=*equiv*=] should be regarded as syntactical elements on a par with [*x***n*], which is not an RE bracket expression.

The standard developers will consider changes to *tr* that allow it to translate characters between different character encodings, or they will consider providing a new utility to accomplish this.

On historical System V systems, a range expression requires enclosing square-brackets, such as:

```
tr '[a-z]' '[A-Z]'
```

However, BSD-based systems did not require the brackets, and this convention is used by POSIX Shell and Utilities to avoid breaking large numbers of BSD scripts:

```
tr a-z A-Z
```

The preceding System V script will continue to work because the brackets, treated as regular characters, are translated to themselves. However, any System V script that relied on *a-z* representing the three characters `'−,'` and `'z'` have to be rewritten as *az*−.

A prior version of IEEE Std 1003.1-200x had a −**c** option that behaved similarly to the −**C** option, but did not supply functionality equivalent to the −**c** option specified in IEEE Std 1003.1-200x. This meant that historical practice of being able to specify *tr* −**d**\200−\377 (which would delete all bytes with the top bit set) would have no effect because, in the C locale, bytes with the values octal 200 to octal 377 are not characters.

The earlier version also said that octal sequences referred to collating elements and could be placed adjacent to each other to specify multi-byte characters. However, it was noted that this caused ambiguities because *tr* would not be able to tell whether adjacent octal sequences were intending to specify multi-byte characters or multiple single byte characters. IEEE Std 1003.1-200x specifies that octal sequences always refer to single byte binary values.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 2.

Issue 6

The −**C** operand is added, and the description of the −**c** operand is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

true — return true value

SYNOPSIS

```
true
```

DESCRIPTION

The *true* utility shall return with exit code zero.

OPTIONS

None.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

Default.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

This utility is typically used in shell scripts, as shown in the EXAMPLES section. The special built-in utility `:` is sometimes more efficient than *true*.

EXAMPLES

This command is executed forever:

```
while true
do
    command
done
```

RATIONALE

The *true* utility has been retained in this volume of IEEE Std 1003.1-200x, even though the shell special built-in **:** provides similar functionality, because *true* is widely used in historical scripts and is less cryptic to novice script readers.

FUTURE DIRECTIONS

None.

SEE ALSO

false, Section 2.9 (on page 2248)

CHANGE HISTORY

First released in Issue 2.

NAME

tsort — topological sort

SYNOPSIS

XSI

```
tsort [file]
```

DESCRIPTION

The *tsort* utility shall write to standard output a totally ordered list of items consistent with a partial ordering of items contained in the input.

The application shall ensure that the input consists of pairs of items (non-empty strings) separated by <blank>s. Pairs of different items indicate ordering. Pairs of identical items indicate presence, but not ordering.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file	A pathname of a text file to order. If no *file* operand is given, the standard input shall be used.

STDIN

The standard input shall be a text file that is used if no *file* operand is given.

INPUT FILES

The input file named by the *file* operand is a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *tsort*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be a text file consisting of the order list produced from the partially ordered input.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *LC_COLLATE* variable need not affect the actions of *tsort*. The output ordering is not lexicographic, but depends on the pairs of items given as input.

EXAMPLES

The command:

```
tsort <<EOF
a b c c d e
g g
f g e f
h h
EOF
```

produces the output:

```
a
b
c
d
e
f
g
h
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

tty — return user's terminal name

SYNOPSIS

```
tty
```

DESCRIPTION

The *tty* utility shall write to the standard output the name of the terminal that is open as standard input. The name that is used shall be equivalent to the string that would be returned by the *ttyname*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x.

OPTIONS

The *tty* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

OPERANDS

None.

STDIN

While no input is read from standard input, standard input shall be examined to determine whether or not it is a terminal, and, if so, to determine the name of the terminal.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *tty*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If standard input is a terminal device, a pathname of the terminal as specified by the *ttyname*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x shall be written in the following format:

```
"%s\n", <terminal name>
```

Otherwise, a message shall be written indicating that standard input is not connected to a terminal. In the POSIX locale, the *tty* utility shall use the format:

```
"not a tty\n"
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Standard input is a terminal.
1	Standard input is not a terminal.
>1	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

This utility checks the status of the file open as standard input against that of a implementation-defined set of files. It is possible that no match can be found, or that the match found need not be the same file as that which was opened for standard input (although they are the same device).

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

The System Interfaces volume of IEEE Std 1003.1-200x, *isatty*( ), *ttyname*( )

CHANGE HISTORY

First released in Issue 2.

Issue 5

The SYNOPSIS is changed to indicate two forms of the command, with the second form marked as obsolete. This is a clarification and does not change the functionality published in previous issues.

Issue 6

The obsolescent –**s** option is removed.

NAME

type — write a description of command type

SYNOPSIS

XSI
```
type name...
```

DESCRIPTION

The *type* utility shall indicate how each argument would be interpreted if used as a command name.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

name	A name to be interpreted.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *type*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PATH	Determine the location of *name*, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output of *type* contains information about each operand in an unspecified format. The information provided typically identifies the operand as a shell built-in, function, alias, or keyword, and where applicable, may display the operand's pathname.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *type* must be aware of the contents of the current shell execution environment (such as the lists of commands, functions, and built-ins processed by *hash*), it is always provided as a shell regular built-in. If it is called in a separate utility execution environment, such as one of the following:

```
nohup type writer
find . −type f | xargs type
```

it might not produce accurate results.

EXAMPLES

None.

CHANGE HISTORY

First released in Issue 2.

NAME

ulimit — set or report file size limit

SYNOPSIS

XSI `ulimit [−f][blocks]`

DESCRIPTION

The *ulimit* utility shall set or report the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.

OPTIONS

The *ulimit* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−f	Set (or report, if no *blocks* operand is present), the file size limit in blocks. The **−f** option shall also be the default case.

OPERANDS

The following operand shall be supported:

blocks	The number of 512-byte blocks to use as the new file size limit.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ulimit*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used when no *blocks* operand is present. If the current number of blocks is limited, the number of blocks in the current limit shall be written in the following format:

```
"%d\n", <number of 512-byte blocks>
```

If there is no current limit on the number of blocks, in the POSIX locale the following format shall be used:

```
"unlimited\n"
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	A request for a higher limit was rejected or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *ulimit* affects the current shell execution environment, it is always provided as a shell regular built-in. If it is called in separate utility execution environment, such as one of the following:

```
nohup ulimit −f 10000
env ulimit 10000
```

it does not affect the file size limit of the caller's environment.

Once a limit has been decreased by a process, it cannot be increased (unless appropriate privileges are involved), even back to the original system limit.

EXAMPLES

Set the file size limit to 51 200 bytes:

```
ulimit −f 100
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

umask — get or set the file mode creation mask

SYNOPSIS

```
umask [−S][mask]
```

DESCRIPTION

The *umask* utility shall set the file mode creation mask of the current shell execution environment (see Section 2.12 (on page 2263)) to the value specified by the *mask* operand. This mask shall affect the initial value of the file permission bits of subsequently created files. If *umask* is called in a subshell or separate utility execution environment, such as one of the following:

```
(umask 002)
nohup umask ...
find . −exec umask ... \;
```

it shall not affect the file mode creation mask of the caller's environment.

If the *mask* operand is not specified, the *umask* utility shall write to standard output the value of the invoking process's file mode creation mask.

OPTIONS

The *umask* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−S Produce symbolic output.

The default output style is unspecified, but shall be recognized on a subsequent invocation of *umask* on the same system as a *mask* operand to restore the previous file mode creation mask.

OPERANDS

The following operand shall be supported:

mask A string specifying the new file mode creation mask. The string is treated in the same way as the *mode* operand described in the EXTENDED DESCRIPTION section for *chmod*. |

For a *symbolic_mode* value, the new value of the file mode creation mask shall be the logical complement of the file permission bits portion of the file mode specified by the *symbolic_mode* string.

In a *symbolic_mode* value, the permissions *op* characters `'+'` and `'−'` shall be interpreted relative to the current file mode creation mask; `'+'` shall cause the bits for the indicated permissions to be cleared in the mask; `'−'` shall cause the bits for the indicated permissions to be set in the mask.

The interpretation of *mode* values that specify file mode bits other than the file permission bits is unspecified.

In the octal integer form of *mode*, the specified bits are set in the file mode creation mask.

The file mode creation mask shall be set to the resulting numeric value.

The default output of a prior invocation of *umask* on the same system with no operand also shall be recognized as a *mask* operand.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *umask*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the *mask* operand is not specified, the *umask* utility shall write a message to standard output that can later be used as a *umask mask* operand.

If −**S** is specified, the message shall be in the following format:

```
"u=%s,g=%s,o=%s\n", <owner permissions>, <group permissions>,
    <other permissions>
```

where the three values shall be combinations of letters from the set {*r*, *w*, *x*}; the presence of a letter shall indicate that the corresponding bit is clear in the file mode creation mask.

If a *mask* operand is specified, there shall be no output written to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The file mode creation mask was successfully changed, or no *mask* operand was supplied.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *umask* affects the current shell execution environment, it is generally provided as a shell regular built-in.

In contrast to the negative permission logic provided by the file mode creation mask and the octal number form of the *mask* argument, the symbolic form of the *mask* argument specifies those permissions that are left alone.

EXAMPLES

Either of the commands:

```
umask a=rx,ug+w
```

```
umask 002
```

sets the mode mask so that subsequently created files have their S_IWOTH bit cleared.

After setting the mode mask with either of the above commands, the *umask* command can be used to write out the current value of the mode mask:

```
$ umask
0002
```

(The output format is unspecified, but historical implementations use the octal integer mode format.)

```
$ umask -S
u=rwx,g=rwx,o=rx
```

Either of these outputs can be used as the mask operand to a subsequent invocation of the *umask* utility.

Assuming the mode mask is set as above, the command:

```
umask g-w
```

sets the mode mask so that subsequently created files have their S_IWGRP and S_IWOTH bits cleared.

The command:

```
umask -- -w
```

sets the mode mask so that subsequently created files have all their write bits cleared. Note that *mask* operands **−r**, **−w**, **−x** or anything beginning with a hyphen, must be preceded by "−−" to keep it from being interpreted as an option.

RATIONALE

Since *umask* affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(umask 002)
nohup umask ...
find . -exec umask ... \;
```

it does not affect the file mode creation mask of the environment of the caller.

The description of the historical utility was modified to allow it to use the symbolic modes of *chmod*. The **−s** option used in early proposals was changed to **−S** because **−s** could be confused with a *symbolic_mode* form of mask referring to the S_ISUID and S_ISGID bits. |

The default output style is implementation-defined to permit implementors to provide migration to the new symbolic style at the time most appropriate to their users. An **–o** flag to force octal mode output was omitted because the octal mode may not be sufficient to specify all of the information that may be present in the file mode creation mask when more secure file access permission checks are implemented.

It has been suggested that trusted systems developers might appreciate ameliorating the requirement that the mode mask ‘‘affects’’ the file access permissions, since it seems access control lists might replace the mode mask to some degree. The wording has been changed to say that it affects the file permission bits, and it leaves the details of the behavior of how they affect the file access permissions to the description in the System Interfaces volume of IEEE Std 1003.1-200x.

FUTURE DIRECTIONS

None.

SEE ALSO

chmod, the System Interfaces volume of IEEE Std 1003.1-200x, *umask*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The octal mode is supported.

NAME

unalias — remove alias definitions

SYNOPSIS

UP
```
unalias alias-name...

unalias -a
```

DESCRIPTION

The *unalias* utility shall remove the definition for each alias name specified. See Section 2.3.1 (on page 2234). The aliases shall be removed from the current shell execution environment; see Section 2.12 (on page 2263).

OPTIONS

The *unalias* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−a	Remove all alias definitions from the current shell execution environment.

OPERANDS

The following operand shall be supported:

alias-name	The name of an alias to be removed.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *unalias*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	XSI Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	One of the *alias-name* operands specified did not represent a valid alias definition, or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since *unalias* affects the current shell execution environment, it is generally provided as a shell regular built-in.

EXAMPLES

None.

RATIONALE

The *unalias* description is based on that from historical KornShell implementations. Known differences exist between that and the C shell. The KornShell version was adopted to be consistent with all the other KornShell features in this volume of IEEE Std 1003.1-200x, such as command line editing.

The −**a** option is the equivalent of the *unalias* * form of the C shell and is provided to address security concerns about unknown aliases entering the environment of a user (or application) through the allowable implementation-defined predefined alias route or as a result of an *ENV* file. (Although *unalias* could be used to simplify the ''secure'' shell script shown in the *command* rationale, it does not obviate the need to quote all command names. An initial call to *unalias* −**a** would have to be quoted in case there was an alias for *unalias*.)

FUTURE DIRECTIONS

None.

SEE ALSO

alias

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

NAME

uname — return system name

SYNOPSIS

```
uname [−snrvma]
```

DESCRIPTION

By default, the *uname* utility shall write the operating system name to standard output. When options are specified, symbols representing one or more system characteristics shall be written to the standard output. The format and contents of the symbols are implementation-defined. On systems conforming to the System Interfaces volume of IEEE Std 1003.1-200x, the symbols written shall be those supported by the *uname*( ) function as defined in the System Interfaces volume of IEEE Std 1003.1-200x.

OPTIONS

The *uname* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−a	Behave as though all of the options **−mnrsv** were specified.
−m	Write the name of the hardware type on which the system is running to standard output.
−n	Write the name of this node within an implementation-defined communications network.
−r	Write the current release level of the operating system implementation.
−s	Write the name of the implementation of the operating system.
−v	Write the current version level of this release of the operating system implementation.

If no options are specified, the *uname* utility shall write the operating system name, as if the **−s** option had been specified.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uname*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

By default, the output shall be a single line of the following form:

```
"%s\n", <sysname>
```

If the −**a** option is specified, the output shall be a single line of the following form:

```
"%s %s %s %s %s\n", <sysname>, <nodename>, <release>,
    <version>, <machine>
```

Additional implementation-defined symbols may be written; all such symbols shall be written at the end of the line of output before the <newline>.

If options are specified to select different combinations of the symbols, only those symbols shall be written, in the order shown above for the −**a** option. If a symbol is not selected for writing, its corresponding trailing <blank>s also shall not be written.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The requested information was successfully written.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Note that any of the symbols could include embedded <space>s, which may affect parsing algorithms if multiple options are selected for output.

The node name is typically a name that the system uses to identify itself for intersystem communication addressing.

EXAMPLES

The following command:

```
uname −sr
```

writes the operating system name and release level, separated by one or more <blank>s.

RATIONALE

It was suggested that this utility cannot be used portably since the format of the symbols is implementation-defined. The POSIX.1 working group could not achieve consensus on defining these formats in the underlying *uname*( ) function, and there was no expectation that this volume of IEEE Std 1003.1-200x would be any more successful. Some applications may still find this historical utility of value. For example, the symbols could be used for system log entries or for comparison with operator or user input.

FUTURE DIRECTIONS

None.

The System Interfaces volume of IEEE Std 1003.1-200x, *uname*( )

CHANGE HISTORY

First released in Issue 2.

NAME

uncompress — expand compressed data

SYNOPSIS

XSI `uncompress [−cfv][file...]`

DESCRIPTION

The *uncompress* utility shall restore files to their original state after they have been compressed using the *compress* utility. If no files are specified, the standard input shall be uncompressed to the standard output. If the invoking process has appropriate privileges, the ownership, modes, access time, and modification time of the original file shall be preserved.

This utility shall support the uncompressing of any files produced by the *compress* utility on the same implementation. For files produced by *compress* on other systems, *uncompress* supports 9 to 14-bit compression (see *compress* (on page 2465), **−b**); it is implementation-defined whether values of **−b** greater than 14 are supported.

OPTIONS

The *uncompress* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c Write to standard output; no files are changed.

−f Do not prompt for overwriting files. Except when run in the background, if **−f** is not given the user shall be prompted as to whether an existing file should be overwritten. If the standard input is not a terminal and **−f** is not given, *uncompress* shall write a diagnostic message to standard error and exit with a status greater than zero.

−v Write messages to standard error concerning the expansion of each file.

OPERANDS

The following operand shall be supported:

file A pathname of a file. If *file* already has the **.Z** suffix specified, it shall be used as the input file and the output file shall be named **file** with the **.Z** suffix removed. Otherwise, *file* shall be used as the name of the output file and **file** with the **.Z** suffix appended shall be used as the input file.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`.

INPUT FILES

Input files shall be in the format produced by the *compress* utility.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uncompress*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When there are no *file* operands or the **–c** option is specified, the uncompressed output is written to standard output.

STDERR

Prompts shall be written to the standard error output under the conditions specified in the DESCRIPTION and OPTIONS sections. The prompts shall contain the *file* pathname, but their format is otherwise unspecified. Otherwise, the standard error output shall be used only for diagnostic messages.

OUTPUT FILES

Output files are the same as the respective input files to *compress*.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

The input file remains unmodified.

APPLICATION USAGE

The limit of 14 on the *compress* **–b** *bits* argument is to achieve portability to all systems (within the restrictions imposed by the lack of an explicit published file format). Some implementations based on 16-bit architectures cannot support 15 or 16-bit uncompression.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

unexpand — convert spaces to tabs

SYNOPSIS

UP `unexpand [ −a| −t tablist][file...]`

DESCRIPTION

The *unexpand* utility shall copy files or standard input to standard output, converting <blank>s at the beginning of each line into the maximum number of <tab>s followed by the minimum number of <space>s needed to fill the same column positions originally filled by the translated <blank>s. By default, tabstops shall be set at every eighth column position. Each <backspace> shall be copied to the output, and shall cause the column position count for tab calculations to be decremented; the count shall never be decremented to a value less than one.

OPTIONS

The *unexpand* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−a In addition to translating <blank>s at the beginning of each line, translate all sequences of two or more <blank>s immediately preceding a tab stop to the maximum number of <tab>s followed by the minimum number of <space>s needed to fill the same column positions originally filled by the translated <blank>s.

−t *tablist* Specify the tab stops. The application shall ensure that the *tablist* option-argument is a single argument consisting of a single positive decimal integer or multiple positive decimal integers, separated by <blank>s or commas, in ascending order. If a single number is given, tabs shall be set *tablist* column positions apart instead of the default 8. If multiple numbers are given, the tabs shall be set at those specific column positions.

The application shall ensure that each tab-stop position *N* is an integer value greater than zero, and the list shall be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position *N* shall cause the next character output to be in the (*N*+1)th column position on that line. When the **−t** option is not specified, the default shall be the equivalent of specifying **−t 8** (except for the interaction with **−a**, described below).

No <space>-to-<tab> conversions shall occur for characters at positions beyond the last of those specified in a multiple tab-stop list.

When **−t** is specified, the presence or absence of the **−a** option shall be ignored; conversion shall not be limited to the processing of leading <blank>s.

OPERANDS

The following operand shall be supported:

file A pathname of a text file to be used as input.

STDIN

See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *unexpand*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the processing of <tab>s and <space>s and for the determination of the width in column positions each character would occupy on an output device.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be equivalent to the input files with the specified <space>-to-<tab> conversions. |

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

One non-intuitive aspect of *unexpand* is its restriction to leading spaces when neither **–a** nor **–t** is specified. Users who desire to always convert all spaces in a file can easily alias *unexpand* to use the **–a** or **–t 8** option.

EXAMPLES

None.

RATIONALE

On several occasions, consideration was given to adding a **–t** option to the *unexpand* utility to complement the **–t** in *expand* (see *expand* (on page 2627)). The historical intent of *unexpand* was to translate multiple <blank>s into tab stops, where tab stops were a multiple of eight column positions on most UNIX systems. An early proposal omitted **–t** because it seemed outside the scope of the UPE; it was not described in any of the base documents. However, hard-coding tab stops every eight columns was not suitable for the international community and broke historical precedents for some vendors in the FORTRAN community, so **–t** was restored in conjunction with the list of valid extension categories considered by the standard developers. Thus, *unexpand* is now the logical converse of *expand*.

FUTURE DIRECTIONS

None.

SEE ALSO

expand, *tabs*

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The definition of the *LC_CTYPE* environment variable is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

unget — undo a previous get of an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI
```
unget [−ns][−r SID] file...
```

DESCRIPTION

The *unget* utility shall reverse the effect of a *get* **−e** done prior to creating the intended new delta.

OPTIONS

The *unget* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−r *SID*	Uniquely identify which delta is no longer intended. (This would have been specified by *get* as the new delta.) The use of this option is necessary only if two or more outstanding *get* commands for editing on the same SCCS file were done by the same person (login name).
−s	Suppress the writing to standard output of the intended delta's SID.
−n	Retain the file that was obtained by *get*, which would normally be removed from the current directory.

OPERANDS

The following operands shall be supported:

file	A pathname of an existing SCCS file or a directory. If *file* is a directory, the *unget* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored. If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only when the *file* operand is specified as `'−'`. Each line of the text file shall be interpreted as an SCCS pathname.

INPUT FILES

Any SCCS files processed shall be files of an unspecified format. |

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *unget*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall consist of a line for each file, in the following format:

```
"%s\n", <SID removed from file>
```

If there is more than one named file or if a directory or standard input is named, each pathname shall be written before each of the preceding lines:

```
"\n%s:\n", <pathname>
```

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

Any SCCS files updated shall be files of an unspecified format. During processing of a *file*, a locking *z-file*, as described in *get*, and a *q-file* (a working copy of the *p-file*), may be created and deleted. The *p-file* and *g-file*, as described in *get*, shall be deleted. |

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

The normative text is reworded to emphasize the term ‘‘shall’’ for implementation requirements.

NAME

uniq — report or filter out repeated lines in a file

SYNOPSIS

```
uniq [−c|−d|−u][−f fields][−s char][input_file [output_file]]
```

DESCRIPTION

The *uniq* utility shall read an input file comparing adjacent lines, and writes one copy of each input line on the output. The second and succeeding copies of repeated adjacent input lines shall not be written.

Repeated lines in the input shall not be detected if they are not adjacent.

OPTIONS

The *uniq* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c	Precede each output line with a count of the number of times the line occurred in the input.
−d	Suppress the writing of lines that are not repeated in the input.
−f *fields*	Ignore the first *fields* fields on each input line when doing comparisons, where *fields* is a positive decimal integer. A field is the maximal string matched by the basic regular expression: `[[:blank:]]*[^[:blank:]]*` If the *fields* option-argument specifies more fields than appear on an input line, a null string shall be used for comparison.
−s *chars*	Ignore the first *chars* characters when doing comparisons, where *chars* shall be a positive decimal integer. If specified in conjunction with the **−f** option, the first *chars* characters after the first *fields* fields shall be ignored. If the *chars* option-argument specifies more characters than remain on an input line, a null string shall be used for comparison.
−u	Suppress the writing of lines that are repeated in the input.

OPERANDS

The following operands shall be supported:

input_file	A pathname of the input file. If the *input_file* operand is not specified, or if the *input_file* is `'−'`, the standard input shall be used.
output_file	A pathname of the output file. If the *output_file* operand is not specified, the standard output shall be used. The results are unspecified if the file named by *output_file* is the file named by *input_file*.

STDIN

The standard input shall be used only if no *input_file* operand is specified or if *input_file* is `'−'`. See the INPUT FILES section.

INPUT FILES

The input file shall be a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uniq*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) which characters constitute a <blank> in the current locale.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used only if no *output_file* operand is specified. See the OUTPUT FILES section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

If the **−c** option is specified, the application shall ensure that the output file is empty or each line shall be of the form:

`"%d %s", <number of duplicates>, <line>`

otherwise, the application shall ensure that the output file is empty or each line shall be of the form:

`"%s", <line>`

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	The utility executed successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *sort* utility can be used to cause repeated lines to be adjacent in the input file.

EXAMPLES

The following input file data (but flushed left) was used for a test series on *uniq*:

```
#01 foo0 bar0 foo1 bar1
#02 bar0 foo1 bar1 foo1
#03 foo0 bar0 foo1 bar1
#04
#05 foo0 bar0 foo1 bar1
#06 foo0 bar0 foo1 bar1
#07 bar0 foo1 bar1 foo0
```

What follows is a series of test invocations of the *uniq* utility that use a mixture of *uniq* options against the input file data. These tests verify the meaning of *adjacent*. The *uniq* utility views the input data as a sequence of strings delimited by `'\n'`. Accordingly, for the *fields*th member of the sequence, *uniq* interprets unique or repreated adjacent lines strictly relative to the *fields*+1th member.

1. This first example tests the line counting option, comparing each line of the input file data starting from the second field:

   ```
   uniq −c −f 1 uniq_0I.t
       1 #01 foo0 bar0 foo1 bar1
       1 #02 bar0 foo1 bar1 foo0
       1 #03 foo0 bar0 foo1 bar1
       1 #04
       2 #05 foo0 bar0 foo1 bar1
       1 #07 bar0 foo1 bar1 foo0
   ```

   The number '2', prefixing the fifth line of output, signifies that the *uniq* utility detected a pair of repeated lines. Given the input data, this can only be true when *uniq* is run using the **−f 1** option (which shall cause *uniq* to ignore the first field on each input line).

2. The second example tests the option to suppress unique lines, comparing each line of the input file data starting from the second field:

   ```
   uniq −d −f 1 uniq_0I.t
   #05 foo0 bar0 foo1 bar1
   ```

3. This test suppresses repeated lines, comparing each line of the input file data starting from the second field:

   ```
   uniq −u −f 1 uniq_0I.t
   #01 foo0 bar0 foo1 bar1
   #02 bar0 foo1 bar1 foo1
   #03 foo0 bar0 foo1 bar1
   #04
   #07 bar0 foo1 bar1 foo0
   ```

4. This suppresses unique lines, comparing each line of the input file data starting from the third character:

   ```
   uniq −d −s 2 uniq_0I.t
   ```

   In the last example, the *uniq* utility found no input matching the above criteria.

RATIONALE

Some historical implementations have limited lines to be 1 080 bytes in length, which does not meet the implied {LINE_MAX} limit.

FUTURE DIRECTIONS

None.

SEE ALSO

comm, *sort*

CHANGE HISTORY

NAME

uucp — system-to-system copy

SYNOPSIS

XSI
```
uucp [−cCdfjmr][−n user] source-file... destination-file
```

DESCRIPTION

The *uucp* utility shall copy files named by the *source-file* arguments to the *destination-file* argument. The files named can be on local or remote systems.

The *uucp* utility cannot guarantee support for all character encodings in all circumstances. For example, transmission data may be restricted to 7 bits by the underlying network, 8-bit data and filenames need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646: 1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used, and that only characters defined in the portable filename character set be used for naming files. The protocol for transfer of files is unspecified by IEEE Std 1003.1-200x.

Typical implementations of this utility require a communications line configured to use the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface, but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exit with a non-zero exit status.

OPTIONS

The *uucp* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c	Do not copy local file to the spool directory for transfer to the remote machine (default).
−C	Force the copy of local files to the spool directory for transfer.
−d	Make all necessary directories for the file copy (default).
−f	Do not make intermediate directories for the file copy.
−j	Write the job identification string to standard output. This job identification can be used by *uustat* to obtain the status or terminate a job.
−m	Send mail to the requester when the copy is completed.
−n *user*	Notify *user* on the remote system that a file was sent.
−r	Do not start the file transfer; just queue the job.

OPERANDS

The following operands shall be supported:

destination-file, *source-file*

A pathname of a file to be copied to, or from, respectively. Either name can be a pathname on the local machine, or can have the form:

```
system-name!pathname
```

where *system-name* is taken from a list of system names that *uucp* knows about. The destination *system-name* can also be a list of names such as:

`system-name!system-name!...!system-name!pathname`

in which case, an attempt is made to send the file via the specified route to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information.

The shell pattern matching notation characters `'?'`, `'*'`, and `"[...]"` appearing in *pathname* shall be expanded on the appropriate system. |

Pathnames can be one of:

1. An absolute pathname.
2. A pathname preceded by ˜*user* where *user* is a login name on the specified system and is replaced by that user's login directory. Note that if an invalid login is specified, the default is to the public directory (called *PUBDIR*; the actual location of *PUBDIR* is implementation-defined).
3. A pathname preceded by ˜/*destination* where *destination* is appended to *PUBDIR*.

   Note: This destination is treated as a filename unless more than one file is being transferred by this request or the destination is already a directory. To ensure that it is a directory, follow the destination with a `'/'`. For example, **˜/dan/** as the destination makes the directory **PUBDIR/dan** if it does not exist and put the requested files in that directory.
4. Anything else shall be prefixed by the current directory. |

If the result is an erroneous pathname for the remote system, the copy shall fail. If the *destination-file* is a directory, the last part of the *source-file* name shall be used. |

The read, write, and execute permissions given by *uucp* are implementation-defined.

STDIN

Not used.

INPUT FILES

The files to be copied are regular files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uucp*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes and multi-character collating elements within bracketed filename patterns.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within bracketed filename patterns (for example, `"'[[:lower:]]*'"`).

LC_MESSAGES

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files (which may be on other systems) are copies of the input files.

If the **–m** is used, mail files are modified.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The domain of remotely accessible files can (and for obvious security reasons usually should) be severely restricted.

Note that the '!' character in addresses has to be escaped when using *csh* as a command interpreter because of its history substitution syntax. For *ksh* and *sh* the escape is not necessary, but may be used.

As noted above, shell metacharacters appearing in pathnames are expanded on the appropriate system. On an internationalized system, this is done under the control of local settings of *LC_COLLATE* and *LC_CTYPE*. Thus, care should be taken when using bracketed filename patterns, as collation and typing rules may vary from one system to another. Also be aware that certain types of expression (that is, equivalence classes, character classes, and collating symbols) need not be supported on non-internationalized systems.

EXAMPLES

None.

NAME

uudecode — decode a binary file

SYNOPSIS

UP
```
uudecode [-o outfile][file]
```

DESCRIPTION

The *uudecode* utility shall read a file, or standard input if no file is specified, that includes data created by the *uuencode* utility. The *uudecode* utility shall scan the input file, searching for data compatible with one of the formats specified in *uuencode* and attempt to create or overwrite the file described by the data (or overridden by the **−o** option). The pathname shall be contained in the data or specified by the **−o** option. The file access permission bits and contents for the file to be produced shall be contained in that data. The mode bits of the created file (other than standard output) shall be set from the file access permission bits contained in the data; that is, other attributes of the mode, including the file mode creation mask (see *umask*), shall not affect the file being produced.

If the pathname of the file to be produced exists, and the user does not have write permission on that file, *uudecode* shall terminate with an error. If the pathname of the file to be produced exists, and the user has write permission on that file, the existing file shall be overwritten.

If the input data was produced by *uuencode* on a system with a different number of bits per byte than on the target system, the results of *uudecode* are unspecified.

OPTIONS

The *uudecode* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:

−o *outfile* A pathname of a file that shall be used instead of any pathname contained in the input data. Specifying an *outfile* option-argument of **/dev/stdout** shall indicate standard output.

OPERANDS

The following operand shall be supported:

file The pathname of a file containing the output of *uuencode*.

STDIN

See the INPUT FILES section.

INPUT FILES

The input files shall be files containing the output of *uuencode*.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uudecode*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the file data header encoded by *uuencode* is – or **/dev/stdout**, or the –**o** **/dev/stdout** option overrides the file data, the standard output shall be in the same format as the file originally encoded by *uuencode*. Otherwise, the standard output shall not be used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output file shall be in the same format as the file originally encoded by *uuencode*.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The user who is invoking *uudecode* must have write permission on any file being created.

The output of *uuencode* is essentially an encoded bit stream that is not cognizant of byte boundaries. It is possible that a 9-bit byte target machine can process input from an 8-bit source, if it is aware of the requirement, but the reverse is unlikely to be satisfying. Of course, the only data that is meaningful for such a transfer between architectures is generally character data.

EXAMPLES

None.

RATIONALE

Input files are not necessarily text files, as stated by an early proposal. Although the *uuencode* output is a text file, that output could have been wrapped within another file or mail message that is not a text file.

The –**o** option is not historical practice, but was added at the request of WG15 so that the user could override the target pathname without having to edit the input data itself.

In early drafts, the [–**o** *outfile*] option-argument allowed the use of – to mean standard output. The symbol – has only been used previously in IEEE Std 1003.1-200x as a standard input indicator. The developers of the standard did not wish to overload the meaning of – in this manner. The **/dev/stdout** concept exists on most modern systems. The **/dev/stdout** syntax does not refer to a new special file. It is just a magic cookie to specify standard output.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The −**o** *outfile* option is added, as specified in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

uuencode — encode a binary file

SYNOPSIS

UP

```
uuencode [−m][file] decode_pathname
```

DESCRIPTION

The *uuencode* utility shall write an encoded version of the named input file, or standard input if no *file* is specified, to standard output. The output shall be encoded using one of the algorithms described in the STDOUT section and shall include the file access permission bits (in *chmod* octal or symbolic notation) of the input file and the *decode_pathname*, for re-creation of the file on another system that conforms to this volume of IEEE Std 1003.1-200x.

OPTIONS

The *uuencode* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:

−m Encode the output using the MIME Base64 algorithm described in STDOUT. If **−m** is not specified, the historical algorithm described in STDOUT shall be used.

OPERANDS

The following operands shall be supported:

decode_pathname
The pathname of the file into which the *uudecode* utility shall place the decoded file. Specifying a *decode_pathname* operand of **/dev/stdout** shall indicate that *uudecode* is to use standard output. If there are characters in *decode_pathname* that are not in the portable filename character set the results are unspecified.

file A pathname of the file to be encoded.

STDIN

See the INPUT FILES section.

INPUT FILES

Input files can be files of any type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uuencode*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

uuencode Base64 Algorithm

The standard output shall be a text file (encoded in the character set of the current locale) that begins with the line:

```
"begin-base64Δ%sΔ%s\n", <mode>, <decode_pathname>
```

and ends with the line:

```
"====\n"
```

In both cases, the lines shall have no preceding or trailing <blank>s.

The encoding process represents 24-bit groups of input bits as output strings of four encoded characters. Proceeding from left to right, a 24-bit input group shall be formed by concatenating three 8-bit input groups. Each 24-bit input group then shall be treated as four concatenated 6-bit groups, each of which shall be translated into a single digit in the base64 alphabet. When encoding a bit stream via the base64 encoding, the bit stream shall be presumed to be ordered with the most-significant bit first. That is, the first bit in the stream shall be the high-order bit in the first byte, and the eighth bit shall be the low-order bit in the first byte, and so on. Each 6-bit group is used as an index into an array of 64 printable characters, as shown in Table 4-21.

Table 4-21 uuencode Base64 Values

Value	Encoding	Value	Encoding	Value	Encoding	Value	Encoding
0	A	17	R	34	i	51	z
1	B	18	S	35	j	52	0
2	C	19	T	36	k	53	1
3	D	20	U	37	l	54	2
4	E	21	V	38	m	55	3
5	F	22	W	39	n	56	4
6	G	23	X	40	o	57	5
7	H	24	Y	41	p	58	6
8	I	25	Z	42	q	59	7
9	J	26	a	43	r	60	8
10	K	27	b	44	s	61	9
11	L	28	c	45	t	62	+
12	M	29	d	46	u	63	/
13	N	30	e	47	v		
14	O	31	f	48	w	(pad)	=
15	P	32	g	49	x		
16	Q	33	h	50	y		

The character referenced by the index shall be placed in the output string.

The output stream (encoded bytes) shall be represented in lines of no more than 76 characters each. All line breaks or other characters not found in the table shall be ignored by decoding software (see *uudecode*).

Special processing shall be performed if fewer than 24 bits are available at the end of a message or encapsulated part of a message. A full encoding quantum shall always be completed at the end of a message. When fewer than 24 input bits are available in an input group, zero bits shall be added (on the right) to form an integral number of 6-bit groups. Output character positions that are not required to represent actual input data shall be set to the character `'='`. Since all base64 input is an integral number of octets, only the following cases can arise:

1. The final quantum of encoding input is an integral multiple of 24 bits; here, the final unit of encoded output shall be an integral multiple of 4 characters with no `'='` padding.
2. The final quantum of encoding input is exactly 16 bits; here, the final unit of encoded output shall be three characters followed by one `'='` padding character.
3. The final quantum of encoding input is exactly 8 bits; here, the final unit of encoded output shall be two characters followed by two `'='` padding characters.

A terminating `"===="` evaluates to nothing and denotes the end of the encoded data.

uuencode Historical Algorithm

The standard output shall be a text file (encoded in the character set of the current locale) that begins with the line:

`"beginΔ%sΔ%s\n"` *<mode>*, *<decode_pathname>*

and ends with the line:

`"end\n"`

In both cases, the lines shall have no preceding or trailing <blank>s.

The algorithm that shall be used for lines in between **begin** and **end** takes three octets as input and writes four characters of output by splitting the input at six-bit intervals into four octets, containing data in the lower six bits only. These octets shall be converted to characters by adding a value of 0x20 to each octet, so that each octet is in the range [0x20,0x5f], and then it shall be assumed to represent a printable character in the ISO/IEC 646:1991 standard encoded character set. It then shall be translated into the corresponding character codes for the codeset in use in the current locale. (For example, the octet 0x41, representing `'A'`, would be translated to `'A'` in the current codeset, such as 0xc1 if it were EBCDIC.)

Where the bits of two octets are combined, the least significant bits of the first octet shall be shifted left and combined with the most significant bits of the second octet shifted right. Thus the three octets *A*, *B*, *C* shall be converted into the four octets:

```
0x20 + (( A >> 2                    ) & 0x3F)
0x20 + (((A << 4) | ((B >> 4) & 0xF)) & 0x3F)
0x20 + (((B << 2) | ((C >> 6) & 0x3)) & 0x3F)
0x20 + (( C                         ) & 0x3F)
```

These octets then shall be translated into the local character set.

Each encoded line contains a length character, equal to the number of characters to be decoded plus 0x20 translated to the local character set as described above, followed by the encoded characters. The maximum number of octets to be encoded on each line shall be 45.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The file is expanded by 35 percent (each three octets become four, plus control information) causing it to take longer to transmit.

Since this utility is intended to create files to be used for data interchange between systems with possibly different codesets, and to represent binary data as a text file, the ISO/IEC 646:1991 standard was chosen for a midpoint in the algorithm as a known reference point. The output from *uuencode* is a text file on the local system. If the output were in the ISO/IEC 646:1991 standard codeset, it might not be a text file (at least because the <newline>s might not match), and the goal of creating a text file would be defeated. If this text file was then carried to another machine with the same codeset, it would be perfectly compatible with that system's *uudecode*. If it was transmitted over a mail system or sent to a machine with a different codeset, it is assumed that, as for every other text file, some translation mechanism would convert it (by the time it reached a user on the other system) into an appropriate codeset. This translation only makes sense from the local codeset, not if the file has been put into a ISO/IEC 646:1991 standard representation first. Similarly, files processed by *uuencode* can be placed in *pax* archives, intermixed with other text files in the same codeset.

EXAMPLES

None.

RATIONALE

A new algorithm was added at the request of the international community to parallel work in RFC 2045 (MIME). As with the historical *uuencode* format, the Base64 Content-Transfer-Encoding is designed to represent arbitrary sequences of octets in a form that is not humanly readable. A 65-character subset of the ISO/IEC 646:1991 standard is used, enabling 6 bits to be represented per printable character. (The extra 65th character, `'='`, is used to signify a special processing function.)

This subset has the important property that it is represented identically in all versions of the ISO/IEC 646:1991 standard, including US ASCII, and all characters in the subset are also represented identically in all versions of EBCDIC. The historical *uuencode* algorithm does not share this property, which is the reason that a second algorithm was added to the ISO POSIX-2 standard.

The string `"===="` was used for the termination instead of the end used in the original format because the latter is a string that could be valid encoded input.

In an early draft, the −**m** option was named −**b** (for Base64), but it was renamed to reflect its relationship to the RFC 2045. A −**u** was also present to invoke the default algorithm, but since this was not historical practice, it was omitted as being unnecessary.

See the RATIONALE section in *uudecode* for the derivation of the **/dev/stdout** symbol.

FUTURE DIRECTIONS

None.

mailx, *uudecode*

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The Base64 algorithm and the ability to output to **/dev/stdout** are added as specified in the IEEE P1003.2b draft standard.

NAME

uustat — uucp status inquiry and job control

SYNOPSIS

XSI
```
uustat [ −q| −k jobid| −r jobid]

uustat [−s system][−u user]
```

DESCRIPTION

The *uustat* utility shall display the status of, or cancel, previously specified *uucp* requests, or provide general status on *uucp* connections to other systems.

When no options are given, *uustat* shall write to standard output the status of all *uucp* requests issued by the current user.

Typical implementations of this utility require a communications line configured to use the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface, but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exit with a non-zero exit status.

OPTIONS

The *uustat* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−q	Write the jobs queued for each machine.
−k *jobid*	Kill the *uucp* request whose job identification is *jobid*. The application shall ensure that the killed *uucp* request belongs to the person invoking *uustat* unless that user has appropriate privileges.
−r *jobid*	Rejuvenate *jobid*. The files associated with *jobid* are touched so that their modification time is set to the current time. This prevents the cleanup program from deleting the job until the jobs modification time reaches the limit imposed by the program.
−s *system*	Write the status of all *uucp* requests for remote system *system*.
−u *user*	Write the status of all *uucp* requests issued by *user*.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uustat*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall consist of information about each job selected, in an unspecified format. The information shall include at least the job ID, the user ID or name, and the remote system name.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

NAME

uux — remote command execution

SYNOPSIS

XSI
```
uux [−np] command−string

uux [−jnp] command−string
```

DESCRIPTION

The *uux* utility shall gather zero or more files from various systems, execute a shell pipeline (see Section 2.9 (on page 2248)) on a specified system, and then send the standard output of the command to a file on a specified system. Only the first command of a pipeline can have a *system-name*! prefix. All other commands in the pipeline shall be executed on the system of the first command.

The following restrictions are applicable to the shell pipeline processed by *uux*:

- In gathering files from different systems, pathname expansion shall not be performed by *uux*. Thus, a request such as:

  ```
  uux "c99 remsys!˜/*.c"
  ```

  would attempt to copy the file named literally ***.c** to the local system.

- The redirection operators `">>"`, `"<<"`, `">|"`, and `">&"` shall not be accepted. Any use of these redirection operators shall cause this utility to write an error message describing the problem and exit with a non-zero exit status.

- The reserved word **!** cannot be used at the head of the pipeline to modify the exit status. (See the *command-string* operand description below.)

- Alias substitution shall not be performed.

A filename can be specified as for *uucp*; it can be an absolute pathname, a pathname preceded by ~*name* (which is replaced by the corresponding login directory), a pathname specified as ~/*dest*(*dest* is prefixed by the public directory called *PUBDIR*; the actual location of *PUBDIR* is implementation-defined), or a simple filename (which is prefixed by *uux* with the current directory). See *uucp* (on page 3163) for the details.

The execution of commands on remote systems shall take place in an execution directory known to the *uucp* system. All files required for the execution shall be put into this directory unless they already reside on that machine. Therefore, the application shall ensure that non-local filenames (without path or machine reference) are unique within the *uux* request.

The *uux* utility shall attempt to get all files to the execution system. For files that are output files, the application shall ensure that the filename is escaped using parentheses.

The remote system shall notify the user by mail if the requested command on the remote system was disallowed or the files were not accessible. This notification can be turned off by the **−n** option.

Typical implementations of this utility require a communications line configured to use the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface, but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exits with a non-zero exit status.

The *uux* utility cannot guarantee support for all character encodings in all circumstances. For example, transmission data may be restricted to 7 bits by the underlying network, 8-bit data and filenames need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used and that only characters defined in the portable filename character set be used for naming files.

OPTIONS

The *uux* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−p	Make the standard input to *uux* the standard input to the *command-string*.
−j	Write the job identification string to standard output. This job identification can be used by *uustat* to obtain the status or terminate a job.
−n	Do not notify the user if the command fails.

OPERANDS

The following operand shall be supported:

command-string
A string made up of one or more arguments that are similar to normal command arguments, except that the command and any filenames can be prefixed by *system-name*!. A null *system-name* shall be interpreted as the local system.

STDIN

The standard input shall not be used unless the '−' or **−p** option is specified; in those cases, the standard input shall be made the standard input of the *command-string*.

INPUT FILES

Input files shall be selected according to the contents of *command-string*.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *uux*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be not used unless the **−j** option is specified; in that case, the job identification string shall be written to standard output in the following format:

```
"%s\n", <jobid>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

Output files shall be created or written, or both, according to the contents of *command-string*.

If the **−n** is not used, mail files shall be modified following any command or file-access failures on the remote system.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Note that, for security reasons, many installations limit the list of commands executable on behalf of an incoming request from *uux*. Many sites permit little more than the receipt of mail via *uux*.

Any characters special to the command interpreter should be quoted either by quoting the entire *command-string* or quoting the special characters as individual arguments.

As noted in *uucp*, shell pattern matching notation characters appearing in pathnames are expanded on the appropriate local system. This is done under the control of local settings of *LC_COLLATE* and *LC_CTYPE*. Thus, care should be taken when using bracketed filename patterns, as collation and typing rules may vary from one system to another. Also be aware that certain types of expression (that is, equivalence classes, character classes, and collating symbols) need not be supported on non-internationalized systems.

EXAMPLES

1. The following command gets **file1** from system **a** and **file2** file from system **b**, executes *diff* on the local system, and puts the results in **file.diff** in the local *PUBDIR* directory. (*PUBDIR* is the *uucp* public directory on the local system.)

   ```
   uux "!diff a!/usr/file1 b!/a4/file2 >!˜/file.diff"
   ```

2. The following command fails because *uux* places all files copied to a system in the same working directory. Although the files **xyz** are from two different systems, their filenames are the same and conflict.

   ```
   uux "!diff a!/usr1/xyz b!/usr2/xyz >!˜/xyz.diff"
   ```

3. The following command succeeds (assuming *diff* is permitted on system **a**) because the file local to system **a** is not copied to the working directory, and hence does not conflict the file from system **c**.

```
uux "a!diff a!/usr/xyz c!/usr/xyz >!~/xyz.diff"
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent SYNOPSIS is removed.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The UN margin code and associated shading are removed from the **–j** option in response to The Open Group Base Resolution bwg2001-003.

NAME

val — validate SCCS files (**DEVELOPMENT**)

SYNOPSIS

XSI
```
val -

val [-s][-m name][-r SID][-y type] file...
```

DESCRIPTION

The *val* utility shall determine whether the specified *file* is an SCCS file meeting the characteristics specified by the options.

OPTIONS

The *val* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the usage of the `'−'` operand is not strictly as intended by the guidelines (that is, reading options and operands from standard input).

The following options shall be supported:

−**m** *name*	Specify a *name*, which is compared with the SCCS %**M**% keyword in *file*; see *get* (on page 2675).
−**r** *SID*	Specify a *SID* (SCCS Identification String), an SCCS delta number. A check shall be made to determine whether the *SID* is ambiguous (for example, −**r 1** is ambiguous because it physically does not exist but implies 1.1, 1.2, and so on, which may exist) or invalid (for example, −**r 1.0** or −**r 1.1.0** are invalid because neither case can exist as a valid delta number). If the *SID* is valid and not ambiguous, a check shall be made to determine whether it actually exists.
−**s**	Silence the diagnostic message normally written to standard output for any error that is detected while processing each named file on a given command line.
−**y** *type*	Specify a *type*, which shall be compared with the SCCS %**Y**% keyword in *file*; see *get* (on page 2675).

OPERANDS

The following operands shall be supported:

file	A pathname of an existing SCCS file. If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read: each line shall be independently processed as if it were a command line argument list. (However, the line is not subjected to any of the shell word expansions, such as parameter expansion or quote removal.) |

STDIN

The standard input shall be a text file used only when the *file* operand is specified as `'−'`.

INPUT FILES

Any SCCS files processed shall be files of an unspecified format. |

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *val*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall consist of informative messages about either:

1. Each file processed
2. Each command line read from standard input

If the standard input is not used, for each *file* operand yielding a discrepancy, the output line shall have the following format:

`"%s: %s\n",` *`<pathname>, <unspecified string>`*

If standard input is used, a line of input shall be written before each of the preceding lines for files containing discrepancies:

`"%s:\n",` *`<input line>`*

STDERR

Not used.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The 8-bit code returned by *val* shall be a disjunction of the possible errors, that is, it can be interpreted as a bit string where set bits are interpreted as follows:

0x80 = Missing file argument.
0x40 = Unknown or duplicate option.
0x20 = Corrupted SCCS file.
0x10 = Cannot open file or file not SCCS.
0x08 = *SID* is invalid or ambiguous.
0x04 = *SID* does not exist.
0x02 = %**Y**%, −**y** mismatch.
0x01 = %**M**%, −**m** mismatch.

Note that *val* can process two or more files on a given command line and can process multiple command lines (when reading the standard input). In these cases an aggregate code shall be returned: a logical OR of the codes generated for each command line and file processed.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since the *val* exit status sets the 0x80 bit, shell applications checking `"$?"` cannot tell if it terminated due to a missing file argument or receipt of a signal.

EXAMPLES

In a directory with three SCCS files, **s.x** (of **t** type ‘‘text’’), **s.y**, and **s.z** (a corrupted file), the following command could produce the output shown:

```
val − <<EOF
−y source s.x
−m y s.y
s.z
EOF
```

```
−y source s.x

    s.x: %Y%, −y mismatch
s.z

    s.z: corrupted SCCS file
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The Open Group Corrigendum U025/4 is applied, correcting a typographical error in the EXIT STATUS.

The normative text is reworded to emphasize the term ‘‘shall’’ for implementation requirements.

NAME

vi — screen-oriented (visual) display editor

SYNOPSIS

UP
```
vi [−rR][−l][−c command][−t tagstring][−w size][file ...]
```

DESCRIPTION

This utility shall be provided on systems that both support the User Portability Utilities option and define the POSIX2_CHAR_TERM symbol. On other systems it is optional.

The *vi* (visual) utility is a screen-oriented text editor. Only the open and visual modes of the editor are described in IEEE Std 1003.1-200x; see the line editor *ex* for additional editing capabilities used in *vi*. The user can switch back and forth between *vi* and *ex* and execute *ex* commands from within *vi*.

This reference page uses the term *edit buffer* to describe the current working text. No specific implementation is implied by this term. All editing changes are performed on the edit buffer, and no changes to it shall affect any file until an editor command writes the file.

When using *vi*, the terminal screen acts as a window into the editing buffer. Changes made to the editing buffer shall be reflected in the screen display; the position of the cursor on the screen shall indicate the position within the editing buffer.

Certain terminals do not have all the capabilities necessary to support the complete *vi* definition. When these commands cannot be supported on such terminals, this condition shall not produce an error message such as ''not an editor command'' or report a syntax error. The implementation may either accept the commands and produce results on the screen that are the result of an unsuccessful attempt to meet the requirements of this volume of IEEE Std 1003.1-200x or report an error describing the terminal-related deficiency.

OPTIONS

The *vi* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−**c** *command*	See the *ex* command description of the −**c** option.
−**r**	See the *ex* command description of the −**r** option.
−**R**	See the *ex* command description of the −**R** option.
−**t** *tagstring*	See the *ex* command description of the −**t** option.
−**w** *size*	See the *ex* command description of the −**w** option.

OPERANDS

See the OPERANDS section of the *ex* command for a description of the operands supported by the *vi* command.

STDIN

If standard input is not a terminal device, the results are undefined. The standard input consists of a series of commands and input text, as described in the EXTENDED DESCRIPTION section.

If a read from the standard input returns an error, or if the editor detects an end-of-file condition from the standard input, it shall be equivalent to a SIGHUP asynchronous event.

INPUT FILES

See the INPUT FILES section of the *ex* command for a description of the input files supported by the *vi* command.

ENVIRONMENT VARIABLES

See the ENVIRONMENT VARIABLES section of the *ex* command for the environment variables that affect the execution of the *vi* command.

ASYNCHRONOUS EVENTS

See the ASYNCHRONOUS EVENTS section of the *ex* for the asynchronous events that affect the execution of the *vi* command.

STDOUT

If standard output is not a terminal device, undefined results occur.

Standard output may be used for writing prompts to the user, for informational messages, and for writing lines from the file.

STDERR

If standard output is not a terminal device, undefined results occur.

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

See the OUTPUT FILES section of the *ex* command for a description of the output files supported by the *vi* command.

EXTENDED DESCRIPTION

If the terminal does not have the capabilities necessary to support an unspecified portion of the *vi* definition, implementations shall start initially in *ex* mode or open mode. Otherwise, after initialization, *vi* shall be in command mode; text input mode can be entered by one of several commands used to insert or change text. In text input mode, <ESC> can be used to return to command mode; other uses of <ESC> are described later in this section; see **Terminate Command or Input Mode** (on page 3194).

Initialization in ex and vi

See **Initialization in ex and vi** (on page 2559) for a description of *ex* and *vi* initialization for the *vi* utility.

Command Descriptions in vi

The following symbols are used in this reference page to represent arguments to commands.

buffer See the description of *buffer* in the EXTENDED DESCRIPTION section of the *ex* utility; see **Command Descriptions in ex** (on page 2569).

In open and visual mode, when a command synopsis shows both [*buffer*] and [*count*] preceding the command name, they can be specified in either order.

count A positive integer used as an optional argument to most commands, either to give a repeat count or as a size. This argument is optional and shall default to 1 unless otherwise specified.

The Synopsis lines for the *vi* commands <control>-G, <control>-L, <control>-R, <control>-], **%**, **&**, **^**, **D**, **m**, **M**, **Q**, **u**, **U**, and **ZZ** do not have *count* as an optional argument. Regardless, it shall not be an error to specify a *count* to these commands, and any specified *count* shall be ignored.

motion An optional trailing argument used by the **!**, **<**, **>**, **c**, **d**, and **y** commands, which is used to indicate the region of text that shall be affected by the command. The motion can be either one of the command characters repeated or one of several other *vi* commands (listed in the following table). Each of the applicable commands specifies the region of text matched by repeating the command; each command that can be used as a motion command specifies the region of text it affects.

Commands that take *motion* arguments operate on either lines or characters, depending on the circumstances. When operating on lines, all lines that fall partially or wholly within the text region specified for the command shall be affected. When operating on characters, only the exact characters in the specified text region shall be affected. Each motion command specifies this individually.

When commands that may be motion commands are not used as motion commands, they shall set the current position to the current line and column as specified.

The following commands shall be valid cursor motion commands:

`<control>-H`
`<newline>`
`<carriage-return>`
`<control>-N`
`<control>-P`
`<space>`
`$`
`%`
`'`*`character`*
`` ` ``*`character`*
`(`
`)`
`+`
`,`
`-`
`/`
`_`
`;`
`?`
`B`
`E`
`F`
`G`
`H`
`L`
`M`
`N`
`T`
`W`
`[[`
`]]`
`^`
`b`
`e`
`f`
`h`
`j`
`k`
`l`
`n`
`t`
`w`
`{`
`|`
`}`
`0`

Any *count* that is specified to a command that has an associated motion command shall be applied to the motion command. If a *count* is applied to both the command and its associated motion command, the effect shall be multiplicative.

The following symbols are used in this section to specify locations in the edit buffer:

current character
The character that is currently indicated by the cursor.

end of a line
The point located between the last non-<newline> (if any) and the terminating <newline> of a line. For an empty line, this location coincides with the beginning of the line.

end of the edit buffer
The location corresponding to the end of the last line in the edit buffer.

The following symbols are used in this section to specify command actions:

bigword In the POSIX locale, *vi* shall recognize four kinds of *bigwords*:

1. A maximal sequence of non-<blank>s preceded and followed by <blank>s or the beginning or end of a line or the edit buffer
2. One or more sequential blank lines
3. The first character in the edit buffer
4. The last non-<newline> in the edit buffer

word In the POSIX locale, *vi* shall recognize five kinds of words:

1. A maximal sequence of letters, digits, and underscores, delimited at both ends by:
   - Characters other than letters, digits, or underscores
   - The beginning or end of a line
   - The beginning or end of the edit buffer
2. A maximal sequence of characters other than letters, digits, underscores, or <blank>s, delimited at both ends by:
   - A letter, digit, underscore
   - <blank>s
   - The beginning or end of a line
   - The beginning or end of the edit buffer
3. One or more sequential blank lines
4. The first character in the edit buffer
5. The last non-<newline> in the edit buffer

section boundary
A *section boundary* is one of the following:

1. A line whose first character is a <form-feed>
2. A line whose first character is an open curly brace (`'{'`)
3. A line whose first character is a period and whose second and third characters match a two-character pair in the **sections** edit option (see *ed*)
4. A line whose first character is a period and whose only other character matches the first character of a two-character pair in the **sections** edit option, where the second character of the two-character pair is a <space>
5. The first line of the edit buffer
6. The last line of the edit buffer if the last line of the edit buffer is empty or if it is a **]]** or **}** command; otherwise, the last non-<newline> of the last line of the edit buffer

paragraph boundary
A *paragraph boundary* is one of the following:

1. A section boundary
2. A line whose first character is a period and whose second and third characters match a two-character pair in the **paragraphs** edit option (see *ed*)
3. A line whose first character is a period and whose only other character matches the first character of a two-character pair in the *paragraphs* edit option, where the second character of the two-character pair is a <space>
4. One or more sequential blank lines

remembered search direction
See the description of remembered search direction in *ed*.

sentence boundary

A *sentence boundary* is one of the following:

1. A paragraph boundary
2. The first non-<blank> that occurs after a paragraph boundary
3. The first non-<blank> that occurs after a period ('.'), exclamation mark ('!'), or question mark ('?'), followed by two <space>s or the end of a line; any number of closing parenthesis (')'), closing brackets (']'), double quote ('"'), or single quote ('\'') characters can appear between the punctuation mark and the two <space>s or end-of-line

In the remainder of the description of the *vi* utility, the term ‘‘buffer line’’ refers to a line in the edit buffer and the term ‘‘display line’’ refers to the line or lines on the display screen used to display one buffer line. The term ‘‘current line’’ refers to a specific ‘‘buffer line’’.

If there are display lines on the screen for which there are no corresponding buffer lines because they correspond to lines that would be after the end of the file, they shall be displayed as a single tilde ('˜') character, plus the terminating <newline>.

The last line of the screen shall be used to report errors or display informational messages. It shall also be used to display the input for ‘‘line-oriented commands’’ (**/**, **?**, **:**, and **!**). When a line-oriented command is executed, the editor shall enter text input mode on the last line on the screen, using the respective command characters as prompt characters. (In the case of the **!** command, the associated motion shall be entered by the user before the editor enters text input mode.) The line entered by the user shall be terminated by a <newline>, a non-<control>-V-escaped <carriage-return>, or unescaped <ESC>. It is unspecified if more characters than require a display width minus one column number of screen columns can be entered.

If any command is executed that overwrites a portion of the screen other than the last line of the screen (for example, the *ex* **suspend**, or **!** commands), other than the *ex* **shell** command, the user shall be prompted for a character before the screen is refreshed and the edit session continued.

<tab>s shall take up the number of columns on the screen set by the **tabstop** edit option (see *ed*), unless there are less than that number of columns before the display margin that will cause the displayed line to be folded; in this case, they shall only take up the number of columns up to that boundary.

The cursor shall be placed on the current line and relative to the current column as specified by each command described in the following sections.

In open mode, if the current line is not already displayed, then it shall be displayed.

In visual mode, if the current line is not displayed, then the lines that are displayed shall be expanded, scrolled, or redrawn to cause an unspecified portion of the current line to be displayed. If the screen is redrawn, no more than the number of display lines specified by the value of the **window** edit option shall be displayed (unless the current line cannot be completely displayed in the number of display lines specified by the **window** edit option) and the current line shall be positioned as close to the center of the displayed lines as possible (within the constraints imposed by the distance of the line from the beginning or end of the edit buffer). If the current line is before the first line in the display and the screen is scrolled, an unspecified portion of the current line shall be placed on the first line of the display. If the current line is after the last line in the display and the screen is scrolled, an unspecified portion of the current line shall be placed on the last line of the display.

In visual mode, if a line from the edit buffer (other than the current line) does not entirely fit into the lines at the bottom of the display that are available for its presentation, the editor may choose not to display any portion of the line. The lines of the display that do not contain text from the edit buffer for this reason shall each consist of a single `'@'` character.

In visual mode, the editor may choose for unspecified reasons to not update lines in the display to correspond to the underlying edit buffer text. The lines of the display that do not correctly correspond to text from the edit buffer for this reason shall consist of a single `'@'` character (plus the terminating <newline>), and the <control>-R command shall cause the editor to update the screen to correctly represent the edit buffer.

Open and visual mode commands that set the current column set it to a column position in the display, and not a character position in the line. In this case, however, the column position in the display shall be calculated for a infinite width display; for example, the column related to a character that is part of a line that has been folded onto additional screen lines will be offset from the display line column where the buffer line begins, not from the beginning of a particular display line.

The display cursor column in the display is based on the value of the current column, as follows, with each rule applied in turn:

1. If the current column is after the last display line column used by the displayed line, the display cursor column shall be set to the last display line column occupied by the last non-<newline> in the current line; otherwise, the display cursor column shall be set to the current column.
2. If the character of which some portion is displayed in the display line column specified by the display cursor column requires more than a single display line column:
    a. If in text input mode, the display cursor column shall be adjusted to the first display line column in which any portion of that character is displayed.
    b. Otherwise, the display cursor column shall be adjusted to the last display line column in which any portion of that character is displayed.

The current column shall not be changed by these adjustments to the display cursor column.

If an error occurs during the parsing or execution of a *vi* command:

- The terminal shall be alerted. Execution of the *vi* command shall stop, and the cursor (for example, the current line and column) shall not be further modified.
- Unless otherwise specified by the following command sections, it is unspecified whether an informational message shall be displayed.
- Any partially entered *vi* command shall be discarded.
- If the *vi* command resulted from a **map** expansion, all characters from that **map** expansion shall be discarded, except as otherwise specified by the **map** command (see *ed*).
- If the *vi* command resulted from the execution of a buffer, no further commands caused by the execution of the buffer shall be executed.

Page Backwards

Synopsis: `[count] <control>-B`

If in open mode, the <control>-B command shall behave identically to the **z** command. Otherwise, if the current line is the first line of the edit buffer, it shall be an error.

If the **window** edit option is less than 3, display a screen where the last line of the display shall be some portion of:

`(current first line) −1`

otherwise, display a screen where the first line of the display shall be some portion of:

`(current first line) − count x ((window edit option) −2)`

If this calculation would result in a line that is before the first line of the edit buffer, the first line of the display shall display some portion of the first line of the edit buffer.

Current line: If no lines from the previous display remain on the screen, set to the last line of the display; otherwise, set to (*line* – the number of new lines displayed on this screen).

Current column: Set to non-<blank>.

Scroll Forward

Synopsis: `[count] <control>-D`

If the current line is the last line of the edit buffer, it shall be an error.

If no *count* is specified, *count* shall default to the *count* associated with the previous <control>-D or <control>-U command. If there was no previous <control>-D or <control>-U command, *count* shall default to the value of the **scroll** edit option.

If in open mode, write lines starting with the line after the current line, until *count* lines or the last line of the file have been written.

Current line: If the current line + *count* is past the last line of the edit buffer, set to the last line of the edit buffer; otherwise, set to the current line + *count*.

Current column: Set to non-<blank>.

Scroll Forward by Line

Synopsis: `[count] <control>-E`

Display the line count lines after the last line currently displayed.

If the last line of the edit buffer is displayed, it shall be an error. If there is no line *count* lines after the last line currently displayed, the last line of the display shall display some portion of the last line of the edit buffer.

Current line: Unchanged if the previous current character is displayed; otherwise, set to the first line displayed.

Current column: Unchanged.

Page Forward

Synopsis: `[count] <control>-F`

If in open mode, the <control>-F command shall behave identically to the **z** command. Otherwise, if the current line is the last line of the edit buffer, it shall be an error.

If the **window** edit option is less than 3, display a screen where the first line of the display shall be some portion of:

`(current last line) +1`

otherwise, display a screen where the first line of the display shall be some portion of:

`(current first line) + count x ((window edit option) −2)`

If this calculation would result in a line that is after the last line of the edit buffer, the last line of the display shall display some portion of the last line of the edit buffer.

Current line: If no lines from the previous display remain on the screen, set to the first line of the display; otherwise, set to (*line* + the number of new lines displayed on this screen).

Current column: Set to non-<blank>.

Display Information

Synopsis: `<control>-G`

This command shall be equivalent to the *ex* **file** command .

Move Cursor Backwards

Synopsis:

```
[count] <control>-H
[count] h
the current erase character (see stty)
```

If there are no characters before the current character on the current line, it shall be an error. If there are less than *count* previous characters on the current line, *count* shall be adjusted to the number of previous characters on the line.

If used as a motion command:

1. The text region shall be from the character before the starting cursor up to and including the *count*th character before the starting cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to (*column* – the number of columns occupied by *count* characters ending with the previous current column).

Move Down

Synopsis:

```
[count] <newline>
[count] <control>-J
[count] <control>-M
[count] <control>-N
[count] j
[count] <carriage-return>
[count] +
```

If there are less than *count* lines after the current line in the edit buffer, it shall be an error.

If used as a motion command:

1. The text region shall include the starting line and the next *count* – 1 lines.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

Current line: Set to *current line* + *count*.

Current column: Set to non-<blank> for the <carriage-return>, <control>-M, and **+** commands; otherwise, unchanged.

Clear and Redisplay

Synopsis: `<control>-L`

If in open mode, clear the screen and redisplay the current line. Otherwise, clear and redisplay the screen.

Current line: Unchanged.

Current column: Unchanged.

Move Up

Synopsis:

```
[count] <control>-P
[count] k
[count] –
```

If there are less than *count* lines before the current line in the edit buffer, it shall be an error.

If used as a motion command:

1. The text region shall include the starting line and the previous *count* lines.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

Current line: Set to *current line* – *count*.

Current column: Set to non-<blank> for the – command; otherwise, unchanged.

Redraw Screen

Synopsis: `<control>-R`

If any lines have been deleted from the display screen and flagged as deleted on the terminal using the **@** convention (see the beginning of the EXTENDED DESCRIPTION section), they shall be redisplayed to match the contents of the edit buffer.

It is unspecified whether lines flagged with **@** because they do not fit on the terminal display shall be affected.

Current line: Unchanged.

Current column: Unchanged.

Scroll Backward

Synopsis: `[`*count*`] <control>-U`

If the current line is the first line of the edit buffer, it shall be an error.

If no *count* is specified, *count* shall default to the *count* associated with the previous <control>-D or <control>-U command. If there was no previous <control>-D or <control>-U command, *count* shall default to the value of the **scroll** edit option.

Current line: If *count* is greater than the current line, set to 1; otherwise, set to the current line – *count*.

Current column: Set to non-<blank>.

Scroll Backward by Line

Synopsis: `[`*count*`] <control>-Y`

Display the line *count* lines before the first line currently displayed.

If the current line is the first line of the edit buffer, it shall be an error. If this calculation would result in a line that is before the first line of the edit buffer, the first line of the display shall display some portion of the first line of the edit buffer.

Current line: Unchanged if the previous current character is displayed; otherwise, set to the first line displayed.

Current column: Unchanged.

Edit the Alternate File

Synopsis: `<control>-ˆ`

This command shall be equivalent to the *ex* **edit** command, with the alternate pathname as its argument.

Terminate Command or Input Mode

Synopsis: `<ESC>`

If a partial *vi* command (as defined by at least one, non-*count* character) has been entered, discard the *count* and the command character(s).

Otherwise, if no command characters have been entered, and the <ESC> was the result of a map expansion, the terminal shall be alerted and the <ESC> character shall be discarded, but it shall not be an error.

Otherwise, it shall be an error.

Current line: Unchanged.

Current column: Unchanged.

Search for tagstring

Synopsis: `<control>-]`

If the current character is not a word or <blank>, it shall be an error.

This command shall be equivalent to the *ex* **tag** command, with the argument to that command defined as follows.

If the current character is a <blank>:

1. Skip all <blank>s after the cursor up to the end of the line.
2. If the end of the line is reached, it shall be an error.

Then, the argument to the *ex* **tag** command shall be the current character and all subsequent characters, up to the first non-word character or the end of the line.

Move Cursor Forward

Synopsis: **[***count***]** `<space>`
[*count***]** `l` (ell)

If there are less than *count* non-<newline>s after the cursor on the current line, *count* shall be adjusted to the number of non-<newline>s after the cursor on the line.

If used as a motion command:

1. If the current or *count*th character after the cursor is the last non-<newline> in the line, the text region shall be comprised of the current character up to and including the last non-<newline> in the line. Otherwise, the text region shall be from the current character up to, but not including, the *count*th character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

If there are no non-<newline>s after the current character on the current line, it shall be an error.

Current line: Unchanged.

Current column: Set to the last column that displays any portion of the *count*th character after the current character.

Replace Text with Results from Shell Command

Synopsis: **[***count***]** `!` *motion shell-commands* `<newline>`

If the motion command is the **!** command repeated:

1. If the edit buffer is empty and no *count* was supplied, the command shall be the equivalent of the *ex* **:read !** command, with the text input, and no text shall be copied to any buffer.
2. Otherwise:
   a. If there are less than *count* −1 lines after the current line in the edit buffer, it shall be an error.

   b. The text region shall be from the current line up to and including the next *count* −1 lines.

Otherwise, the text region shall be the lines in which any character of the text region specified by the motion command appear.

Any text copied to a buffer shall be in line mode.

This command shall be equivalent to the *ex* **!** command for the specified lines.

Move Cursor to End-of-line

Synopsis: `[count] $`

It shall be an error if there are less than (*count* −1) lines after the current line in the edit buffer.

If used as a motion command:

1. If *count* is 1:
   a. It shall be an error if the line is empty.
   b. Otherwise, the text region shall consist of all characters from the starting cursor to the last non-<newline> in the line, inclusive, and any text copied to a buffer shall be in character mode.
2. Otherwise, if the starting cursor position is at or before the first non-<blank> in the line, the text region shall consist of the current and the next *count* −1 lines, and any text saved to a buffer shall be in line mode.
3. Otherwise, the text region shall consist of all characters from the starting cursor to the last non-<newline> in the line that is *count* −1 lines forward from the current line, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the *current line* + *count*−1.

Current column: The current column is set to the last display line column of the last non-<newline> in the line, or column position 1 if the line is empty.

The current column shall be adjusted to be on the last display line column of the last non-<newline> of the current line as subsequent commands change the current line, until a command changes the current column.

Move to Matching Character

Synopsis: `%`

If the character at the current position is not a parenthesis, bracket, or curly brace, search forward in the line to the first one of those characters. If no such character is found, it shall be an error.

The matching character shall be the parenthesis, bracket, or curly brace matching the parenthesis, bracket, or curly brace, respectively, that was at the current position or that was found on the current line.

Matching shall be determined as follows, for an open parenthesis:

1. Set a counter to 1.
2. Search forwards until a parenthesis is found or the end of the edit buffer is reached.

3. If the end of the edit buffer is reached, it shall be an error.
4. If an open parenthesis is found, increment the counter by 1.
5. If a close parenthesis is found, decrement the counter by 1.
6. If the counter is zero, the current character is the matching character.

Matching for a close parenthesis shall be equivalent, except that the search shall be backwards, from the starting character to the beginning of the buffer, a close parenthesis shall increment the counter by 1, and an open parenthesis shall decrement the counter by 1.

Matching for brackets and curly braces shall be equivalent, except that searching shall be done for open and close brackets or open and close curly braces. It is implementation-defined whether other characters are searched for and matched as well.

If used as a motion command:

1. If the matching cursor was after the starting cursor in the edit buffer, and the starting cursor position was at or before the first non-<blank> non-<newline> in the starting line, and the matching cursor position was at or after the last non-<blank> non-<newline> in the matching line, the text region shall consist of the current line to the matching line, inclusive, and any text copied to a buffer shall be in line mode.
2. If the matching cursor was before the starting cursor in the edit buffer, and the starting cursor position was at or after the last non-<blank> non-<newline> in the starting line, and the matching cursor position was at or before the first non-<blank> non-<newline> in the matching line, the text region shall consist of the current line to the matching line, inclusive, and any text copied to a buffer shall be in line mode.
3. Otherwise, the text region shall consist of the starting character to the matching character, inclusive, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line where the matching character is located.

Current column: Set to the last column where any portion of the matching character is displayed.

Repeat Substitution

Synopsis: `&`

Repeat the previous substitution command. This command shall be equivalent to the *ex* **&** command with the current line as its addresses, and without *options*, *count*, or *flags*.

Return to Previous Context at Beginning of Line

Synopsis: `' character`

It shall be an error if there is no line in the edit buffer marked by *character*.

If used as a motion command:

1. If the starting cursor is after the marked cursor, then the locations of the starting cursor and the marked cursor in the edit buffer shall be logically swapped.
2. The text region shall consist of the starting line up to and including the marked line, and any text copied to a buffer shall be in line mode.

If not used as a motion command:

Current line: Set to the line referenced by the mark.

Current column: Set to non-<blank>.

Return to Previous Context

Synopsis: `‘ character`

It shall be an error if the marked line is no longer in the edit buffer. If the marked line no longer contains a character in the saved numbered character position, it shall be as if the marked position is the first non-<blank>.

If used as a motion command:

1. It shall be an error if the marked cursor references the same character in the edit buffer as the starting cursor.
2. If the starting cursor is after the marked cursor, then the locations of the starting cursor and the marked cursor in the edit buffer shall be logically swapped.
3. If the starting line is empty or the starting cursor is at or before the first non-<blank> non-<newline> of the starting line, and the marked cursor line is empty or the marked cursor references the first character of the marked cursor line, the text region shall consist of all lines containing characters from the starting cursor to the line before the marked cursor line, inclusive, and any text copied to a buffer shall be in line mode.
4. Otherwise, if the marked cursor line is empty or the marked cursor references a character at or before the first non-<blank> non-<newline> of the marked cursor line, the region of text shall be from the starting cursor to the last non-<newline> of the line before the marked cursor line, inclusive, and any text copied to a buffer shall be in character mode.
5. Otherwise, the region of text shall be from the starting cursor (inclusive), to the marked cursor (exclusive), and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line referenced by the mark.

Current column: Set to the last column in which any portion of the character referenced by the mark is displayed.

Return to Previous Section

Synopsis: `[[`

Move the cursor backward through the edit buffer to the first character of the previous section boundary, *count* times.

If used as a motion command:

1. If the starting cursor was at the first character of the starting line or the starting line was empty, and the first character of the boundary was the first character of the boundary line, the text region shall consist of the current line up to and including the line where the *count*th next boundary starts, and any text copied to a buffer shall be in line mode.
2. If the boundary was the last line of the edit buffer or the last non-<newline> of the last line of the edit buffer, the text region shall consist of the last character in the edit buffer up to and including the starting character, and any text saved to a buffer shall be in character mode.

3. Otherwise, the text region shall consist of the starting character up to but not including the first character in the *count*th next boundary, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line where the *count*th next boundary in the edit buffer starts.

Current column: Set to the last column in which any portion of the first character of the *count*th next boundary is displayed, or column position 1 if the line is empty.

Move to Next Section

Synopsis:]]

Move the cursor forward through the edit buffer to the first character of the next section boundary, *count* times.

If used as a motion command:

1. If the starting cursor was at the first character of the starting line or the starting line was empty, and the first character of the boundary was the first character of the boundary line, the text region shall consist of the current line up to and including the line where the *count*th previous boundary starts, and any text copied to a buffer shall be in line mode.
2. If the boundary was the first line of the edit buffer, the text region shall consist of the first character in the edit buffer up to but not including the starting character, and any text copied to a buffer shall be in character mode.
3. Otherwise, the text region shall consist of the first character in the *count*th previous section boundary up to but not including the starting character, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line where the *count*th previous boundary in the edit buffer starts.

Current column: Set to the last column in which any portion of the first character of the *count*th previous boundary is displayed, or column position 1 if the line is empty.

Move to First Non-<blank> Position on Current Line

Synopsis: ^

If used as a motion command:

1. If the line has no non-<blank> non-<newline>s, or if the cursor is at the first non-<blank> non-<newline> of the line, it shall be an error.
2. If the cursor is before the first non-<blank> non-<newline> of the line, the text region shall be comprised of the current character, up to, but not including, the first non-<blank> non-<newline> of the line.
3. If the cursor is after the first non-<blank> non-<newline> of the line, the text region shall be from the character before the starting cursor up to and including the first non-<blank> non-<newline> of the line.
4. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to non-<blank>.

Current and line above

Synopsis: `[count] _`

If there are less than *count* –1 lines after the current line in the edit buffer, it shall be an error.

If used as a motion command:

1. If *count* is less than 2, the text region shall be the current line.
2. Otherwise, the text region shall include the starting line and the next *count* –1 lines.
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

Current line: Set to current line + *count* –1.

Current column: Set to non-<blank>.

Move Back to Beginning of Sentence

Synopsis: `[count] (`

Move backward to the beginning of a sentence. This command shall be equivalent to the **[[** command, with the exception that sentence boundaries shall be used instead of section boundaries.

Move Forward to Beginning of Sentence

Synopsis: `[count] )`

Move forward to the beginning of a sentence. This command shall be equivalent to the **]]** command, with the exception that sentence boundaries shall be used instead of section boundaries.

Move Back to Preceding Paragraph

Synopsis: `[count] {`

Move back to the beginning of the preceding paragraph. This command shall be equivalent to the **[[** command, with the exception that paragraph boundaries shall be used instead of section boundaries.

Move Forward to Next Paragraph

Synopsis: `[count] }`

Move forward to the beginning of the next paragraph. This command shall be equivalent to the **]]** command, with the exception that paragraph boundaries shall be used instead of section boundaries.

Move to Specific Column Position

Synopsis: `[count] |`

For the purposes of this command, lines that are too long for the current display and that have been folded shall be treated as having a single, 1–based, number of columns.

If there are less than *count* columns in which characters from the current line are displayed on the screen, *count* shall be adjusted to be the last column in which any portion of the line is displayed on the screen.

If used as a motion command:

1. If the line is empty, or the cursor character is the same as the character on the *count*th column of the line, it shall be an error.
2. If the cursor is before the *count*th column of the line, the text region shall be comprised of the current character, up to but not including the character on the *count*th column of the line.
3. If the cursor is after the *count*th column of the line, the text region shall be from the character before the starting cursor up to and including the character on the *count*th column of the line.
4. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to the last column in which any portion of the character that is displayed in the *count* column of the line is displayed.

Reverse Find Character

Synopsis: `[count] ,`

If the last **F**, **f**, **T**, or **t** command was **F**, **f**, **T**, or **t**, this command shall be equivalent to an **f**, **F**, **t**, or **T** command, respectively, with the specified *count* and the same search character.

If there was no previous **F**, **f**, **T**, or **t** command, it shall be an error.

Repeat

Synopsis: `[count] .`

Repeat the last **!**, **<**, **>**, **A**, **C**, **D**, **I**, **J**, **O**, **P**, **R**, **S**, **X**, **Y**, **a**, **c**, **d**, **i**, **o**, **p**, **r**, **s**, **x**, **y**, or **˜** command. It shall be an error if none of these commands have been executed. Commands (other than commands that enter text input mode) executed as a result of map expansions, shall not change the value of the last repeatable command.

Repeated commands with associated motion commands shall repeat the motion command as well; however, any specified *count* shall replace the *count*(s) that were originally specified to the repeated command or its associated motion command.

If the motion component of the repeated command is **f**, **F**, **t**, or **T**, the repeated command shall not set the remembered search character for the **;** and **,** commands.

If the repeated command is **p** or **P**, and the buffer associated with that command was a numeric buffer named with a number less than 9, the buffer associated with the repeated command shall be set to be the buffer named by the name of the previous buffer logically incremented by 1.

If the repeated character is a text input command, the input text associated with that command is repeated literally:

- Input characters are neither macro or abbreviation-expanded.
- Input characters are not interpreted in any special way with the exception that <newline>, <carriage-return>, and <control>-T behave as described in **Input Mode Commands in vi** (on page 3220).

Current line: Set as described for the repeated command.

Current column: Set as described for the repeated command.

Find Regular Expression

Synopsis: /

If the input line contains no non-<newline>s, it shall be equivalent to a line containing only the last regular expression encountered. The enhanced regular expressions supported by *vi* are described in **Regular Expressions in ex** (on page 2592).

Otherwise, the line shall be interpreted as one or more regular expressions, optionally followed by an address offset or a *vi* **z** command.

If the regular expression is not the last regular expression on the line, or if a line offset or **z** command is specified, the regular expression shall be terminated by an unescaped '/' character, which shall not be used as part of the regular expression. If the regular expression is not the first regular expression on the line, it shall be preceded by zero or more <blank>s, a semicolon, zero or more <blank>s, a leading '/' character, which shall not be interpreted as part of the regular expression. It shall be an error to precede any regular expression with any characters other than these.

Each search shall begin from the character after the first character of the last match (or, if it is the first search, after the cursor). If the **wrapscan** edit option is set, the search shall continue to the character before the starting cursor character; otherwise, to the end of the edit buffer. It shall be an error if any search fails to find a match, and an informational message to this effect shall be displayed.

An optional address offset (see **Addressing in ex** (on page 2562)) can be specified after the last regular expression by including a trailing '/' character after the regular expression and specifying the address offset. This offset will be from the line containing the match for the last regular expression specified. It shall be an error if the line offset would indicate a line address less than 1 or greater than the last line in the edit buffer. An address offset of zero shall be supported. It shall be an error to follow the address offset with any other characters than <blank>s.

If not used as a motion command, an optional **z** command (see **Redraw Window** (on page 3219)) can be specified after the last regular expression by including a trailing '/' character after the regular expression, zero or more <blank>s, a 'z', zero or more <blank>s, an optional new **window** edit option value, zero or more <blank>s, and a location character. The effect shall be as if the **z** command was executed after the / command. It shall be an error to follow the **z** command with any other characters than <blank>s.

The remembered search direction shall be set to forward.

If used as a motion command:

1. It shall be an error if the last match references the same character in the edit buffer as the starting cursor.

2. If any address offset is specified, the last match shall be adjusted by the specified offset as described previously.
3. If the starting cursor is after the last match, then the locations of the starting cursor and the last match in the edit buffer shall be logically swapped.
4. If any address offset is specified, the text region shall consist of all lines containing characters from the starting cursor to the last match line, inclusive, and any text copied to a buffer shall be in line mode.
5. Otherwise, if the starting line is empty or the starting cursor is at or before the first non-<blank> non-<newline> of the starting line, and the last match line is empty or the last match starts at the first character of the last match line, the text region shall consist of all lines containing characters from the starting cursor to the line before the last match line, inclusive, and any text copied to a buffer shall be in line mode.
6. Otherwise, if the last match line is empty or the last match begins at a character at or before the first non-<blank> non-<newline> of the last match line, the region of text shall be from the current cursor to the last non-<newline> of the line before the last match line, inclusive, and any text copied to a buffer shall be in character mode.
7. Otherwise, the region of text shall be from the current cursor (inclusive), to the first character of the last match (exclusive), and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: If a match is found, set to the last matched line plus the address offset, if any; otherwise, unchanged.

Current column: Set to the last column on which any portion of the first character in the last matched string is displayed, if a match is found; otherwise, unchanged.

Move to First Character in Line

Synopsis: `0` (zero)

Move to the first character on the current line. The character `'0'` shall not be interpreted as a command if it is immediately preceded by a digit.

If used as a motion command:

1. If the cursor character is the first character in the line, it shall be an error.
2. The text region shall be from the character before the cursor character up to and including the first character in the line.
3. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: The last column in which any portion of the first character in the line is displayed, or if the line is empty, unchanged.

Execute an ex Command

Synopsis: `:`

Execute one or more *ex* commands.

If any portion of the screen other than the last line of the screen was overwritten by any *ex* command (except **shell**), *vi* shall display a message indicating that it is waiting for an input from the user, and shall then read a character. This action may also be taken for other, unspecified reasons.

If the next character entered is a `':'`, another *ex* command shall be accepted and executed. Any other character shall cause the screen to be refreshed and *vi* shall return to command mode.

Current line: As specified for the *ex* command.

Current column: As specified for the *ex* command.

Repeat Find

Synopsis: `[count] ;`

This command shall be equivalent to the last **F**, **f**, **T**, or **t** command, with the specified *count*, and with the same search character used for the last **F**, **f**, **T**, or **t** command. If there was no previous **F**, **f**, **T**, or **t** command, it shall be an error.

Shift Left

Synopsis: `[count] < motion`

If the motion command is the **<** command repeated:

1. If there are less than *count* −1 lines after the current line in the edit buffer, it shall be an error.
2. The text region shall be from the current line, up to and including the next *count* −1 lines.

Shift any line in the text region specified by the *count* and motion command one shiftwidth (see the *ex* **shiftwidth** option) toward the start of the line, as described by the *ex* **<** command. The unshifted lines shall be copied to the unnamed buffer in line mode.

Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

Current column: Set to non-<blank>.

Shift Right

Synopsis: `[count] > motion`

If the motion command is the **>** command repeated:

1. If there are less than *count* −1 lines after the current line in the edit buffer, it shall be an error.
2. The text region shall be from the current line, up to and including the next *count* −1 lines.

Shift any line with characters in the text region specified by the *count* and motion command one shiftwidth (see the *ex* **shiftwidth** option) away from the start of the line, as described by the *ex* **>** command. The unshifted lines shall be copied into the unnamed buffer in line mode.

Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

Current column: Set to non-<blank>.

Scan Backwards for Regular Expression

Synopsis: `?`

Scan backwards; The **?** command shall be equivalent to the **/** command (see **Find Regular Expression** (on page 3202)) with the following exceptions:

1. The input prompt shall be a `'?'`.
2. Each search shall begin from the character before the first character of the last match (or, if it is the first search, the character before the cursor character).
3. The search direction shall be from the cursor toward the beginning of the edit buffer, and the **wrapscan** edit option shall affect whether the search wraps to the end of the edit buffer and continues.
4. The remembered search direction shall be set to backward.

Execute

Synopsis: `@buffer`

If the *buffer* is specified as **@**, the last buffer executed shall be used. If no previous buffer has been executed, it shall be an error.

Behave as if the contents of the named buffer were entered as standard input. After each line of a line-mode buffer, and all but the last line of a character mode buffer, behave as if a <newline> were entered as standard input.

If an error occurs during this process, an error message shall be written, and no more characters resulting from the execution of this command shall be processed.

If a *count* is specified, behave as if that count were entered as user input before the characters from the **@** buffer were entered.

Current line: As specified for the individual commands.

Current column: As specified for the individual commands.

Reverse Case

Synopsis: `[count] ~`

Reverse the case of the current character and the next *count* −1 characters, such that lowercase characters that have uppercase counterparts shall be changed to uppercase characters, and uppercase characters that have lowercase counterparts shall be changed to lowercase characters, as prescribed by the current locale. No other characters shall be affected by this command.

If there are less than *count* −1 characters after the cursor in the edit buffer, *count* shall be adjusted to the number of characters after the cursor in the edit buffer minus 1.

For the purposes of this command, the next character after the last non-<newline> on the line shall be the next character in the edit buffer.

Current line: Set to the line including the (*count*−1)th character after the cursor.

Current column: Set to the last column in which any portion of the (*count*−1)th character after the cursor is displayed.

Append

Synopsis: `[count] a`

Enter text input mode after the current cursor position. No characters already in the edit buffer shall be affected by this command. A *count* shall cause the input text to be appended *count* −1 more times to the end of the input.

Current line/column: As specified for the text input commands (see **Input Mode Commands in vi** (on page 3220)).

Append at End-of-Line

Synopsis: `[count] A`

This command shall be equivalent to the *vi* command:

```
$ [ count ] a
```

(see **Append**).

Move Backward to Preceding Word

Synopsis: `[count] b`

With the exception that words are used as the delimiter instead of bigwords, this command shall be equivalent to the **B** command.

Move Backward to Preceding Bigword

Synopsis: `[count] B`

If the edit buffer is empty or the cursor is on the first character of the edit buffer, it shall be an error. If less than *count* bigwords begin between the cursor and the start of the edit buffer, *count* shall be adjusted to the number of bigword beginnings between the cursor and the start of the edit buffer.

If used as a motion command:

1. The text region shall be from the first character of the *count*th previous bigword beginning up to but not including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line containing the *current column*.

Current column: Set to the last column upon which any part of the first character of the *count*th previous bigword is displayed.

Change

Synopsis: `[buffer][count] c motion`

If the motion command is the **c** command repeated:

1. The buffer text shall be in line mode.
2. If there are less than *count* −1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next *count* −1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

The replaced text shall be copied into *buffer*, if specified, and into the unnamed buffer. If the text to be replaced contains characters from more than a single line, or the buffer text is in line mode, the replaced text shall be copied into the numeric buffers as well.

If the buffer text is in line mode:

1. Any lines that contain characters in the region shall be deleted, and the editor shall enter text input mode at the beginning of a new line which shall replace the first line deleted.
2. If the **autoindent** edit option is set, **autoindent** characters equal to the **autoindent** characters on the first line deleted shall be inserted as if entered by the user.

Otherwise, if characters from more than one line are in the region of text:

1. The text shall be deleted.
2. Any text remaining in the last line in the text region shall be appended to the first line in the region, and the last line in the region shall be deleted.
3. The editor shall enter text input mode after the last character not deleted from the first line in the text region, if any; otherwise, on the first column of the first line in the region.

Otherwise:

1. If the glyph for `'$'` is smaller than the region, the end of the region shall be marked with a `'$'`.
2. The editor shall enter text input mode, overwriting the region of text.

Current line/column: As specified for the text input commands (see **Input Mode Commands in vi** (on page 3220)).

Change to End-of-Line

Synopsis: `[buffer][count] C`

This command shall be equivalent to the *vi* command:

`[buffer][count] c$`

See the **c** command.

Delete

Synopsis: `[buffer][count] d motion`

If the motion command is the **d** command repeated:

1. The buffer text shall be in line mode.
2. If there are less than *count* –1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next *count* –1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

If in open mode, and the current line is deleted, and the line remains on the display, an `'@'` character shall be displayed as the first glyph of that line.

Delete the region of text into *buffer*, if specified, and into the unnamed buffer. If the text to be deleted contains characters from more than a single line, or the buffer text is in line mode, the deleted text shall be copied into the numeric buffers, as well.

Current line: Set to the first text region line that appears in the edit buffer, unless that line has been deleted, in which case it shall be set to the last line in the edit buffer, or line 1 if the edit buffer is empty.

Current column:

1. If the line is empty, set to column position 1.
2. Otherwise, if the buffer text is in line mode or the motion was from the cursor toward the end of the edit buffer:
   a. If a character from the current line is displayed in the current column, set to the last column that displays any portion of that character.
   b. Otherwise, set to the last column in which any portion of any character in the line is displayed.
3. Otherwise, if a character is displayed in the column that began the text region, set to the last column that displays any portion of that character.
4. Otherwise, set to the last column in which any portion of any character in the line is displayed.

Delete to End-of-Line

Synopsis: `[buffer] D`

Delete the text from the current position to the end of the current line; equivalent to the *vi* command:

```
[buffer] d$
```

Move to End-of-Word

Synopsis: `[count] e`

With the exception that words are used instead of bigwords as the delimiter, this command shall be equivalent to the **E** command.

Move to End-of-Bigword

Synopsis: `[count] E`

If the edit buffer is empty it shall be an error. If less than *count* bigwords end between the cursor and the end of the edit buffer, *count* shall be adjusted to the number of bigword endings between the cursor and the end of the edit buffer.

If used as a motion command:

1. The text region shall be from the last character of the *count*th next bigword up to and including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line containing the current column.

Current column: Set to the last column upon which any part of the last character of the *count*th next bigword is displayed.

Find Character in Current Line (Forward)

Synopsis: `[count] f character`

It shall be an error if *count* occurrences of the character do not occur after the cursor in the line.

If used as a motion command:

1. The text range shall be from the cursor character up to and including the *count*th occurrence of the specified character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to the last column in which any portion of the *count*th occurrence of the specified character after the cursor appears in the line.

Find Character in Current Line (Reverse)

Synopsis: `[count] F character`

It shall be an error if *count* occurrences of the character do not occur before the cursor in the line.

If used as a motion command:

1. The text region shall be from the *count*th occurrence of the specified character before the cursor, up to, but not including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to the last column in which any portion of the *count*th occurrence of the specified character before the cursor appears in the line.

Move to Line

Synopsis: `[count] G`

If *count* is not specified, it shall default to the last line of the edit buffer. If *count* is greater than the last line of the edit buffer, it shall be an error.

If used as a motion command:

1. The text region shall be from the cursor line up to and including the specified line.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

Current line: Set to *count* if *count* is specified; otherwise, the last line.

Current column: Set to non-<blank>.

Move to Top of Screen

Synopsis: `[count] H`

If the beginning of the line *count* greater than the first line of which any portion appears on the display does not exist, it shall be an error.

If used as a motion command:

1. If in open mode, the text region shall be the current line.
2. Otherwise, the text region shall be from the starting line up to and including (the first line of the display + *count* –1).
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

If in open mode, this command shall set the current column to non-<blank> and do nothing else.

Otherwise, it shall set the current line and current column as follows.

Current line: Set to (the first line of the display + *count* –1).

Current column: Set to non-<blank>.

Insert Before Cursor

Synopsis: `[count] i`

Enter text input mode before the current cursor position. No characters already in the edit buffer shall be affected by this command. A *count* shall cause the input text to be appended *count* –1 more times to the end of the input.

Current line/column: As specified for the text input commands (see **Input Mode Commands in vi** (on page 3220)).

Insert at Beginning of Line

Synopsis: `[count] I`

This command shall be equivalent to the *vi* command ^[*count*]**i** command.

Join

Synopsis: `[count] J`

If the current line is the last line in the edit buffer, it shall be an error.

This command shall be equivalent to the *ex* **join** command with no addresses, and an *ex* command *count* value of 1 if *count* was not specified or if a *count* of 1 was specified, and an *ex* command *count* value of *count* −1 for any other value of *count*, except that the current line and column shall be set as follows.

Current line: Unchanged.

Current column: The last column in which any portion of the character following the last character in the initial line is displayed, or the last non-<newline> in the line if no characters were appended.

Move to Bottom of Screen

Synopsis: `[count] L`

If the beginning of the line count less than the last line of which any portion appears on the display does not exist, it shall be an error.

If used as a motion command:

1. If in open mode, the text region shall be the current line.
2. Otherwise, the text region shall include all lines from the starting cursor line to (the last line of the display −(*count* −1)).
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

1. If in open mode, this command shall set the current column to non-<blank> and do nothing else.
2. Otherwise, it shall set the current line and current column as follows.

Current line: Set to (the last line of the display −(*count* −1)).

Current column: Set to non-<blank>.

Mark Position

Synopsis: `m letter`

This command shall be equivalent to the *ex* **mark** command with the specified character as an argument.

Move to Middle of Screen

Synopsis: `M`

The middle line of the display shall be calculated as follows:

`(the top line of the display) + (((number of lines displayed) +1) /2) −1`

If used as a motion command:

1. If in open mode, the text region shall be the current line.
2. Otherwise, the text region shall include all lines from the starting cursor line up to and including the middle line of the display.
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

If in open mode, this command shall set the current column to non-<blank> and do nothing else.

Otherwise, it shall set the current line and current column as follows.

Current line: Set to the middle line of the display.

Current column: Set to non-<blank>.

Repeat Regular Expression Find (Forward)

Synopsis: `n`

If the remembered search direction was forward, the **n** command shall be equivalent to the *vi* **/** command with no characters entered by the user. Otherwise, it shall be equivalent to the *vi* **?** command with no characters entered by the user.

If the **n** command is used as a motion command for the **!** command, the editor shall not enter text input mode on the last line on the screen, and shall behave as if the user entered a single `'!'` character as the text input.

Repeat Regular Expression Find (Reverse)

Synopsis: `N`

Scan for the next match of the last pattern given to **/** or **?**, but in the reverse direction; this is the reverse of **n**.

If the remembered search direction was forward, the **N** command shall be equivalent to the *vi* **?** command with no characters entered by the user. Otherwise, it shall be equivalent to the *vi* **/** command with no characters entered by the user. If the **N** command is used as a motion command for the **!** command, the editor shall not enter text input mode on the last line on the screen, and shall behave as if the user entered a single **!** character as the text input.

Insert Empty Line Below

Synopsis: `o`

Enter text input mode in a new line appended after the current line. A *count* shall cause the input text to be appended *count* −1 more times to the end of the already added text, each time starting on a new, appended line.

Current line/column: As specified for the text input commands (see **Input Mode Commands in vi** (on page 3220)).

Insert Empty Line Above

Synopsis: `O`

Enter text input mode in a new line inserted before the current line. A *count* shall cause the input text to be appended *count* −1 more times to the end of the already added text, each time starting on a new, appended line.

Current line/column: As specified for the text input commands (see **Input Mode Commands in vi** (on page 3220)).

Put from Buffer Following

Synopsis: `[`*`buffer`*`] p`

If no *buffer* is specified, the unnamed buffer shall be used.

If the buffer text is in line mode, the text shall be appended below the current line, and each line of the buffer shall become a new line in the edit buffer. A *count* shall cause the buffer text to be appended *count* −1 more times to the end of the already added text, each time starting on a new, appended line.

If the buffer text is in character mode, the text shall be appended into the current line after the cursor, and each line of the buffer other than the first and last shall become a new line in the edit buffer. A *count* shall cause the buffer text to be appended *count* −1 more times to the end of the already added text, each time starting after the last added character.

Current line: If the buffer text is in line mode, set the line to line +1; otherwise, unchanged.

Current column: If the buffer text is in line mode:

1. If there is a non-<blank> in the first line of the buffer, set to the last column on which any portion of the first non-<blank> in the line is displayed.
2. If there is no non-<blank> in the first line of the buffer, set to the last column on which any portion of the last non-<newline> in the first line of the buffer is displayed.

If the buffer text is in character mode:

1. If the text in the buffer is from more than a single line, then set to the last column on which any portion of the first character from the buffer is displayed.
2. Otherwise, if the buffer is the unnamed buffer, set to the last column on which any portion of the last character from the buffer is displayed.
3. Otherwise, set to the first column on which any portion of the first character from the buffer is displayed.

Put from Buffer Before

Synopsis: `[`*`buffer`*`] P`

If no *buffer* is specified, the unnamed buffer shall be used.

If the buffer text is in line mode, the text shall be inserted above the current line, and each line of the buffer shall become a new line in the edit buffer. A *count* shall cause the buffer text to be appended *count* −1 more times to the end of the already added text, each time starting on a new, appended line.

If the buffer text is in character mode, the text shall be inserted into the current line before the cursor, and each line of the buffer other than the first and last shall become a new line in the edit buffer. A *count* shall cause the buffer text to be appended *count* −1 more times to the end of the already added text, each time starting after the last added character.

Current line: Unchanged.

Current column: If the buffer text is in line mode:

1. If there is a non-<blank> in the first line of the buffer, set to the last column on which any portion of that character is displayed.
2. If there is no non-<blank> in the first line of the buffer, set to the last column on which any portion of the last non-<newline> in the first line of the buffer is displayed.

If the buffer text is in character mode:

1. If the buffer is the unnamed buffer, set to the last column on which any portion of the last character from the buffer is displayed.
2. Otherwise, set to the first column on which any portion of the first character from the buffer is displayed.

Enter ex Mode

Synopsis: `Q`

Leave visual or open mode and enter *ex* command mode.

Current line: Unchanged.

Current column: Unchanged.

Replace Character

Synopsis: `[count] r character`

Replace the *count* characters at and after the cursor with the specified character. If there are less than *count* non-<newline>s at and after the cursor on the line, it shall be an error.

If character is <control>-V, any next character other than the <newline> shall be stripped of any special meaning and used as a literal character.

If character is <ESC>, no replacement shall be made and the current line and current column shall be unchanged.

If character is <carriage-return> or <newline>, *count* new lines shall be appended to the current line. All but the last of these lines shall be empty. *count* characters at and after the cursor shall be discarded, and any remaining characters after the cursor in the current line shall be moved to the last of the new lines. If the **autoindent** edit option is set, they shall be preceded by the same number of **autoindent** characters found on the line from which the command was executed.

Current line: Unchanged unless the replacement character is a <carriage-return> or <newline>, in which case it shall be set to line + *count*.

Current column: Set to the last column position on which a portion of the last replaced character is displayed, or if the replacement character caused new lines to be created, set to non-<blank>.

Replace Characters

Synopsis: `R`

Enter text input mode at the current cursor position possibly replacing text on the current line. A *count* shall cause the input text to be appended *count* −1 more times to the end of the input. |

Current line/column: As specified for the text input commands (see **Input Mode Commands in vi** (on page 3220)).

Substitute Character

Synopsis: `[buffer][count] s`

This command shall be equivalent to the *vi* command:

`[buffer][count] c<space>`

Substitute Lines

Synopsis: `[buffer][count] S`

This command shall be equivalent to the *vi* command:

`[buffer][count] c_`

Move Cursor to Before Character (Forward)

Synopsis: `[count] t character`

It shall be an error if *count* occurrences of the character do not occur after the cursor in the line.

If used as a motion command:

1. The text region shall be from the cursor up to but not including the *count*th occurrence of the specified character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to the last column in which any portion of the character before the *count*th occurrence of the specified character after the cursor appears in the line.

Move Cursor to After Character (Reverse)

Synopsis: `[count] T character`

It shall be an error if *count* occurrences of the character do not occur before the cursor in the line.

If used as a motion command:

1. If the character before the cursor is the specified character, it shall be an error.
2. The text region shall be from the character before the cursor up to but not including the *count*th occurrence of the specified character before the cursor.
3. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Unchanged.

Current column: Set to the last column in which any portion of the character after the *count*th occurrence of the specified character before the cursor appears in the line.

Undo

Synopsis: `u`

This command shall be equivalent to the *ex* **undo** command except that the current line and current column shall be set as follows:

Current line: Set to the first line added or changed if any; otherwise, move to the line preceding any deleted text if one exists; otherwise, move to line 1.

Current column: If undoing an *ex* command, set to the first non-<blank>.

Otherwise, if undoing a text input command:

1. If the command was an **C**, **c**, **O**, **o**, **R**, **S**, or **s** command, the current column shall be set to the value it held when the text input command was entered.
2. Otherwise, set to the last column in which any portion of the first character after the deleted text is displayed, or, if no non-<newline>s follow the text deleted from this line, set to the last column in which any portion of the last non-<newline> in the line is displayed, or 1 if the line is empty.

Otherwise, if a single line was modified (that is, not added or deleted) by the **u** command:

1. If text was added or changed, set to the last column in which any portion of the first character added or changed is displayed.
2. If text was deleted, set to the last column in which any portion of the first character after the deleted text is displayed, or, if no non-<newline>s follow the deleted text, set to the last column in which any portion of the last non-<newline> in the line is displayed, or 1 if the line is empty.

Otherwise, set to non-<blank>.

Undo Current Line

Synopsis: `U`

Restore the current line to its state immediately before the most recent time that it became the current line.

Current line: Unchanged.

Current column: Set to the first column in the line in which any portion of the first character in the line is displayed.

Move to Beginning of Word

Synopsis: `[count] w`

With the exception that words are used as the delimiter instead of bigwords, this command shall be equivalent to the **W** command.

Move to Beginning of Bigword

Synopsis: `[count] W`

If the edit buffer is empty, it shall be an error. If there are less than *count* bigwords between the cursor and the end of the edit buffer, *count* shall be adjusted to move the cursor to the last bigword in the edit buffer.

If used as a motion command:

1. If the associated command is **c**, *count* is 1, and the cursor is on a <blank>, the region of text shall be the current character and no further action shall be taken.
2. If there are less than *count* bigwords between the cursor and the end of the edit buffer, then the command shall succeed, and the region of text shall include the last character of the edit buffer.
3. If there are <blank>s or an end-of-line that precede the *count*th bigword, and the associated command is **c**, the region of text shall be up to and including the last character before the preceding <blank>s or end-of-line.
4. If there are <blank>s or an end-of-line that precede the bigword, and the associated command is **d** or **y**, the region of text shall be up to and including the last <blank> the start of the bigword or end-of-line.
5. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

1. If the cursor is on the last character of the edit buffer, it shall be an error.

Current line: Set to the line containing the current column.

Current column: Set to the last column in which any part of the first character of the *count*th next bigword is displayed.

Delete Character at Cursor

Synopsis: `[buffer][count] x`

Delete the *count* characters at and after the current character into *buffer*, if specified, and into the unnamed buffer.

If the line is empty, it shall be an error. If there are less than *count* non-<newline>s at and after the cursor on the current line, *count* shall be adjusted to the number of non-<newline>s at and after the cursor.

Current line: Unchanged.

Current column: If the line is empty, set to column position 1. Otherwise, if there were *count* or less non-<newline>s at and after the cursor on the current line, set to the last column that displays any part of the last non-<newline> of the line. Otherwise, unchanged.

Delete Character Before Cursor

Synopsis: `[buffer][count] X`

Delete the *count* characters before the current character into *buffer*, if specified, and into the unnamed buffer.

If there are no characters before the current character on the current line, it shall be an error. If there are less than *count* previous characters on the current line, *count* shall be adjusted to the number of previous characters on the line.

Current line: Unchanged.

Current column: Set to (*current column – the width of the deleted characters*).

Yank

Synopsis: `[buffer][count] y motion`

Copy (yank) the region of text into *buffer*, if specified, and into the unnamed buffer.

If the motion command is the **y** command repeated:

1. The buffer shall be in line mode.
2. If there are less than *count* –1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next *count* –1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

Current column:

1. If the motion was from the current cursor position toward the end of the edit buffer, unchanged.
2. Otherwise, if the current line is empty, set to column position 1.
3. Otherwise, set to the last column that displays any part of the first character in the file that is part of the text region specified by the motion command.

Yank Current Line

Synopsis: `[buffer][count] Y`

This command shall be equivalent to the *vi* command:

```
[buffer][count] y_
```

Redraw Window

If in open mode, the **z** command shall have the Synopsis:

Synopsis: `[count] z`

If *count* is not specified, it shall default to the **window** edit option −1. The **z** command shall be equivalent to the *ex* **z** command, with a type character of **=** and a *count* of *count* −2, except that the current line and current column shall be set as follows, and the **window** edit option shall not be affected. If the calculation for the *count* argument would result in a negative number, the *count* argument to the *ex* **z** command shall be zero. A blank line shall be written after the last line is written.

Current line: Unchanged.

Current column: Unchanged.

If not in open mode, the **z** command shall have the following Synopsis:

Synopsis: `[line] z [count] character`

If *line* is not specified, it shall default to the current line. If *line* is specified, but is greater than the number of lines in the edit buffer, it shall default to the number of lines in the edit buffer.

If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in the *ex* **window** command), and the screen shall be redrawn.

line shall be placed as specified by the following characters:

<newline>, <carriage-return>
Place the beginning of the line on the first line of the display.

. Place the beginning of the line in the center of the display. The middle line of the display shall be calculated as described for the **M** command.

− Place an unspecified portion of the line on the last line of the display.

\+ If *line* was specified, equivalent to the <newline> case. If *line* was not specified, display a screen where the first line of the display shall be (current last line) +1. If there are no lines after the last line in the display, it shall be an error.

^ If *line* was specified, display a screen where the last line of the display shall contain an unspecified portion of the first line of a display that had an unspecified portion of the specified line on the last line of the display. If this calculation results in a line before the beginning of the edit buffer, display the first screen of the edit buffer.

Otherwise, display a screen where the last line of the display shall contain an unspecified portion of (current first line −1). If this calculation results in a line before the beginning of the edit buffer, it shall be an error.

Current line: If *line* and the `'^'` character were specified:

1. If the first screen was displayed as a result of the command attempting to display lines before the beginning of the edit buffer: if the first screen was already displayed, unchanged; otherwise, set to (current first line −1).
2. Otherwise, set to the last line of the display.

If *line* and the `'+'` character were specified, set to the first line of the display.

Otherwise, if *line* was specified, set to *line*.

Otherwise, unchanged.

Current column: Set to non-<blank>.

Exit

Synopsis: `ZZ`

This command shall be equivalent to the *ex* **xit** command with no addresses, trailing **!**, or filename (see the *ex* **xit** command).

Input Mode Commands in vi

In text input mode, the current line shall consist of zero or more of the following categories, plus the terminating <newline>:

1. Characters preceding the text input entry point

   Characters in this category shall not be modified during text input mode.

2. **autoindent** characters

   autoindent characters shall be automatically inserted into each line that is created in text input mode, either as a result of entering a <newline> or <carriage-return> while in text input mode, or as an effect of the command itself; for example, **O** or **o** (see the *ex* **autoindent** command), as if entered by the user.

   It shall be possible to erase **autoindent** characters with the <control>-D command; it is unspecified whether they can be erased by <control>-H, <control>-U, and <control>-W characters. Erasing any **autoindent** character turns the glyph into erase-columns and deletes the character from the edit buffer, but does not change its representation on the screen.

3. Text input characters

   Text input characters are the characters entered by the user. Erasing any text input character turns the glyph into erase-columns and deletes the character from the edit buffer, but does not change its representation on the screen.

   Each text input character entered by the user (that does not have a special meaning) shall be treated as follows:

   a. The text input character shall be appended to the last character in the edit buffer from the first, second, or third categories.

   b. If there are no erase-columns on the screen, the text input command was the **R** command, and characters in the fifth category from the original line follow the cursor, the next such character shall be deleted from the edit buffer. If the **slowopen** edit option is not set, the corresponding glyph on the screen shall become erase-columns.

   c. If there are erase-columns on the screen, as many columns as they occupy, or as are necessary, shall be overwritten to display the text input character. (If only part of a multi-column glyph is overwritten, the remainder shall be left on the screen, and continue to be treated as erase-columns; it is unspecified whether the remainder of the glyph is modified in any way.)

   d. If additional display line columns are needed to display the text input character:

      1. If the **slowopen** edit option is set, the text input characters shall be displayed on subsequent display line columns, overwriting any characters displayed in

those columns.

2. Otherwise, any characters currently displayed on or after the column on the display line where the text input character is to be displayed shall be pushed ahead the number of display line columns necessary to display the rest of the text input character.

4. Erase-columns

   Erase-columns are not logically part of the edit buffer, appearing only on the screen, and may be overwritten on the screen by subsequent text input characters. When text input mode ends, all erase-columns shall no longer appear on the screen.

   Erase-columns are initially the region of text specified by the **c** command (see **Change** (on page 3207)) however, erasing **autoindent** or text input characters causes the glyphs of the erased characters to be treated as erase-columns.

5. Characters following the text region for the **c** command, or the text input entry point for all other commands

   Characters in this category shall not be modified during text input mode, except as specified in category 3.b. for the **R** text input command, or as <blank>s deleted when a <newline> or <carriage-return> is entered.

It is unspecified whether it is an error to attempt to erase past the beginning of a line that was created by the entry of a <newline> or <carriage-return> during text input mode. If it is not an error, the editor shall behave as if the erasing character was entered immediately after the last text input character entered on the previous line, and all of the non-<newline>s on the current line shall be treated as erase-columns.

When text input mode is entered, or after a text input mode character is entered (except as specified for the special characters below), the cursor shall be positioned as follows:

1. On the first column that displays any part of the first erase-column, if one exists
2. Otherwise, if the **slowopen** edit option is set, on the first display line column after the last character in the first, second, or third categories, if one exists
3. Otherwise, the first column that displays any part of the first character in the fifth category, if one exists
4. Otherwise, the display line column after the last character in the first, second, or third categories, if one exists
5. Otherwise, on column position 1

The characters that are updated on the screen during text input mode are unspecified, other than that the last text input character shall always be updated, and, if the **slowopen** edit option is not set, the current cursor character shall always be updated.

The following specifications are for command characters entered during text input mode.

NUL

Synopsis: `NUL`

If the first character of the text input is a NUL, the most recently input text shall be input as if entered by the user, and then text input mode shall be exited. The text shall be input literally; that is, characters are neither macro or abbreviation expanded, nor are any characters interpreted in any special manner. It is unspecified whether implementations shall support more than 256 bytes of remembered input text.

<control>-D

Synopsis: `<control>-D`

The <control>-D character shall have no special meaning when in text input mode for a line-oriented command (see **Command Descriptions in vi** (on page 3186)).

This command need not be supported on block-mode terminals.

If the cursor does not follow an **autoindent** character, or an **autoindent** character and a `'0'` or `'^'` character:

1. If the cursor is in column position 1, the <control>-D character shall be discarded and no further action taken.
2. Otherwise, the <control>-D character shall have no special meaning.

If the last input character was a `'0'`, the cursor shall be moved to column position 1.

Otherwise, if the last input character was a `'^'`, the cursor shall be moved to column position 1. In addition, the **autoindent** level for the next input line shall be derived from the same line from which the **autoindent** level for the current input line was derived.

Otherwise, the cursor shall be moved back to the column after the previous shiftwidth (see the *ex* **shiftwidth** command) boundary.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in **Input Mode Commands in vi** (on page 3220).

Current line: Unchanged.

Current column: Set to 1 if the <control>-D was preceded by a `'^'` or `'0'`; otherwise, set to (column −1) −((column −2) % **shiftwidth**).

<control>-H

Synopsis: `<control>-H`

If in text input mode for a line-oriented command, and there are no characters to erase, text input mode shall be terminated, no further action shall be done for this command, and the current line and column shall be unchanged.

If there are characters other than **autoindent** characters that have been input on the current line before the cursor, the cursor shall move back one character.

Otherwise, if there are **autoindent** characters on the current line before the cursor, it is implementation-defined whether the <control>-H command is an error or if the cursor moves back one **autoindent** character.

Otherwise, if the cursor is in column position 1 and there are previous lines that have been input, it is implementation-defined whether the <control>-H command is an error or if it is equivalent to entering <control>-H after the last input character on the previous input line.

Otherwise, it shall be an error.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in **Input Mode Commands in vi** (on page 3220).

The current erase character (see *stty*) shall cause an equivalent action to the <control>-H command, unless the previously inserted character was a backslash, in which case it shall be as if the literal current erase character had been inserted instead of the backslash.

Current line: Unchanged, unless previously input lines are erased, in which case it shall be set to line −1.

Current column: Set to the first column that displays any portion of the character backed up over.

<newline>

Synopsis:
```
<newline>
<carriage-return>
<control>-J
<control>-M
```

If input was part of a line-oriented command, text input mode shall be terminated and the command shall continue execution with the input provided.

Otherwise, terminate the current line. If there are no characters other than **autoindent** characters on the line, all characters on the line shall be discarded. Otherwise, it is unspecified whether the **autoindent** characters in the line are modified by entering these characters.

Continue text input mode on a new line appended after the current line. If the **slowopen** edit option is set, the lines on the screen below the current line shall not be pushed down, but the first of them shall be cleared and shall appear to be overwritten. Otherwise, the lines of the screen below the current line shall be pushed down.

If the **autoindent** edit option is set, an appropriate number of **autoindent** characters shall be added as a prefix to the line as described by the *ex* **autoindent** edit option.

All columns after the cursor that are erase-columns (as described in **Input Mode Commands in vi** (on page 3220)) shall be discarded.

If the **autoindent** edit option is set, all <blank>s immediately following the cursor shall be discarded.

All remaining characters after the cursor shall be transferred to the new line, positioned after any **autoindent** characters.

Current line: Set to current line +1.

Current column: Set to the first column that displays any portion of the first character after the **autoindent** characters on the new line, if any, or the first column position after the last **autoindent** character, if any, or column position 1.

<control>-T

Synopsis: `<control>-T`

The <control>-T character shall have no special meaning when in text input mode for a line-oriented command (see **Command Descriptions in vi** (on page 3186)).

This command need not be supported on block-mode terminals.

Behave as if the user entered the minimum number of <blank>s necessary to move the cursor forward to the column position after the next **shiftwidth** (see the *ex* **shiftwidth** command) boundary.

Current line: Unchanged.

Current column: Set to *column* + **shiftwidth** − ((column −1) % **shiftwidth**).

<control>-U

Synopsis: `<control>-U`

If there are characters other than **autoindent** characters that have been input on the current line before the cursor, the cursor shall move to the first character input after the **autoindent** characters.

Otherwise, if there are **autoindent** characters on the current line before the cursor, it is implementation-defined whether the <control>-U command is an error or if the cursor moves to the first column position on the line.

Otherwise, if the cursor is in column position 1 and there are previous lines that have been input, it is implementation-defined whether the <control>-U command is an error or if it is equivalent to entering <control>-U after the last input character on the previous input line.

Otherwise, it shall be an error.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in **Input Mode Commands in vi** (on page 3220).

The current *kill* character (see *stty*) shall cause an equivalent action to the <control>-U command, unless the previously inserted character was a backslash, in which case it shall be as if the literal current *kill* character had been inserted instead of the backslash.

Current line: Unchanged, unless previously input lines are erased, in which case it shall be set to line −1.

Current column: Set to the first column that displays any portion of the last character backed up over.

<control>-V

Synopsis:
```
<control>-V
<control>-Q
```

Allow the entry of any subsequent character, other than <control>-J or the <newline>, as a literal character, removing any special meaning that it may have to the editor in text input mode. If a <control>-V or <control>-Q is entered before a <control>-J or <newline>, the <control>-V or <control>-Q character shall be discarded, and the <control>-J or <newline> shall behave as described in the <newline> command character during input mode.

For purposes of the display only, the editor shall behave as if a `'^'` character was entered, and the cursor shall be positioned as if overwriting the `'^'` character. When a subsequent character is entered, the editor shall behave as if that character was entered instead of the original <control>-V or <control>-Q character.

Current line: Unchanged.

Current column: Unchanged.

<control>-W

Synopsis: `<control>-W`

If there are characters other than **autoindent** characters that have been input on the current line before the cursor, the cursor shall move back over the last word preceding the cursor (including any <blank>s between the end of the last word and the current cursor); the cursor shall not move to before the first character after the end of any **autoindent** characters.

Otherwise, if there are **autoindent** characters on the current line before the cursor, it is implementation-defined whether the <control>-W command is an error or if the cursor moves to the first column position on the line.

Otherwise, if the cursor is in column position 1 and there are previous lines that have been input, it is implementation-defined whether the <control>-W command is an error or if it is equivalent to entering <control>-W after the last input character on the previous input line.

Otherwise, it shall be an error.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in **Input Mode Commands in vi** (on page 3220).

Current line: Unchanged, unless previously input lines are erased, in which case it shall be set to line −1.

Current column: Set to the first column that displays any portion of the last character backed up over.

<ESC>

Synopsis: `<ESC>`

If input was part of a line-oriented command:

1. If *interrupt* was entered, text input mode shall be terminated and the editor shall return to command mode. The terminal shall be alerted.
2. If <ESC> was entered, text input mode shall be terminated and the command shall continue execution with the input provided.

Otherwise, terminate text input mode and return to command mode.

Any **autoindent** characters entered on newly created lines that have no other non-<newline>s shall be deleted.

Any leading **autoindent** and <blank>s on newly created lines shall be rewritten to be the minimum number of <blank>s possible.

The screen shall be redisplayed as necessary to match the contents of the edit buffer.

Current line: Unchanged.

Current column:

1. If there are text input characters on the current line, the column shall be set to the last column where any portion of the last text input character is displayed.
2. Otherwise, if a character is displayed in the current column, unchanged.
3. Otherwise, set to column position 1.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

When any error is encountered and the standard input is not a terminal device file, *vi* shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

Otherwise, when an unrecoverable error is encountered it shall be equivalent to a SIGHUP asynchronous event.

Otherwise, when an error is encountered, the editor shall behave as specified in **Command Descriptions in vi** (on page 3186).

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

See the RATIONALE for *ex* for more information on *vi*. Major portions of the *vi* utility specification point to *ex* to avoid inadvertent divergence. While *ex* and *vi* have historically been implemented as a single utility, this is not required by IEEE Std 1003.1-200x.

It is recognized that portions of *vi* would be difficult, if not impossible, to implement satisfactorily on a block-mode terminal, or a terminal without any form of cursor addressing, thus it is not a mandatory requirement that such features should work on all terminals. It is the intention, however, that a *vi* implementation should provide the full set of capabilities on all terminals capable of supporting them.

Historically, *vi* exited immediately if the standard input was not a terminal. IEEE Std 1003.1-200x permits, but does not require, this behavior. An end-of-file condition is not equivalent to an end-of-file character. A common end-of-file character, <control>-D, is historically a *vi* command.

The text in the STANDARD OUTPUT section reflects the usage of the verb *display* in this section; some implementations of *vi* use standard output to write to the terminal, but IEEE Std 1003.1-200x does not require that to be the case.

Historically, implementations reverted to open mode if the terminal was incapable of supporting full visual mode. IEEE Std 1003.1-200x requires this behavior. Historically, the open mode of *vi* behaved roughly equivalently to the visual mode, with the exception that only a single line from the edit buffer (one ‘‘buffer line’’) was kept current at any time. This line was normally displayed on the next-to-last line of a terminal with cursor addressing (and the last line performed its normal visual functions for line-oriented commands and messages). In addition, some few commands behaved differently in open mode than in visual mode. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, *ex* and *vi* implementations have expected text to proceed in the usual European/Latin order of left to right, top to bottom. There is no requirement in IEEE Std 1003.1-200x that this be the case. The specification was deliberately written using words like ''before'', ''after'', ''first'', and ''last'' in order to permit implementations to support the natural text order of the language.

Historically, lines past the end of the edit buffer were marked with single tilde (`'~'`) characters; that is, if the one-based display was 20 lines in length, and the last line of the file was on line one, then lines 2-20 would contain only a single `'~'` character.

Historically, the *vi* editor attempted to display only complete lines at the bottom of the screen (it did display partial lines at the top of the screen). If a line was too long to fit in its entirety at the bottom of the screen, the screen lines where the line would have been displayed were displayed as single `'@'` characters, instead of displaying part of the line. IEEE Std 1003.1-200x permits, but does not require, this behavior. Implementations are encouraged to attempt always to display a complete line at the bottom of the screen when doing scrolling or screen positioning by buffer lines.

Historically, lines marked with `'@'` were also used to minimize output to dumb terminals over slow lines; that is, changes local to the cursor were updated, but changes to lines on the screen that were not close to the cursor were simply marked with an `'@'` sign instead of being updated to match the current text. IEEE Std 1003.1-200x permits, but does not require this feature because it is used ever less frequently as terminals become smarter and connections are faster.

Initialization in ex and vi

Historically, *vi* always had a line in the edit buffer, even if the edit buffer was ''empty''. For example:

1. The *ex* command **=** executed from visual mode wrote ''1'' when the buffer was empty.
2. Writes from visual mode of an empty edit buffer wrote files of a single character (a <newline>), while writes from *ex* mode of an empty edit buffer wrote empty files.
3. Put and read commands into an empty edit buffer left an empty line at the top of the edit buffer.

For consistency, IEEE Std 1003.1-200x does not permit any of these behaviors.

Historically, *vi* did not always return the terminal to its original modes; for example, ICRNL was modified if it was not originally set. IEEE Std 1003.1-200x does not permit this behavior.

Command Descriptions in vi

Motion commands are among the most complicated aspects of *vi* to describe. With some exceptions, the text region and buffer type effect of a motion command on a *vi* command are described on a case-by-case basis. The descriptions of text regions in IEEE Std 1003.1-200x are not intended to imply direction; that is, an inclusive region from line n to line $n+5$ is identical to a region from line $n+5$ to line n. This is of more than academic interest—movements to marks can be in either direction, and, if the **wrapscan** option is set, so can movements to search points. Historically, lines are always stored into buffers in text order; that is, from the start of the edit buffer to the end. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, command counts were applied to any associated motion, and were multiplicative to any supplied motion count. For example, **2cw** is the same as **c2w**, and **2c3w** is the same as **c6w**. IEEE Std 1003.1-200x requires this behavior. Historically, *vi* commands that used bigwords, words, paragraphs, and sentences as objects treated groups of empty lines, or lines that contained only <blank>s, inconsistently. Some commands treated them as a single entity, while others treated each line separately. For example, the **w**, **W**, and **B** commands treated groups of empty lines as individual words; that is, the command would move the cursor to each new empty line. The **e** and **E** commands treated groups of empty lines as a single word; that is, the first use would move past the group of lines. The **b** command would just beep at the user, or if done from the start of the line as a motion command, fail in unexpected ways. If the lines contained only (or ended with) <blank>s, the **w** and **W** commands would just beep at the user, the **E** and **e** commands would treat the group as a single word, and the **B** and **b** commands would treat the lines as individual words. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that all *vi* commands treat groups of empty or blank lines as a single entity, and that movement through lines ending with <blank>s be consistent with other movements.

Historically, *vi* documentation indicated that any number of double quotes were skipped after punctuation marks at sentence boundaries; however, implementations only skipped single quotes. IEEE Std 1003.1-200x requires both to be skipped.

Historically, the first and last characters in the edit buffer were word boundaries. This historical practice is required by IEEE Std 1003.1-200x.

Historically, *vi* attempted to update the minimum number of columns on the screen possible, which could lead to misleading information being displayed. IEEE Std 1003.1-200x makes no requirements other than that the current character being entered is displayed correctly, leaving all other decisions in this area up to the implementation.

Historically, lines were arbitrarily folded between columns of any characters that required multiple column positions on the screen, with the exception of tabs, which terminated at the right-hand margin. IEEE Std 1003.1-200x permits the former and requires the latter. Implementations that do not arbitrarily break lines between columns of characters that occupy multiple column positions should not permit the cursor to rest on a column that does not contain any part of a character.

The historical *vi* had a problem in that all movements were by buffer lines, not by display or screen lines. This is often the right thing to do; for example, single line movements, such as **j** or **k**, should work on buffer lines. Commands like **dj**, or **j.**, where **.** is a change command, only make sense for buffer lines. It is not, however, the right thing to do for screen motion or scrolling commands like <control>-D, <control>-F, and **H**. If the window is fairly small, using buffer lines in these cases can result in completely random motion; for example, **1**<control>-D can result in a completely changed screen, without any overlap. This is clearly not what the user wanted. The problem is even worse in the case of the **H**, **L**, and **M** commands—as they position the cursor at the first non-<blank> of the line, they may all refer to the same location in large lines, and will result in no movement at all.

In addition, if the line is larger than the screen, using buffer lines can make it impossible to display parts of the line—there are not any commands that do not display the beginning of the line in historical *vi*, and if both the beginning and end of the line cannot be on the screen at the same time, the user suffers. Finally, the page and half-page scrolling commands historically moved to the first non-<blank> in the new line. If the line is approximately the same size as the screen, this is inadequate because the cursor before and after a <control>-D command will refer to the same location on the screen.

Implementations of *ex* and *vi* exist that do not have these problems because the relevant commands (<control>-B, <control>-D, <control>-F, <control>-U, <control>-Y, <control>-E, **H**, **L**, and **M)** operate on display (screen) lines, not (edit) buffer lines.

IEEE Std 1003.1-200x does not permit this behavior by default because the standard developers believed that users would find it too confusing. However, historical practice has been relaxed.

For example, *ex* and *vi* historically attempted, albeit sometimes unsuccessfully, to never put part of a line on the last lines of a screen; for example, if a line would not fit in its entirety, no part of the line was displayed, and the screen lines corresponding to the line contained single '@' characters. This behavior is permitted, but not required by IEEE Std 1003.1-200x, so that it is possible for implementations to support long lines in small screens more reasonably without changing the commands to be oriented to the display (instead of oriented to the buffer). IEEE Std 1003.1-200x also permits implementations to refuse to edit any edit buffer containing a line that will not fit on the screen in its entirety.

The display area (for example, the value of the **window** edit option) has historically been ‘‘grown’’, or expanded, to display new text when local movements are done in displays where the number of lines displayed is less than the maximum possible. Expansion has historically been the first choice, when the target line is less than the maximum possible expansion value away. Scrolling has historically been the next choice, done when the target line is less than half a display away, and otherwise, the screen was redrawn. There were exceptions, however, in that *ex* commands generally always caused the screen to be redrawn. IEEE Std 1003.1-200x does not specify a standard behavior because there may be external issues, such as connection speed, the number of characters necessary to redraw as opposed to scroll, or terminal capabilities that implementations will have to accommodate.

The current line in IEEE Std 1003.1-200x maps one-to-one to a buffer line in the file. The current column does not. There are two different column values that are described by IEEE Std 1003.1-200x. The first is the current column value as set by many of the *vi* commands. This value is remembered for the lifetime of the editor. The second column value is the actual position on the screen where the cursor rests. The two are not always the same. For example, when the cursor is backed by a multi-column character, the actual cursor position on the screen has historically been the last column of the character in command mode, and the first column of the character in input mode.

Commands that set the current line, but that do not set the current cursor value (for example, **j** and **k**) attempt to get as close as possible to the remembered column position, so that the cursor tends to restrict itself to a vertical column as the user moves around in the edit buffer. IEEE Std 1003.1-200x requires conformance to historical practice, requiring that the display location of the cursor on the display line be adjusted from the current column value as necessary to support this historical behavior.

Historically, only a single line (and for some terminals, a single line minus 1 column) of characters could be entered by the user for the line oriented commands; that is, **:**, **!**, **/**, or **?**. IEEE Std 1003.1-200x permits, but does not require, this limitation.

Historically, ‘‘soft’’ errors in *vi* caused the terminal to be alerted, but no error message was displayed. As a general rule, no error message was displayed for errors in command execution in *vi*, when the error resulted from the user attempting an invalid or impossible action, or when a searched-for object was not found. Examples of soft errors included **h** at the left margin, <control>-B or **[[** at the beginning of the file, **2G** at the end of the file, and so on. In addition, errors such as **%**, **]]**, **}**, **)**, **N**, **n**, **f**, **F**, **t**, and **T** failing to find the searched-for object were soft as well. Less consistently, **/** and **?** displayed an error message if the pattern was not found, **/**, **?**, **N**, and **n** displayed an error message if no previous regular expression had been specified, and **;** did not display an error message if no previous **f**, **F**, **t**, or **T** command had occurred. Also, behavior in this area might reasonably be based on a runtime evaluation of the speed of a network connection. Finally, some implementations have provided error messages for soft errors in order to assist naive users, based on the value of a verbose edit option. IEEE Std 1003.1-200x does not list specific errors for which an error message shall be displayed. Implementations should conform to historical practice in the absence of any strong reason to diverge.

Page Backwards

The <control>-B and <control>-F commands historically considered it an error to attempt to page past the beginning or end of the file, whereas the <control>-D and <control>-U commands simply moved to the beginning or end of the file. For consistency, IEEE Std 1003.1-200x requires the latter behavior for all four commands. All four commands still consider it an error if the current line is at the beginning (<control>-B, <control>-U) or end (<control>-F, <control>-D) of the file. Historically, the <control>-B and <control>-F commands skip two lines in order to include overlapping lines when a single command is entered. This makes less sense in the presence of a *count*, as there will be, by definition, no overlapping lines. The actual calculation used by historical implementations of the *vi* editor for <control>-B was:

```
((current first line) − count x (window edit option)) +2
```

and for <control>-F was:

```
((current first line) + count x (window edit option)) −2
```

This calculation does not work well when intermixing commands with and without counts; for example, **3**<control>-F is not equivalent to entering the <control>-F command three times, and is not reversible by entering the <control>-B command three times. For consistency with other *vi* commands that take counts, IEEE Std 1003.1-200x requires a different calculation.

Scroll Forward

The 4BSD and System V implementations of *vi* differed on the initial value used by the **scroll** command. 4BSD used:

```
((window edit option) +1) /2
```

while System V used the value of the **scroll** edit option. The System V version is specified by IEEE Std 1003.1-200x because the standard developers believed that it was more intuitive and permitted the user a method of setting the scroll value initially without also setting the number of lines that are displayed.

Scroll Forward by Line

Historically, the <control>-E and <control>-Y commands considered it an error if the last and first lines, respectively, were already on the screen. IEEE Std 1003.1-200x requires conformance to historical practice. Historically, the <control>-E and <control>-Y commands had no effect in open mode. For simplicity and consistency of specification, IEEE Std 1003.1-200x requires that they behave as usual, albeit with a single line screen.

Clear and Redisplay

The historical <control>-L command refreshed the screen exactly as it was supposed to be currently displayed, replacing any `'@'` characters for lines that had been deleted but not updated on the screen with refreshed `'@'` characters. The intent of the <control>-L command is to refresh when the screen has been accidentally overwritten; for example, by a **write** command from another user, or modem noise.

Redraw Screen

The historical <control>-R command redisplayed only when necessary to update lines that had been deleted but not updated on the screen and that were flagged with `'@'` characters. There is no requirement that the screen be in any way refreshed if no lines of this form are currently displayed. IEEE Std 1003.1-200x permits implementations to extend this command to refresh lines on the screen flagged with `'@'` characters because they are too long to be displayed in the current framework; however, the current line and column need not be modified.

Search for tagstring

Historically, the first non-<blank> at or after the cursor was the first character, and all subsequent characters that were word characters, up to the end of the line, were included. For example, with the cursor on the leading space or on the `'#'` character in the text `"#bar@"`, the tag was `"#bar"`. On the character `'b'` it was `"bar"`, and on the `'a'`, it was `"ar"`. IEEE Std 1003.1-200x requires this behavior.

Replace Text with Results from Shell Command

Historically, the **<**, **>**, and **!** commands considered most cursor motions other than line-oriented motions an error; for example, the command **>/foo<CR>** succeeded, while the command **>l** failed, even though the text region described by the two commands might be identical. For consistency, all three commands only consider entire lines and not partial lines, and the region is defined as any line that contains a character that was specified by the motion.

Move to Matching Character

Other matching characters have been left implementation-defined in order to allow extensions such as matching `'<'` and `'>'` for searching HTML, or **#ifdef**, **#else**, and **#endif** for searching C source.

Repeat Substitution

IEEE Std 1003.1-200x requires that any **c** and **g** flags specified to the previous substitute command be ignored; however, the **r** flag may still apply, if supported by the implementation.

Return to Previous (Context or Section)

The **[[**, **]]**, **(**, **)**, **{**, and **}** commands are all affected by ‘‘section boundaries’’, but in some historical implementations not all of the commands recognize the same section boundaries. This is a bug, not a feature, and a unique section-boundary algorithm was not described for each command. One special case that is preserved is that the sentence command moves to the end of the last line of the edit buffer while the other commands go to the beginning, in order to preserve the traditional character cut semantics of the sentence command. Historically, *vi* section boundaries at the beginning and end of the edit buffer were the first non-<blank> on the first and last lines of the edit buffer if one exists; otherwise, the last character of the first and last lines of the edit buffer if one exists. To increase consistency with other section locations, this has been simplified by IEEE Std 1003.1-200x to the first character of the first and last lines of the edit buffer, or the first and the last lines of the edit buffer if they are empty.

Sentence boundaries were problematic in the historical *vi*. They were not only the boundaries as defined for the section and paragraph commands, but they were the first non-<blank> that occurred after those boundaries, as well. Historically, the *vi* section commands were documented as taking an optional window size as a *count* preceding the command. This was not implemented in historical versions, so IEEE Std 1003.1-200x requires that the *count* repeat the command, for consistency with other *vi* commands.

Repeat

Historically, mapped commands other than text input commands could not be repeated using the **period** command. IEEE Std 1003.1-200x requires conformance to historical practice.

The restrictions on the interpretation of special characters (for example, <control>-H) in the repetition of text input mode commands is intended to match historical practice. For example, given the input sequence:

```
iab<control>-H<control>-H<control>-Hdef<escape>
```

the user should be informed of an error when the sequence is first entered, but not during a command repetition. The character <control>-T is specifically exempted from this restriction. Historical implementations of *vi* ignored <control>-T characters that were input in the original command during command repetition. IEEE Std 1003.1-200x prohibits this behavior.

Find Regular Expression

Historically, commands did not affect the line searched to or from if the motion command was a search (**/**, **?**, **N**, **n**) and the final position was the start/end of the line. There were some special cases and *vi* was not consistent. IEEE Std 1003.1-200x does not permit this behavior, for consistency. Historical implementations permitted, but were unable to handle searches as motion commands that wrapped (that is, due to the edit option **wrapscan**) to the original location. IEEE Std 1003.1-200x requires that this behavior be treated as an error.

Historically, the syntax `"/RE/0"` was used to force the command to cut text in line mode. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, in open mode, a **z** specified to a search command redisplayed the current line instead of displaying the current screen with the current line highlighted. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Historically, trailing **z** commands were permitted and ignored if entered as part of a search used as a motion command. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Execute an ex Command

Historically, *vi* implementations restricted the commands that could be entered on the colon command line (for example, **append** and **change**), and some other commands were known to cause them to fail catastrophically. For consistency, IEEE Std 1003.1-200x does not permit these restrictions. When executing an *ex* command by entering **:**, it is not possible to enter a <newline> as part of the command because it is considered the end of the command. A different approach is to enter *ex* command mode by using the *vi* **Q** command (and later resuming visual mode with the *ex* **vi** command). In *ex* command mode, the single-line limitation does not exist. So, for example, the following is valid:

```
Q
s/break here/break\
here/
vi
```

IEEE Std 1003.1-200x requires that, if the *ex* command overwrites any part of the screen that would be erased by a refresh, *vi* pauses for a character from the user. Historically, this character could be any character; for example, a character input by the user before the message appeared, or even a mapped character. This is probably a bug, but implementations that have tried to be more rigorous by requiring that the user enter a specific character, or that the user enter a character after the message was displayed, have been forced by user indignation back into historical behavior. IEEE Std 1003.1-200x requires conformance to historical practice.

Shift Left (Right)

Refer to the Rationale for the **!** and **/** commands. Historically, the **<** and **>** commands sometimes moved the cursor to the first non-<blank> (for example if the command was repeated or with **_** as the motion command), and sometimes left it unchanged. IEEE Std 1003.1-200x does not permit this inconsistency, requiring instead that the cursor always move to the first non-<blank>. Historically, the **<** and **>** commands did not support buffer arguments, although some implementations allow the specification of an optional buffer. This behavior is neither required nor disallowed by IEEE Std 1003.1-200x.

Execute

Historically, buffers could execute other buffers, and loops, infinite and otherwise, were possible. IEEE Std 1003.1-200x requires conformance to historical practice. The **buffer* syntax of *ex* is not required in *vi*, because it is not historical practice and has been used in some *vi* implementations to support additional scripting languages.

Reverse Case

Historically, the **~** command ignored any associated *count*, and acted only on the characters in the current line. For consistency with other *vi* commands, IEEE Std 1003.1-200x requires that an associated *count* act on the next *count* characters, and that the command move to subsequent lines if warranted by *count*, to make it possible to modify large pieces of text in a reasonably efficient manner. There exist *vi* implementations that optionally require an associated motion command for the **~** command. Implementations supporting this functionality are encouraged to base it on the **tildedop** edit option and handle the text regions and cursor positioning identically to the **yank** command.

Append

Historically, *count*s specified to the **A**, **a**, **I**, and **i** commands repeated the input of the first line *count* times, and did not repeat the subsequent lines of the input text. IEEE Std 1003.1-200x requires that the entire text input be repeated *count* times.

Move Backward to Preceding Word

Historically, *vi* became confused if word commands were used as motion commands in empty files. IEEE Std 1003.1-200x requires that this be an error. Historical implementations of *vi* had a large number of bugs in the word movement commands, and they varied greatly in behavior in the presence of empty lines, ‘‘words’’ made up of a single character, and lines containing only <blank>s. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Change to End-of-Line

Some historical implementations of the **C** command did not behave as described by IEEE Std 1003.1-200x when the **$** key was remapped because they were implemented by pushing the **$** key onto the input queue and reprocessing it. IEEE Std 1003.1-200x does not permit this behavior. Historically, the **C**, **S**, and **s** commands did not copy replaced text into the numeric buffers. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that they behave like their respective **c** commands in all respects.

Delete

Historically, lines in open mode that were deleted were scrolled up, and an **@** glyph written over the beginning of the line. In the case of terminals that are incapable of the necessary cursor motions, the editor erased the deleted line from the screen. IEEE Std 1003.1-200x requires conformance to historical practice; that is, if the terminal cannot display the '@' character, the line cannot remain on the screen.

Delete to End-of-Line

Some historical implementations of the **D** command did not behave as described by IEEE Std 1003.1-200x when the **$** key was remapped because they were implemented by pushing the **$** key onto the input queue and reprocessing it. IEEE Std 1003.1-200x does not permit this behavior.

Join

An historical oddity of *vi* is that the commands **J**, **1J**, and **2J** are all equivalent. IEEE Std 1003.1-200x requires conformance to historical practice. The *vi* **J** command is specified in terms of the *ex* **join** command with an *ex* command *count* value. The address correction for a *count* that is past the end of the edit buffer is necessary for historical compatibility for both *ex* and *vi*.

Mark Position

Historical practice is that only lowercase letters, plus '‘' and ''', could be used to mark a cursor position. IEEE Std 1003.1-200x requires conformance to historical practice, but encourages implementations to support other characters as marks as well.

Repeat Regular Expression Find (Forward and Reverse)

Historically, the **N** and **n** commands could not be used as motion components for the **c** command. With the exception of the **cN** command, which worked if the search crossed a line boundary, the text region would be discarded, and the user would not be in text input mode. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Insert Empty Line (Below and Above)

Historically, counts to the **O** and **o** commands were used as the number of physical lines to open, if the terminal was dumb and the **slowopen** option was not set. This was intended to minimize traffic over slow connections and repainting for dumb terminals. IEEE Std 1003.1-200x does not permit this behavior, requiring that a *count* to the open command behave as for other text input commands. This change to historical practice was made for consistency, and because a superset of the functionality is provided by the **slowopen** edit option.

Put from Buffer (Following and Before)

Historically, *count*s to the **p** and **P** commands were ignored if the buffer was a line mode buffer, but were (mostly) implemented as described in IEEE Std 1003.1-200x if the buffer was a character mode buffer. Because implementations exist that do not have this limitation, and because pasting lines multiple times is generally useful, IEEE Std 1003.1-200x requires that *count* be supported for all **p** and **P** commands.

Historical implementations of *vi* were widely known to have major problems in the **p** and **P** commands, particularly when unusual regions of text were copied into the edit buffer. The standard developers viewed these as bugs, and they are not permitted for consistency and simplicity of specification.

Historically, a **P** or **p** command (or an *ex* **put** command executed from open or visual mode) executed in an empty file, left an empty line as the first line of the file. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Replace Character

Historically, the **r** command did not correctly handle the *erase* and *word erase* characters as arguments, nor did it handle an associated *count* greater than 1 with a <carriage-return> argument, for which it replaced *count* characters with a single <newline>. IEEE Std 1003.1-200x does not permit these inconsistencies.

Historically, the **r** command permitted the <control>-V escaping of entered characters, such as <ESC> and the <carriage-return>; however, it required two leading <control>-V characters instead of one. IEEE Std 1003.1-200x requires that this be changed for consistency with the other text input commands of *vi*.

Historically, it is an error to enter the **r** command if there are less than *count* characters at or after the cursor in the line. While a reasonable and unambiguous extension would be to permit the **r** command on empty lines, it would require that too large a *count* be adjusted to match the number of characters at or after the cursor for consistency, which is sufficiently different from historical practice to be avoided. IEEE Std 1003.1-200x requires conformance to historical practice.

Replace Characters

Historically, if there were **autoindent** characters in the line on which the **R** command was run, and **autoindent** was set, the first <newline> would be properly indented and no characters would be replaced by the <newline>. Each additional <newline> would replace *n* characters, where *n* was the number of characters that were needed to indent the rest of the line to the proper indentation level. This behavior is a bug and is not permitted by IEEE Std 1003.1-200x.

Undo

Historical practice for cursor positioning after undoing commands was mixed. In most cases, when undoing commands that affected a single line, the cursor was moved to the start of added or changed text, or immediately after deleted text. However, if the user had moved from the line being changed, the column was either set to the first non-<blank>, returned to the origin of the command, or remained unchanged. When undoing commands that affected multiple lines or entire lines, the cursor was moved to the first character in the first line restored. As an example of how inconsistent this was, a search, followed by an **o** text input command, followed by an **undo** would return the cursor to the location where the **o** command was entered, but a **cw** command followed by an **o** command followed by an **undo** would return the cursor to the first non-<blank> of the line. IEEE Std 1003.1-200x requires the most useful of these behaviors, and discards the least useful, in the interest of consistency and simplicity of specification.

Yank

Historically, the **yank** command did not move to the end of the motion if the motion was in the forward direction. It moved to the end of the motion if the motion was in the backward direction, except for the **_** command, or for the **G** and **'** commands when the end of the motion was on the current line. This was further complicated by the fact that for a number of motion commands, the **yank** command moved the cursor but did not update the screen; for example, a subsequent command would move the cursor from the end of the motion, even though the cursor on the screen had not reflected the cursor movement for the **yank** command. IEEE Std 1003.1-200x requires that all **yank** commands associated with backward motions move the cursor to the end of the motion for consistency, and specifically, to make **'** commands as motions consistent with search patterns as motions.

Yank Current Line

Some historical implementations of the **Y** command did not behave as described by IEEE Std 1003.1-200x when the '_' key was remapped because they were implemented by pushing the '_' key onto the input queue and reprocessing it. IEEE Std 1003.1-200x does not permit this behavior.

Redraw Window

Historically, the **z** command always redrew the screen. This is permitted but not required by IEEE Std 1003.1-200x, because of the frequent use of the **z** command in macros such as **map n nz.** for screen positioning, instead of its use to change the screen size. The standard developers believed that expanding or scrolling the screen offered a better interface for users. The ability to redraw the screen is preserved if the optional new window size is specified, and in the <control>-L and <control>-R commands.

The semantics of **z**^ are confusing at best. Historical practice is that the screen before the screen that ended with the specified line is displayed. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, the **z** command would not display a partial line at the top or bottom of the screen. If the partial line would normally have been displayed at the bottom of the screen, the command worked, but the partial line was replaced with '@' characters. If the partial line would normally have been displayed at the top of the screen, the command would fail. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Historically, the **z** command with a line specification of 1 ignored the command. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Historically, the **z** command did not set the cursor column to the first non-<blank> for the character if the first screen was to be displayed, and was already displayed. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Input Mode Commands in vi

Historical implementations of *vi* did not permit the user to erase more than a single line of input, or to use normal erase characters such as *line erase*, *worderase*, and *erase* to erase **autoindent** characters. As there exist implementations of *vi* that do not have these limitations, both behaviors are permitted, but only historical practice is required. In the case of these extensions, *vi* is required to pause at the **autoindent** and previous line boundaries.

Historical implementations of *vi* updated only the portion of the screen where the current cursor character was displayed. For example, consider the *vi* input keystrokes:

```
iabcd<escape>0C<tab>
```

Historically, the <tab> would overwrite the characters `"abcd"` when it was displayed. Other implementations replace only the `'a'` character with the <tab>, and then push the rest of the characters ahead of the cursor. Both implementations have problems. The historical implementation is probably visually nicer for the above example; however, for the keystrokes:

```
iabcd<ESC>0R<tab><ESC>
```

the historical implementation results in the string `"bcd"` disappearing and then magically reappearing when the <ESC> character is entered. IEEE Std 1003.1-200x requires the former behavior when overwriting erase-columns; that is, overwriting characters that are no longer logically part of the edit buffer, and the latter behavior otherwise.

Historical implementations of *vi* discarded the <control>-D and <control>-T characters when they were entered at places where their command functionality was not appropriate. IEEE Std 1003.1-200x requires that the <control>-T functionality always be available, and that <control>-D be treated as any other key when not operating on **autoindent** characters.

NUL

Some historical implementations of *vi* limited the number of characters entered using the NUL input character to 256 bytes. IEEE Std 1003.1-200x permits this limitation; however, implementations are encouraged to remove this limit.

<control>-D

See also Rationale for the input mode command <newline>. The hidden assumptions in the <control>-D command (and in the *vi* **autoindent** specification in general) is that <space>s take up a single column on the screen and that <tab>s are comprised of an integral number of <space>s.

<newline>

Implementations are permitted to rewrite **autoindent** characters in the line when <newline>, <carriage-return>, <control>-D, and <control>-T are entered, or when the **shift** commands are used, because historical implementations have both done so and found it necessary to do so. For example, a <control>-D when the cursor is preceded by a single <tab>, with **tabstop** set to 8, and **shiftwidth** set to 3, will result in the <tab> being replaced by several <space>s.

<control>-T

See also the Rationale for the input mode command <newline>. Historically, <control>-T only worked if no non-<blank>s had yet been input in the current input line. In addition, the characters inserted by <control>-T were treated as **autoindent** characters, and could not be erased using normal user erase characters. Because implementations exist that do not have these limitations, and as moving to a column boundary is generally useful, IEEE Std 1003.1-200x requires that both limitations be removed.

<control>-V

Historically, *vi* used **ˆV**, regardless of the value of the literal-next character of the terminal. IEEE Std 1003.1-200x requires conformance to historical practice.

The uses described for <control>-V can also be accomplished with <control>-Q, which is useful on terminals that use <control>-V for the down-arrow function. However, most historical implementations use <control>-Q for the *termios* START character, so the editor will generally not receive the <control>-Q unless **stty ixon** mode is set to off. (In addition, some historical implementations of *vi* explicitly set **ixon** mode to on, so it was difficult for the user to set it to off.) Any of the command characters described in IEEE Std 1003.1-200x can be made ineffective by their selection as *termios* control characters, using the *stty* utility or other methods described in the System Interfaces volume of IEEE Std 1003.1-200x.

<ESC>

Historically, SIGINT alerted the terminal when used to end input mode. This behavior is permitted, but not required, by IEEE Std 1003.1-200x.

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent SYNOPSIS is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **reindent** command description is added.

The *vi* utility has been extensively rewritten for alignment with the IEEE P1003.2b draft standard.

IEEE PASC Interpretations 1003.2 #57, #62, #63, #64, #78, and #188 are applied. |

IEEE PASC Interpretation 1003.2 #207 is applied, clarifying the description of the **R** command in a manner similar to the descriptions of other text input mode commands such as **i**, **o**, and **O**. |

NAME

wait — await process completion

SYNOPSIS

```
wait [pid...]
```

DESCRIPTION

When an asynchronous list (see Section 2.9.3.1 (on page 2252)) is started by the shell, the process ID of the last command in each element of the asynchronous list shall become known in the current shell execution environment; see Section 2.12 (on page 2263).

If the *wait* utility is invoked with no operands, it shall wait until all process IDs known to the invoking shell have terminated and exit with a zero exit status.

If one or more *pid* operands are specified that represent known process IDs, the *wait* utility shall wait until all of them have terminated. If one or more *pid* operands are specified that represent unknown process IDs, *wait* shall treat them as if they were known process IDs that exited with exit status 127. The exit status returned by the *wait* utility shall be the exit status of the process requested by the last *pid* operand.

The known process IDs are applicable only for invocations of *wait* in the current shell execution environment.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

pid One of the following:

1. The unsigned decimal integer process ID of a command, for which the utility is to wait for the termination.
2. A job control job ID (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.203, Job Control Job ID) that identifies a background process group to be waited for. The job control job ID notation is applicable only for invocations of *wait* in the current shell execution environment; see Section 2.12 (on page 2263). The exit status of *wait* shall be determined by the last command in the pipeline.

   Note: The job control job ID type of *pid* is only available on systems supporting the User Portability Utilities option.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *wait*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If one or more operands were specified, all of them have terminated or were not known by the invoking shell, and the status of the last operand specified is known, then the exit status of *wait* shall be the exit status information of the command indicated by the last operand specified. If the process terminated abnormally due to the receipt of a signal, the exit status shall be greater than 128 and shall be distinct from the exit status generated by other signals, but the exact value is unspecified. (See the *kill* **−l** option.) Otherwise, the *wait* utility shall exit with one of the following values:

0	The *wait* utility was invoked with no operands and all process IDs known by the invoking shell have terminated.
1-126	The *wait* utility detected an error.
127	The command identified by the last *pid* operand specified is unknown.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

On most implementations, *wait* is a shell built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(wait)
nohup wait ...
find . −exec wait ... \;
```

it returns immediately because there are no known process IDs to wait for in those environments.

Historical implementations of interactive shells have discarded the exit status of terminated background processes before each shell prompt. Therefore, the status of background processes was usually lost unless it terminated while *wait* was waiting for it. This could be a serious problem when a job that was expected to run for a long time actually terminated quickly with a syntax or initialization error because the exit status returned was usually zero if the requested process ID was not found. This volume of IEEE Std 1003.1-200x requires the implementation to keep the status of terminated jobs available until the status is requested, so that scripts like:

```
j1&
p1=$!
j2&
wait $p1
echo Job 1 exited with status $?
wait $!
echo Job 2 exited with status $?
```

works without losing status on any of the jobs. The shell is allowed to discard the status of any process that it determines the application cannot get the process ID from the shell. It is also required to remember only {CHILD_MAX} number of processes in this way. Since the only way to get the process ID from the shell is by using the `'!'` shell parameter, the shell is allowed to discard the status of an asynchronous list if `"$!"` was not referenced before another asynchronous list was started. (This means that the shell only has to keep the status of the last asynchronous list started if the application did not reference `"$!"`. If the implementation of the shell is smart enough to determine that a reference to `"$!"` was not saved anywhere that the application can retrieve it later, it can use this information to trim the list of saved information. Note also that a successful call to *wait* with no operands discards the exit status of all asynchronous lists.)

If the exit status of *wait* is greater than 128, there is no way for the application to know if the waited-for process exited with that value or was killed by a signal. Since most utilities exit with small values, there is seldom any ambiguity. Even in the ambiguous cases, most applications just need to know that the asynchronous job failed; it does not matter whether it detected an error and failed or was killed and did not complete its job normally.

EXAMPLES

Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably figure out which signal using *kill* as shown by the following script:

```
sleep 1000&
pid=$!
kill -kill $pid
wait $pid
echo $pid was terminated by a SIG$(kill -l $?) signal.
```

If the following sequence of commands is run in less than 31 seconds:

```
sleep 257 | sleep 31 &
jobs -l %%
```

either of the following commands returns the exit status of the second *sleep* in the pipeline:

```
wait <pid of sleep 31>
wait %%
```

RATIONALE

The description of *wait* does not refer to the *waitpid*( ) function from the System Interfaces volume of IEEE Std 1003.1-200x because that would needlessly overspecify this interface. However, the wording means that *wait* is required to wait for an explicit process when it is given an argument so that the status information of other processes is not consumed. Historical implementations use the *wait*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x until *wait*( ) returns the requested process ID or finds that the requested process does not exist. Because this means that a shell script could not reliably get the status of all background children if a second background job was ever started before the first job finished, it is recommended that the *wait* utility use a method such as the functionality provided by the *waitpid*( ) function.

The ability to wait for multiple *pid* operands was adopted from the KornShell.

This new functionality was added because it is needed to determine the exit status of any asynchronous list accurately. The only compatibility problem that this change creates is for a script like

```
while sleep 60 do
    job& echo Job started $(date) as $!  done
```

which causes the shell to monitor all of the jobs started until the script terminates or runs out of memory. This would not be a problem if the loop did not reference `"$!"` or if the script would occasionally *wait* for jobs it started.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

wc — word, line, and byte or character count

SYNOPSIS

```
wc [−c|−m][−lw][file...]
```

DESCRIPTION

The *wc* utility shall read one or more input files and, by default, write the number of <newline>s, words, and bytes contained in each input file to the standard output.

The utility also shall write a total count for all named files, if more than one input file is specified.

The *wc* utility shall consider a *word* to be a non-zero-length string of characters delimited by white space.

OPTIONS

The *wc* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−c	Write to the standard output the number of bytes in each input file.
−l	Write to the standard output the number of <newline>s in each input file.
−m	Write to the standard output the number of characters in each input file.
−w	Write to the standard output the number of words in each input file.

When any option is specified, *wc* shall report only the information requested by the specified options.

OPERANDS

The following operand shall be supported:

file	A pathname of an input file. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified. See the INPUT FILES section.

INPUT FILES

The input files may be of any type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *wc*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and which characters are defined as white space characters.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES.*

ASYNCHRONOUS EVENTS

Default.

STDOUT

By default, the standard output shall contain an entry for each input file of the form:

```
"%d %d %d %s\n", <newlines>, <words>, <bytes>, <file>
```

If the **−m** option is specified, the number of characters shall replace the <*bytes*> field in this format.

If any options are specified and the **−l** option is not specified, the number of <newline>s shall not be written.

If any options are specified and the **−w** option is not specified, the number of words shall not be written.

If any options are specified and neither **−c** nor **−m** is specified, the number of bytes or characters shall not be written.

If no input *file* operands are specified, no name shall be written and no <blank>s preceding the pathname shall be written.

If more than one input *file* operand is specified, an additional line shall be written, of the same format as the other lines, except that the word **total** (in the POSIX locale) shall be written instead of a pathname and the total of each column shall be written as appropriate. Such an additional line, if any, is written at the end of the output.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The −**m** option is not a switch, but an option at the same level as −**c**. Thus, to produce the full default output with character counts instead of bytes, the command required is:

```
wc −mlw
```

EXAMPLES

None.

RATIONALE

The output file format pseudo-*printf*( ) string differs from the System V version of *wc*:

```
"%7d%7d%7d %s\n"
```

which produces possibly ambiguous and unparsable results for very large files, as it assumes no number shall exceed six digits.

Some historical implementations use only <space>, <tab>, and <newline> as word separators. The equivalent of the ISO C standard *isspace*( ) function is more appropriate.

The −**c** option stands for ''character'' count, even though it counts bytes. This stems from the sometimes erroneous historical view that bytes and characters are the same size. Due to international requirements, the −**m** option (reminiscent of ''multi-byte'') was added to obtain actual character counts.

Early proposals only specified the results when input files were text files. The current specification more closely matches historical practice. (Bytes, words, and <newline>s are counted separately and the results are written when an end-of-file is detected.)

Historical implementations of the *wc* utility only accepted one argument to specify the options −**c**, −**l**, and −**w**. Some of them also had multiple occurrences of an option cause the corresponding count to be written multiple times and had the order of specification of the options affect the order of the fields on output, but did not document either of these. Because common usage either specifies no options or only one option, and because none of this was documented, the changes required by this volume of IEEE Std 1003.1-200x should not break many historical applications (and do not break any historical conforming applications).

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

what — identify SCCS files (**DEVELOPMENT**)

SYNOPSIS

XSI
```
what [−s] file...
```

DESCRIPTION

The *what* utility shall search the given files for all occurrences of the pattern that *get* (see *get* (on page 2675)) substitutes for the %**Z**% keyword (`"@(#)"`) and shall write to standard output what follows until the first occurrence of one of the following:

```
"    >    newline    \    NUL
```

OPTIONS

The *what* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

−s	Quit after finding the first occurrence of the pattern in each file.

OPERANDS

The following operands shall be supported:

file	A pathname of a file to search.

STDIN

Not used.

INPUT FILES

The input files shall be of any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *what*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall consist of the following for each *file* operand:

```
"%s:\n\t%s\n", <pathname>, <identification string>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Any matches were found.
1	Otherwise.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *what* utility is intended to be used in conjunction with the SCCS command *get*, which automatically inserts identifying information, but it can also be used where the information is inserted by any other means.

When the string `"@(#)"` is included in a library routine in a shared library, it might not be found in an **a.out** file using that library routine.

EXAMPLES

If the C-language program in file **f.c** contains:

```
char ident[] = "@(#)identification information";
```

and **f.c** is compiled to yield **f.o** and **a.out**, then the command:

```
what f.c f.o a.out
```

writes:

```
f.c:
    identification information
    ...
f.o:
    identification information
    ...
a.out:
    identification information
    ...
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

who — display who is on the system

SYNOPSIS

```
UP   who [−mTu]

XSI  who [−mu]−s[−bHlprt][file]
     who [−mTu][−abdHlprt][file]
     who −q [file]
     who am i
     who am I
```

DESCRIPTION

The *who* utility shall list various pieces of information about accessible users. The domain of accessibility is implementation-defined.

XSI Based on the options given, *who* can also list the user's name, terminal line, login time, elapsed time since activity occurred on the line, and the process ID of the command interpreter for each current system user.

OPTIONS

The *who* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported. The metavariables, such as <*line*>, refer to fields described in the STDOUT section.

XSI	**−a**	Process the implementation-defined database or named file with the **−b**, **−d**, **−l**, **−p**, **−r**, **−t**, **−T** and **−u** options turned on.
XSI	**−b**	Write the time and date of the last reboot.
XSI	**−d**	Write a list of all processes that have expired and not been respawned by the *init* system process. The <*exit*> field shall appear for dead processes and contain the termination and exit values of the dead process. This can be useful in determining why a process terminated.
XSI	**−H**	Write column headings above the regular output.
XSI	**−l**	(The letter ell.) List only those lines on which the system is waiting for someone to login. The <*name*> field shall be **LOGIN** in such cases. Other fields shall be the same as for user entries except that the <*state*> field does not exist.
	−m	Output only information about the current terminal.
XSI	**−p**	List any other process that is currently active and has been previously spawned by *init*.
XSI	**−q**	(Quick.) List only the names and the number of users currently logged on. When this option is used, all other options shall be ignored.
XSI	**−r**	Write the current *run-level* of the *init* process.
XSI	**−s**	List only the <*name*>, <*line*>, and <*time*> fields. This is the default case.
XSI	**−t**	Indicate the last change to the system clock.

−T	Show the state of each terminal, as described in the STDOUT section.
−u	Write ‘‘idle time’’ for each displayed user in addition to any other information. The idle time is the time since any activity occurred on the user’s terminal. The method of determining this is unspecified. XSI This option shall list only those users who are currently logged in. The <*name*> is the user’s login name. The <*line*> is the name of the line as found in the directory **/dev**. The <*time*> is the time that the user logged in. The <*activity*> is the number of hours and minutes since activity last occurred on that particular line. A dot indicates that the terminal has seen activity in the last minute and is therefore ‘‘current’’. If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry shall be marked <*old*>. This field is useful when trying to determine whether a person is working at the terminal or not. The <*pid*> is the process ID of the user’s login process.

OPERANDS

XSI The following operands shall be supported:

am i, **am I**	In the POSIX locale, limit the output to describing the invoking user, equivalent to the −**m** option. The **am** and **i** or **I** must be separate arguments.
file	Specify a pathname of a file to substitute for the implementation-defined database of logged-on users that *who* uses by default.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *who*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_TIME	Determine the locale used for the format and contents of the date and time strings.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
TZ	Determine the timezone used when writing date and time information. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *who* utility shall write its default format to the standard output in an implementation-defined format, subject only to the requirement of containing the information described above.

XSI OF XSI-conformant systems shall write the default information to the standard output in the following general format:

`<name>[<state>]<line><time>[<activity>][<pid>][<comment>][<exit>]`

The following format shall be used for the **−T** option:

```
"%s %c %s %s\n" <name>, <terminal state>, <terminal name>,
    <time of login>
```

where <*terminal state*> is one of the following characters:

+	The terminal allows write access to other users.
–	The terminal denies write access to other users.
?	The terminal write-access state cannot be determined.

In the POSIX locale, the <*time of login*> shall be equivalent in format to the output of:

```
date +"%b %e %H:%M"
```

If the **−u** option is used with **−T**, the idle time shall be added to the end of the previous format in an unspecified format.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The name *init* used for the system process is the most commonly used on historical systems, but it may vary.

The ''domain of accessibility'' referred to is a broad concept that permits interpretation either on a very secure basis or even to allow a network-wide implementation like the historical *rwho*.

EXAMPLES

None.

RATIONALE

Due to differences between historical implementations, the base options provided were a compromise to allow users to work with those functions. The standard developers also considered removing all the options, but felt that these options offered users valuable functionality. Additional options to match historical systems are available on XSI-conformant systems.

It is recognized that the *who* command may be of limited usefulness, especially in a multi-level secure environment. The standard developers considered, however, that having some standard method of determining the ''accessibility'' of other users would aid user portability.

No format was specified for the default *who* output for systems not supporting the XSI Extension. In such a user-oriented command, designed only for human use, this was not considered to be a deficiency.

The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, and *write* require that they use the same format.

It is acceptable for an implementation to produce no output for an invocation of *who* **mil**.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

NAME

write — write to another user

SYNOPSIS

UP
```
write user_name [terminal]
```

DESCRIPTION

The *write* utility shall read lines from the user's standard input and write them to the terminal of another user. When first invoked, it shall write the message:

```
Message from sender-login-id (sending-terminal) [date]...
```

to *user_name*. When it has successfully completed the connection, the sender's terminal shall be alerted twice to indicate that what the sender is typing is being written to the recipient's terminal.

If the recipient wants to reply, this can be accomplished by typing:

```
write sender-login-id [sending-terminal]
```

upon receipt of the initial message. Whenever a line of input as delimited by a NL, EOF, or EOL special character (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface) is accumulated while in canonical input mode, the accumulated data shall be written on the other user's terminal. Characters shall be processed as follows:

- Typing <alert> shall write the alert character to the recipient's terminal.
- Typing the erase and kill characters shall affect the sender's terminal in the manner described by the **termios** interface in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
- Typing the interrupt or end-of-file characters shall cause *write* to write an appropriate message (`"EOT\n"` in the POSIX locale) to the recipient's terminal and exit.
- Typing characters from *LC_CTYPE* classifications **print** or **space** shall cause those characters to be sent to the recipient's terminal.
- When and only when the *stty* **iexten** local mode is enabled, the existence and processing of additional special control characters and multi-byte or single-byte functions is implementation-defined.
- Typing other non-printable characters shall cause implementation-defined sequences of printable characters to be written to the recipient's terminal.

To write to a user who is logged in more than once, the *terminal* argument can be used to indicate which terminal to write to; otherwise, the recipient's terminal is selected in an implementation-defined manner and an informational message is written to the sender's standard output, indicating which terminal was chosen.

Permission to be a recipient of a *write* message can be denied or granted by use of the *mesg* utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The *write* utility shall fail when the user lacks the appropriate privileges to perform the requested action.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

user_name	Login name of the person to whom the message shall be written. The application shall ensure that this operand is of the form returned by the *who* utility.
terminal	Terminal identification in the same format provided by the *who* utility.

STDIN

Lines to be copied to the recipient's terminal is read from standard input.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *write*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). If the recipient's locale does not use an *LC_CTYPE* equivalent to the sender's, the results are undefined.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

If an interrupt signal is received, *write* shall write an appropriate message on the recipient's terminal and exits with a status of zero. It shall take the standard action for all other signals.

STDOUT

An informational message shall be written to standard output if a recipient is logged in more than once.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The recipient's terminal is used for output.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	The addressed user is not logged on or the addressed user denies permission.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *talk* utility is considered by some users to be a more usable utility on full-screen terminals.

EXAMPLES

None.

RATIONALE

The *write* utility was included in this volume of IEEE Std 1003.1-200x since it can be implemented on all terminal types. The standard developers considered the *talk* utility, which cannot be implemented on certain terminals, to be a ‘‘better’’ communications interface. Both of these programs are in widespread use on historical implementations. Therefore, the standard developers decided that both utilities should be specified.

The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, *who*, and *write* require that they all use or accept the same format.

FUTURE DIRECTIONS

None.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

xargs — construct argument lists and invoke utility

SYNOPSIS

XSI
```
xargs [–t][–p]][–E eofstr][–I replstr][–L number][–n number [–x]]
    [–s size][utility [argument...]]
```

DESCRIPTION

The *xargs* utility shall construct a command line consisting of the *utility* and *argument* operands specified followed by as many arguments read in sequence from standard input as fit in length and number constraints specified by the options. The *xargs* utility shall then invoke the constructed command line and wait for its completion. This sequence shall be repeated until one of the following occurs:

- An end-of-file condition is detected on standard input.
- The logical end-of-file string (see the **–E** *eofstr* option) is found on standard input after double-quote processing, apostrophe processing, and backslash escape processing (see next paragraph).
- An invocation of a constructed command line returns an exit status of 255.

The application shall ensure that arguments in the standard input are separated by unquoted <blank>s, unescaped <blank>s or <newline>s. A string of zero or more non-double-quote (`'"'`) characters and non-<newline>s can be quoted by enclosing them in double-quotes. A string of zero or more non-apostrophe (`'\''`) characters and non-<newline>s can be quoted by enclosing them in apostrophes. Any unquoted character can be escaped by preceding it with a backslash. The utility named by *utility* shall be executed one or more times until the end-of-file is reached or the logical end-of file string is found. The results are unspecified if the utility named by *utility* attempts to read from its standard input.

The generated command line length shall be the sum of the size in bytes of the utility name and each argument treated as strings, including a null byte terminator for each of these strings. The *xargs* utility shall limit the command line length such that when the command line is invoked, the combined argument and environment lists (see the *exec* family of functions in the System Interfaces volume of IEEE Std 1003.1-200x) shall not exceed {ARG_MAX}–2 048 bytes. Within this constraint, if neither the **–n** nor the **–s** option is specified, the default command line length shall be at least {LINE_MAX}.

OPTIONS

The *xargs* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–E *eofstr* Use *eofstr* as the logical end-of-file string. If **–E** is not specified, it is unspecified whether the logical end-of-file string is the underscore character (`'_'`) or the end-of-file string capability is disabled. When *eofstr* is the null string, the logical end-of-file string capability shall be disabled and underscore characters shall be taken literally.

XSI **–I** *replstr* Insert mode: *utility* is executed for each line from standard input, taking the entire line as a single argument, inserting it in *arguments* for each occurrence of *replstr*. A maximum of five arguments in *arguments* can each contain one or more instances of *replstr*. Any <blank>s at the beginning of each line shall be ignored. Constructed arguments cannot grow larger than 255 bytes. Option **–x** shall be forced on.

XSI **–L** *number* The *utility* shall be executed for each non-empty *number* lines of arguments from standard input. The last invocation of *utility* shall be with fewer lines of arguments if fewer than *number* remain. A line is considered to end with the first <newline> unless the last character of the line is a <blank>; a trailing <blank> signals continuation to the next non-empty line, inclusive. The **–L** and **–n** options are mutually-exclusive; the last one specified shall take effect.

–n *number* Invoke *utility* using as many standard input arguments as possible, up to *number* (a positive decimal integer) arguments maximum. Fewer arguments shall be used if:

- The command line length accumulated exceeds the size specified by the **–s** option (or {LINE_MAX} if there is no **–s** option).
- The last iteration has fewer than but not zero, operands remaining.

–p Prompt mode: the user is asked whether to execute *utility* at each invocation. Trace mode (**–t**) is turned on to write the command instance to be executed, followed by a prompt to standard error. An affirmative response read from **/dev/tty** shall execute the command; otherwise, that particular invocation of *utility* shall be skipped.

–s *size* Invoke *utility* using as many standard input arguments as possible yielding a command line length less than *size* (a positive decimal integer) bytes. Fewer arguments shall be used if:

- The total number of arguments exceeds that specified by the **–n** option.
- XSI The total number of lines exceeds that specified by the **–L** option.
- End-of-file is encountered on standard input before *size* bytes are accumulated.

Values of *size* up to at least {LINE_MAX} bytes shall be supported, provided that the constraints specified in the DESCRIPTION are met. It shall not be considered an error if a value larger than that supported by the implementation or exceeding the constraints specified in the DESCRIPTION is given; *xargs* shall use the largest value it supports within the constraints.

–t Enable trace mode. Each generated command line shall be written to standard error just prior to invocation.

–x Terminate if a command line containing *number* arguments (see the **–n** option above) XSI or *number* lines (see the **–L** option above) will not fit in the implied or specified size (see the **–s** option above).

OPERANDS

The following operands shall be supported:

utility The name of the utility to be invoked, found by search path using the *PATH* environment variable, described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables. If *utility* is omitted, the default shall be the *echo* utility. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2266), the results are undefined.

argument An initial option or operand for the invocation of *utility*.

STDIN

The standard input shall be a text file. The results are unspecified if an end-of-file condition is detected immediately following an escaped <newline>.

INPUT FILES

The file **/dev/tty** shall be used to read responses required by the −**p** option.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *xargs*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes and multi-character collating elements used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.
LC_MESSAGES	Determine the locale for the processing of affirmative responses and that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PATH	Determine the location of *utility*, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used for diagnostic messages and the −**t** and −**p** options. If the −**t** option is specified, the *utility* and its constructed argument list shall be written to standard error, as it will be invoked, prior to invocation. If −**p** is specified, a prompt of the following format shall be written (in the POSIX locale):

```
"?..."
```

at the end of the line of the output from −**t**.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All invocations of *utility* returned exit status zero.
1-125	A command line meeting the specified requirements could not be assembled, one or more of the invocations of *utility* returned a non-zero exit status, or some other error occurred.
126	The utility specified by *utility* was found but could not be invoked.
127	The utility specified by *utility* could not be found.

CONSEQUENCES OF ERRORS

If a command line meeting the specified requirements cannot be assembled, the utility cannot be invoked, an invocation of the utility is terminated by a signal, or an invocation of the utility exits with exit status 255, the *xargs* utility shall write a diagnostic message and exit without processing any remaining input.

APPLICATION USAGE

The 255 exit status allows a utility being used by *xargs* to tell *xargs* to terminate if it knows no further invocations using the current data stream will succeed. Thus, *utility* should explicitly *exit* with an appropriate value to avoid accidentally returning with 255.

Note that input is parsed as lines; <blank>s separate arguments. If *xargs* is used to bundle output of commands like *find dir* −**print** or *ls* into commands to be executed, unexpected results are likely if any filenames contain any <blank>s or <newline>s. This can be fixed by using *find* to call a script that converts each file found into a quoted string that is then piped to *xargs*. Note that the quoting rules used by *xargs* are not the same as in the shell. They were not made consistent here because existing applications depend on the current rules and the shell syntax is not fully compatible with it. An easy rule that can be used to transform any string into a quoted form that *xargs* interprets correctly is to precede each character in the string with a backslash.

On implementations with a large value for {ARG_MAX}, *xargs* may produce command lines longer than {LINE_MAX}. For invocation of utilities, this is not a problem. If *xargs* is being used to create a text file, users should explicitly set the maximum command line length with the −**s** option.

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ‘‘failure to find a utility’’ from ‘‘invoked utility exited with an error indication’’. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ‘‘normal error conditions’’ and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

EXAMPLES

1. The following command combines the output of the parenthesised commands onto one line, which is then written to the end-of-file **log**:

   ```
   (logname; date; printf "%s\n" "$0 $*") | xargs >>log
   ```

2. The following command invokes *diff* with successive pairs of arguments originally typed as command line arguments (assuming there are no embedded <blank>s in the elements of the original argument list):

```
printf "%s\n" "$*" | xargs −n 2 −x diff
```

3. In the following commands, the user is asked which files in the current directory are to be archived. The files are archived into **arch**; *a*, one at a time, or *b*, many at a time.

```
a. ls | xargs −p −L 1 ar −r arch
```

```
b. ls | xargs −p −L 1 | xargs ar −r arch
```

4. The following executes with successive pairs of arguments originally typed as command line arguments:

```
echo $* | xargs −n 2 diff
```

5. On XSI-conformant systems, the following moves all files from directory **$1** to directory **$2**, and echoes each move command just before doing it:

```
ls $1 | xargs −I {} −t mv $1/{} $2/{}
```

RATIONALE

The *xargs* utility was usually found only in System V-based systems; BSD systems included an *apply* utility that provided functionality similar to *xargs* −**n** *number*. The SVID lists *xargs* as a software development extension. This volume of IEEE Std 1003.1-200x does not share the view that it is used only for development, and therefore it is not optional.

The classic application of the *xargs* utility is in conjunction with the *find* utility to reduce the number of processes launched by a simplistic use of the *find* −**exec** combination. The *xargs* utility is also used to enforce an upper limit on memory required to launch a process. With this basis in mind, this volume of IEEE Std 1003.1-200x selected only the minimal features required.

Although the 255 exit status is mostly an accident of historical implementations, it allows a utility being used by *xargs* to tell *xargs* to terminate if it knows no further invocations using the current data stream shall succeed. Any non-zero exit status from a utility falls into the 1-125 range when *xargs* exits. There is no statement of how the various non-zero utility exit status codes are accumulated by *xargs*. The value could be the addition of all codes, their highest value, the last one received, or a single value such as 1. Since no algorithm is arguably better than the others, and since many of the standard utilities say little more (portably) than ‘‘pass / fail’’, no new algorithm was invented.

Several other *xargs* options were withdrawn because simple alternatives already exist within this volume of IEEE Std 1003.1-200x. For example, the −**i** *replstr* option can be just as efficiently performed using a shell *for* loop. Since *xargs* calls an *exec* function with each input line, the −**i** option does not usually exploit the grouping capabilities of *xargs*.

The requirement that *xargs* never produce command lines such that invocation of *utility* is within 2 048 bytes of hitting the POSIX *exec* {ARG_MAX} limitations is intended to guarantee that the invoked utility has room to modify its environment variables and command line arguments and still be able to invoke another utility. Note that the minimum {ARG_MAX} allowed by the System Interfaces volume of IEEE Std 1003.1-200x is 4 096 bytes and the minimum value allowed by the this volume of IEEE Std 1003.1-200x is 2 048 bytes; therefore, the 2 048 bytes difference seems reasonable. Note, however, that *xargs* may never be able to invoke a utility if the environment passed in to *xargs* comes close to using {ARG_MAX} bytes.

The version of *xargs* required by this volume of IEEE Std 1003.1-200x is required to wait for the completion of the invoked command before invoking another command. This was done because historical scripts using *xargs* assumed sequential execution. Implementations wanting to provide parallel operation of the invoked utilities are encouraged to add an option enabling parallel invocation, but should still wait for termination of all of the children before *xargs* terminates normally.

The −**e** option was omitted from the ISO POSIX-2: 1993 standard in the belief that the *eofstr* option-argument was recognized only when it was on a line by itself and before quote and escape processing were performed, and that the logical end-of-file processing was only enabled if a −**e** option was specified. In that case, a simple *sed* script could be used to duplicate the −**e** functionality. Further investigation revealed that:

- The logical end-of-file string was checked for after quote and escape processing, making a *sed* script that provided equivalent functionality much more difficult to write.
- The default was to perform logical end-of-file processing with an underscore as the logical end-of-file string.

To correct this misunderstanding, the −**E** *eofstr* option was adopted from the X/Open Portability Guide. Users should note that the description of the −**E** option matches historical documentation of the −**e** option (which was not adopted because it did not support the Utility Syntax Guidelines), by saying that if *eofstr* is the null string, logical end-of-file processing is disabled. Historical implementations of *xargs* actually did not disable logical end-of-file processing; they treated a null argument found in the input as a logical end-of-file string. (A null *string* argument could be generated using single or double quotes (′ ′ or " "). Since this behavior was not documented historically, it is considered to be a bug.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

Second FUTURE DIRECTION added.

Issue 6

The obsolescent −**e**, −**i**, and −**l** options are removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The −**p** option is added.
- In the INPUT FILES section, the file **/dev/tty** is used to read responses required by the −**p** option.
- The STDERR section is updated to describe the −**p** option.

The description of the −**E** option is aligned with the ISO POSIX-2: 1993 standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

yacc — yet another compiler compiler (**DEVELOPMENT**)

SYNOPSIS

CD
```
yacc [−dltv][−b file_prefix][−p sym_prefix] grammar
```

DESCRIPTION

The *yacc* utility shall read a description of a context-free grammar in *file* and write C source code, conforming to the ISO C standard, to a code file, and optionally header information into a header file, in the current directory. The C code shall define a function and related routines and macros for an automaton that executes a parsing algorithm meeting the requirements in **Algorithms** (on page 3272).

The form and meaning of the grammar are described in the EXTENDED DESCRIPTION section.

The C source code and header file shall be produced in a form suitable as input for the C compiler (see *c99* (on page 2413)).

OPTIONS

The *yacc* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−**b** *file_prefix*	Use *file_prefix* instead of **y** as the prefix for all output filenames. The code file **y.tab.c**, the header file **y.tab.h** (created when −**d** is specified), and the description file **y.output** (created when −**v** is specified), shall be changed to *file_prefix***.tab.c**, *file_prefix***.tab.h**, and *file_prefix***.output**, respectively.
−**d**	Write the header file; by default only the code file is written. The **#define** statements that associate the token codes assigned by *yacc* with the user-declared token names. This allows source files other than **y.tab.c** to access the token codes.
−**l**	Produce a code file that does not contain any **#line** constructs. If this option is not present, it is unspecified whether the code file or header file contains **#line** directives. This should only be used after the grammar and the associated actions are fully debugged.
−**p** *sym_prefix*	Use *sym_prefix* instead of **yy** as the prefix for all external names produced by *yacc*. The names affected shall include the functions *yyparse*( ), *yylex*( ), and *yyerror*( ), and the variables *yylval*, *yychar*, and *yydebug*. (In the remainder of this section, the six symbols cited are referenced using their default names only as a notational convenience.) Local names may also be affected by the −**p** option; however, the −**p** option shall not affect **#define** symbols generated by *yacc*.
−**t**	Modify conditional compilation directives to permit compilation of debugging code in the code file. Runtime debugging statements shall always be contained in the code file, but by default conditional compilation directives prevent their compilation.
−**v**	Write a file containing a description of the parser and a report of conflicts generated by ambiguities in the grammar.

OPERANDS

The following operand is required:

grammar	A pathname of a file containing instructions, hereafter called *grammar*, for which a parser is to be created. The format for the grammar is described in the EXTENDED

DESCRIPTION section.

STDIN

Not used.

INPUT FILES

The file *grammar* shall be a text file formatted as specified in the EXTENDED DESCRIPTION section.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *yacc*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*

The *LANG* and *LC_** variables affect the execution of the *yacc* utility as stated. The *main*() function defined in **Yacc Library** (on page 3272) shall call:

```
setlocale(LC_ALL, "")
```

and thus, the program generated by *yacc* also shall be affected by the contents of these variables at runtime.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

If shift/reduce or reduce/reduce conflicts are detected in *grammar*, *yacc* shall write a report of those conflicts to the standard error in an unspecified format.

Standard error shall also be used for diagnostic messages.

OUTPUT FILES

The code file, the header file, and the description file shall be text files. All are described in the following sections.

Code File

This file shall contain the C source code for the *yyparse*( ) function. It shall contain code for the various semantic actions with macro substitution performed on them as described in the EXTENDED DESCRIPTION section. It also shall contain a copy of the **#define** statements in the header file. If a **%union** declaration is used, the declaration for YYSTYPE shall be also included in this file.

Header File

The header file shall contain **#define** statements that associate the token numbers with the token names. This allows source files other than the code file to access the token codes. If a **%union** declaration is used, the declaration for YYSTYPE and an *extern YYSTYPE yylval* declaration shall be also included in this file.

Description File

The description file shall be a text file containing a description of the state machine corresponding to the parser, using an unspecified format. Limits for internal tables (see **Limits** (on page 3273)) shall also be reported, in an implementation-defined manner. (Some implementations may use dynamic allocation techniques and have no specific limit values to report.)

EXTENDED DESCRIPTION

The *yacc* command accepts a language that is used to define a grammar for a target language to be parsed by the tables and code generated by *yacc*. The language accepted by *yacc* as a grammar for the target language is described below using the *yacc* input language itself.

The input *grammar* includes rules describing the input structure of the target language and code to be invoked when these rules are recognized to provide the associated semantic action. The code to be executed shall appear as bodies of text that are intended to be C-language code. The C-language inclusions are presumed to form a correct function when processed by *yacc* into its output files. The code included in this way shall be executed during the recognition of the target language.

Given a grammar, the *yacc* utility generates the files described in the OUTPUT FILES section. The code file can be compiled and linked using *c99*. If the declaration and programs sections of the grammar file did not include definitions of *main*( ), *yylex*( ), and *yyerror*( ), the compiled output requires linking with externally supplied version of those functions. Default versions of *main*( ) and *yyerror*( ) are supplied in the *yacc* library and can be linked in by using the **–l y** operand to *c99*. The *yacc* library interfaces need not support interfaces with other than the default **yy** symbol prefix. The application provides the lexical analyzer function, *yylex*( ); the *lex* utility is specifically designed to generate such a routine.

Input Language

The application shall ensure that every specification file consists of three sections in order: *declarations*, *grammar rules*, and *programs*, separated by double percent signs ("%%"). The declarations and programs sections can be empty. If the latter is empty, the preceding "%%" mark separating it from the rules section can be omitted.

The input is free form text following the structure of the grammar defined below.

Lexical Structure of the Grammar

The <blank>s, <newline>s, and <form-feed>s shall be ignored, except that the application shall ensure that they do not appear in names or multi-character reserved symbols. Comments shall be enclosed in `"/* ... */"`, and can appear wherever a name is valid.

Names are of arbitrary length, made up of letters, periods (`'.'`), underscores (`'_'`), and non-initial digits. Uppercase and lowercase letters are distinct. Conforming applications shall not use names beginning in **yy** or **YY** since the *yacc* parser uses such names. Many of the names appear in the final output of *yacc*, and thus they should be chosen to conform with any additional rules created by the C compiler to be used. In particular they appear in **#define** statements.

A literal shall consist of a single character enclosed in single-quotes (`'\''`). All of the escape sequences supported for character constants by the ISO C standard shall be supported by *yacc*.

The relationship with the lexical analyzer is discussed in detail below.

The application shall ensure that the NUL character is not used in grammar rules or literals.

Declarations Section

The declarations section is used to define the symbols used to define the target language and their relationship with each other. In particular, much of the additional information required to resolve ambiguities in the context-free grammar for the target language is provided here.

Usually *yacc* assigns the relationship between the symbolic names it generates and their underlying numeric value. The declarations section makes it possible to control the assignment of these values.

It is also possible to keep semantic information associated with the tokens currently on the parse stack in a user-defined C-language **union**, if the members of the union are associated with the various names in the grammar. The declarations section provides for this as well.

The first group of declarators below all take a list of names as arguments. That list can optionally be preceded by the name of a C union member (called a *tag* below) appearing within `'<'` and `'>'`. (As an exception to the typographical conventions of the rest of this volume of IEEE Std 1003.1-200x, in this case <*tag*> does not represent a metavariable, but the literal angle bracket characters surrounding a symbol.) The use of *tag* specifies that the tokens named on this line shall be of the same C type as the union member referenced by *tag*. This is discussed in more detail below.

For lists used to define tokens, the first appearance of a given token can be followed by a positive integer (as a string of decimal digits). If this is done, the underlying value assigned to it for lexical purposes shall be taken to be that number.

The following declares *name* to be a token:

```
token [<tag>] name [number][name [number]]...
```

If *tag* is present, the C type for all tokens on this line shall be declared to be the type referenced by *tag*. If a positive integer, *number*, follows a *name*, that value shall be assigned to the token.

The following declares *name* to be a token, and assigns precedence to it:

```
%left [<tag>] name [number][name [number]]...
%right [<tag>] name [number][name [number]]...
```

One or more lines, each beginning with one of these symbols, can appear in this section. All tokens on the same line have the same precedence level and associativity; the lines are in order of increasing precedence or binding strength. **%left** denotes that the operators on that line are left associative, and **%right** similarly denotes right associative operators. If *tag* is present, it shall declare a C type for *name*s as described for **%token**.

The following declares *name* to be a token, and indicates that this cannot be used associatively:

```
%nonassoc [<tag>] name [number][name [number]]...
```

If the parser encounters associative use of this token it reports an error. If *tag* is present, it shall declare a C type for *name*s as described for **%token**.

The following declares that union member *name*s are non-terminals, and thus it is required to have a *tag* field at its beginning:

```
%type <tag> name...
```

Because it deals with non-terminals only, assigning a token number or using a literal is also prohibited. If this construct is present, *yacc* shall perform type checking; if this construct is not present, the parse stack shall hold only the **int** type.

Every name used in *grammar* not defined by a **%token**, **%left**, **%right**, or **%nonassoc** declaration is assumed to represent a non-terminal symbol. The *yacc* utility shall report an error for any non-terminal symbol that does not appear on the left side of at least one grammar rule.

Once the type, precedence, or token number of a name is specified, it shall not be changed. If the first declaration of a token does not assign a token number, *yacc* shall assign a token number. Once this assignment is made, the token number shall not be changed by explicit assignment.

The following declarators do not follow the previous pattern.

The following declares the non-terminal *name* to be the *start symbol*, which represents the largest, most general structure described by the grammar rules:

```
%start name
```

By default, it is the left-hand side of the first grammar rule; this default can be overridden with this declaration.

The following declares the *yacc* value stack to be a union of the various types of values desired:

```
%union { body of union (in C) }
```

By default, the values returned by actions (see below) and the lexical analyzer shall be of type **int**. The *yacc* utility keeps track of types, and it shall insert corresponding union member names in order to perform strict type checking of the resulting parser.

Alternatively, given that at least one <*tag*> construct is used, the union can be declared in a header file (which shall be included in the declarations section by using an **#include** construct within **%{** and **%}**), and a **typedef** used to define the symbol YYSTYPE to represent this union. The effect of **%union** is to provide the declaration of YYSTYPE directly from the *yacc* input.

C-language declarations and definitions can appear in the declarations section, enclosed by the following marks:

```
%{ ... %}
```

These statements shall be copied into the code file, and have global scope within it so that they can be used in the rules and program sections.

The application shall ensure that the declarations section is terminated by the token **%%**.

Grammar Rules in yacc

The rules section defines the context-free grammar to be accepted by the function *yacc* generates, and associates with those rules C-language actions and additional precedence information. The grammar is described below, and a formal definition follows.

The rules section is comprised of one or more grammar rules. A grammar rule has the form:

```
A : BODY ;
```

The symbol **A** represents a non-terminal name, and **BODY** represents a sequence of zero or more *name*s, *literal*s, and *semantic action*s that can then be followed by optional *precedence rule*s. Only the names and literals participate in the formation of the grammar; the semantic actions and precedence rules are used in other ways. The colon and the semicolon are *yacc* punctuation. If there are several successive grammar rules with the same left-hand side, the vertical bar `'|'` can be used to avoid rewriting the left-hand side; in this case the semicolon appears only after the last rule. The BODY part can be empty (or empty of names and literals) to indicate that the non-terminal symbol matches the empty string.

The *yacc* utility assigns a unique number to each rule. Rules using the vertical bar notation are distinct rules. The number assigned to the rule appears in the description file.

The elements comprising a BODY are:

name, *literal* These form the rules of the grammar: *name* is either a *token* or a *non-terminal*; *literal* stands for itself (less the lexically required quotation marks).

semantic action

With each grammar rule, the user can associate actions to be performed each time the rule is recognized in the input process. (Note that the word ‘‘action’’ can also refer to the actions of the parser—shift, reduce, and so on.)

These actions can return values and can obtain the values returned by previous actions. These values are kept in objects of type YYSTYPE (see **%union**). The result value of the action shall be kept on the parse stack with the left-hand side of the rule, to be accessed by other reductions as part of their right-hand side. By using the <*tag*> information provided in the declarations section, the code generated by *yacc* can be strictly type checked and contain arbitrary information. In addition, the lexical analyzer can provide the same kinds of values for tokens, if desired.

An action is an arbitrary C statement and as such can do input or output, call subprograms and alter external variables. An action is one or more C statements enclosed in curly braces `'{'` and `'}'`.

Certain pseudo-variables can be used in the action. These are macros for access to data structures known internally to *yacc*.

$$ The value of the action can be set by assigning it to $$. If type checking is enabled and the type of the value to be assigned cannot be determined, a diagnostic message may be generated.

$*number* This refers to the value returned by the component specified by the token *number* in the right side of a rule, reading from left to right; *number* can be zero or negative. If it is, it refers to the data associated with the name on the parser's stack preceding the leftmost symbol of the current rule. (That is, `"$0"` refers to the name immediately preceding the leftmost name in the current rule, to be found on the parser's stack and `"$−1"` refers to the symbol to *its* left.) If *number* refers to an element past the current point in the rule, or beyond the bottom of the stack, the result is undefined. If type checking is enabled and the type of the value to be assigned cannot be determined, a diagnostic message may be generated.

$<*tag*>*number*
These correspond exactly to the corresponding symbols without the *tag* inclusion, but allow for strict type checking (and preclude unwanted type conversions). The effect is that the macro is expanded to use *tag* to select an element from the YYSTYPE union (using *dataname.tag*). This is particularly useful if *number* is not positive.

$<*tag*>$ This imposes on the reference the type of the union member referenced by *tag*. This construction is applicable when a reference to a left context value occurs in the grammar, and provides *yacc* with a means for selecting a type.

Actions can occur anywhere in a rule (not just at the end); an action can access values returned by actions to its left, and in turn the value it returns can be accessed by actions to its right. An action appearing in the middle of a rule shall be equivalent to replacing the action with a new non-terminal symbol and adding an empty rule with that non-terminal symbol on the left-hand side. The semantic action associated with the new rule shall be equivalent to the original action. The use of actions within rules might introduce conflicts that would not otherwise exist.

By default, the value of a rule shall be the value of the first element in it. If the first element does not have a type (particularly in the case of a literal) and type checking is turned on by **%type** an error message shall result.

precedence The keyword **%prec** can be used to change the precedence level associated with a particular grammar rule. Examples of this are in cases where a unary and binary operator have the same symbolic representation, but need to be given different precedences, or where the handling of an ambiguous if-else construction is necessary. The reserved symbol **%prec** can appear immediately after the body of the grammar rule and can be followed by a token name or a literal. It shall cause the precedence of the grammar rule to become that of the following token name or literal. The action for the rule as a whole can follow **%prec**.

If a program section follows, the application shall ensure that the grammar rules are terminated by **%%**.

Programs Section

The *programs* section can include the definition of the lexical analyzer *yylex*( ), and any other functions, for example those used in the actions specified in the grammar rules. It is unspecified whether the programs section precedes or follows the semantic actions in the output file; therefore, if the application contains any macro definitions and declarations intended to apply to the code in the semantic actions, it shall place them within `"%{ ... %}"` in the declarations section.

Input Grammar

The following input to *yacc* yields a parser for the input to *yacc*. This formal syntax takes precedence over the preceding text syntax description.

The lexical structure is defined less precisely; **Lexical Structure of the Grammar** (on page 3264) defines most terms. The correspondence between the previous terms and the tokens below is as follows.

IDENTIFIER	This corresponds to the concept of *name*, given previously. It also includes literals as defined previously.
C_IDENTIFIER	This is a name, and additionally it is known to be followed by a colon. A literal cannot yield this token.
NUMBER	A string of digits (a non-negative decimal integer).
TYPE, **LEFT**, **MARK**, **LCURL**, **RCURL**	These correspond directly to **%type**, **%left**, **%%**, **%{**, and **%}**.
{ . . . }	This indicates C-language source code, with the possible inclusion of '$' macros as discussed previously.

             | prec ';'
             ;
```

Conflicts

The parser produced for an input grammar may contain states in which conflicts occur. The conflicts occur because the grammar is not LALR(1). An ambiguous grammar always contains at least one LALR(1) conflict. The *yacc* utility shall resolve all conflicts, using either default rules or user-specified precedence rules.

Conflicts are either shift/reduce conflicts or reduce/reduce conflicts. A shift/reduce conflict is where, for a given state and lookahead symbol, both a shift action and a reduce action are possible. A reduce/reduce conflict is where, for a given state and lookahead symbol, reductions by two different rules are possible.

The rules below describe how to specify what actions to take when a conflict occurs. Not all shift/reduce conflicts can be successfully resolved this way because the conflict may be due to something other than ambiguity, so incautious use of these facilities can cause the language accepted by the parser to be much different from that which was intended. The description file shall contain sufficient information to understand the cause of the conflict. Where ambiguity is the reason either the default or explicit rules should be adequate to produce a working parser.

The declared precedences and associativities (see **Declarations Section** (on page 3264)) are used to resolve parsing conflicts as follows:

1. A precedence and associativity is associated with each grammar rule; it is the precedence and associativity of the last token or literal in the body of the rule. If the **%prec** keyword is used, it overrides this default. Some grammar rules might not have both precedence and associativity.
2. If there is a shift/reduce conflict, and both the grammar rule and the input symbol have precedence and associativity associated with them, then the conflict is resolved in favor of the action (shift or reduce) associated with the higher precedence. If the precedences are the same, then the associativity is used; left associative implies reduce, right associative implies shift, and non-associative implies an error in the string being parsed.
3. When there is a shift/reduce conflict that cannot be resolved by rule 2, the shift is done. Conflicts resolved this way are counted in the diagnostic output described in **Error Handling**.
4. When there is a reduce/reduce conflict, a reduction is done by the grammar rule that occurs earlier in the input sequence. Conflicts resolved this way are counted in the diagnostic output described in **Error Handling**.

Conflicts resolved by precedence or associativity shall not be counted in the shift/reduce and reduce/reduce conflicts reported by *yacc* on either standard error or in the description file.

Error Handling

The token **error** shall be reserved for error handling. The name **error** can be used in grammar rules. It indicates places where the parser can recover from a syntax error. The default value of **error** shall be 256. Its value can be changed using a **%token** declaration. The lexical analyzer should not return the value of **error**.

The parser shall detect a syntax error when it is in a state where the action associated with the lookahead symbol is **error**. A semantic action can cause the parser to initiate error handling by executing the macro YYERROR. When YYERROR is executed, the semantic action passes control back to the parser. YYERROR cannot be used outside of semantic actions.

When the parser detects a syntax error, it normally calls *yyerror*( ) with the character string `"syntax error"` as its argument. The call shall not be made if the parser is still recovering from a previous error when the error is detected. The parser is considered to be recovering from a previous error until the parser has shifted over at least three normal input symbols since the last error was detected or a semantic action has executed the macro *yyerrok*. The parser shall not call *yyerror*( ) when YYERROR is executed.

The macro function YYRECOVERING shall return 1 if a syntax error has been detected and the parser has not yet fully recovered from it. Otherwise, zero shall be returned.

When a syntax error is detected by the parser, the parser shall check if a previous syntax error has been detected. If a previous error was detected, and if no normal input symbols have been shifted since the preceding error was detected, the parser checks if the lookahead symbol is an endmarker (see **Interface to the Lexical Analyzer**). If it is, the parser shall return with a non-zero value. Otherwise, the lookahead symbol shall be discarded and normal parsing shall resume.

When YYERROR is executed or when the parser detects a syntax error and no previous error has been detected, or at least one normal input symbol has been shifted since the previous error was detected, the parser shall pop back one state at a time until the parse stack is empty or the current state allows a shift over **error**. If the parser empties the parse stack, it shall return with a non-zero value. Otherwise, it shall shift over **error** and then resume normal parsing. If the parser reads a lookahead symbol before the error was detected, that symbol shall still be the lookahead symbol when parsing is resumed.

The macro *yyerrok* in a semantic action shall cause the parser to act as if it has fully recovered from any previous errors. The macro *yyclearin* shall cause the parser to discard the current lookahead token. If the current lookahead token has not yet been read, *yyclearin* shall have no effect.

The macro YYACCEPT shall cause the parser to return with the value zero. The macro YYABORT shall cause the parser to return with a non-zero value.

Interface to the Lexical Analyzer

The *yylex*( ) function is an integer-valued function that returns a *token number* representing the kind of token read. If there is a value associated with the token returned by *yylex*( ) (see the discussion of *tag* above), it shall be assigned to the external variable *yylval*.

If the parser and *yylex*( ) do not agree on these token numbers, reliable communication between them cannot occur. For (single-byte character) literals, the token is simply the numeric value of the character in the current character set. The numbers for other tokens can either be chosen by *yacc*, or chosen by the user. In either case, the **#define** construct of C is used to allow *yylex*( ) to return these numbers symbolically. The **#define** statements are put into the code file, and the header file if that file is requested. The set of characters permitted by *yacc* in an identifier is larger than that permitted by C. Token names found to contain such characters shall not be included in the **#define** declarations.

If the token numbers are chosen by *yacc*, the tokens other than literals shall be assigned numbers greater than 256, although no order is implied. A token can be explicitly assigned a number by following its first appearance in the declarations section with a number. Names and literals not defined this way retain their default definition. All token numbers assigned by *yacc* shall be unique and distinct from the token numbers used for literals and user-assigned tokens. If duplicate token numbers cause conflicts in parser generation, *yacc* shall report an error; otherwise, it is unspecified whether the token assignment is accepted or an error is reported.

The end of the input is marked by a special token called the *endmarker*, which has a token number that is zero or negative. (These values are invalid for any other token.) All lexical analyzers shall return zero or negative as a token number upon reaching the end of their input. If the tokens up to, but excluding, the endmarker form a structure that matches the start symbol, the parser shall accept the input. If the endmarker is seen in any other context, it shall be considered an error.

Completing the Program

In addition to *yyparse*( ) and *yylex*( ), the functions *yyerror*( ) and *main*( ) are required to make a complete program. The application can supply *main*( ) and *yyerror*( ), or those routines can be obtained from the *yacc* library.

Yacc Library

The following functions shall appear only in the *yacc* library accessible through the **–l y** operand to *c99*; they can therefore be redefined by a conforming application: |

int *main*(**void**)
This function shall call *yyparse*( ) and exit with an unspecified value. Other actions within this function are unspecified.

int *yyerror*(**const char** **s*)
This function shall write the NUL-terminated argument to standard error, followed by a <newline>.

The order of the **–l y** and **–l l** operands given to *c99* is significant; the application shall either provide its own *main*( ) function or ensure that **–l y** precedes **–l l**.

Debugging the Parser

The parser generated by *yacc* shall have diagnostic facilities in it that can be optionally enabled at either compile time or at runtime (if enabled at compile time). The compilation of the runtime debugging code is under the control of YYDEBUG, a preprocessor symbol. If YYDEBUG has a non-zero value, the debugging code shall be included. If its value is zero, the code shall not be included.

In parsers where the debugging code has been included, the external **int** *yydebug* can be used to turn debugging on (with a non-zero value) and off (zero value) at runtime. The initial value of *yydebug* shall be zero.

When **–t** is specified, the code file shall be built such that, if YYDEBUG is not already defined at compilation time (using the *c99* **–D** YYDEBUG option, for example), YYDEBUG shall be set explicitly to 1. When **–t** is not specified, the code file shall be built such that, if YYDEBUG is not already defined, it shall be set explicitly to zero.

The format of the debugging output is unspecified but includes at least enough information to determine the shift and reduce actions, and the input symbols. It also provides information about error recovery.

Algorithms

The parser constructed by *yacc* implements an LALR(1) parsing algorithm as documented in the literature. It is unspecified whether the parser is table-driven or direct-coded.

A parser generated by *yacc* shall never request an input symbol from *yylex*( ) while in a state where the only actions other than the error action are reductions by a single rule.

The literature of parsing theory defines these concepts.

Limits

The *yacc* utility may have several internal tables. The minimum maximums for these tables are shown in the following table. The exact meaning of these values is implementation-defined. The implementation shall define the relationship between these values and between them and any error messages that the implementation may generate should it run out of space for any internal structure. An implementation may combine groups of these resources into a single pool as long as the total available to the user does not fall below the sum of the sizes specified by this section.

Table 4-22 Internal Limits in *yacc*

Limit	Minimum Maximum	Description
{NTERMS}	126	Number of tokens.
{NNONTERM}	200	Number of non-terminals.
{NPROD}	300	Number of rules.
{NSTATES}	600	Number of states.
{MEMSIZE}	5 200	Length of rules. The total length, in names (tokens and non-terminals), of all the rules of the grammar. The left-hand side is counted for each rule, even if it is not explicitly repeated, as specified in **Grammar Rules in yacc** (on page 3266).
{ACTSIZE}	4 000	Number of actions. ''Actions'' here (and in the description file) refer to parser actions (shift, reduce, and so on) not to semantic actions defined in **Grammar Rules in yacc** (on page 3266).

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

If any errors are encountered, the run is aborted and *yacc* exits with a non-zero status. Partial code files and header files files may be produced. The summary information in the description file always shall be produced if the **–v** flag is present.

APPLICATION USAGE

Historical implementations experience name conflicts on the names **yacc.tmp**, **yacc.acts**, **yacc.debug**, **y.tab.c**, **y.tab.h**, and **y.output** if more than one copy of *yacc* is running in a single directory at one time. The **–b** option was added to overcome this problem. The related problem of allowing multiple *yacc* parsers to be placed in the same file was addressed by adding a **–p** option to override the previously hard-coded **yy** variable prefix.

The description of the **–p** option specifies the minimal set of function and variable names that cause conflict when multiple parsers are linked together. YYSTYPE does not need to be changed. Instead, the programmer can use **–b** to give the header files for different parsers different names, and then the file with the *yylex*( ) for a given parser can include the header for that parser. Names such as *yyclearerr* do not need to be changed because they are used only in the actions; they do not have linkage. It is possible that an implementation has other names, either internal ones for implementing things such as *yyclearerr*, or providing non-standard features that it wants to change with **–p**.

Unary operators that are the same token as a binary operator in general need their precedence adjusted. This is handled by the **%prec** advisory symbol associated with the particular grammar rule defining that unary operator. (See **Grammar Rules in yacc** (on page 3266).) Applications are not required to use this operator for unary operators, but the grammars that do not require it are rare.

EXAMPLES

Access to the *yacc* library is obtained with library search operands to *c99*. To use the *yacc* library *main*( ):

```
c99 y.tab.c −l y
```

Both the *lex* library and the *yacc* library contain *main*( ). To access the *yacc main*( ):

```
c99 y.tab.c lex.yy.c −l y −l l
```

This ensures that the *yacc* library is searched first, so that its *main*( ) is used.

The historical *yacc* libraries have contained two simple functions that are normally coded by the application programmer. These functions are similar to the following code:

```
#include <locale.h>
int main(void)
{
    extern int yyparse();

    setlocale(LC_ALL, "");

    /* If the following parser is one created by lex, the
       application must be careful to ensure that LC_CTYPE
       and LC_COLLATE are set to the POSIX locale. */
    (void) yyparse();
    return (0);
}

#include <stdio.h>

int yyerror(const char *msg)
{
    (void) fprintf(stderr, "%s\n", msg);
    return (0);
}
```

RATIONALE

The references in **Referenced Documents** (on page xx) may be helpful in constructing the parser generator. The referenced DeRemer and Pennello article (along with the works it references) describes a technique to generate parsers that conform to this volume of IEEE Std 1003.1-200x. Work in this area continues to be done, so implementors should consult current literature before doing any new implementations. The original Knuth article is the theoretical basis for this kind of parser, but the tables it generates are impractically large for reasonable grammars and should not be used. The ‘‘equivalent to’’ wording is intentional to assure that the best tables that are LALR(1) can be generated.

There has been confusion between the class of grammars, the algorithms needed to generate parsers, and the algorithms needed to parse the languages. They are all reasonably orthogonal. In particular, a parser generator that accepts the full range of LR(1) grammars need not generate a table any more complex than one that accepts SLR(1) (a relatively weak class of LR grammars) for a grammar that happens to be SLR(1). Such an implementation need not recognize the case, either; table compression can yield the SLR(1) table (or one even smaller than that) without recognizing that the grammar is SLR(1). The speed of an LR(1) parser for any class is dependent more upon the table representation and compression (or the code generation if a direct parser is generated) than upon the class of grammar that the table generator handles.

The speed of the parser generator is somewhat dependent upon the class of grammar it handles. However, the original Knuth article algorithms for constructing LR parsers was judged by its author to be impractically slow at that time. Although full LR is more complex than LALR(1), as computer speeds and algorithms improve, the difference (in terms of acceptable wall-clock execution time) is becoming less significant.

Potential authors are cautioned that the referenced DeRemer and Pennello article previously cited identifies a bug (an over-simplification of the computation of LALR(1) lookahead sets) in some of the LALR(1) algorithm statements that preceded it to publication. They should take the time to seek out that paper, as well as current relevant work, particularly Aho's.

The −**b** option was added to provide a portable method for permitting *yacc* to work on multiple separate parsers in the same directory. If a directory contains more than one *yacc* grammar, and both grammars are constructed at the same time (by, for example, a parallel *make* program), conflict results. While the solution is not historical practice, it corrects a known deficiency in historical implementations. Corresponding changes were made to all sections that referenced the filenames **y.tab.c** (now ‘‘the code file’’), **y.tab.h** (now ‘‘the header file’’), and **y.output** (now ‘‘the description file’’).

The grammar for *yacc* input is based on System V documentation. The textual description shows there that the `';'` is required at the end of the rule. The grammar and the implementation do not require this. (The use of **C_IDENTIFIER** causes a reduce to occur in the right place.)

Also, in that implementation, the constructs such as **%token** can be terminated by a semicolon, but this is not permitted by the grammar. The keywords such as **%token** can also appear in uppercase, which is again not discussed. In most places where `'%'` is used, `'\'` can be substituted, and there are alternate spellings for some of the symbols (for example, **%LEFT** can be "%<" or even "\<").

Historically, <*tag*> can contain any characters except `'>'`, including white space, in the implementation. However, since the *tag* must reference a ISO C standard union member, in practice conforming implementations need to support only the set of characters for ISO C standard identifiers in this context.

Some historical implementations are known to accept actions that are terminated by a period. Historical implementations often allow `'$'` in names. A conforming implementation does not need to support either of these behaviors.

Deciding when to use **%prec** illustrates the difficulty in specifying the behavior of *yacc*. There may be situations in which the *grammar* is not, strictly speaking, in error, and yet *yacc* cannot interpret it unambiguously. The resolution of ambiguities in the grammar can in many instances be resolved by providing additional information, such as using **%type** or **%union** declarations. It is often easier and it usually yields a smaller parser to take this alternative when it is appropriate.

The size and execution time of a program produced without the runtime debugging code is usually smaller and slightly faster in historical implementations.

Statistics messages from several historical implementations include the following types of information:

```
n/512 terminals, n/300 non-terminals
n/600 grammar rules, n/1500 states
n shift/reduce, n reduce/reduce conflicts reported
```

```
n/350 working sets used
Memory: states, etc. n/15 000, parser n/15 000
n/600 distinct lookahead sets
n extra closures
n shift entries, n exceptions
n goto entries
n entries saved by goto default
Optimizer space used: input n/15 000, output n/15 000
n table entries, n zero
Maximum spread: n, Maximum offset: n
```

The report of internal tables in the description file is left implementation-defined because all aspects of these limits are also implementation-defined. Some implementations may use dynamic allocation techniques and have no specific limit values to report.

The format of the **y.output** file is not given because specification of the format was not seen to enhance applications portability. The listing is primarily intended to help human users understand and debug the parser; use of **y.output** by a conforming application script would be unusual. Furthermore, implementations have not produced consistent output and no popular format was apparent. The format selected by the implementation should be human-readable, in addition to the requirement that it be a text file.

Standard error reports are not specifically described because they are seldom of use to conforming applications and there was no reason to restrict implementations.

Some implementations recognize `"={"` as equivalent to `'{'` because it appears in historical documentation. This construction was recognized and documented as obsolete as long ago as 1978, in the referenced *Yacc: Yet Another Compiler-Compiler*. This volume of IEEE Std 1003.1-200x chose to leave it as obsolete and omit it.

Multi-byte characters should be recognized by the lexical analyzer and returned as tokens. They should not be returned as multi-byte character literals. The token **error** that is used for error recovery is normally assigned the value 256 in the historical implementation. Thus, the token value 256, which used in many multi-byte character sets, is not available for use as the value of a user-defined token.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the C-Language Development Utilities option.

Minor changes have been added to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

IEEE PASC Interpretation 1003.2 #177 is applied, changing the comment on **RCURL** from the **}%** token to the **%}**.

NAME

zcat — expand and concatenate data

SYNOPSIS

XSI `zcat [file...]`

DESCRIPTION

The *zcat* utility shall write to standard output the uncompressed form of files that have been compressed using the *compress* utility. It is the equivalent of *uncompress* **–c**. Input files are not affected.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file	The pathname of a file previously processed by the *compress* utility. If *file* already has the **.Z** suffix specified, it is used as submitted. Otherwise, the **.Z** suffix is appended to the filename prior to processing.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'–'`.

INPUT FILES

Input files shall be compressed files that are in the format produced by the *compress* utility.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *zcat*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The compressed files given as input shall be written on standard output in their uncompressed form.

STDERR

The standard error shall be used only for diagnostic messages. |

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

Rationale (Informative)

Part A:

Base Definitions

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

6

Appendix A

Rationale for Base Definitions

A.1 Introduction

A.1.1 Scope

IEEE Std 1003.1-200x is one of a family of standards known as POSIX. The family of standards extends to many topics; IEEE Std 1003.1-200x is known as POSIX.1 and consists of both operating system interfaces and shell and utilities. IEEE Std 1003.1-200x is technically identical to The Open Group Base Specifications, Issue 6, which comprise the core volumes of the Single UNIX Specification, Version 3.

Scope of IEEE Std 1003.1-200x

The (paraphrased) goals of this development were to produce a single common revision to the overlapping POSIX.1 and POSIX.2 standards, and the Single UNIX Specification, Version 2. As such, the scope of the revision includes the scopes of the original documents merged.

Since the revision includes merging the Base volumes of the Single UNIX Specification, many features that were previously not *adopted* into earlier revisions of POSIX.1 and POSIX.2 are now included in IEEE Std 1003.1-200x. In most cases, these additions are part of the XSI extension; in other cases the standard developers decided that now was the time to migrate these to the base standard.

The Single UNIX Specification programming environment provides a broad-based functional set of interfaces to support the porting of existing UNIX applications and the development of new applications. The environment also supports a rich set of tools for application development.

The majority of the obsolescent material from the existing POSIX.1 and POSIX.2 standards, and material marked LEGACY from The Open Group's Base specifications, has been removed in this revision. New members of the Legacy Option Group have been added, reflecting the advance in understanding of what is required.

The following IEEE Standards have been added to the base documents in this revision:

- IEEE Std 1003.1d-1999
- IEEE Std 1003.1j-2000
- IEEE Std 1003.1q-2000
- IEEE P1003.1a draft standard
- IEEE Std 1003.2d-1994
- IEEE P1003.2b draft standard
- Selected parts of IEEE Std 1003.1g-2000

Only selected parts of IEEE Std 1003.1g-2000 were included. This was because there is much duplication between the XNS, Issue 5.2 specification (another base document) and the material from IEEE Std 1003.1g-2000, the former document being aligned with the latest networking specifications for IPv6. Only the following sections of IEEE Std 1003.1g-2000 were considered for inclusion:

- General terms related to sockets (2.2.2)
- Socket concepts (5.1 through 5.3 inclusive)
- The *pselect*( ) function (6.2.2.1 and 6.2.3)
- The **<sys/select.h>** header (6.2)

The following were requirements on IEEE Std 1003.1-200x:

- Backward-compatibility

  It was agreed that there should be no breakage of functionality in the existing base documents. This requirement was tempered by changes introduced due to interpretations and corrigenda on the base documents, and any changes introduced in the ISO / IEC 9899: 1999 standard (C Language).

- Architecture and n-bit neutral

  The common standard should not make any implicit assumptions about the system architecture or size of data types; for example, previously some 32-bit implicit assumptions had crept into the standards.

- Extensibility

  It should be possible to extend the common standard without breaking backward-compatibility. For example, the name space should be reserved and structured to avoid duplication of names between the standard and extensions to it.

POSIX.1 and the ISO C standard

Previous revisions of POSIX.1 built upon the ISO C standard by reference only. This revision takes a different approach.

The standard developers believed it essential for a programmer to have a single complete reference place, but recognized that deference to the formal standard had to be addressed for the duplicate interface definitions between the ISO C standard and the Single UNIX Specification.

It was agreed that where an interface has a version in the ISO C standard, the DESCRIPTION section should describe the relationship to the ISO C standard and markings should be added as appropriate to show where the ISO C standard has been extended in the text.

The following block of text was added to each reference page affected:

> *The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.*

and each page was parsed for additions beyond the ISO C standard (that is, including both POSIX and UNIX extensions), and these extensions are marked as CX extensions (for C Extensions).

FIPS Requirements

The Federal Information Processing Standards (FIPS) are a series of U.S. government procurement standards managed and maintained on behalf of the U.S. Department of Commerce by the National Institute of Standards and Technology (NIST).

The following restrictions have been made in this version of IEEE Std 1003.1 in order to align with FIPS 151-2 requirements:

- The implementation supports _POSIX_CHOWN_RESTRICTED.
- The limit {NGROUPS_MAX} is now greater than or equal to 8.
- The implementation supports the setting of the group ID of a file (when it is created) to that of the parent directory.
- The implementation supports _POSIX_SAVED_IDS.
- The implementation supports _POSIX_VDISABLE.
- The implementation supports _POSIX_JOB_CONTROL.
- The implementation supports _POSIX_NO_TRUNC.
- The *read*( ) function returns the number of bytes read when interrupted by a signal and does not return –1.
- The *write*( ) function returns the number of bytes written when interrupted by a signal and does not return –1.
- In the environment for the login shell, the environment variables *LOGNAME* and *HOME* are defined and have the properties described in IEEE Std 1003.1-200x.
- The value of {CHILD_MAX} is now greater than or equal to 25.
- The value of {OPEN_MAX} is now greater than or equal to 20.
- The implementation supports the functionality associated with the symbols CS7, CS8, CSTOPB, PARODD, and PARENB defined in **<termios.h>**.

A.1.2 Conformance

See Section A.2 (on page 3299).

A.1.3 Normative References

There is no additional rationale provided for this section.

A.1.4 Terminology

The meanings specified in IEEE Std 1003.1-200x for the words *shall*, *should*, and *may* are mandated by ISO/IEC directives.

In the Rationale (Informative) volume of IEEE Std 1003.1-200x, the words *shall*, *should*, and *may* are sometimes used to illustrate similar usages in IEEE Std 1003.1-200x. However, the rationale itself does not specify anything regarding implementations or applications.

conformance document

As a practical matter, the conformance document is effectively part of the system documentation. Conformance documents are distinguished by IEEE Std 1003.1-200x so that they can be referred to distinctly.

implementation-defined

This definition is analogous to that of the ISO C standard and, together with *undefined* and *unspecified*, provides a range of specification of freedom allowed to the interface implementor.

may

The use of *may* has been limited as much as possible, due both to confusion stemming from its ordinary English meaning and to objections regarding the desirability of having as few options as possible and those as clearly specified as possible.

The usage of *can* and *may* were selected to contrast optional application behavior (can) against optional implementation behavior (may).

shall

Declarative sentences are sometimes used in IEEE Std 1003.1-200x as if they included the word *shall*, and facilities thus specified are no less required. For example, the two statements:

1. The *foo*( ) function shall return zero.
2. The *foo*( ) function returns zero.

are meant to be exactly equivalent.

should

In IEEE Std 1003.1-200x, the word *should* does not usually apply to the implementation, but rather to the application. Thus, the important words regarding implementations are *shall*, which indicates requirements, and *may*, which indicates options.

obsolescent

The term *obsolescent* means ‘‘do not use this feature in new applications’’. The obsolescence concept is not an ideal solution, but was used as a method of increasing consensus: many more objections would be heard from the user community if some of these historical features were suddenly withdrawn without the grace period obsolescence implies. The phrase ‘‘may be considered for withdrawal in future revisions’’ implies that the result of that consideration might in fact keep those features indefinitely if the predominance of applications do not migrate away from them quickly.

legacy

The term *legacy* was added for compatibility with the Single UNIX Specification. It means ‘‘this feature is historic and optional; do not use this feature in new applications. There are alternate interfaces that are more suitable.’’. It is used exclusively for XSI extensions, and includes facilities that were mandatory in previous versions of the base document but are optional in this revision. This is a way to ‘‘sunset’’ the usage of certain functions. Application writers should not rely on the existence of these facilities in new applications, but should follow the migration path detailed in the APPLICATION USAGE sections of the relevant pages.

The terms *legacy* and *obsolescent* are different: a feature marked LEGACY is not recommended for new work and need not be present on an implementation (if the XSI Legacy Option Group is not supported). A feature noted as obsolescent is supported by all implementations, but may be removed in a future revision; new applications should not use these features.

system documentation

The system documentation should normally describe the whole of the implementation, including any extensions provided by the implementation. Such documents normally contain information at least as detailed as the specifications in IEEE Std 1003.1-200x. Few requirements are made on the system documentation, but the term is needed to avoid a dangling pointer where the conformance document is permitted to point to the system documentation.

undefined

See *implementation-defined*.

unspecified

See *implementation-defined*.

The definitions for *unspecified* and *undefined* appear nearly identical at first examination, but are not. The term *unspecified* means that a conforming program may deal with the unspecified behavior, and it should not care what the outcome is. The term *undefined* says that a conforming program should not do it because no definition is provided for what it does (and implicitly it would care what the outcome was if it tried it). It is important to remember, however, that if the syntax permits the statement at all, it must have some outcome in a real implementation.

Thus, the terms *undefined* and *unspecified* apply to the way the application should think about the feature. In terms of the implementation, it is always ‘‘defined’’—there is always some result, even if it is an error. The implementation is free to choose the behavior it prefers.

This also implies that an implementation, or another standard, could specify or define the result in a useful fashion. The terms apply to IEEE Std 1003.1-200x specifically.

The term *implementation-defined* implies requirements for documentation that are not required for *undefined* (or *unspecified*). Where there is no need for a conforming program to know the definition, the term *undefined* is used, even though *implementation-defined* could also have been used in this context. There could be a fourth term, specifying ‘‘this standard does not say what this does; it is acceptable to define it in an implementation, but it does not need to be documented’’, and undefined would then be used very rarely for the few things for which any definition is not useful. In particular, implementation-defined is used where it is believed that certain classes of application will need to know such details to determine whether the application can be successfully ported to the implementation. Such applications are not always strictly portable, but nevertheless are common and useful; often the requirements met by the application cannot be met without dealing with the issues implied by ‘‘implementation-defined’’.

In many places IEEE Std 1003.1-200x is silent about the behavior of some possible construct. For example, a variable may be defined for a specified range of values and behaviors are described for those values; nothing is said about what happens if the variable has any other value. That kind of silence can imply an error in the standard, but it may also imply that the standard was intentionally silent and that any behavior is permitted. There is a natural tendency to infer that if the standard is silent, a behavior is prohibited. That is not the intent. Silence is intended to be equivalent to the term *unspecified*.

The term *application* is not defined in IEEE Std 1003.1-200x; it is assumed to be a part of general computer science terminology.

Three terms used within IEEE Std 1003.1-200x overlap in meaning: ‘‘macro’’, ‘‘symbolic name’’, and ‘‘symbolic constant’’.

macro

This usually describes a C preprocessor symbol, the result of the **#define** operator, with or without an argument. It may also be used to describe similar mechanisms in editors and text processors.

symbolic name

This can also refer to a C preprocessor symbol (without arguments), but is also used to refer to the names for characters in character sets. In addition, it is sometimes used to refer to host names and even filenames.

symbolic constant

This also refers to a C preprocessor symbol (also without arguments).

In most cases, the difference in semantic content is negligible to nonexistent. Readers should not attempt to read any meaning into the various usages of these terms.

A.1.5 Portability

To aid the identification of options within IEEE Std 1003.1-200x, a notation consisting of margin codes and shading is used. This is based on the notation used in previous revisions of The Open Group's Base specifications.

The benefits of this approach is a reduction in the number of *if* statements within the running text, that makes the text easier to read, and also an identification to the programmer that they need to ensure that their target platforms support the underlying options. For example, if functionality is marked with THR in the margin, it will be available on all systems supporting the Threads option, but may not be available on some others.

A.1.5.1 Codes

This section includes codes for options defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 2.1.6, Options, and the following additional codes for other purposes:

CX	This margin code is used to denote extensions beyond the ISO C standard. For interfaces that are duplicated between IEEE Std 1003.1-200x and the ISO C standard, a CX introduction block describes the nature of the duplication, with any extensions appropriately CX marked and shaded. Where an interface is added to an ISO C standard header, within the header the interface has an appropriate margin marker and shading (for example, CX, XSI, TSF, and so on) and the same marking appears on the reference page in the SYNOPSIS section. This enables a programmer to easily identify that the interface is extending an ISO C standard header.
MX	This margin code is used to denote IEC 60559:1989 standard floating-point extensions.
OB	This margin code is used to denote obsolescent behavior and thus flag a possible future application portability warning.
OH	The Single UNIX Specification has historically tried to reduce the number of headers an application has had to include when using a particular interface. Sometimes this was fewer than the base standard, and hence a notation is used to flag which headers are optional if you are using a system supporting the XSI extension.
XSI	This code is used to denote interfaces and facilities within interfaces only required on systems supporting the XSI extension. This is introduced to support the Single UNIX Specification.
XSR	This code is used to denote interfaces and facilities within interfaces only required on systems supporting STREAMS. This is introduced to support the Single UNIX Specification, although it is defined in a way so that it can standalone from the XSI notation.

A.1.5.2 Margin Code Notation

Since some features may depend on one or more options, or require more than one options, a notation is used. Where a feature requires support of a single option, a single margin code will occur in the margin. If it depends on two options and both are required, then the codes will appear with a <space> separator. If either of two options are required then a logical OR is denoted using the **'|'** symbol. If more than two codes are used, a special notation is used.

A.2 Conformance

The terms *profile* and *profiling* are used throughout this section.

A profile of a standard or standards is a codified set of option selections, such that by being conformant to a profile, particular classes of users are specifically supported.

These conformance definitions are descended from those in the ISO POSIX-1:1996 standard, but with changes for the following:

- The addition of profiling options, allowing larger profiles of options such as the XSI extension used by the Single UNIX Specification. In effect, it has profiled itself (that is, created a self-profile).
- The addition of a definition of subprofiling considerations, to allow smaller profiles of options.
- The addition of a hierarchy of super-options for XSI; these were formerly known as *Feature Groups* in The Open Group System Interfaces and Headers, Issue 5 specification.
- Options from the ISO POSIX-2:1993 standard are also now included as IEEE Std 1003.1-200x merges the functionality from it.

A.2.1 Implementation Conformance

These definitions allow application developers to know what to depend on in an implementation.

There is no definition of a *strictly conforming implementation*; that would be an implementation that provides *only* those facilities specified by POSIX.1 with no extensions whatsoever. This is because no actual operating system implementation can exist without system administration and initialization facilities that are beyond the scope of POSIX.1.

A.2.1.1 Requirements

The word ''support'' is used in certain instances, rather than ''provide'', in order to allow an implementation that has no resident software development facilities, but that supports the execution of a *Strictly Conforming POSIX.1 Application*, to be a *conforming implementation*.

A.2.1.2 Documentation

The conformance documentation is required to use the same numbering scheme as POSIX.1 for purposes of cross-referencing. All options that an implementation chooses shall be reflected in **<limits.h>** and **<unistd.h>**.

Note that the use of ''may'' in terms of where conformance documents record where implementations may vary, implies that it is not required to describe those features identified as undefined or unspecified.

Other aspects of systems must be evaluated by purchasers for suitability. Many systems incorporate buffering facilities, maintaining updated data in volatile storage and transferring such updates to non-volatile storage asynchronously. Various exception conditions, such as a power failure or a system crash, can cause this data to be lost. The data may be associated with a file that is still open, with one that has been closed, with a directory, or with any other internal system data structures associated with permanent storage. This data can be lost, in whole or part, so that only careful inspection of file contents could determine that an update did not occur.

Also, interrelated file activities, where multiple files and/or directories are updated, or where space is allocated or released in the file system structures, can leave inconsistencies in the relationship between data in the various files and directories, or in the file system itself. Such inconsistencies can break applications that expect updates to occur in a specific sequence, so that updates in one place correspond with related updates in another place.

For example, if a user creates a file, places information in the file, and then records this action in another file, a system or power failure at this point followed by restart may result in a state in which the record of the action is permanently recorded, but the file created (or some of its information) has been lost. The consequences of this to the user may be undesirable. For a user on such a system, the only safe action may be to require the system administrator to have a policy that requires, after any system or power failure, that the entire file system must be restored from the most recent backup copy (causing all intervening work to be lost).

The characteristics of each implementation will vary in this respect and may or may not meet the requirements of a given application or user. Enforcement of such requirements is beyond the scope of POSIX.1. It is up to the purchaser to determine what facilities are provided in an implementation that affect the exposure to possible data or sequence loss, and also what underlying implementation techniques and/or facilities are provided that reduce or limit such loss or its consequences.

A.2.1.3 POSIX Conformance

This really means conformance to the base standard; however, since this revision includes the core material of the Single UNIX Specification, the standard developers decided that it was appropriate to segment the conformance requirements into two, the former for the base standard, and the latter for the Single UNIX Specification.

Within POSIX.1 there are some symbolic constants that, if defined, indicate that a certain option is enabled. Other symbolic constants exist in POSIX.1 for other reasons.

As part of the revision some alignment has occurred of the options with the FIPS 151-2 profile on the POSIX.1-1990 standard. The following options from the POSIX.1-1990 standard are now mandatory:

- _POSIX_JOB_CONTROL
- _POSIX_SAVED_IDS
- _POSIX_VDISABLE

A POSIX-conformant system may support the XSI extensions of the Single UNIX Specification. This was intentional since the standard developers intend them to be upwards-compatible, so that a system conforming to the Single UNIX Specification can also conform to the base standard at the same time.

A.2.1.4 XSI Conformance

This section is added since the revision merges in the base volumes of the Single UNIX Specification.

XSI conformance can be thought of as a profile, selecting certain options from IEEE Std 1003.1-200x.

A.2.1.5 Option Groups

The concept of *Option Groups* is introduced to IEEE Std 1003.1-200x to allow collections of related functions or options to be grouped together. This has been used as follows: the *XSI Option Groups* have been created to allow super-options, collections of underlying options and related functions, to be collectively supported by XSI-conforming systems. These reflect the *Feature Groups* from The Open Group System Interfaces and Headers, Issue 5 specification.

The standard developers considered the matter of subprofiling and decided it was better to include an enabling mechanism rather than detailed normative requirements. A set of subprofiling options was developed and included later in this volume of IEEE Std 1003.1-200x as an informative illustration.

A.2.1.6 Options

The final subsections within *Implementation Conformance* list the core options within IEEE Std 1003.1-200x. This includes both options for the System Interfaces volume of IEEE Std 1003.1-200x and the Shell and Utilities volume of IEEE Std 1003.1-200x.

A.2.2 Application Conformance

These definitions guide users or adaptors of applications in determining on which implementations an application will run and how much adaptation would be required to make it run on others. These definitions are modeled after related ones in the ISO C standard.

POSIX.1 occasionally uses the expressions *portable application* or *conforming application*. As they are used, these are synonyms for any of these terms. The differences between the classes of application conformance relate to the requirements for other standards, the options supported (such as the XSI extension) or, in the case of the Conforming POSIX.1 Application Using Extensions, to implementation extensions. When one of the less explicit expressions is used, it should be apparent from the context of the discussion which of the more explicit names is appropriate

A.2.2.1 Strictly Conforming POSIX Application

This definition is analogous to that of a ISO C standard *conforming program*.

The major difference between a *Strictly Conforming POSIX Application* and a ISO C standard *strictly conforming program* is that the latter is not allowed to use features of POSIX that are not in the ISO C standard.

A.2.2.2 Conforming POSIX Application

Examples of <National Bodies> include ANSI, BSI, and AFNOR.

A.2.2.3 Conforming POSIX Application Using Extensions

Due to possible requirements for configuration or implementation characteristics in excess of the specifications in **<limits.h>** or related to the hardware (such as array size or file space), not every Conforming POSIX Application Using Extensions will run on every conforming implementation.

A.2.2.4 Strictly Conforming XSI Application

This is intended to be upwards-compatible with the definition of a Strictly Conforming POSIX Application, with the addition of the facilities and functionality included in the XSI extension.

A.2.2.5 Conforming XSI Application Using Extensions

Such applications may use extensions beyond the facilities defined by IEEE Std 1003.1-200x including the XSI extension, but need to document the additional requirements.

A.2.3 Language-Dependent Services for the C Programming Language

POSIX.1 is, for historical reasons, both a specification of an operating system interface, shell and utilities, and a C binding for that specification. Efforts had been previously undertaken to generate a language-independent specification; however, that had failed, and the fact that the ISO C standard is the *de facto* primary language on POSIX and the UNIX system makes this a necessary and workable situation.

A.2.4 Other Language-Related Specifications

There is no additional rationale provided for this section.

A.3 Definitions

The definitions in this section are stated so that they can be used as exact substitutes for the terms in text. They should not contain requirements or cross-references to sections within IEEE Std 1003.1-200x; that is accomplished by using an informative note. In addition, the term should not be included in its own definition. Where requirements or descriptions need to be addressed but cannot be included in the definitions, due to not meeting the above criteria, these occur in the General Concepts chapter.

In this revision, the definitions have been reworked extensively to meet style requirements and to include terms from the base documents (see the Scope).

Many of these definitions are necessarily circular, and some of the terms (such as *process*) are variants of basic computing science terms that are inherently hard to define. Where some definitions are more conceptual and contain requirements, these appear in the General Concepts chapter. Those listed in this section appear in an alphabetical glossary format of terms.

Some definitions must allow extension to cover terms or facilities that are not explicitly mentioned in IEEE Std 1003.1-200x. For example, the definition of *Extended Security Controls* permits implementations beyond those defined in IEEE Std 1003.1-200x.

Some terms in the following list of notes do not appear in IEEE Std 1003.1-200x; these are marked prefixed with a asterisk (*). Many of them have been specifically excluded from IEEE Std 1003.1-200x because they concern system administration, implementation, or other issues that are not specific to the programming interface. Those are marked with a reason, such as ‘‘implementation-defined’’.

Appropriate Privileges

One of the fundamental security problems with many historical UNIX systems has been that the privilege mechanism is monolithic—a user has either no privileges or *all* privileges. Thus, a successful ‘‘trojan horse’’ attack on a privileged process defeats all security provisions. Therefore, POSIX.1 allows more granular privilege mechanisms to be defined. For many historical implementations of the UNIX system, the presence of the term *appropriate privileges* in POSIX.1 may be understood as a synonym for *superuser* (UID 0). However, other systems have emerged where this is not the case and each discrete controllable action has *appropriate privileges* associated with it. Because this mechanism is implementation-defined, it must be described in the conformance document. Although that description affects several parts of POSIX.1 where the term *appropriate privilege* is used, because the term *implementation-defined* only appears here, the description of the entire mechanism and its effects on these other sections belongs in this equivalent section of the conformance document. This is especially convenient for implementations with a single mechanism that applies in all areas, since it only needs to be described once.

Byte

The restriction that a byte is now exactly eight bits was a conscious decision by the standard developers. It came about due to a combination of factors, primarily the use of the type **int8_t** within the networking functions and the alignment with the ISO / IEC 9899: 1999 standard, where the **intN_t** types are now defined.

According to the ISO / IEC 9899: 1999 standard:

- The **[u]intN_t** types must be two’s complement with no padding bits and no illegal values.
- All types (apart from bit fields, which are not relevant here) must oocupy an integral number of bytes.
- If a type with width W occupies B bytes with C bits per byte (C is the value of {CHAR_BIT}), then it has P padding bits where $P+W=B*C$.
- For **int8_t** we therefore have $P=0$, $W=8$. Since $B\geq1$, $C\geq8$, the only solution is $B=1$, $C=8$.

The standard developers also felt that this was not an undue restriction for the current state of the art for this version of IEEE Std 1003.1-200x, but recognize that if industry trends continue, a wider character type may be required in the future.

Character

The term *character* is used to mean a sequence of one or more bytes representing a single graphic symbol. The deviation in the exact text of the ISO C standard definition for *byte* meets the intent of the rationale of the ISO C standard also clears up the ambiguity raised by the term *basic execution character set*. The octet-minimum requirement is a reflection of the {CHAR_BIT} value.

Clock Tick

The ISO C standard defines a similar interval for use by the *clock*( ) function. There is no requirement that these intervals be the same. In historical implementations these intervals are different.

Command

The terms *command* and *utility* are related but have distinct meanings. Command is defined as ‘‘a directive to a shell to perform a specific task’’. The directive can be in the form of a single utility name (for example, *ls*), or the directive can take the form of a compound command (for example, `"ls | grep name | pr"`). A utility is a program that can be called by name from a shell. Issuing only the name of the utility to a shell is the equivalent of a one-word command. A utility may be invoked as a separate program that executes in a different process than the command language interpreter, or it may be implemented as a part of the command language interpreter. For example, the *echo* command (the directive to perform a specific task) may be implemented such that the *echo* utility (the logic that performs the task of echoing) is in a separate program; therefore, it is executed in a process that is different from the command language interpreter. Conversely, the logic that performs the *echo* utility could be built into the command language interpreter; therefore, it could execute in the same process as the command language interpreter.

The terms *tool* and *application* can be thought of as being synonymous with *utility* from the perspective of the operating system kernel. Tools, applications, and utilities historically have run, typically, in processes above the kernel level. Tools and utilities historically have been a part of the operating system non-kernel code and have performed system-related functions, such as listing directory contents, checking file systems, repairing file systems, or extracting system status information. Applications have not generally been a part of the operating system, and they perform non-system-related functions, such as word processing, architectural design, mechanical design, workstation publishing, or financial analysis. Utilities have most frequently been provided by the operating system distributor, applications by third-party software distributors, or by the users themselves. Nevertheless, IEEE Std 1003.1-200x does not differentiate between tools, utilities, and applications when it comes to receiving services from the system, a shell, or the standard utilities. (For example, the *xargs* utility invokes another utility; it would be of fairly limited usefulness if the users could not run their own applications in place of the standard utilities.) Utilities are not applications in the sense that they are not themselves subject to the restrictions of IEEE Std 1003.1-200x or any other standard—there is no requirement for *grep*, *stty*, or any of the utilities defined here to be any of the classes of conforming applications.

Column Positions

In most 1-byte character sets, such as ASCII, the concept of column positions is identical to character positions and to bytes. Therefore, it has been historically acceptable for some implementations to describe line folding or tab stops or table column alignment in terms of bytes or character positions. Other character sets pose complications, as they can have internal representations longer than one octet and they can have display characters that have different widths on the terminal screen or printer.

In IEEE Std 1003.1-200x the term *column positions* has been defined to mean character—not byte—positions in input files (such as ‘‘column position 7 of the FORTRAN input’’). Output files describe the column position in terms of the display width of the narrowest printable character in the character set, adjusted to fit the characteristics of the output device. It is very possible that *n* column positions will not be able to hold *n* characters in some character sets, unless all of those characters are of the narrowest width. It is assumed that the implementation is aware of the width of the various characters, deriving this information from the value of *LC_CTYPE*, and thus can determine how many column positions to allot for each character in those utilities where it is important.

The term *column position* was used instead of the more natural *column* because the latter is frequently used in the different contexts of columns of figures, columns of table values, and so on. Wherever confusion might result, these latter types of columns are referred to as *text* *columns*.

Controlling Terminal

The question of which of possibly several special files referring to the terminal is meant is not addressed in POSIX.1. The filename **/dev/tty** is a synonym for the controlling terminal associated with a process.

Device Number*

The concept is handled in *stat*( ) as *ID of device*.

Direct I/O

Historically, direct I/O refers to the system bypassing intermediate buffering, but may be extended to cover implementation-defined optimizations.

Directory

The format of the directory file is implementation-defined and differs radically between System V and 4.3 BSD. However, routines (derived from 4.3 BSD) for accessing directories and certain constraints on the format of the information returned by those routines are described in the **<dirent.h>** header.

Directory Entry

Throughout IEEE Std 1003.1-200x, the term *link* is used (about the *link*( ) function, for example) in describing the objects that point to files from directories.

Display

The Shell and Utilities volume of IEEE Std 1003.1-200x assigns precise requirements for the terms *display* and *write*. Some historical systems have chosen to implement certain utilities without using the traditional file descriptor model. For example, the *vi* editor might employ direct screen memory updates on a personal computer, rather than a *write*( ) system call. An instance of user prompting might appear in a dialog box, rather than with standard error. When the Shell and Utilities volume of IEEE Std 1003.1-200x uses the term *display*, the method of outputting to the terminal is unspecified; many historical implementations use *termcap* or *terminfo*, but this is not a requirement. The term *write* is used when the Shell and Utilities volume of IEEE Std 1003.1-200x mandates that a file descriptor be used and that the output can be redirected. However, it is assumed that when the writing is directly to the terminal (it has not been redirected elsewhere), there is no practical way for a user or test suite to determine whether a file descriptor is being used. Therefore, the use of a file descriptor is mandated only for the redirection case and the implementation is free to use any method when the output is not redirected. The verb *write* is used almost exclusively, with the very few exceptions of those utilities where output redirection need not be supported: *tabs*, *talk*, *tput*, and *vi*.

Dot

The symbolic name *dot* is carefully used in POSIX.1 to distinguish the working directory filename from a period or a decimal point.

Dot-Dot

Historical implementations permit the use of these filenames without their special meanings. Such use precludes any meaningful use of these filenames by a Conforming POSIX.1 Application. Therefore, such use is considered an extension, the use of which makes an implementation non-conforming; see also Section A.4.11 (on page 3327).

Epoch

Historically, the origin of UNIX system time was referred to as ‘‘00:00:00 GMT, January 1, 1970’’. Greenwich Mean Time is actually not a term acknowledged by the international standards community; therefore, this term, *Epoch*, is used to abbreviate the reference to the actual standard, Coordinated Universal Time.

FIFO Special File

See *pipe* in **Pipe** (on page 3314).

File

It is permissible for an implementation-defined file type to be non-readable or non-writable.

File Classes

These classes correspond to the historical sets of permission bits. The classes are general to allow implementations flexibility in expanding the access mechanism for more stringent security environments. Note that a process is in one and only one class, so there is no ambiguity.

Filename

At the present time, the primary responsibility for truncating filenames containing multi-byte characters must reside with the application. Some industry groups involved in internationalization believe that in the future the responsibility must reside with the kernel. For the moment, a clearer understanding of the implications of making the kernel responsible for truncation of multi-byte filenames is needed.

Character-level truncation was not adopted because there is no support in POSIX.1 that advises how the kernel distinguishes between single and multi-byte characters. Until that time, it must be incumbent upon application writers to determine where multi-byte characters must be truncated.

File System

Historically, the meaning of this term has been overloaded with two meanings: that of the complete file hierarchy, and that of a mountable subset of that hierarchy; that is, a mounted file system. POSIX.1 uses the term *file system* in the second sense, except that it is limited to the scope of a process (and a process’ root directory). This usage also clarifies the domain in which a file serial number is unique.

Graphic Character

This definition is made available for those definitions (in particular, *TZ*) which must exclude control characters.

Group Database

See **User Database** (on page 3322).

Group File*

Implementation-defined; see **User Database** (on page 3322).

Historical Implementations*

This refers to previously existing implementations of programming interfaces and operating systems that are related to the interface specified by POSIX.1.

Hosted Implementation*

This refers to a POSIX.1 implementation that is accomplished through interfaces from the POSIX.1 services to some alternate form of operating system kernel services. Note that the line between a hosted implementation and a native implementation is blurred, since most implementations will provide some services directly from the kernel and others through some indirect path. (For example, *fopen*( ) might use *open*( ); or *mkfifo*( ) might use *mknod*( ).) There is no necessary relationship between the type of implementation and its correctness, performance, and/or reliability.

Implementation*

This term is generally used instead of its synonym, *system*, to emphasize the consequences of decisions to be made by system implementors. Perhaps if no options or extensions to POSIX.1 were allowed, this usage would not have occurred.

The term *specific implementation* is sometimes used as a synonym for *implementation*. This should not be interpreted too narrowly; both terms can represent a relatively broad group of systems. For example, a hardware vendor could market a very wide selection of systems that all used the same instruction set, with some systems desktop models and others large multi-user minicomputers. This wide range would probably share a common POSIX.1 operating system, allowing an application compiled for one to be used on any of the others; this is a [*specific*]*implementation*.

However, that wide range of machines probably has some differences between the models. Some may have different clock rates, different file systems, different resource limits, different network connections, and so on, depending on their sizes or intended usages. Even on two identical machines, the system administrators may configure them differently. Each of these different systems is known by the term *a specific instance of a specific implementation*. This term is only used in the portions of POSIX.1 dealing with runtime queries: *sysconf*( ) and *pathconf*( ).

Incomplete Pathname*

Absolute pathname has been adequately defined.

Job Control

In order to understand the job control facilities in POSIX.1 it is useful to understand how they are used by a job control-cognizant shell to create the user interface effect of job control.

While the job control facilities supplied by POSIX.1 can, in theory, support different types of interactive job control interfaces supplied by different types of shells, there was historically one | particular interface that was most common when the standard was originally developed | (provided by BSD C Shell). This discussion describes that interface as a means of illustrating how the POSIX.1 job control facilities can be used.

Job control allows users to selectively stop (suspend) the execution of processes and continue (resume) their execution at a later point. The user typically employs this facility via the interactive interface jointly supplied by the terminal I/O driver and a command interpreter (shell).

The user can launch jobs (command pipelines) in either the foreground or background. When launched in the foreground, the shell waits for the job to complete before prompting for additional commands. When launched in the background, the shell does not wait, but immediately prompts for new commands.

If the user launches a job in the foreground and subsequently regrets this, the user can type the suspend character (typically set to <control>-Z), which causes the foreground job to stop and the shell to begin prompting for new commands. The stopped job can be continued by the user (via special shell commands) either as a foreground job or as a background job. Background jobs can also be moved into the foreground via shell commands.

If a background job attempts to access the login terminal (controlling terminal), it is stopped by the terminal driver and the shell is notified, which, in turn, notifies the user. (Terminal access includes *read*( ) and certain terminal control functions, and conditionally includes *write*( ).) The user can continue the stopped job in the foreground, thus allowing the terminal access to succeed in an orderly fashion. After the terminal access succeeds, the user can optionally move the job into the background via the suspend character and shell commands.

Implementing Job Control Shells

The interactive interface described previously can be accomplished using the POSIX.1 job control facilities in the following way.

The key feature necessary to provide job control is a way to group processes into jobs. This grouping is necessary in order to direct signals to a single job and also to identify which job is in the foreground. (There is at most one job that is in the foreground on any controlling terminal at a time.)

The concept of *process groups* is used to provide this grouping. The shell places each job in a separate process group via the *setpgid*( ) function. To do this, the *setpgid*( ) function is invoked by the shell for each process in the job. It is actually useful to invoke *setpgid*( ) twice for each process: once in the child process, after calling *fork*( ) to create the process, but before calling one of the *exec* family of functions to begin execution of the program, and once in the parent shell process, after calling *fork*( ) to create the child. The redundant invocation avoids a race condition by ensuring that the child process is placed into the new process group before either the parent or the child relies on this being the case. The *process group ID* for the job is selected by the shell to be equal to the *process ID* of one of the processes in the job. Some shells choose to make one process in the job be the parent of the other processes in the job (if any). Other shells (for example, the C Shell) choose to make themselves the parent of all processes in the pipeline (job). In order to support this latter case, the *setpgid*( ) function accepts a process group ID parameter since the correct process group ID cannot be inherited from the shell. The shell itself is considered to be a job and is the sole process in its own process group.

The shell also controls which job is currently in the foreground. A foreground and background job differ in two ways: the shell waits for a foreground command to complete (or stop) before continuing to read new commands, and the terminal I/O driver inhibits terminal access by background jobs (causing the processes to stop). Thus, the shell must work cooperatively with the terminal I/O driver and have a common understanding of which job is currently in the foreground. It is the user who decides which command should be currently in the foreground, and the user informs the shell via shell commands. The shell, in turn, informs the terminal I/O driver via the *tcsetpgrp*( ) function. This indicates to the terminal I/O driver the process group ID of the foreground process group (job). When the current foreground job either stops or terminates, the shell places itself in the foreground via *tcsetpgrp*( ) before prompting for additional commands. Note that when a job is created the new process group begins as a background process group. It requires an explicit act of the shell via *tcsetpgrp*( ) to move a process group (job) into the foreground.

When a process in a job stops or terminates, its parent (for example, the shell) receives synchronous notification by calling the *waitpid*( ) function with the WUNTRACED flag set. Asynchronous notification is also provided when the parent establishes a signal handler for SIGCHLD and does not specify the SA_NOCLDSTOP flag. Usually all processes in a job stop as a unit since the terminal I/O driver always sends job control stop signals to all processes in the process group.

To continue a stopped job, the shell sends the SIGCONT signal to the process group of the job. In addition, if the job is being continued in the foreground, the shell invokes *tcsetpgrp*( ) to place the job in the foreground before sending SIGCONT. Otherwise, the shell leaves itself in the foreground and reads additional commands.

There is additional flexibility in the POSIX.1 job control facilities that allows deviations from the typical interface. Clearing the TOSTOP terminal flag allows background jobs to perform *write*( ) functions without stopping. The same effect can be achieved on a per-process basis by having a process set the signal action for SIGTTOU to SIG_IGN.

Note that the terms *job* and *process group* can be used interchangeably. A login session that is not using the job control facilities can be thought of as a large collection of processes that are all in the same job (process group). Such a login session may have a partial distinction between foreground and background processes; that is, the shell may choose to wait for some processes before continuing to read new commands and may not wait for other processes. However, the terminal I/O driver will consider all these processes to be in the foreground since they are all members of the same process group.

In addition to the basic job control operations already mentioned, a job control-cognizant shell needs to perform the following actions.

When a foreground (not background) job stops, the shell must sample and remember the current terminal settings so that it can restore them later when it continues the stopped job in the foreground (via the *tcgetattr*( ) and *tcsetattr*( ) functions).

Because a shell itself can be spawned from a shell, it must take special action to ensure that subshells interact well with their parent shells.

A subshell can be spawned to perform an interactive function (prompting the terminal for commands) or a non-interactive function (reading commands from a file). When operating non-interactively, the job control shell will refrain from performing the job control-specific actions described above. It will behave as a shell that does not support job control. For example, all *jobs* will be left in the same process group as the shell, which itself remains in the process group established for it by its parent. This allows the shell and its children to be treated as a single job by a parent shell, and they can be affected as a unit by terminal keyboard signals.

An interactive subshell can be spawned from another job control-cognizant shell in either the foreground or background. (For example, from the C Shell, the user can execute the command, csh &.) Before the subshell activates job control by calling *setpgid*( ) to place itself in its own process group and *tcsetpgrp*( ) to place its new process group in the foreground, it needs to ensure that it has already been placed in the foreground by its parent. (Otherwise, there could be multiple job control shells that simultaneously attempt to control mediation of the terminal.) To determine this, the shell retrieves its own process group via *getpgrp*( ) and the process group of the current foreground job via *tcgetpgrp*( ). If these are not equal, the shell sends SIGTTIN to its own process group, causing itself to stop. When continued later by its parent, the shell repeats the process group check. When the process groups finally match, the shell is in the foreground and it can proceed to take control. After this point, the shell ignores all the job control stop signals so that it does not inadvertently stop itself.

Implementing Job Control Applications

Most applications do not need to be aware of job control signals and operations; the intuitively correct behavior happens by default. However, sometimes an application can inadvertently interfere with normal job control processing, or an application may choose to overtly effect job control in cooperation with normal shell procedures.

An application can inadvertently subvert job control processing by ‘‘blindly’’ altering the handling of signals. A common application error is to learn how many signals the system supports and to ignore or catch them all. Such an application makes the assumption that it does not know what this signal is, but knows the right handling action for it. The system may initialize the handling of job control stop signals so that they are being ignored. This allows shells that do not support job control to inherit and propagate these settings and hence to be immune to stop signals. A job control shell will set the handling to the default action and propagate this, allowing processes to stop. In doing so, the job control shell is taking responsibility for restarting the stopped applications. If an application wishes to catch the stop signals itself, it should first determine their inherited handling states. If a stop signal is being ignored, the application should continue to ignore it. This is directly analogous to the recommended handling of SIGINT described in the referenced UNIX Programmer’s Manual.

If an application is reading the terminal and has disabled the interpretation of special characters (by clearing the ISIG flag), the terminal I/O driver will not send SIGTSTP when the suspend character is typed. Such an application can simulate the effect of the suspend character by recognizing it and sending SIGTSTP to its process group as the terminal driver would have done. Note that the signal is sent to the process group, not just to the application itself; this ensures that other processes in the job also stop. (Note also that other processes in the job could be children, siblings, or even ancestors.) Applications should not assume that the suspend character is <control>-Z (or any particular value); they should retrieve the current setting at startup.

Implementing Job Control Systems

The intent in adding 4.2 BSD-style job control functionality was to adopt the necessary 4.2 BSD programmatic interface with only minimal changes to resolve syntactic or semantic conflicts with System V or to close recognized security holes. The goal was to maximize the ease of providing both conforming implementations and Conforming POSIX.1 Applications.

It is only useful for a process to be affected by job control signals if it is the descendant of a job control shell. Otherwise, there will be nothing that continues the stopped process.

POSIX.1 does not specify how controlling terminal access is affected by a user logging out (that is, by a controlling process terminating). 4.2 BSD uses the *vhangup*( ) function to prevent any access to the controlling terminal through file descriptors opened prior to logout. System V does not prevent controlling terminal access through file descriptors opened prior to logout (except for the case of the special file, **/dev/tty**). Some implementations choose to make processes immune from job control after logout (that is, such processes are always treated as if in the foreground); other implementations continue to enforce foreground/background checks after logout. Therefore, a Conforming POSIX.1 Application should not attempt to access the controlling terminal after logout since such access is unreliable. If an implementation chooses to deny access to a controlling terminal after its controlling process exits, POSIX.1 requires a certain type of behavior (see **Controlling Terminal** (on page 3305)).

Kernel*

See *system call*.

Library Routine*

See *system call*.

Logical Device*

Implementation-defined.

Map

The definition of map is included to clarify the usage of mapped pages in the description of the behavior of process memory locking.

Memory-Resident

The term *memory-resident* is historically understood to mean that the so-called resident pages are actually present in the physical memory of the computer system and are immune from swapping, paging, copy-on-write faults, and so on. This is the actual intent of IEEE Std 1003.1-200x in the process memory locking section for implementations where this is logical. But for some implementations—primarily mainframes—actually locking pages into primary storage is not advantageous to other system objectives, such as maximizing throughput. For such implementations, memory locking is a ‘‘hint’’ to the implementation that the application wishes to avoid situations that would cause long latencies in accessing memory. Furthermore, there are other implementation-defined issues with minimizing memory access latencies that ‘‘memory residency’’ does not address—such as MMU reload faults. The definition attempts to accommodate various implementations while allowing conforming applications to specify to the implementation that they want or need the best memory access times that the implementation can provide.

Memory Object*

The term *memory object* usually implies shared memory. If the object is the same as a filename in the file system name space of the implementation, it is expected that the data written into the memory object be preserved on disk. A memory object may also apply to a physical device on an implementation. In this case, writes to the memory object are sent to the controller for the device and reads result in control registers being returned.

Mount Point*

The directory on which a *mounted file system* is mounted. This term, like *mount*( ) and *umount*( ), was not included because it was implementation-defined.

Mounted File System*

See *file system*.

Name

There are no explicit limits in IEEE Std 1003.1-200x on the sizes of names, words (see the definition of word in the Base Definitions volume of IEEE Std 1003.1-200x), lines, or other objects. However, other implicit limits do apply: shell script lines produced by many of the standard utilities cannot exceed {LINE_MAX} and the sum of exported variables comes under the {ARG_MAX} limit. Historical shells dynamically allocate memory for names and words and parse incoming lines a character at a time. Lines cannot have an arbitrary {LINE_MAX} limit because of historical practice, such as makefiles, where *make* removes the <newline>s associated with the commands for a target and presents the shell with one very long line. The text on INPUT FILES in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 1.11, Utility Description Defaults does allow a shell to run out of memory, but it cannot have arbitrary programming limits.

Native Implementation*

This refers to an implementation of POSIX.1 that interfaces directly to an operating system kernel; see also *hosted implementation* and *cooperating implementation*. A similar concept is a native UNIX system, which would be a kernel derived from one of the original UNIX system products.

Nice Value

This definition is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions, such as adding realtime priorities, make the notion of a single underlying priority for all scheduling policies problematic. Some implementations may implement the features related to *nice* to affect all processes on the system, others to affect just the general time-sharing activities implied by IEEE Std 1003.1-200x, and others may have no effect at all. Because of the use of ‘‘implementation-defined’’ in *nice* and *renice*, a wide range of implementation strategies is possible.

Open File Description

An *open file description*, as it is currently named, describes how a file is being accessed. What is currently called a *file descriptor* is actually just an identifier or ‘‘handle’’; it does not actually describe anything.

The following alternate names were discussed:

- For *open file description*:
  open instance, *file access description*, *open file information*, and *file access information*.
- For *file descriptor*:
  file handle, *file number* (c.f., *fileno*( )). Some historical implementations use the term *file table entry*.

Orphaned Process Group

Historical implementations have a concept of an orphaned process, which is a process whose parent process has exited. When job control is in use, it is necessary to prevent processes from being stopped in response to interactions with the terminal after they no longer are controlled by a job control-cognizant program. Because signals generated by the terminal are sent to a process group and not to individual processes, and because a signal may be provoked by a process that is not orphaned, but sent to another process that is orphaned, it is necessary to define an orphaned process group. The definition assumes that a process group will be manipulated as a group and that the job control-cognizant process controlling the group is outside of the group and is the parent of at least one process in the group (so that state changes may be reported via *waitpid*( )). Therefore, a group is considered to be controlled as long as at least one process in the group has a parent that is outside of the process group, but within the session.

This definition of orphaned process groups ensures that a session leader’s process group is always considered to be orphaned, and thus it is prevented from stopping in response to terminal signals.

Page

The term *page* is defined to support the description of the behavior of memory mapping for shared memory and memory mapped files, and the description of the behavior of process memory locking. It is not intended to imply that shared memory/file mapping and memory locking are applicable only to ‘‘paged’’ architectures. For the purposes of IEEE Std 1003.1-200x, whatever the granularity on which an architecture supports mapping or locking is considered to be a ‘‘page’’ . If an architecture cannot support the memory mapping or locking functions specified by IEEE Std 1003.1-200x on any granularity, then these options will not be implemented on the architecture.

Passwd File*

Implementation-defined; see **User Database** (on page 3322).

Parent Directory

There may be more than one directory entry pointing to a given directory in some implementations. The wording here identifies that exactly one of those is the parent directory. In *pathname resolution*, dot-dot is identified as the way that the unique directory is identified. (That is, the parent directory is the one to which dot-dot points.) In the case of a remote file system, if the same file system is mounted several times, it would appear as if they were distinct file systems (with interesting synchronization properties).

Pipe

It proved convenient to define a pipe as a special case of a FIFO, even though historically the latter was not introduced until System III and does not exist at all in 4.3 BSD.

Portable Filename Character Set

The encoding of this character set is not specified—specifically, ASCII is not required. But the implementation must provide a unique character code for each of the printable graphics specified by POSIX.1; see also Section A.4.6 (on page 3324).

Situations where characters beyond the portable filename character set (or historically ASCII or the ISO/IEC 646:1991 standard) would be used (in a context where the portable filename character set or the ISO/IEC 646:1991 standard is required by POSIX.1) are expected to be common. Although such a situation renders the use technically non-compliant, mutual agreement among the users of an extended character set will make such use portable between those users. Such a mutual agreement could be formalized as an optional extension to POSIX.1. (Making it required would eliminate too many possible systems, as even those systems using the ISO/IEC 646:1991 standard as a base character set extend their character sets for Western Europe and the rest of the world in different ways.)

Nothing in POSIX.1 is intended to preclude the use of extended characters where interchange is not required or where mutual agreement is obtained. It has been suggested that in several places ‘‘should’’ be used instead of ‘‘shall’’. Because (in the worst case) use of any character beyond the portable filename character set would render the program or data not portable to all possible systems, no extensions are permitted in this context.

Regular File

POSIX.1 does not intend to preclude the addition of structuring data (for example, record lengths) in the file, as long as such data is not visible to an application that uses the features described in POSIX.1.

Root Directory

This definition permits the operation of *chroot*( ), even though that function is not in POSIX.1; see also *file hierarchy*.

Root File System*

Implementation-defined.

Root of a File System*

Implementation-defined; see *mount point*.

Signal

The definition implies a double meaning for the term. Although a signal is an event, common usage implies that a signal is an identifier of the class of event.

Superuser*

This concept, with great historical significance to UNIX system users, has been replaced with the notion of appropriate privileges.

Supplementary Group ID

The POSIX.1-1990 standard is inconsistent in its treatment of supplementary groups. The definition of supplementary group ID explicitly permits the effective group ID to be included in the set, but wording in the description of the *setuid*( ) and *setgid*( ) functions states: ‘‘Any supplementary group IDs of the calling process remain unchanged by these function calls’’. In the case of *setgid*( ) this contradicts that definition. In addition, some felt that the unspecified behavior in the definition of supplementary group IDs adds unnecessary portability problems. The standard developers considered several solutions to this problem:

1. Reword the description of *setgid*( ) to permit it to change the supplementary group IDs to reflect the new effective group ID. A problem with this is that it adds more ‘‘may’’s to the wording and does not address the portability problems of this optional behavior.
2. Mandate the inclusion of the effective group ID in the supplementary set (giving {NGROUPS_MAX} a minimum value of 1). This is the behavior of 4.4 BSD. In that system, the effective group ID is the first element of the array of supplementary group IDs (there is no separate copy stored, and changes to the effective group ID are made only in the supplementary group set). By convention, the initial value of the effective group ID is duplicated elsewhere in the array so that the initial value is not lost when executing a set-group-ID program.
3. Change the definition of supplementary group ID to exclude the effective group ID and specify that the effective group ID does not change the set of supplementary group IDs. This is the behavior of 4.2 BSD, 4.3 BSD, and System V, Release 4.
4. Change the definition of supplementary group ID to exclude the effective group ID, and require that *getgroups*( ) return the union of the effective group ID and the supplementary group IDs.
5. Change the definition of {NGROUPS_MAX} to be one more than the number of supplementary group IDs, so it continues to be the number of values returned by *getgroups*( ) and existing applications continue to work. This alternative is effectively the same as the second (and might actually have the same implementation).

The standard developers decided to permit either 2 or 3. The effective group ID is orthogonal to the set of supplementary group IDs, and it is implementation-defined whether *getgroups*( ) returns this. If the effective group ID is returned with the set of supplementary group IDs, then all changes to the effective group ID affect the supplementary group set returned by *getgroups*( ). It is permissible to eliminate duplicates from the list returned by *getgroups*( ). However, if a group ID is contained in the set of supplementary group IDs, setting the group ID to that value and then to a different value should not remove that value from the supplementary group IDs.

The definition of supplementary group IDs has been changed to not include the effective group ID. This simplifies permanent rationale and makes the relevant functions easier to understand. The *getgroups*( ) function has been modified so that it can, on an implementation-defined basis, return the effective group ID. By making this change, functions that modify the effective group ID do not need to discuss adding to the supplementary group list; the only view into the supplementary group list that the application writer has is through the *getgroups*( ) function.

Symbolic Link

Many implementations associate no attributes, including ownership with symbolic links. Security experts encouraged consideration for defining these attributes as optional. Consideration was given to changing *utime*( ) to allow modification of the times for a symbolic link, or as an alternative adding an *lutime*( ) interface. Modifications to *chown*( ) were also considered: allow changing symbolic link ownership or alternatively adding *lchown*( ). As a result of the problems encountered in defining attributes for symbolic links (and interfaces to access/modify those attributes) and since implementations exist that do not associate these attributes with symbolic links, only the file type bits in the *st_mode* member and the *st_size* member of the **stat** structure are required to be applicable to symbolic links.

Historical implementations were followed when determining which interfaces should apply to symbolic links. Interfaces that historically followed symbolic links include *chmod*( ), *link*( ), and *utime*( ). Interfaces that historically do not follow symbolic links include *chown*( ), *lstat*( ), *readlink*( ), *rename*( ), *remove*( ), *rmdir*( ), and *unlink*( ). IEEE Std 1003.1-200x deviates from historical practice only in the case of *chown*( ). Because there is no requirement that there be an association of ownership with symbolic links, there was no point in requiring an interface to change ownership. In addition, other implementations of symbolic links have modified *chown*( ) to follow symbolic links.

In the case of symbolic links, IEEE Std 1003.1-200x states that a trailing slash is considered to be the final component of a pathname rather than the pathname component that preceded it. This is the behavior of historical implementations. For example, for **/a/b** and **/a/b/**, if **/a/b** is a symbolic link to a directory, then **/a/b** refers to the symbolic link, and **/a/b/** is the same as **/a/b/.**, which is the directory to which the symbolic link points.

For multi-level security purposes, it is possible to have the link read mode govern permission for the *readlink*( ) function. It is also possible that the read permissions of the directory containing the link be used for this purpose. Implementations may choose to use either of these methods; however, this is not current practice and neither method is specified.

Several reasons were advanced for requiring that when a symbolic link is used as the source argument to the *link*( ) function, the resulting link will apply to the file named by the contents of the symbolic link rather than to the symbolic link itself. This is the case in historical implementations. This action was preferred, as it supported the traditional idea of persistence with respect to the target of a hard link. This decision is appropriate in light of a previous decision not to require association of attributes with symbolic links, thereby allowing implementations which do not use inodes. Opposition centered on the lack of symmetry on the part of the *link*( ) and *unlink*( ) function pair with respect to symbolic links.

Because a symbolic link and its referenced object coexist in the file system name space, confusion can arise in distinguishing between the link itself and the referenced object. Historically, utilities and system calls have adopted their own link following conventions in a somewhat *ad hoc* fashion. Rules for a uniform approach are outlined here, although historical practice has been adhered to as much as was possible. To promote consistent system use, user-written utilities are encouraged to follow these same rules.

Symbolic links are handled either by operating on the link itself, or by operating on the object referenced by the link. In the latter case, an application or system call is said to follow the link. Symbolic links may reference other symbolic links, in which case links are dereferenced until an object that is not a symbolic link is found, a symbolic link that references a file that does not exist is found, or a loop is detected. (Current implementations do not detect loops, but have a limit on the number of symbolic links that they will dereference before declaring it an error.)

There are four domains for which default symbolic link policy is established in a system. In almost all cases, there are utility options that override this default behavior. The four domains are as follows:

1. Symbolic links specified to system calls that take filename arguments
2. Symbolic links specified as command line filename arguments to utilities that are not performing a traversal of a file hierarchy
3. Symbolic links referencing files not of type directory, specified to utilities that are performing a traversal of a file hierarchy
4. Symbolic links referencing files of type directory, specified to utilities that are performing a traversal of a file hierarchy

First Domain

The first domain is considered in earlier rationale.

Second Domain

The reason this category is restricted to utilities that are not traversing the file hierarchy is that some standard utilities take an option that specifies a hierarchical traversal, but by default operate on the arguments themselves. Generally, users specifying the option for a file hierarchy traversal wish to operate on a single, physical hierarchy, and therefore symbolic links, which may reference files outside of the hierarchy, are ignored. For example, *chown owner file* is a different operation from the same command with the –**R** option specified. In this example, the behavior of the command *chown owner file* is described here, while the behavior of the command *chown* –**R** *owner file* is described in the third and fourth domains.

The general rule is that the utilities in this category follow symbolic links named as arguments.

Exceptions in the second domain are:

- The *mv* and *rm* utilities do not follow symbolic links named as arguments, but respectively attempt to rename or delete them.
- The *ls* utility is also an exception to this rule. For compatibility with historical systems, when the –**R** option is not specified, the *ls* utility follows symbolic links named as arguments if the –**L** option is specified or if the –**F**, –**d**, or –**l** options are not specified. (If the –**L** option is specified, *ls* always follows symbolic links; it is the only utility where the –**L** option affects its behavior even though a tree walk is not being performed.)

All other standard utilities, when not traversing a file hierarchy, always follow symbolic links named as arguments.

Historical practice is that the –**h** option is specified if standard utilities are to act upon symbolic links instead of upon their targets. Examples of commands that have historically had a –**h** option for this purpose are the *chgrp*, *chown*, *file*, and *test* utilities.

Third Domain

The third domain is symbolic links, referencing files not of type directory, specified to utilities that are performing a traversal of a file hierarchy. (This includes symbolic links specified as command line filename arguments or encountered during the traversal.)

The intention of the Shell and Utilities volume of IEEE Std 1003.1-200x is that the operation that the utility is performing is applied to the symbolic link itself, if that operation is applicable to symbolic links. The reason that the operation is not required is that symbolic links in some implementations do not have such attributes as a file owner, and therefore the *chown* operation would be meaningless. If symbolic links on the system have an owner, it is the intention that the utility *chown* cause the owner of the symbolic link to change. If symbolic links do not have an owner, the symbolic link should be ignored. Specifically, by default, no change should be made to the file referenced by the symbolic link.

Fourth Domain

The fourth domain is symbolic links referencing files of type directory, specified to utilities that are performing a traversal of a file hierarchy. (This includes symbolic links specified as command line filename arguments or encountered during the traversal.)

Most standard utilities do not, by default, indirect into the file hierarchy referenced by the symbolic link. (The Shell and Utilities volume of IEEE Std 1003.1-200x uses the informal term *physical walk* to describe this case. The case where the utility does indirect through the symbolic link is termed a *logical walk*.)

There are three reasons for the default to a physical walk:

1. With very few exceptions, a physical walk has been the historical default on UNIX systems supporting symbolic links. Because some utilities (that is, *rm*) must default to a physical walk, regardless, changing historical practice in this regard would be confusing to users and needlessly incompatible.

2. For systems where symbolic links have the historical file attributes (that is, *owner*, *group*, *mode*), defaulting to a logical traversal would require the addition of a new option to the commands to modify the attributes of the link itself. This is painful and more complex than the alternatives.

3. There is a security issue with defaulting to a logical walk. Historically, the command *chown* **–R** *user file* has been safe for the superuser because *setuid* and *setgid* bits were lost when the ownership of the file was changed. If the walk were logical, changing ownership would no longer be safe because a user might have inserted a symbolic link pointing to any file in the tree. Again, this would necessitate the addition of an option to the commands doing hierarchy traversal to not indirect through the symbolic links, and historical scripts doing recursive walks would instantly become security problems. While this is mostly an issue for system administrators, it is preferable to not have different defaults for different classes of users.

As consistently as possible, users may cause standard utilities performing a file hierarchy traversal to follow any symbolic links named on the command line, regardless of the type of file they reference, by specifying the **–H** (for half logical) option. This option is intended to make the command line name space look like the logical name space.

As consistently as possible, users may cause standard utilities performing a file hierarchy traversal to follow any symbolic links named on the command line as well as any symbolic links encountered during the traversal, regardless of the type of file they reference, by specifying the **–L** (for logical) option. This option is intended to make the entire name space look like the logical name space.

For consistency, implementors are encouraged to use the −**P** (for physical) flag to specify the physical walk in utilities that do logical walks by default for whatever reason. The only standard utilities that require the −**P** option are *cd* and *pwd*; see the note below.

When one or more of the −**H**, −**L**, and −**P** flags can be specified, the last one specified determines the behavior of the utility. This permits users to alias commands so that the default behavior is a logical walk and then override that behavior on the command line.

Exceptions in the Third and Fourth Domains

The *ls* and *rm* utilities are exceptions to these rules. The *rm* utility never follows symbolic links and does not support the −**H**, −**L**, or −**P** options. Some historical versions of *ls* always followed symbolic links given on the command line whether the −**L** option was specified or not. Historical versions of *ls* did not support the −**H** option. In IEEE Std 1003.1-200x, unless one of the −**H** or −**L** options is specified, the *ls* utility only follows symbolic links to directories that are given as operands. The *ls* utility does not support the −**P** option.

The Shell and Utilities volume of IEEE Std 1003.1-200x requires that the standard utilities *ls*, *find*, and *pax* detect infinite loops when doing logical walks; that is, a directory, or more commonly a symbolic link, that refers to an ancestor in the current file hierarchy. If the file system itself is corrupted, causing the infinite loop, it may be impossible to recover. Because *find* and *ls* are often used in system administration and security applications, they should attempt to recover and continue as best as they can. The *pax* utility should terminate because the archive it was creating is by definition corrupted. Other, less vital, utilities should probably simply terminate as well. Implementations are strongly encouraged to detect infinite loops in all utilities.

Historical practice is shown in Table A-1 (on page 3320). The heading **SVID3** stands for the Third Edition of the System V Interface Definition.

Historically, several shells have had built-in versions of the *pwd* utility. In some of these shells, *pwd* reported the physical path, and in others, the logical path. Implementations of the shell corresponding to IEEE Std 1003.1-200x must report the logical path by default. Earlier versions of IEEE Std 1003.1-200x did not require the *pwd* utility to be a built-in utility. Now that *pwd* is required to set an environment variable in the current shell execution environment, it must be a built-in utility.

The *cd* command is required, by default, to treat the filename dot-dot logically. Implementors are required to support the −**P** flag in *cd* so that users can have their current environment handled physically. In 4.3 BSD, *chgrp* during tree traversal changed the group of the symbolic link, not the target. Symbolic links in 4.4 BSD do not have *owner*, *group*, *mode*, or other standard UNIX system file attributes.

Table A-1 Historical Practice for Symbolic Links

Utility	SVID3	4.3 BSD	4.4 BSD	POSIX	Comments
cd				**–L**	Treat `".."` logically.
cd				**–P**	`".."` physically.
chgrp			**–H**	**–H**	Follow command line symlinks.
chgrp			**–h**	**–L**	Follow symlinks.
chgrp	**–h**			**–h**	Affect the symlink.
chmod					Affect the symlink.
chmod			**–H**		Follow command line symlinks.
chmod			**–h**		Follow symlinks.
chown			**–H**	**–H**	Follow command line symlinks.
chown			**–h**	**–L**	Follow symlinks.
chown	**–h**			**–h**	Affect the symlink.
cp			**–H**	**–H**	Follow command line symlinks.
cp			**–h**	**–L**	Follow symlinks.
cpio	**–L**		**–L**		Follow symlinks.
du			**–H**	**–H**	Follow command line symlinks.
du			**–h**	**–L**	Follow symlinks.
file	**–h**			**–h**	Affect the symlink.
find			**–H**	**–H**	Follow command line symlinks.
find			**–h**	**–L**	Follow symlinks.
find	**–follow**		**–follow**		Follow symlinks.
ln	**–s**	**–s**	**–s**	**–s**	Create a symbolic link.
ls	**–L**	**–L**	**–L**	**–L**	Follow symlinks.
ls				**–H**	Follow command line symlinks.
mv					Operates on the symlink.
pax			**–H**	**–H**	Follow command line symlinks.
pax			**–h**	**–L**	Follow symlinks.
pwd				**–L**	Printed path may contain symlinks.
pwd				**–P**	Printed path will not contain symlinks.
rm					Operates on the symlink.
tar			**–H**		Follow command line symlinks.
tar		**–h**	**–h**		Follow symlinks.
test	**–h**		**–h**	**–h**	Affect the symlink.

Synchronously-Generated Signal

Those signals that may be generated synchronously include SIGABRT, SIGBUS, SIGILL, SIGFPE, SIGPIPE, and SIGSEGV.

Any signal sent via the *raise*( ) function or a *kill*( ) function targeting the current process is also considered synchronous.

System Call*

The distinction between a *system call* and a *library routine* is an implementation detail that may differ between implementations and has thus been excluded from POSIX.1.

See ‘‘Interface, Not Implementation’’ in the Preface.

System Reboot

A *system reboot* is an event initiated by an unspecified circumstance that causes all processes (other than special system processes) to be terminated in an implementation-defined manner, after which any changes to the state and contents of files created or written to by a Conforming POSIX.1 Application prior to the event are implementation-defined.

Synchronized I/O Data (and File) Integrity Completion

These terms specify that for synchronized read operations, pending writes must be successfully completed before the read operation can complete. This is motivated by two circumstances. Firstly, when synchronizing processes can access the same file, but not share common buffers (such as for a remote file system), this requirement permits the reading process to guarantee that it can read data written remotely. Secondly, having data written synchronously is insufficient to guarantee the order with respect to a subsequent write by a reading process, and thus this extra read semantic is necessary.

Text File

The term *text file* does not prevent the inclusion of control or other non-printable characters (other than NUL). Therefore, standard utilities that list text files as inputs or outputs are either able to process the special characters or they explicitly describe their limitations within their individual descriptions. The definition of *text file* has caused controversy. The only difference between text and binary files is that text files have lines of less than {LINE_MAX} bytes, with no NUL characters, each terminated by a <newline>. The definition allows a file with a single <newline>, but not a totally empty file, to be called a text file. If a file ends with an incomplete line it is not strictly a text file by this definition. The <newline> referred to in IEEE Std 1003.1-200x is not some generic line separator, but a single character; files created on systems where they use multiple characters for ends of lines are not portable to all conforming systems without some translation process unspecified by IEEE Std 1003.1-200x.

Thread

IEEE Std 1003.1-200x defines a thread to be a flow of control within a process. Each thread has a minimal amount of private state; most of the state associated with a process is shared among all of the threads in the process. While most multi-thread extensions to POSIX have taken this approach, others have made different decisions.

Note: The choice to put threads within a process does not constrain implementations to implement threads in that manner. However, all functions have to behave as though threads share the indicated state information with the process from which they were created.

Threads need to share resources in order to cooperate. Memory has to be widely shared between threads in order for the threads to cooperate at a fine level of granularity. Threads keep data structures and the locks protecting those data structures in shared memory. For a data structure to be usefully shared between threads, such structures should not refer to any data that can only be interpreted meaningfully by a single thread. Thus, any system resources that might be referred to in data structures need to be shared between all threads. File descriptors, pathnames, and pointers to stack variables are all things that programmers want to share between their threads. Thus, the file descriptor table, the root directory, the current working directory, and the address space have to be shared.

Library implementations are possible as long as the effective behavior is as if system services invoked by one thread do not suspend other threads. This may be difficult for some library implementations on systems that do not provide asynchronous facilities.

See Section B.2.9 (on page 3439) for additional rationale.

Thread ID

See Section B.2.9.2 (on page 3455) for additional rationale.

Thread-Safe Function

All functions required by IEEE Std 1003.1-200x need to be thread-safe; see Section A.4.16 (on page 3330) and Section B.2.9.1 (on page 3452) for additional rationale.

User Database

There are no references in IEEE Std 1003.1-200x to a *passwd file* or a *group file*, and there is no requirement that the *group* or *passwd* databases be kept in files containing editable text. Many large timesharing systems use *passwd* databases that are hashed for speed. Certain security classifications prohibit certain information in the *passwd* database from being publicly readable.

The term *encoded* is used instead of *encrypted* in order to avoid the implementation connotations (such as reversibility or use of a particular algorithm) of the latter term.

The *getgrent*( ), *setgrent*( ), *endgrent*( ), *getpwent*( ), *setpwent*( ), and *endpwent*( ) functions are not included as part of the base standard because they provide a linear database search capability that is not generally useful (the *getpwuid*( ), *getpwnam*( ), *getgrgid*( ), and *getgrnam*( ) functions are provided for keyed lookup) and because in certain distributed systems, especially those with different authentication domains, it may not be possible or desirable to provide an application with the ability to browse the system databases indiscriminately. They are provided on XSI-conformant systems due to their historical usage by many existing applications.

A change from historical implementations is that the structures used by these functions have fields of the types **gid_t** and **uid_t**, which are required to be defined in the **<sys/types.h>** header. IEEE Std 1003.1-200x requires implementations to ensure that these types are defined by inclusion of **<grp.h>** and **<pwd.h>**, respectively, without imposing any name space pollution or errors from redefinition of types.

IEEE Std 1003.1-200x is silent about the content of the strings containing user or group names. These could be digit strings. IEEE Std 1003.1-200x is also silent as to whether such digit strings bear any relationship to the corresponding (numeric) user or group ID.

Database Access

The thread-safe versions of the user and group database access functions return values in user-supplied buffers instead of possibly using static data areas that may be overwritten by each call.

Virtual Processor*

The term *virtual processor* was chosen as a neutral term describing all kernel-level schedulable entities, such as processes, Mach tasks, or lightweight processes. Implementing threads using multiple processes as virtual processors, or implementing multiplexed threads above a virtual processor layer, should be possible, provided some mechanism has also been implemented for sharing state between processes or virtual processors. Many systems may also wish to provide implementations of threads on systems providing ‘‘shared processes’’ or ‘‘variable-weight processes’’. It was felt that exposing such implementation details would severely limit the type of systems upon which the threads interface could be supported and prevent certain types of valid implementations. It was also determined that a virtual processor interface was out of the scope of the Rationale (Informative) volume of IEEE Std 1003.1-200x.

XSI

This is introduced to allow IEEE Std 1003.1-200x to be adopted as an IEEE standard and an Open Group Technical Standard, serving both the POSIX and the Single UNIX Specification in a core set of volumes.

The term *XSI* has been used for 10 years in connection with the XPG series and the first and second versions of the base volumes of the Single UNIX Specification. The XSI margin code was introduced to denote the extended or more restrictive semantics beyond POSIX that are applicable to UNIX systems.

A.4 General Concepts

A.4.1 Concurrent Execution

There is no additional rationale provided for this section.

A.4.2 Directory Protection

There is no additional rationale provided for this section.

A.4.3 Extended Security Controls

Allowing an implementation to define extended security controls enables the use of IEEE Std 1003.1-200x in environments that require different or more rigorous security than that provided in POSIX.1. Extensions are allowed in two areas: privilege and file access permissions. The semantics of these areas have been defined to permit extensions with reasonable, but not exact, compatibility with all existing practices. For example, the elimination of the superuser definition precludes identifying a process as privileged or not by virtue of its effective user ID.

A.4.4 File Access Permissions

A process should not try to anticipate the result of an attempt to access data by *a priori* use of these rules. Rather, it should make the attempt to access data and examine the return value (and possibly *errno* as well), or use *access*( ). An implementation may include other security mechanisms in addition to those specified in POSIX.1, and an access attempt may fail because of those additional mechanisms, even though it would succeed according to the rules given in this section. (For example, the user's security level might be lower than that of the object of the access attempt.) The supplementary group IDs provide another reason for a process to not attempt to anticipate the result of an access attempt.

A.4.5 File Hierarchy

Though the file hierarchy is commonly regarded to be a tree, POSIX.1 does not define it as such for three reasons:

1. Links may join branches.
2. In some network implementations, there may be no single absolute root directory; see *pathname resolution*.
3. With symbolic links, the file system need not be a tree or even a directed acyclic graph.

A.4.6 Filenames

Historically, certain filenames have been reserved. This list includes **core**, **/etc/passwd**, and so on. Conforming applications should avoid these.

Most historical implementations prohibit case folding in filenames; that is, treating uppercase and lowercase alphabetic characters as identical. However, some consider case folding desirable:

- For user convenience
- For ease-of-implementation of the POSIX.1 interface as a hosted system on some popular operating systems

Variants, such as maintaining case distinctions in filenames, but ignoring them in comparisons, have been suggested. Methods of allowing escaped characters of the case opposite the default have been proposed.

Many reasons have been expressed for not allowing case folding, including:

- No solid evidence has been produced as to whether case-sensitivity or case-insensitivity is more convenient for users.
- Making case-insensitivity a POSIX.1 implementation option would be worse than either having it or not having it, because:
  - — More confusion would be caused among users.
  - — Application developers would have to account for both cases in their code.
  - — POSIX.1 implementors would still have other problems with native file systems, such as short or otherwise constrained filenames or pathnames, and the lack of hierarchical directory structure.
- Case folding is not easily defined in many European languages, both because many of them use characters outside the US ASCII alphabetic set, and because:
  - — In Spanish, the digraph `"ll"` is considered to be a single letter, the capitalized form of which may be either `"Ll"` or `"LL"`, depending on context.
  - — In French, the capitalized form of a letter with an accent may or may not retain the accent, depending on the country in which it is written.
  - — In German, the sharp ess may be represented as a single character resembling a Greek beta (β) in lowercase, but as the digraph `"SS"` in uppercase.
  - — In Greek, there are several lowercase forms of some letters; the one to use depends on its position in the word. Arabic has similar rules.
- Many East Asian languages, including Japanese, Chinese, and Korean, do not distinguish case and are sometimes encoded in character sets that use more than one byte per character.
- Multiple character codes may be used on the same machine simultaneously. There are several ISO character sets for European alphabets. In Japan, several Japanese character codes are commonly used together, sometimes even in filenames; this is evidently also the case in China. To handle case insensitivity, the kernel would have to at least be able to distinguish for which character sets the concept made sense.
- The file system implementation historically deals only with bytes, not with characters, except for slash and the null byte.
- The purpose of POSIX.1 is to standardize the common, existing definition, not to change it. Mandating case-insensitivity would make all historical implementations non-standard.

- Not only the interface, but also application programs would need to change, counter to the purpose of having minimal changes to existing application code.
- At least one of the original developers of the UNIX system has expressed objection in the strongest terms to either requiring case-insensitivity or making it an option, mostly on the basis that POSIX.1 should not hinder portability of application programs across related implementations in order to allow compatibility with unrelated operating systems.

Two proposals were entertained regarding case folding in filenames:

1. Remove all wording that previously permitted case folding.

   Rationale Case folding is inconsistent with portable filename character set definition and filename definition (all characters except slash and null). No known implementations allowing all characters except slash and null also do case folding.

2. Change ‘‘though this practice is not recommended:’’ to ‘‘although this practice is strongly discouraged.’’

   Rationale If case folding must be included in POSIX.1, the wording should be stronger to discourage the practice.

The consensus selected the first proposal. Otherwise, a conforming application would have to assume that case folding would occur when it was not wanted, but that it would not occur when it was wanted.

A.4.7 File Times Update

This section reflects the actions of historical implementations. The times are not updated immediately, but are only marked for update by the functions. An implementation may update these times immediately.

The accuracy of the time update values is intentionally left unspecified so that systems can control the bandwidth of a possible covert channel.

The wording was carefully chosen to make it clear that there is no requirement that the conformance document contain information that might incidentally affect file update times. Any function that performs pathname resolution might update several *st_atime* fields. Functions such as *getpwnam*( ) and *getgrnam*( ) might update the *st_atime* field of some specific file or files. It is intended that these are not required to be documented in the conformance document, but they should appear in the system documentation.

A.4.8 Host and Network Byte Order

There is no additional rationale provided for this section.

A.4.9 Measurement of Execution Time

The methods used to measure the execution time of processes and threads, and the precision of these measurements, may vary considerably depending on the software architecture of the implementation, and on the underlying hardware. Implementations can also make tradeoffs between the scheduling overhead and the precision of the execution time measurements. IEEE Std 1003.1-200x does not impose any requirement on the accuracy of the execution time; it instead specifies that the measurement mechanism and its precision are implementation-defined.

A.4.10 Memory Synchronization

In older multi-processors, access to memory by the processors was strictly multiplexed. This meant that a processor executing program code interrogates or modifies memory in the order specified by the code and that all the memory operation of all the processors in the system appear to happen in some global order, though the operation histories of different processors are interleaved arbitrarily. The memory operations of such machines are said to be sequentially consistent. In this environment, threads can synchronize using ordinary memory operations. For example, a producer thread and a consumer thread can synchronize access to a circular data buffer as follows:

```
int rdptr = 0;
int wrptr = 0;
data_t buf[BUFSIZE];

Thread 1:
    while (work_to_do) {
        int next;

        buf[wrptr] = produce();
        next = (wrptr + 1) % BUFSIZE;
        while (rdptr == next)
            ;
        wrptr = next;
}

Thread 2:
    while (work_to_do) {
        while (rdptr == wrptr)
            ;
        consume(buf[rdptr]);
        rdptr = (rdptr + 1) % BUFSIZE;
    }
```

In modern multi-processors, these conditions are relaxed to achieve greater performance. If one processor stores values in location A and then location B, then other processors loading data from location B and then location A may see the new value of B but the old value of A. The memory operations of such machines are said to be weakly ordered. On these machines, the circular buffer technique shown in the example will fail because the consumer may see the new value of *wrptr* but the old value of the data in the buffer. In such machines, synchronization can only be achieved through the use of special instructions that enforce an order on memory operations. Most high-level language compilers only generate ordinary memory operations to take advantage of the increased performance. They usually cannot determine when memory operation order is important and generate the special ordering instructions. Instead, they rely on the programmer to use synchronization primitives correctly to ensure that modifications to a location in memory are ordered with respect to modifications and/or access to the same location in other threads. Access to read-only data need not be synchronized. The resulting program is said to be data race-free.

Synchronization is still important even when accessing a single primitive variable (for example, an integer). On machines where the integer may not be aligned to the bus data width or be larger than the data width, a single memory load may require multiple memory cycles. This means that it may be possible for some parts of the integer to have an old value while other parts have a newer value. On some processor architectures this cannot happen, but portable programs cannot rely on this.

In summary, a portable multi-threaded program, or a multi-process program that shares writable memory between processes, has to use the synchronization primitives to synchronize data access. It cannot rely on modifications to memory being observed by other threads in the order written in the program or even on modification of a single variable being seen atomically.

Conforming applications may only use the functions listed to synchronize threads of control with respect to memory access. There are many other candidates for functions that might also be used. Examples are: signal sending and reception, or pipe writing and reading. In general, any function that allows one thread of control to wait for an action caused by another thread of control is a candidate. IEEE Std 1003.1-200x does not require these additional functions to synchronize memory access since this would imply the following:

- All these functions would have to be recognized by advanced compilation systems so that memory operations and calls to these functions are not reordered by optimization.
- All these functions would potentially have to have memory synchronization instructions added, depending on the particular machine.
- The additional functions complicate the model of how memory is synchronized and make automatic data race detection techniques impractical.

Formal definitions of the memory model were rejected as unreadable by the vast majority of programmers. In addition, most of the formal work in the literature has concentrated on the memory as provided by the hardware as opposed to the application programmer through the compiler and runtime system. It was believed that a simple statement intuitive to most programmers would be most effective. IEEE Std 1003.1-200x defines functions that can be used to synchronize access to memory, but it leaves open exactly how one relates those functions to the semantics of each function as specified elsewhere in IEEE Std 1003.1-200x. IEEE Std 1003.1-200x also does not make a formal specification of the partial ordering in time that the functions can impose, as that is implied in the description of the semantics of each function. It simply states that the programmer has to ensure that modifications do not occur ‘‘simultaneously’’ with other access to a memory location.

A.4.11 Pathname Resolution

It is necessary to differentiate between the definition of pathname and the concept of pathname resolution with respect to the handling of trailing slashes. By specifying the behavior here, it is not possible to provide an implementation that is conforming but extends all interfaces that handle pathnames to also handle strings that are not legal pathnames (because they have trailing slashes).

Pathnames that end with one or more trailing slash characters must refer to directory paths. Previous versions of IEEE Std 1003.1-200x were not specific about the distinction between trailing slashes on files and directories, and both were permitted.

Two types of implementation have been prevalent; those that ignored trailing slash characters on all pathnames regardless, and those that only permitted them only on existing directories.

IEEE Std 1003.1-200x requires that a pathname with a trailing slash character be treated as if it had a trailing `"/."` everywhere.

Note that this change does not break any conforming applications; since there were two different types of implementation, no application could have portably depended on either behavior. This change does however require some implementations to be altered to remain compliant. Substantial discussion over a three-year period has shown that the benefits to application developers outweighs the disadvantages for some vendors. |

On a historical note, some early applications automatically appended a `'/'` to every path. Rather than fix the applications, the system implementation was modified to accept this behavior by ignoring any trailing slash.

Each directory has exactly one parent directory which is represented by the name **dot-dot** in the first directory. No other directory, regardless of linkages established by symbolic links, is considered the parent directory by IEEE Std 1003.1-200x.

There are two general categories of interfaces involving pathname resolution: those that follow the symbolic link, and those that do not. There are several exceptions to this rule; for example, *open*(*path*,O_CREAT | O_EXCL) will fail when *path* names a symbolic link. However, in all other situations, the *open*( ) function will follow the link.

What the filename **dot-dot** refers to relative to the root directory is implementation-defined. In Version 7 it refers to the root directory itself; this is the behavior mentioned in IEEE Std 1003.1-200x. In some networked systems the construction **/../hostname/** is used to refer to the root directory of another host, and POSIX.1 permits this behavior.

Other networked systems use the construct **//hostname** for the same purpose; that is, a double initial slash is used. There is a potential problem with existing applications that create full pathnames by taking a trunk and a relative pathname and making them into a single string separated by `'/'`, because they can accidentally create networked pathnames when the trunk is `'/'`. This practice is not prohibited because such applications can be made to conform by simply changing to use `"//"` as a separator instead of `'/'`:

- If the trunk is `'/'`, the full pathname will begin with `"///"` (the initial `'/'` and the separator `"//"`). This is the same as `'/'`, which is what is desired. (This is the general case of making a relative pathname into an absolute one by prefixing with `"///"` instead of `'/'`.)
- If the trunk is `"/A"`, the result is `"/A//..."`; since non-leading sequences of two or more slashes are treated as a single slash, this is equivalent to the desired `"/A/..."`.
- If the trunk is `"//A"`, the implementation-defined semantics will apply. (The multiple slash rule would apply.)

Application developers should avoid generating pathnames that start with `"//"`. Implementations are strongly encouraged to avoid using this special interpretation since a number of applications currently do not follow this practice and may inadvertently generate `"//..."`.

The term *root directory* is only defined in POSIX.1 relative to the process. In some implementations, there may be no absolute root directory. The initialization of the root directory of a process is implementation-defined.

A.4.12 Process ID Reuse

There is no additional rationale provided for this section.

A.4.13 Scheduling Policy

There is no additional rationale provided for this section.

A.4.14 Seconds Since the Epoch

Coordinated Universal Time (UTC) includes leap seconds. However, in POSIX time (seconds since the Epoch), leap seconds are ignored (not applied) to provide an easy and compatible method of computing time differences. Broken-down POSIX time is therefore not necessarily UTC, despite its appearance.

As of September 2000, 24 leap seconds had been added to UTC since the Epoch, 1 January, 1970. Historically, one leap second is added every 15 months on average, so this offset can be expected to grow steadily with time.

Most systems' notion of ''time'' is that of a continuously increasing value, so this value should increase even during leap seconds. However, not only do most systems not keep track of leap seconds, but most systems are probably not synchronized to any standard time reference. Therefore, it is inappropriate to require that a time represented as seconds since the Epoch precisely represent the number of seconds between the referenced time and the Epoch.

It is sufficient to require that applications be allowed to treat this time as if it represented the number of seconds between the referenced time and the Epoch. It is the responsibility of the vendor of the system, and the administrator of the system, to ensure that this value represents the number of seconds between the referenced time and the Epoch as closely as necessary for the application being run on that system.

It is important that the interpretation of time names and *seconds since the Epoch* values be consistent across conforming systems; that is, it is important that all conforming systems interpret ''536 457 599 seconds since the Epoch'' as 59 seconds, 59 minutes, 23 hours 31 December 1986, regardless of the accuracy of the system's idea of the current time. The expression is given to assure a consistent interpretation, not to attempt to specify the calendar. The relationship between *tm_yday* and the day of week, day of month, and month is presumed to be specified elsewhere and is not given in POSIX.1.

Consistent interpretation of *seconds since the Epoch* can be critical to certain types of distributed applications that rely on such timestamps to synchronize events. The accrual of leap seconds in a time standard is not predictable. The number of leap seconds since the Epoch will likely increase. POSIX.1 is more concerned about the synchronization of time between applications of astronomically short duration.

Note that *tm_yday* is zero-based, not one-based, so the day number in the example above is 364. Note also that the division is an integer division (discarding remainder) as in the C language.

Note also that the meaning of *gmtime*( ), *localtime*( ), and *mktime*( ) is specified in terms of this expression. However, the ISO C standard computes *tm_yday* from *tm_mday*, *tm_mon*, and *tm_year* in *mktime*( ). Because it is stated as a (bidirectional) relationship, not a function, and because the conversion between month-day-year and day-of-year dates is presumed well known and is also a relationship, this is not a problem.

Implementations that implement **time_t** as a signed 32-bit integer will overflow in 2 038. The data size for **time_t** is as per the ISO C standard definition, which is implementation-defined.

See also **Epoch** (on page 3306).

The topic of whether seconds since the Epoch should account for leap seconds has been debated on a number of occasions, and each time consensus was reached (with acknowledged dissent each time) that the majority of users are best served by treating all days identically. (That is, the majority of applications were judged to assume a single length—as measured in seconds since the Epoch—for all days. Thus, leap seconds are not applied to seconds since the Epoch.) Those applications which do care about leap seconds can determine how to handle them in whatever way those applications feel is best. This was particularly emphasized because there was disagreement about what the best way of handling leap seconds might be. It is a practical impossibility to mandate that a conforming implementation must have a fixed relationship to any particular official clock (consider isolated systems, or systems performing ‘‘reruns’’ by setting the clock to some arbitrary time).

Note that as a practical consequence of this, the length of a second as measured by some external standard is not specified. This unspecified second is nominally equal to an International System (SI) second in duration. Applications must be matched to a system that provides the particular handling of external time in the way required by the application.

A.4.15 Semaphore

There is no additional rationale provided for this section.

A.4.16 Thread-Safety

Where the interface of a function required by IEEE Std 1003.1-200x precludes thread-safety, an alternate form that shall be thread-safe is provided. The names of these thread-safe forms are the same as the non-thread-safe forms with the addition of the suffix ‘‘_r’’. The suffix ‘‘_r’’ is historical, where the `'r'` stood for ‘‘reentrant’’.

In some cases, thread-safety is provided by restricting the arguments to an existing function.

See also Section B.2.9.1 (on page 3452).

A.4.17 Tracing

Refer to Section B.2.11 (on page 3468).

There is no additional rationale provided for this section.

A.4.20 Utility

There is no additional rationale provided for this section.

A.4.21 Variable Assignment

There is no additional rationale provided for this section.

A.5 File Format Notation

The notation for spaces allows some flexibility for application output. Note that an empty character position in *format* represents one or more <blank>s on the output (not *white space*, which can include <newline>s). Therefore, another utility that reads that output as its input must be prepared to parse the data using *scanf*( ), *awk*, and so on. The `'Δ'` character is used when exactly one <space> is output.

The treatment of integers and spaces is different from the *printf*( ) function in that they can be surrounded with <blank>s. This was done so that, given a format such as:

```
"%d\n",<foo>
```

the implementation could use a *printf*( ) call such as:

```
printf("%6d\n", foo);
```

and still conform. This notation is thus somewhat like *scanf*( ) in addition to *printf*( ).

The *printf*( ) function was chosen as a model because most of the standard developers were familiar with it. One difference from the C function *printf*( ) is that the `l` and `h` conversion specifier characters are not used. As expressed by the Shell and Utilities volume of IEEE Std 1003.1-200x, there is no differentiation between decimal values for type **int**, type **long**, or type **short**. The conversion specifications `%d` or `%i` should be interpreted as an arbitrary length sequence of digits. Also, no distinction is made between single precision and double precision numbers (**float** or **double** in C). These are simply referred to as floating-point numbers.

Many of the output descriptions in the Shell and Utilities volume of IEEE Std 1003.1-200x use the term *line*, such as:

```
"%s", <input line>
```

Since the definition of *line* includes the trailing <newline> already, there is no need to include a `'\n'` in the format; a double <newline> would otherwise result.

A.6 Character Set

A.6.1 Portable Character Set

The portable character set is listed in full so there is no dependency on the ISO/IEC 646:1991 standard (or historically ASCII) encoded character set, although the set is identical to the characters defined in the International Reference version of the ISO/IEC 646:1991 standard.

IEEE Std 1003.1-200x poses no requirement that multiple character sets or codesets be supported, leaving this as a marketing differentiation for implementors. Although multiple charmap files are supported, it is the responsibility of the implementation to provide the file(s); if only one is provided, only that one will be accessible using the *localedef* **−f** option.

The statement about invariance in codesets for the portable character set is worded to avoid precluding implementations where multiple incompatible codesets are available (for instance, ASCII and EBCDIC). The standard utilities cannot be expected to produce predictable results if they access portable characters that vary on the same implementation.

Not all character sets need include the portable character set, but each locale must include it. For example, a Japanese-based locale might be supported by a mixture of character sets: JIS X 0201 Roman (a Japanese version of the ISO/IEC 646:1991 standard), JIS X 0208, and JIS X 0201 Katakana. Not all of these character sets include the portable characters, but at least one does (JIS X 0201 Roman).

A.6.2 Character Encoding

Encoding mechanisms based on single shifts, such as the EUC encoding used in some Asian and other countries, can be supported via the current charmap mechanism. With single-shift encoding, each character is preceded by a shift code (SS2 or SS3). A complete EUC code, consisting of the portable character set (G0) and up to three additional character sets (G1, G2, G3), can be described using the current charmap mechanism; the encoding for each character in additional character sets G2 and G3 must then include their single-shift code. Other mechanisms to support locales based on encoding mechanisms such as locking shift are not addressed by this volume of IEEE Std 1003.1-200x.

A.6.3 C Language Wide-Character Codes

There is no additional rationale provided for this section.

A.6.4 Character Set Description File

IEEE PASC Interpretation 1003.2 #196 is applied, removing three lines of text dealing with ranges of symbolic names using position constant values which had been erroneously included in the final 1003.2b draft. |

A.6.4.1 State-Dependent Character Encodings

A requirement was considered that would force utilities to eliminate any redundant locking shifts, but this was left as a quality of implementation issue.

This change satisfies the following requirement from the ISO POSIX-2: 1993 standard, Annex H.1:

> *The support of state-dependent (shift encoding) character sets should be addressed fully. See descriptions of these in the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.2, Character Encoding. If such character encodings are supported, it is expected that this will impact the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.2, Character Encoding, the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale, the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 9, Regular Expressions , and the comm, cut, diff, grep, head, join, paste, and tail utilities.*

The character set description file provides:

- The capability to describe character set attributes (such as collation order or character classes) independent of character set encoding, and using only the characters in the portable character set. This makes it possible to create generic *localedef* source files for all codesets that share the portable character set (such as the ISO 8859 family or IBM Extended ASCII).
- Standardized symbolic names for all characters in the portable character set, making it possible to refer to any such character regardless of encoding.

Implementations are free to choose their own symbolic names, as long as the names identified by this volume of IEEE Std 1003.1-200x are also defined; this provides support for already existing ‘‘character names’’.

The names selected for the members of the portable character set follow the ISO/IEC 8859-1: 1998 standard and the ISO/IEC 10646-1: 2000 standard. However, several commonly used UNIX system names occur as synonyms in the list:

- The historical UNIX system names are used for control characters.

- The word ‘‘slash’’ is given in addition to ‘‘solidus’’.
- The word ‘‘backslash’’ is given in addition to ‘‘reverse-solidus’’.
- The word ‘‘hyphen’’ is given in addition to ‘‘hyphen-minus’’.
- The word ‘‘period’’ is given in addition to ‘‘full-stop’’.
- For digits, the word ‘‘digit’’ is eliminated.
- For letters, the words ‘‘Latin Capital Letter’’ and ‘‘Latin Small Letter’’ are eliminated.
- The words ‘‘left brace’’ and ‘‘right brace’’ are given in addition to ‘‘left-curly-bracket’’ and ‘‘right-curly-bracket’’.
- The names of the digits are preferred over the numbers to avoid possible confusion between `'0'` and `'O'`, and between `'1'` and `'l'` (one and the letter ell).

The names for the control characters in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 6, Character Set were taken from the ISO/IEC 4873: 1991 standard.

The charmap file was introduced to resolve problems with the portability of, especially, *localedef* sources. IEEE Std 1003.1-200x assumes that the portable character set is constant across all locales, but does not prohibit implementations from supporting two incompatible codings, such as both ASCII and EBCDIC. Such dual-support implementations should have all charmaps and *localedef* sources encoded using one portable character set, in effect cross-compiling for the other environment. Naturally, charmaps (and *localedef* sources) are only portable without transformation between systems using the same encodings for the portable character set. They can, however, be transformed between two sets using only a subset of the actual characters (the portable character set). However, the particular coded character set used for an application or an implementation does not necessarily imply different characteristics or collation; on the contrary, these attributes should in many cases be identical, regardless of codeset. The charmap provides the capability to define a common locale definition for multiple codesets (the same *localedef* source can be used for codesets with different extended characters; the ability in the charmap to define empty names allows for characters missing in certain codesets).

The **<escape_char>** declaration was added at the request of the international community to ease the creation of portable charmap files on terminals not implementing the default backslash escape. The **<comment_char>** declaration was added at the request of the international community to eliminate the potential confusion between the number sign and the pound sign.

The octal number notation with no leading zero required was selected to match those of *awk* and *tr* and is consistent with that used by *localedef*. To avoid confusion between an octal constant and the back-references used in *localedef* source, the octal, hexadecimal, and decimal constants shall contain at least two digits. As single-digit constants are relatively rare, this should not impose any significant hardship. Provision is made for more digits to account for systems in which the byte size is larger than 8 bits. For example, a Unicode (ISO/IEC 10646-1: 2000 standard) system that has defined 16-bit bytes may require six octal, four hexadecimal, and five decimal digits.

The decimal notation is supported because some newer international standards define character values in decimal, rather than in the old column/row notation.

The charmap identifies the coded character sets supported by an implementation. At least one charmap shall be provided, but no implementation is required to provide more than one. Likewise, implementations can allow users to generate new charmaps (for instance, for a new version of the ISO 8859 family of coded character sets), but does not have to do so. If users are allowed to create new charmaps, the system documentation describes the rules that apply (for instance, ‘‘only coded character sets that are supersets of the ISO/IEC 646: 1991 standard IRV, no multi-byte characters'').

This addition of the **WIDTH** specification satisfies the following requirement from the ISO POSIX-2: 1993 standard, Annex H.1:

> (9) *The definition of column position relies on the implementation's knowledge of the integral width of the characters. The charmap or LC_CTYPE locale definitions should be enhanced to allow application specification of these widths.*

The character ''width'' information was first considered for inclusion under *LC_CTYPE* but was moved because it is more closely associated with the information in the *charmap* than information in the locale source (cultural conventions information). Concerns were raised that formalizing this type of information is moving the locale source definition from the codeset-independent entity that it was designed to be to a repository of codeset-specific information. A similar issue occurred with the **<code_set_name>**, **<mb_cur_max>**, and **<mb_cur_min>** information, which was resolved to reside in the *charmap* definition.

The width definition was added to the IEEE P1003.2b draft standard with the intent that the *wcswidth*( ) and/or *wcwidth*( ) functions (currently specified in the System Interfaces volume of IEEE Std 1003.1-200x) be the mechanism to retrieve the character width information.

A.7 Locale

A.7.1 General

The description of locales is based on work performed in the UniForum Technical Committee Subcommittee on Internationalization. Wherever appropriate, keywords are taken from the ISO C standard or the X/Open Portability Guide.

The value used to specify a locale with environment variables is the name specified as the *name* operand to the *localedef* utility when the locale was created. This provides a verifiable method to create and invoke a locale.

The ''object'' definitions need not be portable, as long as ''source'' definitions are. Strictly speaking, source definitions are portable only between implementations using the same character set(s). Such source definitions, if they use symbolic names only, easily can be ported between systems using different codesets, as long as the characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set) have common values between the codesets; this is frequently the case in historical implementations. Of source, this requires that the symbolic names used for characters outside the portable character set be identical between character sets. The definition of symbolic names for characters is outside the scope of IEEE Std 1003.1-200x, but is certainly within the scope of other standards organizations.

Applications can select the desired locale by invoking the *setlocale*( ) function (or equivalent) with the appropriate value. If the function is invoked with an empty string, the value of the corresponding environment variable is used. If the environment variable is not set or is set to the empty string, the implementation sets the appropriate environment as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

A.7.2 POSIX Locale

The POSIX locale is equal to the C locale. To avoid being classified as a C-language function, the name has been changed to the POSIX locale; the environment variable value can be either `"POSIX"` or, for historical reasons, `"C"`.

The POSIX definitions mirror the historical UNIX system behavior.

The use of symbolic names for characters in the tables does not imply that the POSIX locale must be described using symbolic character names, but merely that it may be advantageous to do so.

A.7.3 Locale Definition

The decision to separate the file format from the *localedef* utility description was only partially editorial. Implementations may provide other interfaces than *localedef*. Requirements on ‘‘the utility’’, mostly concerning error messages, are described in this way because they are meant to affect the other interfaces implementations may provide as well as *localedef*.

The text about POSIX2_LOCALEDEF does not mean that internationalization is optional; only that the functionality of the *localedef* utility is. REs, for instance, must still be able to recognize, for example, character class expressions such as `"[[:alpha:]]"`. A possible analogy is with an applications development environment; while all conforming implementations must be capable of executing applications, not all need to have the development environment installed. The assumption is that the capability to modify the behavior of utilities (and applications) via locale settings must be supported. If the *localedef* utility is not present, then the only choice is to select an existing (presumably implementation-documented) locale. An implementation could, for example, choose to support only the POSIX locale, which would in effect limit the amount of changes from historical implementations quite drastically. The *localedef* utility is still required, but would always terminate with an exit code indicating that no locale could be created. Supported locales must be documented using the syntax defined in this chapter. (This ensures that users can accurately determine what capabilities are provided. If the implementation decides to provide additional capabilities to the ones in this chapter, that is already provided for.)

If the option is present (that is, locales can be created), then the *localedef* utility must be capable of creating locales based on the syntax and rules defined in this chapter. This does not mean that the implementation cannot also provide alternate means for creating locales.

The octal, decimal, and hexadecimal notations are the same employed by the charmap facility (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.4, Character Set Description File). To avoid confusion between an octal constant and a back-reference, the octal, hexadecimal, and decimal constants must contain at least two digits. As single-digit constants are relatively rare, this should not impose any significant hardship. Provision is made for more digits to account for systems in which the byte size is larger than 8 bits. For example, a Unicode (see the ISO/IEC 10646-1:2000 standard) system that has defined 16-bit bytes may require six octal, four hexadecimal, and five decimal digits. As with the charmap file, multi-byte characters are described in the locale definition file using ‘‘big-endian’’ notation for reasons of portability. There is no requirement that the internal representation in the computer memory be in this same order.

One of the guidelines used for the development of this volume of IEEE Std 1003.1-200x is that characters outside the invariant part of the ISO/IEC 646:1991 standard should not be used in portable specifications. The backslash character is not in the invariant part; the number sign is, but with multiple representations: as a number sign, and as a pound sign. As far as general usage of these symbols, they are covered by the ‘‘grandfather clause’’, but for newly defined interfaces, the WG15 POSIX working group has requested that POSIX provide alternate representations. Consequently, while the default escape character remains the backslash and the default comment character is the number sign, implementations are required to recognize alternative representations, identified in the applicable source file via the **<escape_char>** and **<comment_char>** keywords.

A.7.3.1 LC_CTYPE

The *LC_CTYPE* category is primarily used to define the encoding-independent aspects of a character set, such as character classification. In addition, certain encoding-dependent characteristics are also defined for an application via the *LC_CTYPE* category. IEEE Std 1003.1-200x does not mandate that the encoding used in the locale is the same as the one used by the application because an implementation may decide that it is advantageous to define locales in a system-wide encoding rather than having multiple, logically identical locales in different encodings, and to convert from the application encoding to the system-wide encoding on usage. Other implementations could require encoding-dependent locales.

In either case, the *LC_CTYPE* attributes that are directly dependent on the encoding, such as **<mb_cur_max>** and the display width of characters, are not user-specifiable in a locale source and are consequently not defined as keywords.

Implementations may define additional keywords or extend the *LC_CTYPE* mechanism to allow application-defined keywords.

The text ‘‘The ellipsis specification shall only be valid within a single encoded character set’’ is present because it is possible to have a locale supported by multiple character encodings, as explained in the rationale for the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set. An example given there is of a possible Japanese-based locale supported by a mixture of the character sets JIS X 0201 Roman, JIS X 0208, and JIS X 0201 Katakana. Attempting to express a range of characters across these sets is not logical and the implementation is free to reject such attempts.

As the *LC_CTYPE* character classes are based on the ISO C standard character class definition, the category does not support multi-character elements. For instance, the German character <sharp-s> is traditionally classified as a lowercase letter. There is no corresponding uppercase letter; in proper capitalization of German text, the <sharp-s> will be replaced by "SS"; that is, by two characters. This kind of conversion is outside the scope of the **toupper** and **tolower** keywords.

Where IEEE Std 1003.1-200x specifies that only certain characters can be specified, as for the keywords **digit** and **xdigit**, the specified characters shall be from the portable character set, as shown. As an example, only the Arabic digits 0 through 9 are acceptable as digits.

The character classes **digit**, **xdigit**, **lower**, **upper**, and **space** have a set of automatically included characters. These only need to be specified if the character values (that is, encoding) differs from the implementation default values. It is not possible to define a locale without these automatically included characters unless some implementation extension is used to prevent their inclusion. Such a definition would not be a proper superset of the C locale, and thus, it might not be possible for the standard utilities to be implemented as programs conforming to the ISO C standard.

The definition of character class **digit** requires that only ten characters—the ones defining digits—can be specified; alternate digits (for example, Hindi or Kanji) cannot be specified here. However, the encoding may vary if an implementation supports more than one encoding.

The definition of character class **xdigit** requires that the characters included in character class **digit** are included here also and allows for different symbols for the hexadecimal digits 10 through 15.

The inclusion of the **charclass** keyword satisfies the following requirement from the ISO POSIX-2: 1993 standard, Annex H.1:

(3) *The LC_CTYPE (2.5.2.1) locale definition should be enhanced to allow user-specified additional character classes, similar in concept to the ISO C standard Multibyte Support Extension (MSE) is_wctype( ) function.*

This keyword was previously included in The Open Group specifications and is now mandated in the Shell and Utilities volume of IEEE Std 1003.1-200x.

The symbolic constant {CHARCLASS_NAME_MAX} was also adopted from The Open Group specifications. Application portability is enhanced by the use of symbolic constants.

A.7.3.2 LC_COLLATE

The rules governing collation depend to some extent on the use. At least five different levels of increasingly complex collation rules can be distinguished:

1. *Byte/machine code order*: This is the historical collation order in the UNIX system and many proprietary operating systems. Collation is here performed character by character, without any regard to context. The primary virtue is that it usually is quite fast and also completely deterministic; it works well when the native machine collation sequence matches the user expectations.

2. *Character order*: On this level, collation is also performed character by character, without regard to context. The order between characters is, however, not determined by the code values, but on the expectations by the user of the ‘‘correct’’ order between characters. In addition, such a (simple) collation order can specify that certain characters collate equally (for example, uppercase and lowercase letters).

3. *String ordering*: On this level, entire strings are compared based on relatively straightforward rules. Several ‘‘passes’’ may be required to determine the order between two strings. Characters may be ignored in some passes, but not in others; the strings may be compared in different directions; and simple string substitutions may be performed before strings are compared. This level is best described as ‘‘dictionary’’ ordering; it is based on the spelling, not the pronunciation, or meaning, of the words.

4. *Text search ordering*: This is a further refinement of the previous level, best described as ‘‘telephone book ordering’’; some common homonyms (words spelled differently but with the same pronunciation) are collated together; numbers are collated as if they were spelled out, and so on.

5. *Semantic-level ordering*: Words and strings are collated based on their meaning; entire words (such as ‘‘the’’) are eliminated; the ordering is not deterministic. This usually requires special software and is highly dependent on the intended use.

While the historical collation order formally is at level 1, for the English language it corresponds roughly to elements at level 2. The user expects to see the output from the *ls* utility sorted very much as it would be in a dictionary. While telephone book ordering would be an optimal goal for standard collation, this was ruled out as the order would be language-dependent. Furthermore, a requirement was that the order must be determined solely from the text string and the collation rules; no external information (for example, ‘‘pronunciation dictionaries’’) could be required.

As a result, the goal for the collation support is at level 3. This also matches the requirements for the Canadian collation order, as well as other, known collation requirements for alphabetic scripts. It specifically rules out collation based on pronunciation rules or based on semantic analysis of the text.

The syntax for the *LC_COLLATE* category source meets the requirements for level 3 and has been verified to produce the correct result with examples based on French, Canadian, and Danish collation order. Because it supports multi-character collating elements, it is also capable of supporting collation in codesets where a character is expressed using non-spacing characters followed by the base character (such as the ISO / IEC 6937: 1994 standard).

The directives that can be specified in an operand to the **order_start** keyword are based on the requirements specified in several proposed standards and in customary use. The following is a rephrasing of rules defined for ‘‘lexical ordering in English and French’’ by the Canadian Standards Association (the text in square brackets is rephrased):

- Once special characters [punctuation] have been removed from original strings, the ordering is determined by scanning forwards (left to right) [disregarding case and diacriticals].
- In case of equivalence, special characters are once again removed from original strings and the ordering is determined by scanning backwards (starting from the rightmost character of the string and back), character by character [disregarding case but considering diacriticals].
- In case of repeated equivalence, special characters are removed again from original strings and the ordering is determined by scanning forwards, character by character [considering both case and diacriticals].
- If there is still an ordering equivalence after the first three rules have been applied, then only special characters and the position they occupy in the string are considered to determine ordering. The string that has a special character in the lowest position comes first. If two strings have a special character in the same position, the character [with the lowest collation value] comes first. In case of equality, the other special characters are considered until there is a difference or until all special characters have been exhausted.

It is estimated that this part of IEEE Std 1003.1-200x covers the requirements for all European languages, and no particular problems are anticipated with Slavic or Middle East character sets.

The Far East (particularly Japanese / Chinese) collations are often based on contextual information and pronunciation rules (the same ideogram can have different meanings and different pronunciations). Such collation, in general, falls outside the desired goal of IEEE Std 1003.1-200x. There are, however, several other collation rules (stroke / radical or ‘‘most common pronunciation’’) that can be supported with the mechanism described here.

The character order is defined by the order in which characters and elements are specified between the **order_start** and **order_end** keywords. Weights assigned to the characters and elements define the collation sequence; in the absence of weights, the character order is also the collation sequence.

The **position** keyword provides the capability to consider, in a compare, the relative position of characters not subject to **IGNORE**. As an example, consider the two strings `"o-ring"` and `"or-ing"`. Assuming the hyphen is subject to **IGNORE** on the first pass, the two strings compare equal, and the position of the hyphen is immaterial. On second pass, all characters except the hyphen are subject to **IGNORE**, and in the normal case the two strings would again compare equal. By taking position into account, the first collates before the second.

A.7.3.3 LC_MONETARY

The currency symbol does not appear in *LC_MONETARY* because it is not defined in the C locale of the ISO C standard.

The ISO C standard limits the size of decimal points and thousands delimiters to single-byte values. In locales based on multi-byte coded character sets, this cannot be enforced; IEEE Std 1003.1-200x does not prohibit such characters, but makes the behavior unspecified (in the text ''In contexts where other standards ...'').

The grouping specification is based on, but not identical to, the ISO C standard. The −1 signals that no further grouping shall be performed; the equivalent of {CHAR_MAX} in the ISO C standard.

The text ''the value is not available in the locale'' is taken from the ISO C standard and is used instead of the ''unspecified'' text in early proposals. There is no implication that omitting these keywords or assigning them values of `" "` or −1 produces unspecified results; such omissions or assignments eliminate the effects described for the keyword or produce zero-length strings, as appropriate.

The locale definition is an extension of the ISO C standard *localeconv*( ) specification. In particular, rules on how **currency_symbol** is treated are extended to also cover **int_curr_symbol**, and **p_set_by_space** and **n_sep_by_space** have been augmented with the value 2, which places a <space> between the sign and the symbol (if they are adjacent; otherwise, it should be treated as a 0). The following table shows the result of various combinations:

		p_sep_by_space		
		2	**1**	**0**
p_cs_precedes = 1	**p_sign_posn** = 0	`($1.25)`	`($ 1.25)`	`($1.25)`
	p_sign_posn = 1	`+ $1.25`	`+$ 1.25`	`+$1.25`
	p_sign_posn = 2	`$1.25 +`	`$ 1.25+`	`$1.25+`
	p_sign_posn = 3	`+ $1.25`	`+$ 1.25`	`+$1.25`
	p_sign_posn = 4	`$ +1.25`	`$+ 1.25`	`$+1.25`
p_cs_precedes = 0	**p_sign_posn** = 0	`(1.25 $)`	`(1.25 $)`	`(1.25$)`
	p_sign_posn = 1	`+1.25 $`	`+1.25 $`	`+1.25$`
	p_sign_posn = 2	`1.25$ +`	`1.25 $+`	`1.25$+`
	p_sign_posn = 3	`1.25+ $`	`1.25 +$`	`1.25+$`
	p_sign_posn = 4	`1.25$ +`	`1.25 $+`	`1.25$+`

The following is an example of the interpretation of the **mon_grouping** keyword. Assuming that the value to be formatted is 123456789 and the **mon_thousands_sep** is `'''`, then the following table shows the result. The third column shows the equivalent string in the ISO C standard that would be used by the *localeconv*( ) function to accommodate this grouping.

mon_grouping	**Formatted Value**	**ISO C String**
3;−1	123456'789	`"\3\177"`
3	123'456'789	`"\3"`
3;2;−1	1234'56'789	`"\3\2\177"`
3;2	12'34'56'789	`"\3\2"`
−1	123456789	`"\177"`

In these examples, the octal value of {CHAR_MAX} is 177.

A.7.3.4 *LC_NUMERIC*

See the rationale for *LC_MONETARY* for a description of the behavior of grouping.

A.7.3.5 *LC_TIME*

Although certain of the conversion specifications in the POSIX locale (such as the name of the month) are shown with initial capital letters, this need not be the case in other locales. Programs using these conversion specifications may need to adjust the capitalization if the output is going to be used at the beginning of a sentence.

The *LC_TIME* descriptions of **abday**, **day**, **mon**, and **abmon** imply a Gregorian style calendar (7-day weeks, 12-month years, leap years, and so on). Formatting time strings for other types of calendars is outside the scope of IEEE Std 1003.1-200x.

While the ISO 8601: 2000 standard numbers the weekdays starting with Monday, historical practice is to use the Sunday as the first day. Rather than change the order and introduce potential confusion, the days must be specified beginning with Sunday; previous references to ‘‘first day’’ have been removed. Note also that the Shell and Utilities volume of IEEE Std 1003.1-200x *date* utility supports numbering compliant with the ISO 8601: 2000 standard. |

As specified under *date* in the Shell and Utilities volume of IEEE Std 1003.1-200x and *strftime*( ) in the System Interfaces volume of IEEE Std 1003.1-200x, the conversion specifications corresponding to the optional keywords consist of a modifier followed by a traditional conversion specification (for instance, `%Ex`). If the optional keywords are not supported by the implementation or are unspecified for the current locale, these modified conversion specifications are treated as the traditional conversion specifications. For example, assume the following keywords:

```
alt_digits   "0th";"1st";"2nd";"3rd";"4th";"5th";\
             "6th";"7th";"8th";"9th";"10th"

d_fmt        "The %Od day of %B in %Y"
```

On July 4th 1776, the `%x` conversion specifications would result in `"The 4th day of July in 1776"`, while on July 14th 1789 it would result in `"The 14 day of July in 1789"`. It can be noted that the above example is for illustrative purposes only; the `%O` modifier is primarily intended to provide for Kanji or Hindi digits in *date* formats.

The following is an example for Japan that supports the current plus last three Emperors and reverts to Western style numbering for years prior to the Meiji era. The example also allows for the custom of using a special name for the first year of an era instead of using 1. (The examples substitute romaji where kanji should be used.)

```
era_d_fmt "%EY%mgatsu%dnichi (%a)"

era    "+:2:1990/01/01:+*:Heisei:%EC%Eynen";\
       "+:1:1989/01/08:1989/12/31:Heisei:%ECgannen";\
       "+:2:1927/01/01:1989/01/07:Shouwa:%EC%Eynen";\
       "+:1:1926/12/25:1926/12/31:Shouwa:%ECgannen";\
       "+:2:1913/01/01:1926/12/24:Taishou:%EC%Eynen";\
       "+:1:1912/07/30:1912/12/31:Taishou:%ECgannen";\
       "+:2:1869/01/01:1912/07/29:Meiji:%EC%Eynen";\
       "+:1:1868/09/08:1868/12/31:Meiji:%ECgannen";\
       "-:1868:1868/09/07:-*::%Ey"
```

Assuming that the current date is September 21, 1991, a request to *date* or *strftime*( ) would yield the following results:

```
%Ec - Heisei3nen9gatsu21nichi (Sat) 14:39:26
%EC - Heisei
%Ex - Heisei3nen9gatsu21nichi (Sat)
%Ey - 3
%EY - Heisei3nen
```

Example era definitions for the Republic of China:

```
era     "+:2:1913/01/01:+*:ChungHwaMingGuo:%EC%EyNen";\
        "+:1:1912/1/1:1912/12/31:ChungHwaMingGuo:%ECYuenNen";\
        "+:1:1911/12/31:-*:MingChien:%EC%EyNen"
```

Example definitions for the Christian Era:

```
era     "+:0:0001/01/01:+*:AD:%EC %Ey";\
        "+:1:-0001/12/31:-*:BC:%Ey %EC"
```

A.7.3.6 LC_MESSAGES

The **yesstr** and **nostr** locale keywords and the YESSTR and NOSTR *langinfo* items were formerly used to match user affirmative and negative responses. In IEEE Std 1003.1-200x, the **yesexpr**, **noexpr**, YESEXPR, and NOEXPR extended regular expressions have replaced them. Applications should use the general locale-based messaging facilities to issue prompting messages which include sample desired responses.

A.7.4 Locale Definition Grammar

There is no additional rationale provided for this section.

A.7.4.1 Locale Lexical Conventions

There is no additional rationale provided for this section.

A.7.4.2 Locale Grammar

There is no additional rationale provided for this section.

A.7.5 Locale Definition Example

The following is an example of a locale definition file that could be used as input to the *localedef* utility. It assumes that the utility is executed with the −**f** option, naming a *charmap* file with (at least) the following content:

```
CHARMAP
<space>      \x20
<dollar>     \x24
<A>          \101
<a>          \141
<A-acute>    \346
<a-acute>    \365
<A-grave>    \300
<a-grave>    \366
<b>          \142
<C>          \103
<c>          \143
<c-cedilla>  \347
<d>          \x64
<H>          \110
<h>          \150
<eszet>      \xb7
<s>          \x73
<z>          \x7a
END CHARMAP
```

It should not be taken as complete or to represent any actual locale, but only to illustrate the syntax.

```
#
LC_CTYPE
lower   <a>;<b>;<c>;<c-cedilla>;<d>;...;<z>
upper   A;B;C;Ç;...;Z
space   \x20;\x09;\x0a;\x0b;\x0c;\x0d
blank   \040;\011
toupper (<a>,<A>);(b,B);(c,C);(ç,Ç);(d,D);(z,Z)
END LC_CTYPE
#
LC_COLLATE
#
# The following example of collation is based on
# Canadian standard Z243.4.1-1998, "Canadian Alphanumeric
# Ordering Standard For Character sets of CSA Z234.4 Standard".
# (Other parts of this example locale definition file do not
# purport to relate to Canada, or to any other real culture.)
# The proposed standard defines a 4-weight collation, such that
# in the first pass, characters are compared without regard to
# case or accents; in second pass, backwards compare without
# regard to case; in the third pass, forward compare without
# regard to diacriticals. In the 3 first passes, non-alphabetic
# characters are ignored; in the fourth pass, only special
# characters are considered, such that "The string that has a
# special character in the lowest position comes first. If two
# strings have a special character in the same position, the
# collation value of the special character determines ordering.
#
# Only a subset of the character set is used here; mostly to
# illustrate the set-up.
```

```
#

A.8 Environment Variables

A.8.1 Environment Variable Definition

The variable *environ* is not intended to be declared in any header, but rather to be declared by the user for accessing the array of strings that is the environment. This is the traditional usage of the symbol. Putting it into a header could break some programs that use the symbol for their own purposes.

The decision to restrict conforming systems to the use of digits, uppercase letters, and underscores for environment variable names allows applications to use lowercase letters in their environment variable names without conflicting with any conforming system.

In addition to the obvious conflict with the shell syntax for positional parameter substitution, some historical applications (including some shells) exclude names with leading digits from the environment.

A.8.2 Internationalization Variables

The text about locale implies that any utilities written in standard C and conforming to IEEE Std 1003.1-200x must issue the following call:

```
setlocale(LC_ALL, "")
```

If this were omitted, the ISO C standard specifies that the C locale would be used.

If any of the environment variables are invalid, it makes sense to default to an implementation-defined, consistent locale environment. It is more confusing for a user to have partial settings occur in case of a mistake. All utilities would then behave in one language/cultural environment. Furthermore, it provides a way of forcing the whole environment to be the implementation-defined default. Disastrous results could occur if a pipeline of utilities partially uses the environment variables in different ways. In this case, it would be appropriate for utilities that use *LANG* and related variables to exit with an error if any of the variables are invalid. For example, users typing individual commands at a terminal might want *date* to work if *LC_MONETARY* is invalid as long as *LC_TIME* is valid. Since these are conflicting reasonable alternatives, IEEE Std 1003.1-200x leaves the results unspecified if the locale environment variables would not produce a complete locale matching the specification of the user.

The locale settings of individual categories cannot be truly independent and still guarantee correct results. For example, when collating two strings, characters must first be extracted from each string (governed by *LC_CTYPE*) before being mapped to collating elements (governed by *LC_COLLATE*) for comparison. That is, if *LC_CTYPE* is causing parsing according to the rules of a large, multi-byte code set (potentially returning 20 000 or more distinct character codeset values), but *LC_COLLATE* is set to handle only an 8-bit codeset with 256 distinct characters, meaningful results are obviously impossible.

The *LC_MESSAGES* variable affects the language of messages generated by the standard utilities.

The description of the environment variable names starting with the characters ‘‘LC_’’ acknowledges the fact that the interfaces presented may be extended as new international functionality is required. In the ISO C standard, names preceded by ‘‘LC_’’ are reserved in the name space for future categories.

To avoid name clashes, new categories and environment variables are divided into two classifications: *implementation-independent* and *implementation-defined*.

Implementation-independent names will have the following format:

`LC_NAME`

where *NAME* is the name of the new category and environment variable. Capital letters must be used for implementation-independent names.

Implementation-defined names must be in lowercase letters, as below:

`LC_name`

A.8.3 Other Environment Variables

The quoted form of the timezone variable allows timezone names of the form UTC+1 (or any name that contains the character plus (`'+'`), the character minus (`'−'`), or digits), which may be appropriate for countries that do not have an official timezone name. It would be coded as <UTC+1>+1<UTC+2>, which would cause *std* to have a value of UTC+1 and *dst* a value of UTC+2, each with a length of 5 characters. This does not appear to conflict with any existing usage. The characters `'<'` and `'>'` were chosen for quoting because they are easier to parse visually than a quoting character that does not provide some sense of bracketing (and in a string like this, such bracketing is helpful). They were also chosen because they do not need special treatment when assigning to the *TZ* variable. Users are often confused by embedding quotes in a string. Because `'<'` and `'>'` are meaningful to the shell, the whole string would have to be quoted, but that is easily explained. (Parentheses would have presented the same problems.) Although the `'>'` symbol could have been permitted in the string by either escaping it or doubling it, it seemed of little value to require that. This could be provided as an extension if there was a need. Timezone names of this new form lead to a requirement that the value of {_POSIX_TZNAME_MAX} change from 3 to 6.

COLUMNS, LINES

The default value for the number of column positions, *COLUMNS*, and screen height, *LINES*, are unspecified because historical implementations use different methods to determine values corresponding to the size of the screen in which the utility is run. This size is typically known to the implementation through the value of *TERM*, or by more elaborate methods such as extensions to the *stty* utility or knowledge of how the user is dynamically resizing windows on a bit-mapped display terminal. Users should not need to set these variables in the environment unless there is a specific reason to override the default behavior of the implementation, such as to display data in an area arbitrarily smaller than the terminal or window. Values for these variables that are not decimal integers greater than zero are implicitly undefined values; it is unnecessary to enumerate all of the possible values outside of the acceptable set.

PATH

Many historical implementations of the Bourne shell do not interpret a trailing colon to represent the current working directory and are thus non-conforming. The C Shell and the KornShell conform to IEEE Std 1003.1-200x on this point. The usual name of dot may also be used to refer to the current working directory.

Many implementations historically have used a default value of **/bin** and **/usr/bin** for the *PATH* variable. IEEE Std 1003.1-200x does not mandate this default path be identical to that retrieved from *getconf* _CS_PATH because it is likely that the standardized utilities may be provided in another directory separate from the directories used by some historical applications.

LOGNAME

In most implementations, the value of such a variable is easily forged, so security-critical applications should rely on other means of determining user identity. *LOGNAME* is required to be constructed from the portable filename character set for reasons of interchange. No diagnostic condition is specified for violating this rule, and no requirement for enforcement exists. The intent of the requirement is that if extended characters are used, the ‘‘guarantee’’ of portability implied by a standard is void.

SHELL

The *SHELL* variable names the preferred shell of the user; it is a guide to applications. There is no direct requirement that that shell conform to IEEE Std 1003.1-200x; that decision should rest with the user. It is the intention of the standard developers that alternative shells be permitted, if the user chooses to develop or acquire one. An operating system that builds its shell into the ‘‘kernel’’ in such a manner that alternative shells would be impossible does not conform to the spirit of IEEE Std 1003.1-200x.

CHANGE HISTORY

Issue 6

Changed format of *TZ* field to allow for the quoted form as defined in previous versions of the ISO POSIX-1 standard.

A.9 Regular Expressions

Rather than repeating the description of REs for each utility supporting REs, the standard developers preferred a common, comprehensive description of regular expressions in one place. The most common behavior is described here, and exceptions or extensions to this are documented for the respective utilities, as appropriate.

The BRE corresponds to the *ed* or historical *grep* type, and the ERE corresponds to the historical *egrep* type (now *grep* −**E**).

The text is based on the *ed* description and substantially modified, primarily to aid developers and others in the understanding of the capabilities and limitations of REs. Much of this was influenced by internationalization requirements.

It should be noted that the definitions in this section do not cover the *tr* utility; the *tr* syntax does not employ REs.

The specification of REs is particularly important to internationalization because pattern matching operations are very basic operations in business and other operations. The syntax and rules of REs are intended to be as intuitive as possible to make them easy to understand and use. The historical rules and behavior do not provide that capability to non-English language users, and do not provide the necessary support for commonly used characters and language constructs. It was necessary to provide extensions to the historical RE syntax and rules to accommodate other languages.

As they are limited to bracket expressions, the rationale for these modifications is in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3.5, RE Bracket Expression.

A.9.1 Regular Expression Definitions

It is possible to determine what strings correspond to subexpressions by recursively applying the leftmost longest rule to each subexpression, but only with the proviso that the overall match is leftmost longest. For example, matching `"\(ac*\)c*d[ac]*\1"` against *acdacaaa* matches *acdacaaa* (with \1=*a*); simply matching the longest match for `"\(ac*\)"` would yield \1=*ac*, but the overall match would be smaller (*acdac*). Conceptually, the implementation must examine every possible match and among those that yield the leftmost longest total matches, pick the one that does the longest match for the leftmost subexpression, and so on. Note that this means that matching by subexpressions is context-dependent: a subexpression within a larger RE may match a different string from the one it would match as an independent RE, and two instances of the same subexpression within the same larger RE may match different lengths even in similar sequences of characters. For example, in the ERE `"(a.*b)(a.*b)"`, the two identical subexpressions would match four and six characters, respectively, of *accbaccccb*.

The definition of *single character* has been expanded to include also collating elements consisting of two or more characters; this expansion is applicable only when a bracket expression is included in the BRE or ERE. An example of such a collating element may be the Dutch *ij*, which collates as a `'y'`. In some encodings, a ligature "i with j" exists as a character and would represent a single-character collating element. In another encoding, no such ligature exists, and the two-character sequence *ij* is defined as a multi-character collating element. Outside brackets, the *ij* is treated as a two-character RE and matches the same characters in a string. Historically, a bracket expression only matched a single character. The ISO POSIX-2:1993 standard required bracket expressions like `"[^[:lower:]]"` to match multi-character collating elements such as `"ij"`. However, this requirement led to behavior that many users did not expect and that could not feasibly be mimicked in user code, and it was rarely if ever implemented correctly. The current standard leaves it unspecified whether a bracket expression matches a multi-character collating element, allowing both historical and ISO POSIX-2:1993 standard implementations to conform.

Also, in the current standard, it is unspecified whether character class expressions like `"[:lower:]"` can include multi-character collating elements like `"ij"`; hence `"[[:lower:]]"` can match `"ij"`, and `"[^[:lower:]]"` can fail to match `"ij"`. Common practice is for a character class expression to match a collating element if it matches the collating element's first character.

A.9.2 Regular Expression General Requirements

The definition of which sequence is matched when several are possible is based on the leftmost-longest rule historically used by deterministic recognizers. This rule is easier to define and describe, and arguably more useful, than the first-match rule historically used by non-deterministic recognizers. It is thought that dependencies on the choice of rule are rare; carefully contrived examples are needed to demonstrate the difference.

A formal expression of the leftmost-longest rule is:

> The search is performed as if all possible suffixes of the string were tested for a prefix matching the pattern; the longest suffix containing a matching prefix is chosen, and the longest possible matching prefix of the chosen suffix is identified as the matching sequence.

Historically, most RE implementations only match lines, not strings. However, that is more an effect of the usage than of an inherent feature of REs themselves. Consequently, IEEE Std 1003.1-200x does not regard <newline>s as special; they are ordinary characters, and both a period and a non-matching list can match them. Those utilities (like *grep*) that do not allow <newline>s to match are responsible for eliminating any <newline> from strings before matching against the RE. The *regcomp*( ) function, however, can provide support for such processing without violating the rules of this section.

Some implementations of *egrep* have had very limited flexibility in handling complex EREs. IEEE Std 1003.1-200x does not attempt to define the complexity of a BRE or ERE, but does place a lower limit on it—any RE must be handled, as long as it can be expressed in 256 bytes or less. (Of course, this does not place an upper limit on the implementation.) There are historical programs using a non-deterministic-recognizer implementation that should have no difficulty with this limit. It is possible that a good approach would be to attempt to use the faster, but more limited, deterministic recognizer for simple expressions and to fall back on the non-deterministic recognizer for those expressions requiring it. Non-deterministic implementations must be careful to observe the rules on which match is chosen; the longest match, not the first match, starting at a given character is used.

The term *invalid* highlights a difference between this section and some others: IEEE Std 1003.1-200x frequently avoids mandating of errors for syntax violations because they can be used by implementors to trigger extensions. However, the authors of the internationalization features of REs wanted to mandate errors for certain conditions to identify usage problems or non-portable constructs. These are identified within this rationale as appropriate. The remaining syntax violations have been left implicitly or explicitly undefined. For example, the BRE construct `"\{1,2,3\}"` does not comply with the grammar. A conforming application cannot rely on it producing an error nor matching the literal characters `"\{1,2,3\}"`. The term ‘‘undefined’’ was used in favor of ‘‘unspecified’’ because many of the situations are considered errors on some implementations, and the standard developers considered that consistency throughout the section was preferable to mixing undefined and unspecified.

A.9.3 Basic Regular Expressions

There is no additional rationale provided for this section.

A.9.3.1 BREs Matching a Single Character or Collating Element

There is no additional rationale provided for this section.

A.9.3.2 BRE Ordinary Characters

There is no additional rationale provided for this section.

A.9.3.3 BRE Special Characters

There is no additional rationale provided for this section.

A.9.3.4 Periods in BREs

There is no additional rationale provided for this section.

A.9.3.5 RE Bracket Expression

Range expressions are, historically, an integral part of REs. However, the requirements of ‘‘natural language behavior’’ and portability do conflict. In the POSIX locale, ranges must be treated according to the collating sequence and include such characters that fall within the range based on that collating sequence, regardless of character values. In other locales, ranges have unspecified behavior.

Some historical implementations allow range expressions where the ending range point of one range is also the starting point of the next (for instance, `"[a–m–o]"`). This behavior should not be permitted, but to avoid breaking historical implementations, it is now *undefined* whether it is a valid expression and how it should be interpreted.

Current practice in *awk* and *lex* is to accept escape sequences in bracket expressions as per the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions, while the normal ERE behavior is to regard such a sequence as consisting of two characters. Allowing the *awk*/*lex* behavior in EREs would change the normal behavior in an unacceptable way; it is expected that *awk* and *lex* will decode escape sequences in EREs before passing them to *regcomp*( ) or comparable routines. Each utility describes the escape sequences it accepts as an exception to the rules in this section; the list is not the same, for historical reasons.

As noted previously, the new syntax and rules have been added to accommodate other languages than English. The remainder of this section describes the rationale for these modifications.

In the POSIX locale, a regular expression that starts with a range expression matches a set of strings that are contiguously sorted, but this is not necessarily true in other locales. For example, a French locale might have the following behavior:

```
$ ls
alpha   Alpha   estimé   ESTIMÉ   été   eurêka
$ ls [a-e]*
alpha   Alpha   estimé  eurêka
```

Such disagreements between matching and contiguous sorting are unavoidable because POSIX sorting cannot be implemented in terms of a deterministic finite-state automaton (DFA), but range expressions by design are implementable in terms of DFAs.

Historical implementations used native character order to interpret range expressions. The ISO POSIX-2: 1993 standard instead required collating element order (CEO): the order that collating elements were specified between the **order_start** and **order_end** keywords in the *LC_COLLATE* category of the current locale. CEO had some advantages in portability over the native character order, but it also had some disadvantages:

- CEO could not feasibly be mimicked in user code, leading to inconsistencies between POSIX matchers and matchers in popular user programs like Emacs, *ksh*, and Perl.
- CEO caused range expressions to match accented and capitalized letters contrary to many users' expectations. For example, `"[a-e]"` typically matched both `'E'` and `'á'` but neither `'A'` nor `'é'`.
- CEO was not consistent across implementations. In practice, CEO was often less portable than native character order. For example, it was common for the CEOs of two implementation-supplied locales to disagree, even if both locales were named `"da_DK"`.

Because of these problems, some implementations of regular expressions continued to use native character order. Others used the collation sequence, which is more consistent with sorting than either CEO or native order, but which departs further from the traditional POSIX semantics because it generally requires `"[a-e]"` to match either `'A'` or `'E'` but not both. As a result of this kind of implementation variation, programmers who wanted to write portable regular expressions could not rely on the ISO POSIX-2: 1993 standard guarantees in practice.

While revising the standard, lengthy consideration was given to proposals to attack this problem by adding an API for querying the CEO to allow user-mode matchers, but none of these proposals had implementation experience and none achieved consensus. Leaving the standard alone was also considered, but rejected due to the problems described above.

The current standard leaves unspecified the behavior of a range expression outside the POSIX locale. This makes it clearer that conforming applications should avoid range expressions outside the POSIX locale, and it allows implementations and compatible user-mode matchers to interpret range expressions using native order, CEO, collation sequence, or other, more advanced techniques.

The ISO POSIX-2: 1993 standard required `"[b-a]"` to be an invalid expression in the POSIX locale, but this requirement has been relaxed in this version of the standard so that `"[b-a]"` can instead be treated as a valid expression that does not match any string.

A.9.3.6 BREs Matching Multiple Characters

The limit of nine back-references to subexpressions in the RE is based on the use of a single-digit identifier; increasing this to multiple digits would break historical applications. This does not imply that only nine subexpressions are allowed in REs. The following is a valid BRE with ten subexpressions:

```
\(\(\(ab\)*c\)*d\)\(ef\)*\(gh\)\{2\}\(ij\)*\(kl\)*\(mn\)*\(op\)*\(qr\)*
```

The standard developers regarded the common historical behavior, which supported `"\n*"`, but not `"\n\{min,max\}"`, `"\(...\)*"`, or `"\(...\)\{min,max\}"`, as a non-intentional result of a specific implementation, and they supported both duplication and interval expressions following subexpressions and back-references.

The changes to the processing of the back-reference expression remove an unspecified or ambiguous behavior in the Shell and Utilities volume of IEEE Std 1003.1-200x, aligning it with the requirements specified for the *regcomp*( ) expression, and is the result of PASC Interpretation 1003.2-92 #43 submitted for the ISO POSIX-2: 1993 standard.

A.9.3.7 *BRE Precedence*

There is no additional rationale provided for this section.

A.9.3.8 *BRE Expression Anchoring*

Often, the dollar sign is viewed as matching the ending <newline> in text files. This is not strictly true; the <newline> is typically eliminated from the strings to be matched, and the dollar sign matches the terminating null character.

The ability of `'^'`, `'$'`, and `'*'` to be non-special in certain circumstances may be confusing to some programmers, but this situation was changed only in a minor way from historical practice to avoid breaking many historical scripts. Some consideration was given to making the use of the anchoring characters undefined if not escaped and not at the beginning or end of strings. This would cause a number of historical BREs, such as `"2^10"`, `"$HOME"`, and `"$1.35"`, that relied on the characters being treated literally, to become invalid.

However, one relatively uncommon case was changed to allow an extension used on some implementations. Historically, the BREs `"^foo"` and `"\(^foo\)"` did not match the same string, despite the general rule that subexpressions and entire BREs match the same strings. To increase consensus, IEEE Std 1003.1-200x has allowed an extension on some implementations to treat these two cases in the same way by declaring that anchoring *may* occur at the beginning or end of a subexpression. Therefore, portable BREs that require a literal circumflex at the beginning or a dollar sign at the end of a subexpression must escape them. Note that a BRE such as `"a\(^bc\)"` will either match `"a^bc"` or nothing on different systems under the rules.

ERE anchoring has been different from BRE anchoring in all historical systems. An unescaped anchor character has never matched its literal counterpart outside a bracket expression. Some implementations treated `"foo$bar"` as a valid expression that never matched anything; others treated it as invalid. IEEE Std 1003.1-200x mandates the former, valid unmatched behavior.

Some implementations have extended the BRE syntax to add alternation. For example, the subexpression `"\(foo$\|bar\)"` would match either `"foo"` at the end of the string or `"bar"` anywhere. The extension is triggered by the use of the undefined `"\|"` sequence. Because the BRE is undefined for portable scripts, the extending system is free to make other assumptions, such that the `'$'` represents the end-of-line anchor in the middle of a subexpression. If it were not for the extension, the `'$'` would match a literal dollar sign under the rules.

A.9.4 Extended Regular Expressions

As with BREs, the standard developers decided to make the interpretation of escaped ordinary characters undefined.

The right parenthesis is not listed as an ERE special character because it is only special in the context of a preceding left parenthesis. If found without a preceding left parenthesis, the right parenthesis has no special meaning.

The *interval expression*, `"{m,n}"`, has been added to EREs. Historically, the interval expression has only been supported in some ERE implementations. The standard developers estimated that the addition of interval expressions to EREs would not decrease consensus and would also make BREs more of a subset of EREs than in many historical implementations.

It was suggested that, in addition to interval expressions, back-references (`'\n'`) should also be added to EREs. This was rejected by the standard developers as likely to decrease consensus.

In historical implementations, multiple duplication symbols are usually interpreted from left to right and treated as additive. As an example, `"a+*b"` matches zero or more instances of `'a'` followed by a `'b'`. In IEEE Std 1003.1-200x, multiple duplication symbols are undefined; that is, they cannot be relied upon for conforming applications. One reason for this is to provide some scope for future enhancements.

The precedence of operations differs between EREs and those in *lex*; in *lex*, for historical reasons, interval expressions have a lower precedence than concatenation.

A.9.4.1 EREs Matching a Single Character or Collating Element

There is no additional rationale provided for this section.

A.9.4.2 ERE Ordinary Characters

There is no additional rationale provided for this section.

A.9.4.3 ERE Special Characters

There is no additional rationale provided for this section.

A.9.4.4 Periods in EREs

There is no additional rationale provided for this section.

A.9.4.5 ERE Bracket Expression

There is no additional rationale provided for this section.

A.9.4.6 EREs Matching Multiple Characters

There is no additional rationale provided for this section.

A.9.4.7 ERE Alternation

There is no additional rationale provided for this section.

A.9.4.8 ERE Precedence

There is no additional rationale provided for this section.

A.9.4.9 ERE Expression Anchoring

There is no additional rationale provided for this section.

A.9.5 Regular Expression Grammar

The grammars are intended to represent the range of acceptable syntaxes available to conforming applications. There are instances in the text where undefined constructs are described; as explained previously, these allow implementation extensions. There is no intended requirement that an implementation extension must somehow fit into the grammars shown here.

The BRE grammar does not permit L_ANCHOR or R_ANCHOR inside `"\("` and `"\)"` (which implies that `'^'` and `'$'` are ordinary characters). This reflects the semantic limits on the application, as noted in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3.8, BRE Expression Anchoring. Implementations are permitted to extend the language to interpret `'^'` and `'$'` as anchors in these locations, and as such, conforming applications cannot use unescaped `'^'` and `'$'` in positions inside `"\("` and `"\)"` that might be interpreted as anchors.

The ERE grammar does not permit several constructs that the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4.2, ERE Ordinary Characters and the Base Definitions volume of

IEEE Std 1003.1-200x, Section 9.4.3, ERE Special Characters specify as having undefined results:

- ORD_CHAR preceded by `'\'`
- *ERE_dupl_symbol*(s) appearing first in an ERE, or immediately following `'|'`, `'^'`, or `'('`
- `'{'` not part of a valid *ERE_dupl_symbol*
- `'|'` appearing first or last in an ERE, or immediately following `'|'` or `'('`, or immediately preceding `')'`

Implementations are permitted to extend the language to allow these. Conforming applications cannot use such constructs.

A.9.5.1 BRE/ERE Grammar Lexical Conventions

There is no additional rationale provided for this section.

A.9.5.2 RE and Bracket Expression Grammar

The removal of the *Back_open_paren Back_close_paren* option from the *nondupl_RE* specification is the result of PASC Interpretation 1003.2-92 #43 submitted for the ISO POSIX-2:1993 standard. Although the grammar required support for null subexpressions, this section does not describe the meaning of, and historical practice did not support, this construct.

A.9.5.3 ERE Grammar

There is no additional rationale provided for this section.

A.10 Directory Structure and Devices

A.10.1 Directory Structure and Files

A description of the historical **/usr/tmp** was omitted, removing any concept of differences in emphasis between the **/** and **/usr** directories. The descriptions of **/bin**, **/usr/bin**, **/lib**, and **/usr/lib** were omitted because they are not useful for applications. In an early draft, a distinction was made between system and application directory usage, but this was not found to be useful.

The directories **/** and **/dev** are included because the notion of a hierarchical directory structure is key to other information presented elsewhere in IEEE Std 1003.1-200x. In early drafts, it was argued that special devices and temporary files could conceivably be handled without a directory structure on some implementations. For example, the system could treat the characters `"/tmp"` as a special token that would store files using some non-POSIX file system structure. This notion was rejected by the standard developers, who required that all the files in this section be implemented via POSIX file systems.

The **/tmp** directory is retained in IEEE Std 1003.1-200x to accommodate historical applications that assume its availability. Implementations are encouraged to provide suitable directory names in the environment variable *TMPDIR* and applications are encouraged to use the contents of *TMPDIR* for creating temporary files.

The standard files **/dev/null** and **/dev/tty** are required to be both readable and writable to allow applications to have the intended historical access to these files.

The standard file **/dev/console** has been added for alignment with the Single UNIX Specification.

A.10.2 Output Devices and Terminal Types

There is no additional rationale provided for this section.

A.11 General Terminal Interface

If the implementation does not support this interface on any device types, it should behave as if it were being used on a device that is not a terminal device (in most cases *errno* will be set to [ENOTTY] on return from functions defined by this interface). This is based on the fact that many applications are written to run both interactively and in some non-interactive mode, and they adapt themselves at runtime. Requiring that they all be modified to test an environment variable to determine whether they should try to adapt is unnecessary. On a system that provides no general terminal interface, providing all the entry points as stubs that return [ENOTTY] (or an equivalent, as appropriate) has the same effect and requires no changes to the application.

Although the needs of both interface implementors and application developers were addressed throughout IEEE Std 1003.1-200x, this section pays more attention to the needs of the latter. This is because, while many aspects of the programming interface can be hidden from the user by the application developer, the terminal interface is usually a large part of the user interface. Although to some extent the application developer can build missing features or work around inappropriate ones, the difficulties of doing that are greater in the terminal interface than elsewhere. For example, efficiency prohibits the average program from interpreting every character passing through it in order to simulate character erase, line kill, and so on. These functions should usually be done by the operating system, possibly at the interrupt level.

The *tc**( ) functions were introduced as a way of avoiding the problems inherent in the traditional *ioctl*( ) function and in variants of it that were proposed. For example, *tcsetattr*( ) is specified in place of the use of the TCSETA *ioctl*( ) command function. This allows specification of all the arguments in a manner consistent with the ISO C standard unlike the varying third argument of *ioctl*( ), which is sometimes a pointer (to any of many different types) and sometimes an **int**.

The advantages of this new method include:

- It allows strict type checking.
- The direction of transfer of control data is explicit.
- Portable capabilities are clearly identified.
- The need for a general interface routine is avoided.
- Size of the argument is well-defined (there is only one type).

The disadvantages include:

- No historical implementation used the new method.
- There are many small routines instead of one general-purpose one.
- The historical parallel with *fcntl*( ) is broken.

The issue of modem control was excluded from IEEE Std 1003.1-200x on the grounds that:

- It was concerned with setting and control of hardware timers.
- The appropriate timers and settings vary widely internationally.

- Feedback from European computer manufacturers indicated that this facility was not consistent with European needs and that specification of such a facility was not a requirement for portability.

A.11.1 Interface Characteristics

A.11.1.1 Opening a Terminal Device File

There is no additional rationale provided for this section.

A.11.1.2 Process Groups

There is a potential race when the members of the foreground process group on a terminal leave that process group, either by exit or by changing process groups. After the last process exits the process group, but before the foreground process group ID of the terminal is changed (usually by a job-control shell), it would be possible for a new process to be created with its process ID equal to the terminal's foreground process group ID. That process might then become the process group leader and accidentally be placed into the foreground on a terminal that was not necessarily its controlling terminal. As a result of this problem, the controlling terminal is defined to not have a foreground process group during this time.

The cases where a controlling terminal has no foreground process group occur when all processes in the foreground process group either terminate and are waited for or join other process groups via *setpgid*( ) or *setsid*( ). If the process group leader terminates, this is the first case described; if it leaves the process group via *setpgid*( ), this is the second case described (a process group leader cannot successfully call *setsid*( )). When one of those cases causes a controlling terminal to have no foreground process group, it has two visible effects on applications. The first is the value returned by *tcgetpgrp*( ). The second (which occurs only in the case where the process group leader terminates) is the sending of signals in response to special input characters. The intent of IEEE Std 1003.1-200x is that no process group be wrongly identified as the foreground process group by *tcgetpgrp*( ) or unintentionally receive signals because of placement into the foreground.

In 4.3 BSD, the old process group ID continues to be used to identify the foreground process group and is returned by the function equivalent to *tcgetpgrp*( ). In that implementation it is possible for a newly created process to be assigned the same value as a process ID and then form a new process group with the same value as a process group ID. The result is that the new process group would receive signals from this terminal for no apparent reason, and IEEE Std 1003.1-200x precludes this by forbidding a process group from entering the foreground in this way. It would be more direct to place part of the requirement made by the last sentence under *fork*( ), but there is no convenient way for that section to refer to the value that *tcgetpgrp*( ) returns, since in this case there is no process group and thus no process group ID.

One possibility for a conforming implementation is to behave similarly to 4.3 BSD, but to prevent this reuse of the ID, probably in the implementation of *fork*( ), as long as it is in use by the terminal.

Another possibility is to recognize when the last process stops using the terminal's foreground process group ID, which is when the process group lifetime ends, and to change the terminal's foreground process group ID to a reserved value that is never used as a process ID or process group ID. (See the definition of *process group lifetime* in the definitions section.) The process ID can then be reserved until the terminal has another foreground process group.

The 4.3 BSD implementation permits the leader (and only member) of the foreground process group to leave the process group by calling the equivalent of *setpgid*( ) and to later return, expecting to return to the foreground. There are no known application needs for this behavior, and IEEE Std 1003.1-200x neither requires nor forbids it (except that it is forbidden for session leaders) by leaving it unspecified.

A.11.1.3 The Controlling Terminal

IEEE Std 1003.1-200x does not specify a mechanism by which to allocate a controlling terminal. This is normally done by a system utility (such as *getty*) and is considered an administrative feature outside the scope of IEEE Std 1003.1-200x.

Historical implementations allocate controlling terminals on certain *open*( ) calls. Since *open*( ) is part of POSIX.1, its behavior had to be dealt with. The traditional behavior is not required because it is not very straightforward or flexible for either implementations or applications. However, because of its prevalence, it was not practical to disallow this behavior either. Thus, a mechanism was standardized to ensure portable, predictable behavior in *open*( ).

Some historical implementations deallocate a controlling terminal on the last system-wide close. This behavior in neither required nor prohibited. Even on implementations that do provide this behavior, applications generally cannot depend on it due to its system-wide nature.

A.11.1.4 Terminal Access Control

The access controls described in this section apply only to a process that is accessing its controlling terminal. A process accessing a terminal that is not its controlling terminal is effectively treated the same as a member of the foreground process group. While this may seem unintuitive, note that these controls are for the purpose of job control, not security, and job control relates only to a process' controlling terminal. Normal file access permissions handle security.

If the process calling *read*( ) or *write*( ) is in a background process group that is orphaned, it is not desirable to stop the process group, as it is no longer under the control of a job control shell that could put it into foreground again. Accordingly, calls to *read*( ) or *write*( ) functions by such processes receive an immediate error return. This is different from 4.2 BSD, which kills orphaned processes that receive terminal stop signals. |

The foreground / background / orphaned process group check performed by the terminal driver must be repeatedly performed until the calling process moves into the foreground or until the process group of the calling process becomes orphaned. That is, when the terminal driver determines that the calling process is in the background and should receive a job control signal, it sends the appropriate signal (SIGTTIN or SIGTTOU) to every process in the process group of the calling process and then it allows the calling process to immediately receive the signal. The latter is typically performed by blocking the process so that the signal is immediately noticed. Note, however, that after the process finishes receiving the signal and control is returned to the driver, the terminal driver must reexecute the foreground / background / orphaned process group check. The process may still be in the background, either because it was continued in the background by a job-control shell, or because it caught the signal and did nothing.

The terminal driver repeatedly performs the foreground / background / orphaned process group checks whenever a process is about to access the terminal. In the case of *write*( ) or the control *tc**( ) functions, the check is performed at the entry of the function. In the case of *read*( ), the check is performed not only at the entry of the function, but also after blocking the process to wait for input characters (if necessary). That is, once the driver has determined that the process calling the *read*( ) function is in the foreground, it attempts to retrieve characters from the input queue. If the queue is empty, it blocks the process waiting for characters. When characters are available and control is returned to the driver, the terminal driver must return to the repeated foreground / background / orphaned process group check again. The process may have moved from the foreground to the background while it was blocked waiting for input characters.

A.11.1.5 Input Processing and Reading Data

There is no additional rationale provided for this section.

A.11.1.6 Canonical Mode Input Processing

The term *character* is intended here. ERASE should erase the last character, not the last byte. In the case of multi-byte characters, these two may be different.

4.3 BSD has a WERASE character that erases the last ‘‘word’’ typed (but not any preceding <blank>s or <tab>s). A word is defined as a sequence of non-<blank>s, with <tab>s counted as <blank>s. Like ERASE, WERASE does not erase beyond the beginning of the line. This WERASE feature has not been specified in POSIX.1 because it is difficult to define in the international environment. It is only useful for languages where words are delimited by <blank>s. In some ideographic languages, such as Japanese and Chinese, words are not delimited at all. The WERASE character should presumably take one back to the beginning of a sentence in those cases; practically, this means it would not get much use for those languages.

It should be noted that there is a possible inherent deadlock if the application and implementation conflict on the value of MAX_CANON. With ICANON set (if IXOFF is enabled) and more than MAX_CANON characters transmitted without a <linefeed>, transmission will be stopped, the <linefeed> (or <carriage-return> when ICRLF is set) will never arrive, and the *read*( ) will never be satisfied.

An application should not set IXOFF if it is using canonical mode unless it knows that (even in the face of a transmission error) the conditions described previously cannot be met or unless it is prepared to deal with the possible deadlock in some other way, such as timeouts.

It should also be noted that this can be made to happen in non-canonical mode if the trigger value for sending IXOFF is less than VMIN and VTIME is zero.

A.11.1.7 Non-Canonical Mode Input Processing

Some points to note about MIN and TIME:

1. The interactions of MIN and TIME are not symmetric. For example, when MIN>0 and TIME=0, TIME has no effect. However, in the opposite case where MIN=0 and TIME>0, both MIN and TIME play a role in that MIN is satisfied with the receipt of a single character.
2. Also note that in case A (MIN>0, TIME>0), TIME represents an inter-character timer, while in case C (MIN=0, TIME>0), TIME represents a read timer.

These two points highlight the dual purpose of the MIN/TIME feature. Cases A and B, where MIN>0, exist to handle burst-mode activity (for example, file transfer programs) where a program would like to process at least MIN characters at a time. In case A, the inter-character timer is activated by a user as a safety measure; in case B, it is turned off.

Cases C and D exist to handle single-character timed transfers. These cases are readily adaptable to screen-based applications that need to know if a character is present in the input queue before refreshing the screen. In case C, the read is timed; in case D, it is not.

Another important note is that MIN is always just a minimum. It does not denote a record length. That is, if a program does a read of 20 bytes, MIN is 10, and 25 characters are present, 20 characters shall be returned to the user. In the special case of MIN=0, this still applies: if more than one character is available, they all will be returned immediately.

A.11.1.8 Writing Data and Output Processing

There is no additional rationale provided for this section.

A.11.1.9 Special Characters

There is no additional rationale provided for this section.

A.11.1.10 Modem Disconnect

There is no additional rationale provided for this section.

A.11.1.11 Closing a Terminal Device File

IEEE Std 1003.1-200x does not specify that a *close*( ) on a terminal device file include the equivalent of a call to *tcflow*(*fd*,TCOON).

An implementation that discards output at the time *close*( ) is called after reporting the return value to the *write*( ) call that data was written does not conform with IEEE Std 1003.1-200x. An application has functions such as *tcdrain*( ), *tcflush*( ), and *tcflow*( ) available to obtain the detailed behavior it requires with respect to flushing of output.

At the time of the last close on a terminal device, an application relinquishes any ability to exert flow control via *tcflow*( ).

A.11.2 Parameters that Can be Set

A.11.2.1 The termios Structure

This structure is part of an interface that, in general, retains the historic grouping of flags. Although a more optimal structure for implementations may be possible, the degree of change to applications would be significantly larger.

A.11.2.2 Input Modes

Some historical implementations treated a long break as multiple events, as many as one per character time. The wording in POSIX.1 explicitly prohibits this.

Although the ISTRIP flag is normally superfluous with today's terminal hardware and software, it is historically supported. Therefore, applications may be using ISTRIP, and there is no technical problem with supporting this flag. Also, applications may wish to receive only 7-bit input bytes and may not be connected directly to the hardware terminal device (for example, when a connection traverses a network).

Also, there is no requirement in general that the terminal device ensures that high-order bits beyond the specified character size are cleared. ISTRIP provides this function for 7-bit characters, which are common.

In dealing with multi-byte characters, the consequences of a parity error in such a character, or in an escape sequence affecting the current character set, are beyond the scope of POSIX.1 and are best dealt with by the application processing the multi-byte characters.

A.11.2.3 Output Modes

POSIX.1 does not describe postprocessing of output to a terminal or detailed control of that from a conforming application. (That is, translation of <newline> to <carriage-return> followed by <linefeed> or <tab> processing.) There is nothing that a conforming application should do to its output for a terminal because that would require knowledge of the operation of the terminal. It is the responsibility of the operating system to provide postprocessing appropriate to the output device, whether it is a terminal or some other type of device.

Extensions to POSIX.1 to control the type of postprocessing already exist and are expected to continue into the future. The control of these features is primarily to adjust the interface between the system and the terminal device so the output appears on the display correctly. This should be set up before use by any application.

In general, both the input and output modes should not be set absolutely, but rather modified from the inherited state.

A.11.2.4 Control Modes

This section could be misread that the symbol ‘‘CSIZE’’ is a title in the **termios** *c_cflag* field . Although it does serve that function, it is also a required symbol, as a literal reading of POSIX.1 (and the caveats about typography) would indicate.

A.11.2.5 Local Modes

Non-canonical mode is provided to allow fast bursts of input to be read efficiently while still allowing single-character input.

The ECHONL function historically has been in many implementations. Since there seems to be no technical problem with supporting ECHONL, it is included in POSIX.1 to increase consensus.

The alternate behavior possible when ECHOK or ECHOE are specified with ICANON is permitted as a compromise depending on what the actual terminal hardware can do. Erasing characters and lines is preferred, but is not always possible.

A.11.2.6 Special Control Characters

Permitting VMIN and VTIME to overlap with VEOF and VEOL was a compromise for historical implementations. Only when backwards-compatibility of object code is a serious concern to an implementor should an implementation continue this practice. Correct applications that work with the overlap (at the source level) should also work if it is not present, but not the reverse.

A.12 Utility Conventions

A.12.1 Utility Argument Syntax

The standard developers considered that recent trends toward diluting the SYNOPSIS sections of historical reference pages to the equivalent of:

```
command [options][operands]
```

were a disservice to the reader. Therefore, considerable effort was placed into rigorous definitions of all the command line arguments and their interrelationships. The relationships depicted in the synopses are normative parts of IEEE Std 1003.1-200x; this information is sometimes repeated in textual form, but that is only for clarity within context.

The use of ''undefined'' for conflicting argument usage and for repeated usage of the same option is meant to prevent conforming applications from using conflicting arguments or repeated options unless specifically allowed (as is the case with *ls*, which allows simultaneous, repeated use of the **−C**, **−l**, and **−1** options). Many historical implementations will tolerate this usage, choosing either the first or the last applicable argument. This tolerance can continue, but conforming applications cannot rely upon it. (Other implementations may choose to print usage messages instead.)

The use of ''undefined'' for conflicting argument usage also allows an implementation to make reasonable extensions to utilities where the implementor considers mutually-exclusive options according to IEEE Std 1003.1-200x to have a sensible meaning and result.

IEEE Std 1003.1-200x does not define the result of a command when an option-argument or operand is not followed by ellipses and the application specifies more than one of that option-argument or operand. This allows an implementation to define valid (although non-standard) behavior for the utility when more than one such option or operand is specified.

Allowing <blank>s after an option (that is, placing an option and its option-argument into separate argument strings) when IEEE Std 1003.1-200x does not require it encourages portability of users, while still preserving backwards-compatibility of scripts. Inserting <blank>s between the option and the option-argument is preferred; however, historical usage has not been consistent in this area; therefore, <blank>s are required to be handled by all implementations, but implementations are also allowed to handle the historical syntax. Another justification for selecting the multiple-argument method was that the single-argument case is inherently ambiguous when the option-argument can legitimately be a null string.

IEEE Std 1003.1-200x explicitly states that digits are permitted as operands and option-arguments. The lower and upper bounds for the values of the numbers used for operands and option-arguments were derived from the ISO C standard values for {LONG_MIN} and {LONG_MAX}. The requirement on the standard utilities is that numbers in the specified range do not cause a syntax error, although the specification of a number need not be semantically correct for a particular operand or option-argument of a utility. For example, the specification of:

```
dd obs=3000000000
```

would yield undefined behavior for the application and could be a syntax error because the number 3 000 000 000 is outside of the range −2 147 483 647 to +2 147 483 647. On the other hand:

```
dd obs=2000000000
```

may cause some error, such as ''blocksize too large'', rather than a syntax error.

A.12.2 Utility Syntax Guidelines

This section is based on the rules listed in the SVID. It was included for two reasons:

1. The individual utility descriptions in the Shell and Utilities volume of IEEE Std 1003.1-200x, Chapter 4, Utilities needed a set of common (although not universal) actions on which they could anchor their descriptions of option and operand syntax. Most of the standard utilities actually do use these guidelines, and many of their historical implementations use the *getopt*( ) function for their parsing. Therefore, it was simpler to cite the rules and merely identify exceptions.

2. Writers of conforming applications need suggested guidelines if the POSIX community is to avoid the chaos of historical UNIX system command syntax. |

It is recommended that all *future* utilities and applications use these guidelines to enhance ‘‘user portability’’. The fact that some historical utilities could not be changed (to avoid breaking historical applications) should not deter this future goal.

The voluntary nature of the guidelines is highlighted by repeated uses of the word *should* throughout. This usage should not be misinterpreted to imply that utilities that claim conformance in their OPTIONS sections do not always conform.

Guidelines 1 and 2 are offered as guidance for locales using Latin alphabets. No recommendations are made by IEEE Std 1003.1-200x concerning utility naming in other locales.

In the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.9.1, Simple Commands, it is further stated that a command used in the Shell Command Language cannot be named with a trailing colon.

Guideline 3 was changed to allow alphanumeric characters (letters and digits) from the character set to allow compatibility with historical usage. Historical practice allows the use of digits wherever practical, and there are no portability issues that would prohibit the use of digits. In fact, from an internationalization viewpoint, digits (being non-language-dependent) are preferable over letters (a **–2** is intuitively self-explanatory to any user, while in the **–f** *filename* the letter `'f'` is a mnemonic aid only to speakers of Latin-based languages where ‘‘filename’’ happens to translate to a word that begins with `'f'`. Since guideline 3 still retains the word ‘‘single’’, multi-digit options are not allowed. Instances of historical utilities that used them have been marked obsolescent, with the numbers being changed from option names to option-arguments.

It was difficult to achieve a satisfactory solution to the problem of name space in option characters. When the standard developers desired to extend the historical *cc* utility to accept ISO C standard programs, they found that all of the portable alphabet was already in use by various vendors. Thus, they had to devise a new name, *c89*, rather than something like *cc* **–X**. There were suggestions that implementors be restricted to providing extensions through various means (such as using a plus sign as the option delimiter or using option characters outside the alphanumeric set) that would reserve all of the remaining alphanumeric characters for future POSIX standards. These approaches were resisted because they lacked the historical style of UNIX systems. Furthermore, if a vendor-provided option should become commonly used in the industry, it would be a candidate for standardization. It would be desirable to standardize such a feature using historical practice for the syntax (the semantics can be standardized with any syntax). This would not be possible if the syntax was one reserved for the vendor. However, since the standardization process may lead to minor changes in the semantics, it may prove to be better for a vendor to use a syntax that will not be affected by standardization.

Guideline 8 includes the concept of comma-separated lists in a single argument. It is up to the utility to parse such a list itself because *getopt*( ) just returns the single string. This situation was retained so that certain historical utilities would not violate the guidelines. Applications preparing for international use should be aware of an occasional problem with comma-separated lists: in some locales, the comma is used as the radix character. Thus, if an application is preparing operands for a utility that expects a comma-separated lists, it should avoid generating non-integer values through one of the means that is influenced by setting the *LC_NUMERIC* variable (such as *awk*, *bc*, *printf*, or *printf*( )).

Applications calling any utility with a first operand starting with `'−'` should usually specify −−, as indicated by Guideline 10, to mark the end of the options. This is true even if the SYNOPSIS in the Shell and Utilities volume of IEEE Std 1003.1-200x does not specify any options; implementations may provide options as extensions to the Shell and Utilities volume of IEEE Std 1003.1-200x. The standard utilities that do not support Guideline 10 indicate that fact in the OPTIONS section of the utility description.

Guideline 11 was modified to clarify that the order of different options should not matter relative to one another. However, the order of repeated options that also have option-arguments may be significant; therefore, such options are required to be interpreted in the order that they are specified. The *make* utility is an instance of a historical utility that uses repeated options in which the order is significant. Multiple files are specified by giving multiple instances of the −**f** option; for example:

```
make −f common_header −f specific_rules target
```

Guideline 13 does not imply that all of the standard utilities automatically accept the operand `'−'` to mean standard input or output, nor does it specify the actions of the utility upon encountering multiple `'−'` operands. It simply says that, by default, `'−'` operands are not used for other purposes in the file reading or writing (but not when using *stat*, *unlink*, *touch*, and so on) utilities. All information concerning actual treatment of the `'−'` operand is found in the individual utility sections.

An area of concern was that as implementations mature, implementation-defined utilities and implementation-defined utility options will result. The idea was expressed that there needed to be a standard way, say an environment variable or some such mechanism, to identify implementation-defined utilities separately from standard utilities that may have the same name. It was decided that there already exist several ways of dealing with this situation and that it is outside of the POSIX.2 scope to attempt to standardize in the area of non-standard items. A method that exists on some historical implementations is the use of the so-called **/local/bin** or **/usr/local/bin** directory to separate local or additional copies or versions of utilities. Another method that is also used is to isolate utilities into completely separate domains. Still another method to ensure that the desired utility is being used is to request the utility by its full pathname. There are many approaches to this situation; the examples given above serve to illustrate that there is more than one.

A.13 Headers

A.13.1 Format of Entries

Each header reference page has a common layout of sections describing the interface. This layout is similar to the manual page or ‘‘man’’ page format shipped with most UNIX systems, and each header has sections describing the SYNOPSIS and DESCRIPTION. These are the two sections that relate to conformance.

Additional sections are informative, and add considerable information for the application developer. APPLICATION USAGE sections provide additional caveats, issues, and recommendations to the developer. RATIONALE sections give additional information on the decisions made in defining the interface.

FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in the future, and often cautions the developer to architect the code to account for a change in this area. Note that a future directions statement should not be taken as a commitment to adopt a feature or interface in the future.

The CHANGE HISTORY section describes when the interface was introduced, and how it has changed.

Option labels and margin markings in the page can be useful in guiding the application developer.

Rationale (Informative)

Part B:

System Interfaces

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

Appendix B

Rationale for System Interfaces

B.1 Introduction

B.1.1 Scope

Refer to Section A.1.1 (on page 3293).

B.1.2 Conformance

Refer to Section A.2 (on page 3299).

B.1.3 Normative References

There is no additional rationale provided for this section.

B.1.4 Change History

The change history is provided as an informative section, to track changes from previous issues of IEEE Std 1003.1-200x.

The following sections describe changes made to the System Interfaces volume of IEEE Std 1003.1-200x since Issue 5 of the base document. The CHANGE HISTORY section for each entry details the technical changes that have been made to that entry since Issue 5. Changes between earlier issues of the base document and Issue 5 are not included.

The change history between Issue 5 and Issue 6 also lists the changes since the ISO POSIX-1: 1996 standard.

Changes from Issue 5 to Issue 6 (IEEE Std 1003.1-200x)

The following list summarizes the major changes that were made in the System Interfaces volume of IEEE Std 1003.1-200x from Issue 5 to Issue 6:

- This volume of IEEE Std 1003.1-200x is extensively revised so it can be both an IEEE POSIX Standard and an Open Group Technical Standard.
- The POSIX System Interfaces requirements incorporate support of FIPS 151-2.
- The POSIX System Interfaces requirements are updated to align with some features of the Single UNIX Specification.
- A RATIONALE section is added to each reference page.
- Networking interfaces from the XNS, Issue 5.2 specification are incorporated.
- IEEE Std 1003.1d-1999 is incorporated.
- IEEE Std 1003.1j-2000 is incorporated.
- IEEE Std 1003.1q-2000 is incorporated.
- IEEE P1003.1a draft standard is incorporated.

- Existing functionality is aligned with the ISO / IEC 9899: 1999 standard.
- New functionality from the ISO / IEC 9899: 1999 standard is incorporated.
- IEEE PASC Interpretations are applied.
- The Open Group corrigenda and resolutions are applied.

New Features in Issue 6

The functions first introduced in Issue 6 (over the Issue 5 Base document) are listed in the table below:

New Functions in Issue 6		
acosf( )	*catanhl*( )	*cprojf*( )
acoshf( )	*catanl*( )	*cprojl*( )

B.1.5 Terminology

Refer to Section A.1.4 (on page 3295).

B.1.6 Definitions

Refer to Section A.3 (on page 3302).

B.1.7 Relationship to Other Formal Standards

There is no additional rationale provided for this section.

B.1.8 Portability

Refer to Section A.1.5 (on page 3298).

B.1.8.1 Codes

Refer to Section A.1.5.1 (on page 3298).

B.1.9 Format of Entries

Each system interface reference page has a common layout of sections describing the interface. This layout is similar to the manual page or ‘‘man’’ page format shipped with most UNIX systems, and each header has sections describing the SYNOPSIS, DESCRIPTION, RETURN VALUE, and ERRORS. These are the four sections that relate to conformance.

Additional sections are informative, and add considerable information for the application developer. EXAMPLES sections provide example usage. APPLICATION USAGE sections provide additional caveats, issues, and recommendations to the developer. RATIONALE sections give additional information on the decisions made in defining the interface.

FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in the future, and often cautions the developer to architect the code to account for a change in this area. Note that a future directions statement should not be taken as a commitment to adopt a feature or interface in the future.

The CHANGE HISTORY section describes when the interface was introduced, and how it has changed.

Option labels and margin markings in the page can be useful in guiding the application developer.

B.2 General Information

B.2.1 Use and Implementation of Functions

The information concerning the use of functions was adapted from a description in the ISO C standard. Here is an example of how an application program can protect itself from functions that may or may not be macros, rather than true functions:

The *atoi*( ) function may be used in any of several ways:

- By use of its associated header (possibly generating a macro expansion):

  ```
  #include <stdlib.h>
  /* ... */
  i = atoi(str);
  ```

- By use of its associated header (assuredly generating a true function call):

  ```
  #include <stdlib.h>
  #undef atoi
  /* ... */
  i = atoi(str);
  ```

  or:

  ```
  #include <stdlib.h>
  /* ... */
  i = (atoi) (str);
  ```

- By explicit declaration:

  ```
  extern int atoi (const char *);
  /* ... */
  i = atoi(str);
  ```

- By implicit declaration:

  ```
  /* ... */
  i = atoi(str);
  ```

  (Assuming no function prototype is in scope. This is not allowed by the ISO C standard for functions with variable arguments; furthermore, parameter type conversion ‘‘widening’’ is subject to different rules in this case.)

Note that the ISO C standard reserves names starting with `'_'` for the compiler. Therefore, the compiler could, for example, implement an intrinsic, built-in function *_asm_builtin_atoi*( ), which it recognized and expanded into inline assembly code. Then, in **<stdlib.h>**, there could be the following:

```
#define atoi(X) _asm_builtin_atoi(X)
```

The user’s ‘‘normal’’ call to *atoi*( ) would then be expanded inline, but the implementor would also be required to provide a callable function named *atoi*( ) for use when the application requires it; for example, if its address is to be stored in a function pointer variable.

B.2.2 The Compilation Environment

B.2.2.1 POSIX.1 Symbols

This and the following section address the issue of ‘‘name space pollution’’. The ISO C standard requires that the name space beyond what it reserves not be altered except by explicit action of the application writer. This section defines the actions to add the POSIX.1 symbols for those headers where both the ISO C standard and POSIX.1 need to define symbols, and also where the XSI Extension extends the base standard.

When headers are used to provide symbols, there is a potential for introducing symbols that the application writer cannot predict. Ideally, each header should only contain one set of symbols, but this is not practical for historical reasons. Thus, the concept of feature test macros is included. Two feature test macros are explicitly defined by IEEE Std 1003.1-200x; it is expected that future revisions may add to this.

Note: Feature test macros allow an application to announce to the implementation its desire to have certain symbols and prototypes exposed. They should not be confused with the version test macros and constants for options in **<unistd.h>** which are the implementation’s way of announcing functionality to the application.

It is further intended that these feature test macros apply only to the headers specified by IEEE Std 1003.1-200x. Implementations are expressly permitted to make visible symbols not specified by IEEE Std 1003.1-200x, within both POSIX.1 and other headers, under the control of feature test macros that are not defined by IEEE Std 1003.1-200x.

The _POSIX_C_SOURCE Feature Test Macro

Since _POSIX_SOURCE specified by the POSIX.1-1990 standard did not have a value associated with it, the _POSIX_C_SOURCE macro replaces it, allowing an application to inform the system of the revision of the standard to which it conforms. This symbol will allow implementations to support various revisions of IEEE Std 1003.1-200x simultaneously. For instance, when either _POSIX_SOURCE is defined or _POSIX_C_SOURCE is defined as 1, the system should make visible the same name space as permitted and required by the POSIX.1-1990 standard. When _POSIX_C_SOURCE is defined, the state of _POSIX_SOURCE is completely irrelevant.

It is expected that C bindings to future POSIX standards will define new values for _POSIX_C_SOURCE, with each new value reserving the name space for that new standard, plus all earlier POSIX standards.

The _XOPEN_SOURCE Feature Test Macro

The feature test macro _XOPEN_SOURCE is provided as the announcement mechanism for the application that it requires functionality from the Single UNIX Specification. _XOPEN_SOURCE must be defined to the value 600 before the inclusion of any header to enable the functionality in the Single UNIX Specification. Its definition subsumes the use of _POSIX_SOURCE and _POSIX_C_SOURCE.

An extract of code from a conforming application, that appears before any **#include** statements, is given below:

```
#define _XOPEN_SOURCE 600 /* Single UNIX Specification, Version 3 */
```

```
#include ...
```

Note that the definition of _XOPEN_SOURCE with the value 600 makes the definition of _POSIX_C_SOURCE redundant and it can safely be omitted.

B.2.2.2 The Name Space

The reservation of identifiers is paraphrased from the ISO C standard. The text is included because it needs to be part of IEEE Std 1003.1-200x, regardless of possible changes in future versions of the ISO C standard.

These identifiers may be used by implementations, particularly for feature test macros. Implementations should not use feature test macro names that might be reasonably used by a standard.

Including headers more than once is a reasonably common practice, and it should be carried forward from the ISO C standard. More significantly, having definitions in more than one header is explicitly permitted. Where the potential declaration is ‘‘benign’’ (the same definition twice) the declaration can be repeated, if that is permitted by the compiler. (This is usually true of macros, for example.) In those situations where a repetition is not benign (for example, **typedef**s), conditional compilation must be used. The situation actually occurs both within the ISO C standard and within POSIX.1: **time_t** should be in **<sys/types.h>**, and the ISO C standard mandates that it be in **<time.h>**.

The area of name space pollution *versus* additions to structures is difficult because of the macro structure of C. The following discussion summarizes all the various problems with and objections to the issue.

Note the phrase ‘‘user-defined macro’’. Users are not permitted to define macro names (or any other name) beginning with `"_[A-Z_]"`. Thus, the conflict cannot occur for symbols reserved to the vendor’s name space, and the permission to add fields automatically applies, without qualification, to those symbols.

1. Data structures (and unions) need to be defined in headers by implementations to meet certain requirements of POSIX.1 and the ISO C standard.

2. The structures defined by POSIX.1 are typically minimal, and any practical implementation would wish to add fields to these structures either to hold additional related information or for backwards-compatibility (or both). Future standards (and *de facto* standards) would also wish to add to these structures. Issues of field alignment make it impractical (at least in the general case) to simply omit fields when they are not defined by the particular standard involved.

   Struct **dirent** is an example of such a minimal structure (although one could argue about whether the other fields need visible names). The *st_rdev* field of most implementations’ **stat** structure is a common example where extension is needed and where a conflict could occur.

3. Fields in structures are in an independent name space, so the addition of such fields presents no problem to the C language itself in that such names cannot interact with identically named user symbols because access is qualified by the specific structure name.

4. There is an exception to this: macro processing is done at a lexical level. Thus, symbols added to a structure might be recognized as user-provided macro names at the location where the structure is declared. This only can occur if the user-provided name is declared as a macro before the header declaring the structure is included. The user’s use of the name after the declaration cannot interfere with the structure because the symbol is hidden and only accessible through access to the structure. Presumably, the user would not declare such a macro if there was an intention to use that field name.

5. Macros from the same or a related header might use the additional fields in the structure, and those field names might also collide with user macros. Although this is a less frequent occurrence, since macros are expanded at the point of use, no constraint on the order of use

of names can apply.

6. An ‘‘obvious’’ solution of using names in the reserved name space and then redefining them as macros when they should be visible does not work because this has the effect of exporting the symbol into the general name space. For example, given a (hypothetical) system-provided header **<h.h>**, and two parts of a C program in **a.c** and **b.c**, in header **<h.h>**:

   ```
   struct foo {
       int __i;
   }

   #ifdef _FEATURE_TEST
   #define i __i;
   #endif
   ```

   In file **a.c**:

   ```
   #include h.h
   extern int i;
   ...
   ```

   In file **b.c**:

   ```
   extern int i;
   ...
   ```

   The symbol that the user thinks of as *i* in both files has an external name of *__i* in **a.c**; the same symbol *i* in **b.c** has an external name *i* (ignoring any hidden manipulations the compiler might perform on the names). This would cause a mysterious name resolution problem when **a.o** and **b.o** are linked.

   Simply avoiding definition then causes alignment problems in the structure.

   A structure of the form:

   ```
   struct foo {
       union {
           int __i;
   #ifdef _FEATURE_TEST
           int i;
   #endif
       } __ii;
   }
   ```

   does not work because the name of the logical field *i* is *__ii.i*, and introduction of a macro to restore the logical name immediately reintroduces the problem discussed previously (although its manifestation might be more immediate because a syntax error would result if a recursive macro did not cause it to fail first).

7. A more workable solution would be to declare the structure:

```
struct foo {
#ifdef _FEATURE_TEST
    int i;
#else
    int __i;
#endif
}
```

However, if a macro (particularly one required by a standard) is to be defined that uses this field, two must be defined: one that uses *i*, the other that uses *__i*. If more than one additional field is used in a macro and they are conditional on distinct combinations of features, the complexity goes up as 2^n.

All this leaves a difficult situation: vendors must provide very complex headers to deal with what is conceptually simple and safe—adding a field to a structure. It is the possibility of user-provided macros with the same name that makes this difficult.

Several alternatives were proposed that involved constraining the user's access to part of the name space available to the user (as specified by the ISO C standard). In some cases, this was only until all the headers had been included. There were two proposals discussed that failed to achieve consensus:

1. Limiting it for the whole program.
2. Restricting the use of identifiers containing only uppercase letters until after all system headers had been included. It was also pointed out that because macros might wish to access fields of a structure (and macro expansion occurs totally at point of use) restricting names in this way would not protect the macro expansion, and thus the solution was inadequate.

It was finally decided that reservation of symbols would occur, but as constrained.

The current wording also allows the addition of fields to a structure, but requires that user macros of the same name not interfere. This allows vendors to do one of the following:

- Not create the situation (do not extend the structures with user-accessible names or use the solution in (7) above)
- Extend their compilers to allow some way of adding names to structures and macros safely

There are at least two ways that the compiler might be extended: add new preprocessor directives that turn off and on macro expansion for certain symbols (without changing the value of the macro) and a function or lexical operation that suppresses expansion of a word. The latter seems more flexible, particularly because it addresses the problem in macros as well as in declarations.

The following seems to be a possible implementation extension to the C language that will do this: any token that during macro expansion is found to be preceded by three `'#'` symbols shall not be further expanded in exactly the same way as described for macros that expand to their own name as in Section 3.8.3.4 of the ISO C standard. A vendor may also wish to implement this as an operation that is lexically a function, which might be implemented as:

```
#define __safe_name(x) ###x
```

Using a function notation would insulate vendors from changes in standards until such a functionality is standardized (if ever). Standardization of such a function would be valuable because it would then permit third parties to take advantage of it portably in software they may supply.

The symbols that are ‘‘explicitly permitted, but not required by IEEE Std 1003.1-200x’’ include those classified below. (That is, the symbols classified below might, but are not required to, be present when _POSIX_C_SOURCE is defined to have the value 20010xL.)

- Symbols in **<limits.h>** and **<unistd.h>** that are defined to indicate support for options or limits that are constant at compile-time.
- Symbols in the name space reserved for the implementation by the ISO C standard.
- Symbols in a name space reserved for a particular type of extension (for example, type names ending with **_t** in **<sys/types.h>**).
- Additional members of structures or unions whose names do not reduce the name space reserved for applications.

Since both implementations and future revisions of IEEE Std 1003.1-200x and other POSIX standards may use symbols in the reserved spaces described in these tables, there is a potential for name space clashes. To avoid future name space clashes when adding symbols, implementations should not use the posix_, POSIX_, or _POSIX_ prefixes.

B.2.3 Error Numbers

It was the consensus of the standard developers that to allow the conformance document to state that an error occurs and under what conditions, but to disallow a statement that it never occurs, does not make sense. It could be implied by the current wording that this is allowed, but to reduce the possibility of future interpretation requests, it is better to make an explicit statement.

The ISO C standard requires that *errno* be an assignable lvalue. Originally, the definition in POSIX.1 was stricter than that in the ISO C standard, **extern int** *errno*, in order to support historical usage. In a multi-threaded environment, implementing *errno* as a global variable results in non-deterministic results when accessed. It is required, however, that *errno* work as a per-thread error reporting mechanism. In order to do this, a separate *errno* value has to be maintained for each thread. The following section discusses the various alternative solutions that were considered. |

In order to avoid this problem altogether for new functions, these functions avoid using *errno* and, instead, return the error number directly as the function return value; a return value of zero indicates that no error was detected.

For any function that can return errors, the function return value is not used for any purpose other than for reporting errors. Even when the output of the function is scalar, it is passed through a function argument. While it might have been possible to allow some scalar outputs to be coded as negative function return values and mixed in with positive error status returns, this was rejected—using the return value for a mixed purpose was judged to be of limited use and error prone.

Checking the value of *errno* alone is not sufficient to determine the existence or type of an error, since it is not required that a successful function call clear *errno*. The variable *errno* should only be examined when the return value of a function indicates that the value of *errno* is meaningful. In that case, the function is required to set the variable to something other than zero.

The variable *errno* shall never be set to zero by any function call; to do so would contradict the ISO C standard.

POSIX.1 requires (in the ERRORS sections of function descriptions) certain error values to be set in certain conditions because many existing applications depend on them. Some error numbers, such as [EFAULT], are entirely implementation-defined and are noted as such in their description in the ERRORS section. This section otherwise allows wide latitude to the implementation in handling error reporting.

Some of the ERRORS sections in IEEE Std 1003.1-200x have two subsections. The first:

> ‘‘The function shall fail if:’’

could be called the ‘‘mandatory’’ section.

The second:

> ‘‘The function may fail if:’’

could be informally known as the ‘‘optional’’ section.

Attempting to infer the quality of an implementation based on whether it detects optional error conditions is not useful.

Following each one-word symbolic name for an error, there is a description of the error. The rationale for some of the symbolic names follows:

[ECANCELED]	This spelling was chosen as being more common.
[EFAULT]	Most historical implementations do not catch an error and set *errno* when an invalid address is given to the functions *wait*( ), *time*( ), or *times*( ). Some implementations cannot reliably detect an invalid address. And most systems that detect invalid addresses will do so only for a system call, not for a library routine.
[EFTYPE]	This error code was proposed in earlier proposals as ‘‘Inappropriate operation for file type’’, meaning that the operation requested is not appropriate for the file specified in the function call. This code was proposed, although the same idea was covered by [ENOTTY], because the connotations of the name would be misleading. It was pointed out that the *fcntl*( ) function uses the error code [EINVAL] for this notion, and hence all instances of [EFTYPE] were changed to this code.
[EINTR]	POSIX.1 prohibits conforming implementations from restarting interrupted system calls. However, it does not require that [EINTR] be returned when another legitimate value may be substituted; for example, a partial transfer count when *read*( ) or *write*( ) are interrupted. This is only given when the signal catching function returns normally as opposed to returns by mechanisms like *longjmp*( ) or *siglongjmp*( ).
[ELOOP]	In specifying conditions under which implementations would generate this error, the following goals were considered: • To ensure that actual loops are detected, including loops that result from symbolic links across distributed file systems. • To ensure that during pathname resolution an application can rely on the ability to follow at least {SYMLOOP_MAX} symbolic links in the absence of a loop. • To allow implementations to provide the capability of traversing more than {SYMLOOP_MAX} symbolic links in the absence of a loop. • To allow implementations to detect loops and generate the error prior to encountering {SYMLOOP_MAX} symbolic links.

[ENAMETOOLONG]	When a symbolic link is encountered during pathname resolution, the contents of that symbolic link are used to create a new pathname. The standard developers intended to allow, but not require, that implementations enforce the restriction of {PATH_MAX} on the result of this pathname substitution.
[ENOMEM]	The term *main memory* is not used in POSIX.1 because it is implementation-defined.
[ENOTSUP]	This error code is to be used when an implementation chooses to implement the required functionality of IEEE Std 1003.1-200x but does not support optional facilities defined by IEEE Std 1003.1-200x. The return of [ENOSYS] is to be taken to indicate that the function of the interface is not supported at all; the function will always fail with this error code.
[ENOTTY]	The symbolic name for this error is derived from a time when device control was done by *ioctl*( ) and that operation was only permitted on a terminal interface. The term *TTY* is derived from *teletypewriter*, the devices to which this error originally applied.
[EOVERFLOW]	Most of the uses of this error code are related to large file support. Typically, these cases occur on systems which support multiple programming environments with different sizes for **off_t**, but they may also occur in connection with remote file systems. In addition, when different programming environments have different widths for types such as **int** and **uid_t**, several functions may encounter a condition where a value in a particular environment is too wide to be represented. In that case, this error should be raised. For example, suppose the currently running process has 64-bit **int**, and file descriptor 9223372036854775807 is open and does not have the close-on-*exec* flag set. If the process then uses *execl*( ) to *exec* a file compiled in a programming environment with 32-bit **int**, the call to *execl*( ) can fail with *errno* set to [EOVERFLOW]. A similar failure can occur with *execl*( ) if any of the user IDs or any of the group IDs to be assigned to the new process image are out of range for the executed file's programming environment. Note, however, that this condition cannot occur for functions that are explicitly described as always being successful, such as *getpid*( ).
[EPIPE]	This condition normally generates the signal SIGPIPE; the error is returned if the signal does not terminate the process.
[EROFS]	In historical implementations, attempting to *unlink*( ) or *rmdir*( ) a mount point would generate an [EBUSY] error. An implementation could be envisioned where such an operation could be performed without error. In this case, if *either* the directory entry or the actual data structures reside on a read-only file system, [EROFS] is the appropriate error to generate. (For example, changing the link count of a file on a read-only file system could not be done, as is required by *unlink*( ), and thus an error should be reported.)

Three error numbers, [EDOM], [EILSEQ], and [ERANGE], were added to this section primarily for consistency with the ISO C standard.

Alternative Solutions for Per-Thread errno

The usual implementation of *errno* as a single global variable does not work in a multi-threaded environment. In such an environment, a thread may make a POSIX.1 call and get a −1 error return, but before that thread can check the value of *errno*, another thread might have made a second POSIX.1 call that also set *errno*. This behavior is unacceptable in robust programs. There were a number of alternatives that were considered for handling the *errno* problem:

- Implement *errno* as a per-thread integer variable.
- Implement *errno* as a service that can access the per-thread error number.
- Change all POSIX.1 calls to accept an extra status argument and avoid setting *errno*.
- Change all POSIX.1 calls to raise a language exception.

The first option offers the highest level of compatibility with existing practice but requires special support in the linker, compiler, and/or virtual memory system to support the new concept of thread private variables. When compared with current practice, the third and fourth options are much cleaner, more efficient, and encourage a more robust programming style, but they require new versions of all of the POSIX.1 functions that might detect an error. The second option offers compatibility with existing code that uses the **<errno.h>** header to define the symbol *errno*. In this option, *errno* may be a macro defined:

```
#define errno  (*__errno())
extern int      *__errno();
```

This option may be implemented as a per-thread variable whereby an *errno* field is allocated in the user space object representing a thread, and whereby the function *__errno*( ) makes a system call to determine the location of its user space object and returns the address of the *errno* field of that object. Another implementation, one that avoids calling the kernel, involves allocating stacks in chunks. The stack allocator keeps a side table indexed by chunk number containing a pointer to the thread object that uses that chunk. The *__errno*( ) function then looks at the stack pointer, determines the chunk number, and uses that as an index into the chunk table to find its thread object and thus its private value of *errno*. On most architectures, this can be done in four to five instructions. Some compilers may wish to implement *__errno*( ) inline to improve performance.

Disallowing Return of the [EINTR] Error Code

Many blocking interfaces defined by IEEE Std 1003.1-200x may return [EINTR] if interrupted during their execution by a signal handler. Blocking interfaces introduced under the Threads option do not have this property. Instead, they require that the interface appear to be atomic with respect to interruption. In particular, clients of blocking interfaces need not handle any possible [EINTR] return as a special case since it will never occur. If it is necessary to restart operations or complete incomplete operations following the execution of a signal handler, this is handled by the implementation, rather than by the application.

Requiring applications to handle [EINTR] errors on blocking interfaces has been shown to be a frequent source of often unreproducible bugs, and it adds no compelling value to the available functionality. Thus, blocking interfaces introduced for use by multi-threaded programs do not use this paradigm. In particular, in none of the functions *flockfile*( ), *pthread_cond_timedwait*( ), *pthread_cond_wait*( ), *pthread_join*( ), *pthread_mutex_lock*( ), and *sigwait*( ) did providing [EINTR] returns add value, or even particularly make sense. Thus, these functions do not provide for an [EINTR] return, even when interrupted by a signal handler. The same arguments can be applied to *sem_wait*( ), *sem_trywait*( ), *sigwaitinfo*( ), and *sigtimedwait*( ), but implementations are permitted to return [EINTR] error codes for these functions for compatibility with earlier versions of IEEE Std 1003.1-200x. Applications cannot rely on calls to these functions returning [EINTR] error codes when signals are delivered to the calling thread, but they should allow for the possibility.

B.2.3.1 Additional Error Numbers

The ISO C standard defines the name space for implementations to add additional error numbers.

B.2.4 Signal Concepts

Historical implementations of signals, using the *signal*( ) function, have shortcomings that make them unreliable for many application uses. Because of this, a new signal mechanism, based very closely on the one of 4.2 BSD and 4.3 BSD, was added to POSIX.1.

Signal Names

The restriction on the actual type used for **sigset_t** is intended to guarantee that these objects can always be assigned, have their address taken, and be passed as parameters by value. It is not intended that this type be a structure including pointers to other data structures, as that could impact the portability of applications performing such operations. A reasonable implementation could be a structure containing an array of some integer type.

The signals described in IEEE Std 1003.1-200x must have unique values so that they may be named as parameters of **case** statements in the body of a C language **switch** clause. However, implementation-defined signals may have values that overlap with each other or with signals specified in IEEE Std 1003.1-200x. An example of this is SIGABRT, which traditionally overlaps some other signal, such as SIGIOT.

SIGKILL, SIGTERM, SIGUSR1, and SIGUSR2 are ordinarily generated only through the explicit use of the *kill*( ) function, although some implementations generate SIGKILL under extraordinary circumstances. SIGTERM is traditionally the default signal sent by the *kill* command.

The signals SIGBUS, SIGEMT, SIGIOT, SIGTRAP, and SIGSYS were omitted from POSIX.1 because their behavior is implementation-defined and could not be adequately categorized. Conforming implementations may deliver these signals, but must document the circumstances under which they are delivered and note any restrictions concerning their delivery. The signals SIGFPE, SIGILL, and SIGSEGV are similar in that they also generally result only from programming errors. They were included in POSIX.1 because they do indicate three relatively well-categorized conditions. They are all defined by the ISO C standard and thus would have to be defined by any system with a ISO C standard binding, even if not explicitly included in POSIX.1.

There is very little that a Conforming POSIX.1 Application can do by catching, ignoring, or masking any of the signals SIGILL, SIGTRAP, SIGIOT, SIGEMT, SIGBUS, SIGSEGV, SIGSYS, or SIGFPE. They will generally be generated by the system only in cases of programming errors. While it may be desirable for some robust code (for example, a library routine) to be able to detect and recover from programming errors in other code, these signals are not nearly sufficient for that purpose. One portable use that does exist for these signals is that a command interpreter can recognize them as the cause of a process' termination (with *wait*( )) and print an appropriate message. The mnemonic tags for these signals are derived from their PDP-11 origin.

The signals SIGSTOP, SIGTSTP, SIGTTIN, SIGTTOU, and SIGCONT are provided for job control and are unchanged from 4.2 BSD. The signal SIGCHLD is also typically used by job control shells to detect children that have terminated or, as in 4.2 BSD, stopped.

Some implementations, including System V, have a signal named SIGCLD, which is similar to SIGCHLD in 4.2 BSD. POSIX.1 permits implementations to have a single signal with both names. POSIX.1 carefully specifies ways in which conforming applications can avoid the semantic differences between the two different implementations. The name SIGCHLD was chosen for POSIX.1 because most current application usages of it can remain unchanged in conforming applications. SIGCLD in System V has more cases of semantics that POSIX.1 does not specify, and thus applications using it are more likely to require changes in addition to the name change.

The signals SIGUSR1 and SIGUSR2 are commonly used by applications for notification of exceptional behavior and are described as ‘‘reserved as application-defined’’ so that such use is not prohibited. Implementations should not generate SIGUSR1 or SIGUSR2, except when explicitly requested by *kill*( ). It is recommended that libraries not use these two signals, as such use in libraries could interfere with their use by applications calling the libraries. If such use is unavoidable, it should be documented. It is prudent for non-portable libraries to use non-standard signals to avoid conflicts with use of standard signals by portable libraries.

There is no portable way for an application to catch or ignore non-standard signals. Some implementations define the range of signal numbers, so applications can install signal-catching functions for all of them. Unfortunately, implementation-defined signals often cause problems when caught or ignored by applications that do not understand the reason for the signal. While the desire exists for an application to be more robust by handling all possible signals (even those only generated by *kill*( )), no existing mechanism was found to be sufficiently portable to include in POSIX.1. The value of such a mechanism, if included, would be diminished given that SIGKILL would still not be catchable.

A number of new signal numbers are reserved for applications because the two user signals defined by POSIX.1 are insufficient for many realtime applications. A range of signal numbers is specified, rather than an enumeration of additional reserved signal names, because different applications and application profiles will require a different number of application signals. It is not desirable to burden all application domains and therefore all implementations with the maximum number of signals required by all possible applications. Note that in this context, signal numbers are essentially different signal priorities.

The relatively small number of required additional signals, {_POSIX_RTSIG_MAX}, was chosen so as not to require an unreasonably large signal mask/set. While this number of signals defined in POSIX.1 will fit in a single 32-bit word signal mask, it is recognized that most existing implementations define many more signals than are specified in POSIX.1 and, in fact, many implementations have already exceeded 32 signals (including the ‘‘null signal’’). Support of {_POSIX_RTSIG_MAX} additional signals may push some implementation over the single 32-bit word line, but is unlikely to push any implementations that are already over that line beyond the 64-signal line.

B.2.4.1 Signal Generation and Delivery

The terms defined in this section are not used consistently in documentation of historical systems. Each signal can be considered to have a lifetime beginning with *generation* and ending with *delivery* or *acceptance*. The POSIX.1 definition of *delivery* does not exclude ignored signals; this is considered a more consistent definition. This revised text in several parts of IEEE Std 1003.1-200x clarifies the distinct semantics of asynchronous signal *delivery* and synchronous signal *acceptance*. The previous wording attempted to categorize both under the term *delivery*, which led to conflicts over whether the effects of asynchronous signal delivery applied to synchronous signal acceptance.

Signals generated for a process are delivered to only one thread. Thus, if more than one thread is eligible to receive a signal, one has to be chosen. The choice of threads is left entirely up to the implementation both to allow the widest possible range of conforming implementations and to give implementations the freedom to deliver the signal to the ‘‘easiest possible’’ thread should there be differences in ease of delivery between different threads.

Note that should multiple delivery among cooperating threads be required by an application, this can be trivially constructed out of the provided single-delivery semantics. The construction of a *sigwait_multiple*( ) function that accomplishes this goal is presented with the rationale for *sigwaitinfo*( ).

Implementations should deliver unblocked signals as soon after they are generated as possible. However, it is difficult for POSIX.1 to make specific requirements about this, beyond those in *kill*( ) and *sigprocmask*( ). Even on systems with prompt delivery, scheduling of higher priority processes is always likely to cause delays.

In general, the interval between the generation and delivery of unblocked signals cannot be detected by an application. Thus, references to pending signals generally apply to blocked, pending signals. An implementation registers a signal as pending on the process when no thread has the signal unblocked and there are no threads blocked in a *sigwait*( ) function for that signal. Thereafter, the implementation delivers the signal to the first thread that unblocks the signal or calls a *sigwait*( ) function on a signal set containing this signal rather than choosing the recipient thread at the time the signal is sent.

In the 4.3 BSD system, signals that are blocked and set to SIG_IGN are discarded immediately upon generation. For a signal that is ignored as its default action, if the action is SIG_DFL and the signal is blocked, a generated signal remains pending. In the 4.1 BSD system and in System V, Release 3, two other implementations that support a somewhat similar signal mechanism, all ignored, blocked signals remain pending if generated. Because it is not normally useful for an application to simultaneously ignore and block the same signal, it was unnecessary for POSIX.1 to specify behavior that would invalidate any of the historical implementations.

There is one case in some historical implementations where an unblocked, pending signal does not remain pending until it is delivered. In the System V implementation of *signal*( ), pending signals are discarded when the action is set to SIG_DFL or a signal-catching routine (as well as to SIG_IGN). Except in the case of setting SIGCHLD to SIG_DFL, implementations that do this do not conform completely to POSIX.1. Some earlier proposals for POSIX.1 explicitly stated this, but these statements were redundant due to the requirement that functions defined by POSIX.1 not change attributes of processes defined by POSIX.1 except as explicitly stated.

POSIX.1 specifically states that the order in which multiple, simultaneously pending signals are delivered is unspecified. This order has not been explicitly specified in historical implementations, but has remained quite consistent and been known to those familiar with the implementations. Thus, there have been cases where applications (usually system utilities) have been written with explicit or implicit dependencies on this order. Implementors and others porting existing applications may need to be aware of such dependencies.

When there are multiple pending signals that are not blocked, implementations should arrange for the delivery of all signals at once, if possible. Some implementations stack calls to all pending signal-catching routines, making it appear that each signal-catcher was interrupted by the next signal. In this case, the implementation should ensure that this stacking of signals does not violate the semantics of the signal masks established by *sigaction*( ). Other implementations process at most one signal when the operating system is entered, with remaining signals saved for later delivery. Although this practice is widespread, this behavior is neither standardized nor endorsed. In either case, implementations should attempt to deliver signals associated with the current state of the process (for example, SIGFPE) before other signals, if possible.

In 4.2 BSD and 4.3 BSD, it is not permissible to ignore or explicitly block SIGCONT, because if blocking or ignoring this signal prevented it from continuing a stopped process, such a process could never be continued (only killed by SIGKILL). However, 4.2 BSD and 4.3 BSD do block SIGCONT during execution of its signal-catching function when it is caught, creating exactly this problem. A proposal was considered to disallow catching SIGCONT in addition to ignoring and blocking it, but this limitation led to objections. The consensus was to require that SIGCONT always continue a stopped process when generated. This removed the need to disallow ignoring or explicit blocking of the signal; note that SIG_IGN and SIG_DFL are equivalent for SIGCONT .

B.2.4.2 Realtime Signal Generation and Delivery

The Realtime Signals Extension option to POSIX.1 signal generation and delivery behavior is required for the following reasons:

- The **sigevent** structure is used by other POSIX.1 functions that result in asynchronous event notifications to specify the notification mechanism to use and other information needed by the notification mechanism. IEEE Std 1003.1-200x defines only three symbolic values for the notification mechanism. SIGEV_NONE is used to indicate that no notification is required when the event occurs. This is useful for applications that use asynchronous I/O with polling for completion. SIGEV_SIGNAL indicates that a signal shall be generated when the event occurs. SIGEV_NOTIFY provides for ‘‘callback functions’’ for asynchronous notifications done by a function call within the context of a new thread. This provides a multi-threaded process a more natural means of notification than signals. The primary difficulty with previous notification approaches has been to specify the environment of the notification routine.

  — One approach is to limit the notification routine to call only functions permitted in a signal handler. While the list of permissible functions is clearly stated, this is overly restrictive.

  — A second approach is to define a new list of functions or classes of functions that are explicitly permitted or not permitted. This would give a programmer more lists to deal with, which would be awkward.

  — The third approach is to define completely the environment for execution of the notification function. A clear definition of an execution environment for notification is provided by executing the notification function in the environment of a newly created thread.

  Implementations may support additional notification mechanisms by defining new values for *sigev_notify* .

  For a notification type of SIGEV_SIGNAL, the other members of the **sigevent** structure defined by IEEE Std 1003.1-200x specify the realtime signal—that is, the signal number and application-defined value that differentiates between occurrences of signals with the same number—that will be generated when the event occurs. The structure is defined in **<signal.h>**, even though the structure is not directly used by any of the signal functions, because it is part of the signals interface used by the POSIX.1b ‘‘client functions’’. When the client functions include **<signal.h>** to define the signal names, the **sigevent** structure will also be defined.

  An application-defined value passed to the signal handler is used to differentiate between different ‘‘events’’ instead of requiring that the application use different signal numbers for several reasons:

  - — Realtime applications potentially handle a very large number of different events. Requiring that implementations support a correspondingly large number of distinct signal numbers will adversely impact the performance of signal delivery because the signal masks to be manipulated on entry and exit to the handlers will become large.
  - — Event notifications are prioritized by signal number (the rationale for this is explained in the following paragraphs) and the use of different signal numbers to differentiate between the different event notifications overloads the signal number more than has already been done. It also requires that the application writer make arbitrary assignments of priority to events that are logically of equal priority.

  A union is defined for the application-defined value so that either an integer constant or a pointer can be portably passed to the signal-catching function. On some architectures a pointer cannot be cast to an **int** and *vice versa*.

  Use of a structure here with an explicit notification type discriminant rather than explicit parameters to realtime functions, or embedded in other realtime structures, provides for future extensions to IEEE Std 1003.1-200x. Additional, perhaps more efficient, notification mechanisms can be supported for existing realtime function interfaces, such as timers and asynchronous I/O, by extending the **sigevent** structure appropriately. The existing realtime function interfaces will not have to be modified to use any such new notification mechanism. The revised text concerning the SIGEV_SIGNAL value makes consistent the semantics of the members of the **sigevent** structure, particularly in the definitions of *lio_listio*( ) and *aio_fsync*( ). For uniformity, other revisions cause this specification to be referred to rather than inaccurately duplicated in the descriptions of functions and structures using the **sigevent** structure. The revised wording does not relax the requirement that the signal number be in the range SIGRTMIN to SIGRTMAX to guarantee queuing and passing of the application value, since that requirement is still implied by the signal names.

- IEEE Std 1003.1-200x is intentionally vague on whether ''non-realtime'' signal-generating mechanisms can result in a **siginfo_t** being supplied to the handler on delivery. In one existing implementation, a **siginfo_t** is posted on signal generation, even though the implementation does not support queuing of multiple occurrences of a signal. It is not the intent of IEEE Std 1003.1-200x to preclude this, independent of the mandate to define signals that do support queuing. Any interpretation that appears to preclude this is a mistake in the reading or writing of the standard.

- Signals handled by realtime signal handlers might be generated by functions or conditions that do not allow the specification of an application-defined value and do not queue. IEEE Std 1003.1-200x specifies the *si_code* member of the **siginfo_t** structure used in existing practice and defines additional codes so that applications can detect whether an application-defined value is present or not. The code SI_USER for *kill*( )-generated signals is adopted from existing practice.

- The *sigaction*( ) *sa_flags* value SA_SIGINFO tells the implementation that the signal-catching function expects two additional arguments. When the flag is not set, a single argument, the signal number, is passed as specified by IEEE Std 1003.1-200x. Although IEEE Std 1003.1-200x does not explicitly allow the *info* argument to the handler function to be NULL, this is existing practice. This provides for compatibility with programs whose signal-catching functions are not prepared to accept the additional arguments. IEEE Std 1003.1-200x is explicitly unspecified as to whether signals actually queue when SA_SIGINFO is not set for a signal, as there appear to be no benefits to applications in specifying one behavior or another. One existing implementation queues a **siginfo_t** on each signal generation, unless the signal is already pending, in which case the implementation discards the new **siginfo_t**; that is, the queue length is never greater than one. This implementation only examines SA_SIGINFO on signal delivery, discarding the queued **siginfo_t** if its delivery was not requested.

IEEE Std 1003.1-200x specifies several new values for the *si_code* member of the **siginfo_t** structure. In existing practice, a *si_code* value of less than or equal to zero indicates that the signal was generated by a process via the *kill*( ) function. In existing practice, values of *si_code* that provide additional information for implementation-generated signals, such as SIGFPE or SIGSEGV , are all positive. Thus, if implementations define the new constants specified in IEEE Std 1003.1-200x to be negative numbers, programs written to use existing practice will not break. IEEE Std 1003.1-200x chose not to attempt to specify existing practice values of *si_code* other than SI_USER both because it was deemed beyond the scope of IEEE Std 1003.1-200x and because many of the values in existing practice appear to be platform and implementation-defined. But, IEEE Std 1003.1-200x does specify that if an implementation—for example, one that does not have existing practice in this area—chooses to define additional values for *si_code*, these values have to be different from the values of the symbols specified by IEEE Std 1003.1-200x. This will allow conforming applications to differentiate between signals generated by one of the POSIX.1b asynchronous events and those generated by other implementation events in a manner compatible with existing practice.

The unique values of *si_code* for the POSIX.1b asynchronous events have implications for implementations of, for example, asynchronous I/O or message passing in user space library code. Such an implementation will be required to provide a hidden interface to the signal generation mechanism that allows the library to specify the standard values of *si_code*.

Existing practice also defines additional members of **siginfo_t**, such as the process ID and user ID of the sending process for *kill*( )-generated signals. These members were deemed not necessary to meet the requirements of realtime applications and are not specified by IEEE Std 1003.1-200x. Neither are they precluded.

The third argument to the signal-catching function, *context*, is left undefined by IEEE Std 1003.1-200x, but is specified in the interface because it matches existing practice for the SA_SIGINFO flag. It was considered undesirable to require a separate implementation for SA_SIGINFO for POSIX conformance on implementations that already support the two additional parameters.

- The requirement to deliver lower numbered signals in the range SIGRTMIN to SIGRTMAX first, when multiple unblocked signals are pending, results from several considerations:

  — A method is required to prioritize event notifications. The signal number was chosen instead of, for instance, associating a separate priority with each request, because an implementation has to check pending signals at various points and select one for delivery when more than one is pending. Specifying a selection order is the minimal additional semantic that will achieve prioritized delivery. If a separate priority were to be associated with queued signals, it would be necessary for an implementation to search all non-empty, non-blocked signal queues and select from among them the pending signal with the highest priority. This would significantly increase the cost of and decrease the determinism of signal delivery.

  — Given the specified selection of the lowest numeric unblocked pending signal, preemptive priority signal delivery can be achieved using signal numbers and signal masks by ensuring that the *sa_mask* for each signal number blocks all signals with a higher numeric value.

  For realtime applications that want to use only the newly defined realtime signal numbers without interference from the standard signals, this can be achieved by blocking all of the standard signals in the process signal mask and in the *sa_mask* installed by the signal action for the realtime signal handlers.

IEEE Std 1003.1-200x explicitly leaves unspecified the ordering of signals outside of the range of realtime signals and the ordering of signals within this range with respect to those outside the range. It was believed that this would unduly constrain implementations or standards in the future definition of new signals.

B.2.4.3 Signal Actions

Early proposals mentioned SIGCONT as a second exception to the rule that signals are not delivered to stopped processes until continued. Because IEEE Std 1003.1-200x now specifies that SIGCONT causes the stopped process to continue when it is generated, delivery of SIGCONT is not prevented because a process is stopped, even without an explicit exception to this rule.

Ignoring a signal by setting the action to SIG_IGN (or SIG_DFL for signals whose default action is to ignore) is not the same as installing a signal-catching function that simply returns. Invoking such a function will interrupt certain system functions that block processes (for example, *wait*( ), *sigsuspend*( ), *pause*( ), *read*( ), *write*( )) while ignoring a signal has no such effect on the process.

Historical implementations discard pending signals when the action is set to SIG_IGN. However, they do not always do the same when the action is set to SIG_DFL and the default action is to ignore the signal. IEEE Std 1003.1-200x requires this for the sake of consistency and also for completeness, since the only signal this applies to is SIGCHLD, and IEEE Std 1003.1-200x disallows setting its action to SIG_IGN.

Some implementations (System V, for example) assign different semantics for SIGCLD depending on whether the action is set to SIG_IGN or SIG_DFL. Since POSIX.1 requires that the default action for SIGCHLD be to ignore the signal, applications should always set the action to SIG_DFL in order to avoid SIGCHLD.

Whether or not an implementation allows SIG_IGN as a SIGCHLD disposition to be inherited across a call to one of the *exec* family of functions or *posix_spawn*( ) is explicitly left as unspecified. This change was made as a result of IEEE PASC Interpretation 1003.1 #132, and permits the implementation to decide between the following alternatives:

- Unconditionally leave SIGCHLD set to SIG_IGN, in which case the implementation would not allow applications that assume inheritance of SIG_DFL to conform to IEEE Std 1003.1-200x without change. The implementation would, however, retain an ability to control applications that create child processes but never call on the *wait* family of functions, potentially filling up the process table.
- Unconditionally reset SIGCHLD to SIG_DFL, in which case the implementation would allow applications that assume inheritance of SIG_DFL to conform. The implementation would, however, lose an ability to control applications that spawn child processes but never reap them.
- Provide some mechanism, not specified in IEEE Std 1003.1-200x, to control inherited SIGCHLD dispositions.

Some implementations (System V, for example) will deliver a SIGCLD signal immediately when a process establishes a signal-catching function for SIGCLD when that process has a child that has already terminated. Other implementations, such as 4.3 BSD, do not generate a new SIGCHLD signal in this way. In general, a process should not attempt to alter the signal action for the SIGCHLD signal while it has any outstanding children. However, it is not always possible for a process to avoid this; for example, shells sometimes start up processes in pipelines with other processes from the pipeline as children. Processes that cannot ensure that they have no children when altering the signal action for SIGCHLD thus need to be prepared for, but not depend on, generation of an immediate SIGCHLD signal.

The default action of the stop signals (SIGSTOP , SIGTSTP, SIGTTIN, SIGTTOU) is to stop a process that is executing. If a stop signal is delivered to a process that is already stopped, it has no effect. In fact, if a stop signal is generated for a stopped process whose signal mask blocks the signal, the signal will never be delivered to the process since the process must receive a SIGCONT, which discards all pending stop signals, in order to continue executing.

The SIGCONT signal shall continue a stopped process even if SIGCONT is blocked (or ignored). However, if a signal-catching routine has been established for SIGCONT, it will not be entered until SIGCONT is unblocked.

If a process in an orphaned process group stops, it is no longer under the control of a job control shell and hence would not normally ever be continued. Because of this, orphaned processes that receive terminal-related stop signals (SIGTSTP , SIGTTIN, SIGTTOU, but not SIGSTOP) must not be allowed to stop. The goal is to prevent stopped processes from languishing forever. (As SIGSTOP is sent only via *kill*( ), it is assumed that the process or user sending a SIGSTOP can send a SIGCONT when desired.) Instead, the system must discard the stop signal. As an extension, it may also deliver another signal in its place. 4.3 BSD sends a SIGKILL, which is overly effective because SIGKILL is not catchable. Another possible choice is SIGHUP. 4.3 BSD also does this for orphaned processes (processes whose parent has terminated) rather than for members of orphaned process groups; this is less desirable because job control shells manage process groups. POSIX.1 also prevents SIGTTIN and SIGTTOU signals from being generated for processes in orphaned process groups as a direct result of activity on a terminal, preventing infinite loops when *read*( ) and *write*( ) calls generate signals that are discarded; see Section A.11.1.4 (on page 3357). A similar restriction on the generation of SIGTSTP was considered, but that would be unnecessary and more difficult to implement due to its asynchronous nature.

Although POSIX.1 requires that signal-catching functions be called with only one argument, there is nothing to prevent conforming implementations from extending POSIX.1 to pass additional arguments, as long as Strictly Conforming POSIX.1 Applications continue to compile and execute correctly. Most historical implementations do, in fact, pass additional, signal-specific arguments to certain signal-catching routines.

There was a proposal to change the declared type of the signal handler to:

```
void func (int sig, ...);
```

The usage of ellipses (`"..."`) is ISO C standard syntax to indicate a variable number of arguments. Its use was intended to allow the implementation to pass additional information to the signal handler in a standard manner.

Unfortunately, this construct would require all signal handlers to be defined with this syntax because the ISO C standard allows implementations to use a different parameter passing mechanism for variable parameter lists than for non-variable parameter lists. Thus, all existing signal handlers in all existing applications would have to be changed to use the variable syntax in order to be standard and portable. This is in conflict with the goal of Minimal Changes to Existing Application Code.

When terminating a process from a signal-catching function, processes should be aware of any interpretation that their parent may make of the status returned by *wait*( ) or *waitpid*( ). In particular, a signal-catching function should not call *exit*(0) or *_exit*(0) unless it wants to indicate successful termination. A non-zero argument to *exit*( ) or *_exit*( ) can be used to indicate unsuccessful termination. Alternatively, the process can use *kill*( ) to send itself a fatal signal (first ensuring that the signal is set to the default action and not blocked). See also the RATIONALE section of the *_exit*( ) function.

The behavior of *unsafe* functions, as defined by this section, is undefined when they are invoked from signal-catching functions in certain circumstances. The behavior of reentrant functions, as defined by this section, is as specified by POSIX.1, regardless of invocation from a signal-catching function. This is the only intended meaning of the statement that reentrant functions may be used in signal-catching functions without restriction. Applications must still consider all effects of such functions on such things as data structures, files, and process state. In particular, application writers need to consider the restrictions on interactions when interrupting *sleep*( ) (see *sleep*( )) and interactions among multiple handles for a file description. The fact that any specific function is listed as reentrant does not necessarily mean that invocation of that function from a signal-catching function is recommended.

In order to prevent errors arising from interrupting non-reentrant function calls, applications should protect calls to these functions either by blocking the appropriate signals or through the use of some programmatic semaphore. POSIX.1 does not address the more general problem of synchronizing access to shared data structures. Note in particular that even the ‘‘safe’’ functions may modify the global variable *errno*; the signal-catching function may want to save and restore its value. The same principles apply to the reentrancy of application routines and asynchronous data access.

Note that *longjmp*( ) and *siglongjmp*( ) are not in the list of reentrant functions. This is because the code executing after *longjmp*( ) or *siglongjmp*( ) can call any unsafe functions with the same danger as calling those unsafe functions directly from the signal handler. Applications that use *longjmp*( ) or *siglongjmp*( ) out of signal handlers require rigorous protection in order to be portable. Many of the other functions that are excluded from the list are traditionally implemented using either the C language *malloc*( ) or *free*( ) functions or the ISO C standard I/O library, both of which traditionally use data structures in a non-reentrant manner. Because any combination of different functions using a common data structure can cause reentrancy problems, POSIX.1 does not define the behavior when any unsafe function is called in a signal handler that interrupts any unsafe function.

The only realtime extension to signal actions is the addition of the additional parameters to the signal-catching function. This extension has been explained and motivated in the previous section. In making this extension, though, developers of POSIX.1b ran into issues relating to function prototypes. In response to input from the POSIX.1 standard developers, members were added to the **sigaction** structure to specify function prototypes for the newer signal-catching function specified by POSIX.1b. These members follow changes that are being made to POSIX.1. Note that IEEE Std 1003.1-200x explicitly states that these fields may overlap so that a union can be defined. This will enable existing implementations of POSIX.1 to maintain binary-compatibility when these extensions are added.

The **siginfo_t** structure was adopted for passing the application-defined value to match existing practice, but the existing practice has no provision for an application-defined value, so this was added. Note that POSIX normally reserves the ‘‘_t’’ type designation for opaque types. The **siginfo_t** structure breaks with this convention to follow existing practice and thus promote portability. Standardization of the existing practice for the other members of this structure may be addressed in the future.

Although it is not explicitly visible to applications, there are additional semantics for signal actions implied by queued signals and their interaction with other POSIX.1b realtime functions. Specifically:

- It is not necessary to queue signals whose action is SIG_IGN.
- For implementations that support POSIX.1b timers, some interaction with the timer functions at signal delivery is implied to manage the timer overrun count.

B.2.4.4 *Signal Effects on Other Functions*

The most common behavior of an interrupted function after a signal-catching function returns is for the interrupted function to give an [EINTR] error. However, there are a number of specific exceptions, including *sleep*( ) and certain situations with *read*( ) and *write*( ).

The historical implementations of many functions defined by IEEE Std 1003.1-200x are not interruptible, but delay delivery of signals generated during their execution until after they complete. This is never a problem for functions that are guaranteed to complete in a short (imperceptible to a human) period of time. It is normally those functions that can suspend a process indefinitely or for long periods of time (for example, *wait*( ), *pause*( ), *sigsuspend*( ), *sleep*( ), or *read*( )/*write*( ) on a slow device like a terminal] that are interruptible. This permits applications to respond to interactive signals or to set timeouts on calls to most such functions with *alarm*( ). Therefore, implementations should generally make such functions (including ones defined as extensions) interruptible.

Functions not mentioned explicitly as interruptible may be so on some implementations, possibly as an extension where the function gives an [EINTR] error. There are several functions (for example, *getpid*( ), *getuid*( )) that are specified as never returning an error, which can thus never be extended in this way.

B.2.5 Standard I/O Streams

B.2.5.1 *Interaction of File Descriptors and Standard I/O Streams*

There is no additional rationale provided for this section.

B.2.5.2 *Stream Orientation and Encoding Rules*

There is no additional rationale provided for this section.

B.2.6 STREAMS

STREAMS are introduced into IEEE Std 1003.1-200x as part of the alignment with the Single UNIX Specification, but marked as an option in recognition that not all systems may wish to implement the facility. The option within IEEE Std 1003.1-200x is denoted by the XSR margin marker. The standard developers made this option independent of the XSI option.

STREAMS are a method of implementing network services and other character-based input/output mechanisms, with the STREAM being a full-duplex connection between a process and a device. STREAMS provides direct access to protocol modules, and optional protocol modules can be interposed between the process-end of the STREAM and the device-driver at the device-end of the STREAM. Pipes can be implemented using the STREAMS mechanism, so they can provide process-to-process as well as process-to-device communications.

This section introduces STREAMS I/O, the message types used to control them, an overview of the priority mechanism, and the interfaces used to access them.

B.2.6.1 *Accessing STREAMS*

There is no additional rationale provided for this section.

B.2.7 XSI Interprocess Communication

There are two forms of IPC supported as options in IEEE Std 1003.1-200x. The traditional System V IPC routines derived from the SVID—that is, the *msg**( ), *sem**( ), and *shm**( ) interfaces—are mandatory on XSI-conformant systems. Thus, all XSI-conformant systems provide the same mechanisms for manipulating messages, shared memory, and semaphores.

In addition, the POSIX Realtime Extension provides an alternate set of routines for those systems supporting the appropriate options.

The application writer is presented with a choice: the System V interfaces or the POSIX interfaces (loosely derived from the Berkeley interfaces). The XSI profile prefers the System V interfaces, but the POSIX interfaces may be more suitable for realtime or other performance-sensitive applications.

B.2.7.1 IPC General Information

General information that is shared by all three mechanisms is described in this section. The common permissions mechanism is briefly introduced, describing the mode bits, and how they are used to determine whether or not a process has access to read or write/alter the appropriate instance of one of the IPC mechanisms. All other relevant information is contained in the reference pages themselves.

The semaphore type of IPC allows processes to communicate through the exchange of semaphore values. A semaphore is a positive integer. Since many applications require the use of more than one semaphore, XSI-conformant systems have the ability to create sets or arrays of semaphores.

Calls to support semaphores include:

semctl( ), *semget*( ), *semop*( )

Semaphore sets are created by using the *semget*( ) function.

The message type of IPC allows process to communicate through the exchange of data stored in buffers. This data is transmitted between processes in discrete portions known as messages.

Calls to support message queues include:

msgctl( ), *msgget*( ), *msgrcv*( ), *msgsnd*( )

The share memory type of IPC allows two or more processes to share memory and consequently the data contained therein. This is done by allowing processes to set up access to a common memory address space. This sharing of memory provides a fast means of exchange of data between processes.

Calls to support shared memory include:

shmctl( ), *shmdt*( ), *shmget*( )

The *ftok*( ) interface is also provided.

B.2.8 Realtime

Advisory Information

POSIX.1b contains an Informative Annex with proposed interfaces for ‘‘real-time files’’. These interfaces could determine groups of the exact parameters required to do ‘‘direct I/O’’ or ‘‘extents’’. These interfaces were objected to by a significant portion of the balloting group as too complex. A conforming application had little chance of correctly navigating the large parameter space to match its desires to the system. In addition, they only applied to a new type of file (realtime files) and they told the implementation exactly what to do as opposed to advising the implementation on application behavior and letting it optimize for the system the (portable) application was running on. For example, it was not clear how a system that had a disk array should set its parameters.

There seemed to be several overall goals:

- Optimizing sequential access
- Optimizing caching behavior
- Optimizing I/O data transfer
- Preallocation

The advisory interfaces, *posix_fadvise*( ) and *posix_madvise*( ), satisfy the first two goals. The POSIX_FADV_SEQUENTIAL and POSIX_MADV_SEQUENTIAL advice tells the implementation to expect serial access. Typically the system will prefetch the next several serial accesses in order to overlap I/O. It may also free previously accessed serial data if memory is tight. If the application is not doing serial access it can use POSIX_FADV_WILLNEED and POSIX_MADV_WILLNEED to accomplish I/O overlap, as required. When the application advises POSIX_FADV_RANDOM or POSIX_MADV_RANDOM behavior, the implementation usually tries to fetch a minimum amount of data with each request and it does not expect much locality. POSIX_FADV_DONTNEED and POSIX_MADV_DONTNEED allow the system to free up caching resources as the data will not be required in the near future.

POSIX_FADV_NOREUSE tells the system that caching the specified data is not optimal. For file I/O, the transfer should go directly to the user buffer instead of being cached internally by the implementation. To portably perform direct disk I/O on all systems, the application must perform its I/O transfers according to the following rules:

1. The user buffer should be aligned according to the {POSIX_REC_XFER_ALIGN} *pathconf*( ) variable.
2. The number of bytes transferred in an I/O operation should be a multiple of the {POSIX_ALLOC_SIZE_MIN} *pathconf*( ) variable.
3. The offset into the file at the start of an I/O operation should be a multiple of the {POSIX_ALLOC_SIZE_MIN} *pathconf*( ) variable.
4. The application should ensure that all threads which open a given file specify POSIX_FADV_NOREUSE to be sure that there is no unexpected interaction between threads using buffered I/O and threads using direct I/O to the same file.

In some cases, a user buffer must be properly aligned in order to be transferred directly to/from the device. The {POSIX_REC_XFER_ALIGN} *pathconf*( ) variable tells the application the proper alignment.

The preallocation goal is met by the space control function, *posix_fallocate*( ). The application can use *posix_fallocate*( ) to guarantee no [ENOSPC] errors and to improve performance by prepaying any overhead required for block allocation.

Implementations may use information conveyed by a previous *posix_fadvise*( ) call to influence the manner in which allocation is performed. For example, if an application did the following calls:

```
fd = open("file");
posix_fadvise(fd, offset, len, POSIX_FADV_SEQUENTIAL);
posix_fallocate(fd, len, size);
```

an implementation might allocate the file contiguously on disk.

Finally, the *pathconf*( ) variables {POSIX_REC_MIN_XFER_SIZE}, {POSIX_REC_MAX_XFER_SIZE}, and {POSIX_REC_INCR_XFER_SIZE} tell the application a range of transfer sizes that are recommended for best I/O performance.

Where bounded response time is required, the vendor can supply the appropriate settings of the advisories to achieve a guaranteed performance level.

The interfaces meet the goals while allowing applications using regular files to take advantage of performance optimizations. The interfaces tell the implementation expected application behavior which the implementation can use to optimize performance on a particular system with a particular dynamic load.

The *posix_memalign*( ) function was added to allow for the allocation of specifically aligned buffers; for example, for {POSIX_REC_XFER_ALIGN}.

The working group also considered the alternative of adding a function which would return an aligned pointer to memory within a user supplied buffer. This was not considered to be the best method, because it potentially wastes large amounts of memory when buffers need to be aligned on large alignment boundaries.

Message Passing

This section provides the rationale for the definition of the message passing interface in IEEE Std 1003.1-200x. This is presented in terms of the objectives, models, and requirements imposed upon this interface.

- Objectives

  Many applications, including both realtime and database applications, require a means of passing arbitrary amounts of data between cooperating processes comprising the overall application on one or more processors. Many conventional interfaces for interprocess communication are insufficient for realtime applications in that efficient and deterministic data passing methods cannot be implemented. This has prompted the definition of message passing interfaces providing these facilities:

  — Open a message queue.

  — Send a message to a message queue.

  — Receive a message from a queue, either synchronously or asynchronously.

  — Alter message queue attributes for flow and resource control.

  It is assumed that an application may consist of multiple cooperating processes and that these processes may wish to communicate and coordinate their activities. The message passing facility described in IEEE Std 1003.1-200x allows processes to communicate through system-wide queues. These message queues are accessed through names that may be pathnames. A message queue can be opened for use by multiple sending and/or multiple receiving processes.

- Background on Embedded Applications

  Interprocess communication utilizing message passing is a key facility for the construction of deterministic, high-performance realtime applications. The facility is present in all realtime systems and is the framework upon which the application is constructed. The performance of the facility is usually a direct indication of the performance of the resulting application.

  Realtime applications, especially for embedded systems, are typically designed around the performance constraints imposed by the message passing mechanisms. Applications for embedded systems are typically very tightly constrained. Application writers expect to design and control the entire system. In order to minimize system costs, the writer will attempt to use all resources to their utmost and minimize the requirement to add additional memory or processors.

  The embedded applications usually share address spaces and only a simple message passing mechanism is required. The application can readily access common data incurring only mutual-exclusion overheads. The models desired are the simplest possible with the application building higher-level facilities only when needed.

- Requirements

  The following requirements determined the features of the message passing facilities defined in IEEE Std 1003.1-200x:

  — Naming of Message Queues

  The mechanism for gaining access to a message queue is a pathname evaluated in a context that is allowed to be a file system name space, or it can be independent of any file system. This is a specific attempt to allow implementations based on either method in order to address both embedded systems and to also allow implementation in larger systems.

  The interface of *mq_open*( ) is defined to allow but not require the access control and name conflicts resulting from utilizing a file system for name resolution. All required behavior is specified for the access control case. Yet a conforming implementation, such as an embedded system kernel, may define that there are no distinctions between users and may define that all process have all access privileges.

  — Embedded System Naming

  Embedded systems need to be able to utilize independent name spaces for accessing the various system objects. They typically do not have a file system, precluding its utilization as a common name resolution mechanism. The modularity of an embedded system limits the connections between separate mechanisms that can be allowed.

  Embedded systems typically do not have any access protection. Since the system does not support the mixing of applications from different areas, and usually does not even have the concept of an authorization entity, access control is not useful.

  — Large System Naming

  On systems with more functionality, the name resolution must support the ability to use the file system as the name resolution mechanism/object storage medium and to have control over access to the objects. Utilizing the pathname space can result in further errors when the names conflict with other objects.

  — Fixed Size of Messages

The interfaces impose a fixed upper bound on the size of messages that can be sent to a specific message queue. The size is set on an individual queue basis and cannot be changed dynamically.

The purpose of the fixed size is to increase the ability of the system to optimize the implementation of *mq_send*( ) and *mq_receive*( ). With fixed sizes of messages and fixed numbers of messages, specific message blocks can be pre-allocated. This eliminates a significant amount of checking for errors and boundary conditions. Additionally, an implementation can optimize data copying to maximize performance. Finally, with a restricted range of message sizes, an implementation is better able to provide deterministic operations.

— Prioritization of Messages

Message prioritization allows the application to determine the order in which messages are received. Prioritization of messages is a key facility that is provided by most realtime kernels and is heavily utilized by the applications. The major purpose of having priorities in message queues is to avoid priority inversions in the message system, where a high-priority message is delayed behind one or more lower-priority messages. This allows the applications to be designed so that they do not need to be interrupted in order to change the flow of control when exceptional conditions occur. The prioritization does add additional overhead to the message operations in those cases it is actually used but a clever implementation can optimize for the FIFO case to make that more efficient.

— Asynchronous Notification

The interface supports the ability to have a task asynchronously notified of the availability of a message on the queue. The purpose of this facility is to allow the task to perform other functions and yet still be notified that a message has become available on the queue.

To understand the requirement for this function, it is useful to understand two models of application design: a single task performing multiple functions and multiple tasks performing a single function. Each of these models has advantages.

Asynchronous notification is required to build the model of a single task performing multiple operations. This model typically results from either the expectation that interruption is less expensive than utilizing a separate task or from the growth of the application to include additional functions.

Semaphores

Semaphores are a high-performance process synchronization mechanism. Semaphores are named by null-terminated strings of characters.

A semaphore is created using the *sem_init*( ) function or the *sem_open*( ) function with the O_CREAT flag set in *oflag*.

To use a semaphore, a process has to first initialize the semaphore or inherit an open descriptor for the semaphore via *fork*( ).

A semaphore preserves its state when the last reference is closed. For example, if a semaphore has a value of 13 when the last reference is closed, it will have a value of 13 when it is next opened.

When a semaphore is created, an initial state for the semaphore has to be provided. This value is a non-negative integer. Negative values are not possible since they indicate the presence of blocked processes. The persistence of any of these objects across a system crash or a system reboot is undefined. Conforming applications shall not depend on any sort of persistence across a system reboot or a system crash.

- Models and Requirements

  A realtime system requires synchronization and communication between the processes comprising the overall application. An efficient and reliable synchronization mechanism has to be provided in a realtime system that will allow more than one schedulable process mutually-exclusive access to the same resource. This synchronization mechanism has to allow for the optimal implementation of synchronization or systems implementors will define other, more cost-effective methods.

  At issue are the methods whereby multiple processes (tasks) can be designed and implemented to work together in order to perform a single function. This requires interprocess communication and synchronization. A semaphore mechanism is the lowest level of synchronization that can be provided by an operating system.

  A semaphore is defined as an object that has an integral value and a set of blocked processes associated with it. If the value is positive or zero, then the set of blocked processes is empty; otherwise, the size of the set is equal to the absolute value of the semaphore value. The value of the semaphore can be incremented or decremented by any process with access to the semaphore and must be done as an indivisible operation. When a semaphore value is less than or equal to zero, any process that attempts to lock it again will block or be informed that it is not possible to perform the operation.

  A semaphore may be used to guard access to any resource accessible by more than one schedulable task in the system. It is a global entity and not associated with any particular process. As such, a method of obtaining access to the semaphore has to be provided by the operating system. A process that wants access to a critical resource (section) has to wait on the semaphore that guards that resource. When the semaphore is locked on behalf of a process, it knows that it can utilize the resource without interference by any other cooperating process in the system. When the process finishes its operation on the resource, leaving it in a well-defined state, it posts the semaphore, indicating that some other process may now obtain the resource associated with that semaphore.

  In this section, mutexes and condition variables are specified as the synchronization mechanisms between threads.

  These primitives are typically used for synchronizing threads that share memory in a single process. However, this section provides an option allowing the use of these synchronization interfaces and objects between processes that share memory, regardless of the method for sharing memory.

  Much experience with semaphores shows that there are two distinct uses of synchronization: locking, which is typically of short duration; and waiting, which is typically of long or unbounded duration. These distinct usages map directly onto mutexes and condition variables, respectively.

  Semaphores are provided in IEEE Std 1003.1-200x primarily to provide a means of synchronization for processes; these processes may or may not share memory. Mutexes and condition variables are specified as synchronization mechanisms between threads; these threads always share (some) memory. Both are synchronization paradigms that have been in widespread use for a number of years. Each set of primitives is particularly well matched to certain problems.

  With respect to binary semaphores, experience has shown that condition variables and mutexes are easier to use for many synchronization problems than binary semaphores. The primary reason for this is the explicit appearance of a Boolean predicate that specifies when the condition wait is satisfied. This Boolean predicate terminates a loop, including the call to *pthread_cond_wait*( ). As a result, extra wakeups are benign since the predicate governs whether the thread will actually proceed past the condition wait. With stateful primitives, such as binary semaphores, the wakeup in itself typically means that the wait is satisfied. The burden of ensuring correctness for such waits is thus placed on *all* signalers of the semaphore rather than on an *explicitly coded* Boolean predicate located at the condition wait. Experience has shown that the latter creates a major improvement in safety and ease-of-use.

Counting semaphores are well matched to dealing with producer/consumer problems, including those that might exist between threads of different processes, or between a signal handler and a thread. In the former case, there may be little or no memory shared by the processes; in the latter case, one is not communicating between co-equal threads, but between a thread and an interruptlike entity. It is for these reasons that IEEE Std 1003.1-200x allows semaphores to be used by threads.

Mutexes and condition variables have been effectively used with and without priority inheritance, priority ceiling, and other attributes to synchronize threads that share memory. The efficiency of their implementation is comparable to or better than that of other synchronization primitives that are sometimes harder to use (for example, binary semaphores). Furthermore, there is at least one known implementation of Ada tasking that uses these primitives. Mutexes and condition variables together constitute an appropriate, sufficient, and complete set of interthread synchronization primitives.

Efficient multi-threaded applications require high-performance synchronization primitives. Considerations of efficiency and generality require a small set of primitives upon which more sophisticated synchronization functions can be built.

- Standardization Issues

  It is possible to implement very high-performance semaphores using test-and-set instructions on shared memory locations. The library routines that implement such a high-performance interface has to properly ensure that a *sem_wait*( ) or *sem_trywait*( ) operation that cannot be performed will issue a blocking semaphore system call or properly report the condition to the application. The same interface to the application program would be provided by a high-performance implementation.

B.2.8.1 Realtime Signals

Realtime Signals Extension

This portion of the rationale presents models, requirements, and standardization issues relevant to the Realtime Signals Extension. This extension provides the capability required to support reliable, deterministic, asynchronous notification of events. While a new mechanism, unencumbered by the historical usage and semantics of POSIX.1 signals, might allow for a more efficient implementation, the application requirements for event notification can be met with a small number of extensions to signals. Therefore, a minimal set of extensions to signals to support the application requirements is specified.

The realtime signal extensions specified in this section are used by other realtime functions requiring asynchronous notification:

- Models

  The model supported is one of multiple cooperating processes, each of which handles multiple asynchronous external events. Events represent occurrences that are generated as the result of some activity in the system. Examples of occurrences that can constitute an event include:

— Completion of an asynchronous I/O request

— Expiration of a POSIX.1b timer

— Arrival of an interprocess message

— Generation of a user-defined event

Processing of these events may occur synchronously via polling for event notifications or asynchronously via a software interrupt mechanism. Existing practice for this model is well established for traditional proprietary realtime operating systems, realtime executives, and realtime extended POSIX-like systems.

A contrasting model is that of ‘‘cooperating sequential processes’’ where each process handles a single priority of events via polling. Each process blocks while waiting for events, and each process depends on the preemptive, priority-based process scheduling mechanism to arbitrate between events of different priority that need to be processed concurrently. Existing practice for this model is also well established for small realtime executives that typically execute in an unprotected physical address space, but it is just emerging in the context of a fuller function operating system with multiple virtual address spaces.

It could be argued that the cooperating sequential process model, and the facilities supported by the POSIX Threads Extension obviate a software interrupt model. But, even with the cooperating sequential process model, the need has been recognized for a software interrupt model to handle exceptional conditions and process aborting, so the mechanism must be supported in any case. Furthermore, it is not the purview of IEEE Std 1003.1-200x to attempt to convince realtime practitioners that their current application models based on software interrupts are ‘‘broken’’ and should be replaced by the cooperating sequential process model. Rather, it is the charter of IEEE Std 1003.1-200x to provide standard extensions to mechanisms that support existing realtime practice.

- Requirements

This section discusses the following realtime application requirements for asynchronous event notification:

— Reliable delivery of asynchronous event notification

The events notification mechanism shall guarantee delivery of an event notification. Asynchronous operations (such as asynchronous I/O and timers) that complete significantly after they are invoked have to guarantee that delivery of the event notification can occur at the time of completion.

— Prioritized handling of asynchronous event notifications

The events notification mechanism shall support the assigning of a user function as an event notification handler. Furthermore, the mechanism shall support the preemption of an event handler function by a higher priority event notification and shall support the selection of the highest priority pending event notification when multiple notifications (of different priority) are pending simultaneously.

The model here is based on hardware interrupts. Asynchronous event handling allows the application to ensure that time-critical events are immediately processed when delivered, without the indeterminism of being at a random location within a polling loop. Use of handler priority allows the specification of how handlers are interrupted by other higher priority handlers.

  - Differentiation between multiple occurrences of event notifications of the same type

    The events notification mechanism shall pass an application-defined value to the event handler function. This value can be used for a variety of purposes, such as enabling the application to identify which of several possible events of the same type (for example, timer expirations) has occurred.

  - Polled reception of asynchronous event notifications

    The events notification mechanism shall support blocking and non-blocking polls for asynchronous event notification.

    The polled mode of operation is often preferred over the interrupt mode by those practitioners accustomed to this model. Providing support for this model facilitates the porting of applications based on this model to POSIX.1b conforming systems.

  - Deterministic response to asynchronous event notifications

    The events notification mechanism shall not preclude implementations that provide deterministic event dispatch latency and shall minimize the number of system calls needed to use the event facilities during realtime processing.

- Rationale for Extension

  POSIX.1 signals have many of the characteristics necessary to support the asynchronous handling of event notifications, and the Realtime Signals Extension addresses the following deficiencies in the POSIX.1 signal mechanism:

  - Signals do not support reliable delivery of event notification. Subsequent occurrences of a pending signal are not guaranteed to be delivered.

  - Signals do not support prioritized delivery of event notifications. The order of signal delivery when multiple unblocked signals are pending is undefined.

  - Signals do not support the differentiation between multiple signals of the same type.

B.2.8.2 Asynchronous I/O

Many applications need to interact with the I/O subsystem in an asynchronous manner. The asynchronous I/O mechanism provides the ability to overlap application processing and I/O operations initiated by the application. The asynchronous I/O mechanism allows a single process to perform I/O simultaneously to a single file multiple times or to multiple files multiple times.

Overview

Asynchronous I/O operations proceed in logical parallel with the processing done by the application after the asynchronous I/O has been initiated. Other than this difference, asynchronous I/O behaves similarly to normal I/O using *read*( ), *write*( ), *lseek*( ), and *fsync*( ). The effect of issuing an asynchronous I/O request is as if a separate thread of execution were to perform atomically the implied *lseek*( ) operation, if any, and then the requested I/O operation (either *read*( ), *write*( ), or *fsync*( )). There is no seek implied with a call to *aio_fsync*( ). Concurrent asynchronous operations and synchronous operations applied to the same file update the file as if the I/O operations had proceeded serially.

When asynchronous I/O completes, a signal can be delivered to the application to indicate the completion of the I/O. This signal can be used to indicate that buffers and control blocks used for asynchronous I/O can be reused. Signal delivery is not required for an asynchronous operation and may be turned off on a per-operation basis by the application. Signals may also be synchronously polled using *aio_suspend*( ), *sigtimedwait*( ), or *sigwaitinfo*( ).

Normal I/O has a return value and an error status associated with it. Asynchronous I/O returns a value and an error status when the operation is first submitted, but that only relates to whether the operation was successfully queued up for servicing. The I/O operation itself also has a return status and an error value. To allow the application to retrieve the return status and the error value, functions are provided that, given the address of an asynchronous I/O control block, yield the return and error status associated with the operation. Until an asynchronous I/O operation is done, its error status shall be [EINPROGRESS]. Thus, an application can poll for completion of an asynchronous I/O operation by waiting for the error status to become equal to a value other than [EINPROGRESS]. The return status of an asynchronous I/O operation is undefined so long as the error status is equal to [EINPROGRESS].

Storage for asynchronous operation return and error status may be limited. Submission of asynchronous I/O operations may fail if this storage is exceeded. When an application retrieves the return status of a given asynchronous operation, therefore, any system-maintained storage used for this status and the error status may be reclaimed for use by other asynchronous operations.

Asynchronous I/O can be performed on file descriptors that have been enabled for POSIX.1b synchronized I/O. In this case, the I/O operation still occurs asynchronously, as defined herein; however, the asynchronous operation I/O in this case is not completed until the I/O has reached either the state of synchronized I/O data integrity completion or synchronized I/O file integrity completion, depending on the sort of synchronized I/O that is enabled on the file descriptor.

Models

Three models illustrate the use of asynchronous I/O: a journalization model, a data acquisition model, and a model of the use of asynchronous I/O in supercomputing applications.

- Journalization Model

  Many realtime applications perform low-priority journalizing functions. Journalizing requires that logging records be queued for output without blocking the initiating process.

- Data Acquisition Model

  A data acquisition process may also serve as a model. The process has two or more channels delivering intermittent data that must be read within a certain time. The process issues one asynchronous read on each channel. When one of the channels needs data collection, the process reads the data and posts it through an asynchronous write to secondary memory for future processing.

- Supercomputing Model

  The supercomputing community has used asynchronous I/O much like that specified herein for many years. This community requires the ability to perform multiple I/O operations to multiple devices with a minimal number of entries to ‘‘the system’’; each entry to ‘‘the system’’ provokes a major delay in operations when compared to the normal progress made by the application. This existing practice motivated the use of combined *lseek*( ) and *read*( ) or *write*( ) calls, as well as the *lio_listio*( ) call. Another common practice is to disable signal notification for I/O completion, and simply poll for I/O completion at some interval by which the I/O should be completed. Likewise, interfaces like *aio_cancel*( ) have been in successful commercial use for many years. Note also that an underlying implementation of asynchronous I/O will require the ability, at least internally, to cancel outstanding asynchronous I/O, at least when the process exits. (Consider an asynchronous read from a terminal, when the process intends to exit immediately.)

Requirements

Asynchronous input and output for realtime implementations have these requirements:

- The ability to queue multiple asynchronous read and write operations to a single open instance. Both sequential and random access should be supported.
- The ability to queue asynchronous read and write operations to multiple open instances.
- The ability to obtain completion status information by polling and/or asynchronous event notification.
- Asynchronous event notification on asynchronous I/O completion is optional.
- It has to be possible for the application to associate the event with the *aiocbp* for the operation that generated the event.
- The ability to cancel queued requests.
- The ability to wait upon asynchronous I/O completion in conjunction with other types of events.
- The ability to accept an *aio_read*( ) and an *aio_cancel*( ) for a device that accepts a *read*( ), and the ability to accept an *aio_write*( ) and an *aio_cancel*( ) for a device that accepts a *write*( ). This does not imply that the operation is asynchronous.

Standardization Issues

The following issues are addressed by the standardization of asynchronous I/O:

- Rationale for New Interface

  Non-blocking I/O does not satisfy the needs of either realtime or high-performance computing models; these models require that a process overlap program execution and I/O processing. Realtime applications will often make use of direct I/O to or from the address space of the process, or require synchronized (unbuffered) I/O; they also require the ability to overlap this I/O with other computation. In addition, asynchronous I/O allows an application to keep a device busy at all times, possibly achieving greater throughput. Supercomputing and database architectures will often have specialized hardware that can provide true asynchrony underlying the logical asynchrony provided by this interface. In addition, asynchronous I/O should be supported by all types of files and devices in the same manner.

- Effect of Buffering

  If asynchronous I/O is performed on a file that is buffered prior to being actually written to the device, it is possible that asynchronous I/O will offer no performance advantage over normal I/O; the cycles *stolen* to perform the asynchronous I/O will be taken away from the running process and the I/O will occur at interrupt time. This potential lack of gain in performance in no way obviates the need for asynchronous I/O by realtime applications, which very often will use specialized hardware support; multiple processors; and/or unbuffered, synchronized I/O.

B.2.8.3 Memory Management

All memory management and shared memory definitions are located in the **<sys/mman.h>** header. This is for alignment with historical practice.

Memory Locking Functions

This portion of the rationale presents models, requirements, and standardization issues relevant to process memory locking.

- Models

  Realtime systems that conform to IEEE Std 1003.1-200x are expected (and desired) to be supported on systems with demand-paged virtual memory management, non-paged swapping memory management, and physical memory systems with no memory management hardware. The general case, however, is the demand-paged, virtual memory system with each POSIX process running in a virtual address space. Note that this includes architectures where each process resides in its own virtual address space and architectures where the address space of each process is only a portion of a larger global virtual address space.

  The concept of memory locking is introduced to eliminate the indeterminacy introduced by paging and swapping, and to support an upper bound on the time required to access the memory mapped into the address space of a process. Ideally, this upper bound will be the same as the time required for the processor to access ‘‘main memory’’, including any address translation and cache miss overheads. But some implementations—primarily on mainframes—will not actually force locked pages to be loaded and held resident in main memory. Rather, they will handle locked pages so that accesses to these pages will meet the performance metrics for locked process memory in the implementation. Also, although it is not, for example, the intention that this interface, as specified, be used to lock process memory into ‘‘cache’’, it is conceivable that an implementation could support a large static RAM memory and define this as ‘‘main memory’’ and use a large[r] dynamic RAM as ‘‘backing store’’. These interfaces could then be interpreted as supporting the locking of process memory into the static RAM. Support for multiple levels of backing store would require extensions to these interfaces.

  Implementations may also use memory locking to guarantee a fixed translation between virtual and physical addresses where such is beneficial to improving determinancy for direct-to/from-process input/output. IEEE Std 1003.1-200x does not guarantee to the application that the virtual-to-physical address translations, if such exist, are fixed, because such behavior would not be implementable on all architectures on which implementations of IEEE Std 1003.1-200x are expected. But IEEE Std 1003.1-200x does mandate that an implementation define, for the benefit of potential users, whether or not locking guarantees fixed translations.

  Memory locking is defined with respect to the address space of a process. Only the pages mapped into the address space of a process may be locked by the process, and when the pages are no longer mapped into the address space—for whatever reason—the locks established with respect to that address space are removed. Shared memory areas warrant special mention, as they may be mapped into more than one address space or mapped more than once into the address space of a process; locks may be established on pages within these areas with respect to several of these mappings. In such a case, the lock state of the underlying physical pages is the logical OR of the lock state with respect to each of the mappings. Only when all such locks have been removed are the shared pages considered unlocked.

In recognition of the page granularity of Memory Management Units (MMU), and in order to support locking of ranges of address space, memory locking is defined in terms of ''page'' granularity. That is, for the interfaces that support an address and size specification for the region to be locked, the address must be on a page boundary, and all pages mapped by the specified range are locked, if valid. This means that the length is implicitly rounded up to a multiple of the page size. The page size is implementation-defined and is available to applications as a compile time symbolic constant or at runtime via *sysconf*( ).

A ''real memory'' POSIX.1b implementation that has no MMU could elect not to support these interfaces, returning [ENOSYS]. But an application could easily interpret this as meaning that the implementation would unconditionally page or swap the application when such is not the case. It is the intention of IEEE Std 1003.1-200x that such a system could define these interfaces as ''NO-OPs'', returning success without actually performing any function except for mandated argument checking.

- Requirements

For realtime applications, memory locking is generally considered to be required as part of application initialization. This locking is performed after an application has been loaded (that is, *exec*'d) and the program remains locked for its entire lifetime. But to support applications that undergo major mode changes where, in one mode, locking is required, but in another it is not, the specified interfaces allow repeated locking and unlocking of memory within the lifetime of a process.

When a realtime application locks its address space, it should not be necessary for the application to then ''touch'' all of the pages in the address space to guarantee that they are resident or else suffer potential paging delays the first time the page is referenced. Thus, IEEE Std 1003.1-200x requires that the pages locked by the specified interfaces be resident when the locking functions return successfully.

Many architectures support system-managed stacks that grow automatically when the current extent of the stack is exceeded. A realtime application has a requirement to be able to ''preallocate'' sufficient stack space and lock it down so that it will not suffer page faults to grow the stack during critical realtime operation. There was no consensus on a portable way to specify how much stack space is needed, so IEEE Std 1003.1-200x supports no specific interface for preallocating stack space. But an application can portably lock down a specific amount of stack space by specifying MCL_FUTURE in a call to *memlockall*( ) and then calling a dummy function that declares an automatic array of the desired size.

Memory locking for realtime applications is also generally considered to be an ''all or nothing'' proposition. That is, the entire process, or none, is locked down. But, for applications that have well-defined sections that need to be locked and others that do not, IEEE Std 1003.1-200x supports an optional set of interfaces to lock or unlock a range of process addresses. Reasons for locking down a specific range include:

— An asynchronous event handler function that must respond to external events in a deterministic manner such that page faults cannot be tolerated

— An input/output ''buffer'' area that is the target for direct-to-process I/O, and the overhead of implicit locking and unlocking for each I/O call cannot be tolerated

Finally, locking is generally viewed as an ''application-wide'' function. That is, the application is globally aware of which regions are locked and which are not over time. This is in contrast to a function that is used temporarily within a ''third party'' library routine whose function is unknown to the application, and therefore must have no ''side effects''. The specified interfaces, therefore, do not support ''lock stacking'' or ''lock nesting'' within a process. But, for pages that are shared between processes or mapped more than once into a process address space, ''lock stacking'' is essentially mandated by the requirement that unlocking of pages that are mapped by more that one process or more than once by the same process does not affect locks established on the other mappings.

There was some support for ''lock stacking'' so that locking could be transparently used in functions or opaque modules. But the consensus was not to burden all implementations with lock stacking (and reference counting), and an implementation option was proposed. There were strong objections to the option because applications would have to support both options in order to remain portable. The consensus was to eliminate lock stacking altogether, primarily through overwhelming support for the System V ''m[un]lock[all]'' interface on which IEEE Std 1003.1-200x is now based.

Locks are not inherited across *fork*( )s because some implementations implement *fork*( ) by creating new address spaces for the child. In such an implementation, requiring locks to be inherited would lead to new situations in which a fork would fail due to the inability of the system to lock sufficient memory to lock both the parent and the child. The consensus was that there was no benefit to such inheritance. Note that this does not mean that locks are removed when, for instance, a thread is created in the same address space. |

Similarly, locks are not inherited across *exec* because some implementations implement *exec* by unmapping all of the pages in the address space (which, by definition, removes the locks on these pages), and maps in pages of the *exec*'d image. In such an implementation, requiring locks to be inherited would lead to new situations in which *exec* would fail. Reporting this failure would be very cumbersome to detect in time to report to the calling process, and no appropriate mechanism exists for informing the *exec*'d process of its status. |

It was determined that, if the newly loaded application required locking, it was the responsibility of that application to establish the locks. This is also in keeping with the general view that it is the responsibility of the application to be aware of all locks that are established.

There was one request to allow (not mandate) locks to be inherited across *fork*( ), and a request for a flag, MCL_INHERIT, that would specify inheritance of memory locks across *exec*s. Given the difficulties raised by this and the general lack of support for the feature in IEEE Std 1003.1-200x, it was not added. IEEE Std 1003.1-200x does not preclude an implementation from providing this feature for administrative purposes, such as a ''run'' command that will lock down and execute specified program. Additionally, the rationale for the objection equated *fork*( ) with creating a thread in the address space. IEEE Std 1003.1-200x does not mandate releasing locks when creating additional threads in an existing process.

- Standardization Issues

One goal of IEEE Std 1003.1-200x is to define a set of primitives that provide the necessary functionality for realtime applications, with consideration for the needs of other application domains where such were identified, which is based to the extent possible on existing industry practice.

The Memory Locking option is required by many realtime applications to tune performance. Such a facility is accomplished by placing constraints on the virtual memory system to limit paging of time of the process or of critical sections of the process. This facility should not be used by most non-realtime applications.

Optional features provided in IEEE Std 1003.1-200x allow applications to lock selected address ranges with the caveat that the process is responsible for being aware of the page granularity of locking and the unnested nature of the locks.

Mapped Files Functions

The Memory Mapped Files option provides a mechanism that allows a process to access files by directly incorporating file data into its address space. Once a file is ‘‘mapped’’ into a process address space, the data can be manipulated by instructions as memory. The use of mapped files can significantly reduce I/O data movement since file data does not have to be copied into process data buffers as in *read*( ) and *write*( ). If more than one process maps a file, its contents are shared among them. This provides a low overhead mechanism by which processes can synchronize and communicate.

- Historical Perspective

  Realtime applications have historically been implemented using a collection of cooperating processes or tasks. In early systems, these processes ran on bare hardware (that is, without an operating system) with no memory relocation or protection. The application paradigms that arose from this environment involve the sharing of data between the processes.

  When realtime systems were implemented on top of vendor-supplied operating systems, the paradigm or performance benefits of direct access to data by multiple processes was still deemed necessary. As a result, operating systems that claim to support realtime applications must support the shared memory paradigm.

  Additionally, a number of realtime systems provide the ability to map specific sections of the physical address space into the address space of a process. This ability is required if an application is to obtain direct access to memory locations that have specific properties (for example, refresh buffers or display devices, dual ported memory locations, DMA target locations). The use of this ability is common enough to warrant some degree of standardization of its interface. This ability overlaps the general paradigm of shared memory in that, in both instances, common global objects are made addressable by individual processes or tasks.

  Finally, a number of systems also provide the ability to map process addresses to files. This provides both a general means of sharing persistent objects, and using files in a manner that optimizes memory and swapping space usage.

  Simple shared memory is clearly a special case of the more general file mapping capability. In addition, there is relatively widespread agreement and implementation of the file mapping interface. In these systems, many different types of objects can be mapped (for example, files, memory, devices, and so on) using the same mapping interfaces. This approach both minimizes interface proliferation and maximizes the generality of programs using the mapping interfaces.

- Memory Mapped Files Usage

  A memory object can be concurrently mapped into the address space of one or more processes. The *mmap*( ) and *munmap*( ) functions allow a process to manipulate their address space by mapping portions of memory objects into it and removing them from it. When multiple processes map the same memory object, they can share access to the underlying data. Implementations may restrict the size and alignment of mappings to be on *page*-size boundaries. The page size, in bytes, is the value of the system-configurable variable {PAGESIZE}, typically accessed by calling *sysconf*( ) with a *name* argument of _SC_PAGESIZE. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size.

  To map memory, a process first opens a memory object. The *ftruncate*( ) function can be used to contract or extend the size of the memory object even when the object is currently mapped. If the memory object is extended, the contents of the extended areas are zeros.

After opening a memory object, the application maps the object into its address space using the *mmap*( ) function call. Once a mapping has been established, it remains mapped until unmapped with *munmap*( ), even if the memory object is closed. The *mprotect*( ) function can be used to change the memory protections initially established by *mmap*( ).

A *close*( ) of the file descriptor, while invalidating the file descriptor itself, does not unmap any mappings established for the memory object. The address space, including all mapped regions, is inherited on *fork*( ). The entire address space is unmapped on process termination or by successful calls to any of the *exec* family of functions.

The *msync*( ) function is used to force mapped file data to permanent storage.

- Effects on Other Functions

When the Memory Mapped Files option is supported, the operation of the *open*( ), *creat*( ), and *unlink*( ) functions are a natural result of using the file system name space to map the global names for memory objects.

The *ftruncate*( ) function can be use to set the length of a sharable memory object.

The meaning of *stat*( ) fields other than the size and protection information is undefined on implementations where memory objects are not implemented using regular files. When regular files are used, the times reflect when the implementation updated the file image of the data, not when a process updated the data in memory.

The operations of *fdopen*( ), *write*( ), *read*( ), and *lseek*( ) were made unspecified for objects opened with *shm_open*( ), so that implementations that did not implement memory objects as regular files would not have to support the operation of these functions on shared memory objects.

The behavior of memory objects with respect to *close*( ), *dup*( ), *dup2*( ), *open*( ), *close*( ), *fork*( ), *_exit*( ), and the *exec* family of functions is the same as the behavior of the existing practice of the *mmap*( ) function.

A memory object can still be referenced after a close. That is, any mappings made to the file are still in effect, and reads and writes that are made to those mappings are still valid and are shared with other processes that have the same mapping. Likewise, the memory object can still be used if any references remain after its name(s) have been deleted. Any references that remain after a close must not appear to the application as file descriptors.

This is existing practice for *mmap*( ) and *close*( ). In addition, there are already mappings present (text, data, stack) that do not have open file descriptors. The text mapping in particular is considered a reference to the file containing the text. The desire was to treat all mappings by the process uniformly. Also, many modern implementations use *mmap*( ) to implement shared libraries, and it would not be desirable to keep file descriptors for each of the many libraries an application can use. It was felt there were many other existing programs that used this behavior to free a file descriptor, and thus IEEE Std 1003.1-200x could not forbid it and still claim to be using existing practice.

For implementations that implement memory objects using memory only, memory objects will retain the memory allocated to the file after the last close and will use that same memory on the next open. Note that closing the memory object is not the same as deleting the name, since the memory object is still defined in the memory object name space.

The locks of *fcntl*( ) do not block any read or write operation, including read or write access to shared memory or mapped files. In addition, implementations that only support shared memory objects should not be required to implement record locks. The reference to *fcntl*( ) is added to make this point explicitly. The other *fcntl*( ) commands are useful with shared memory objects.

The size of pages that mapping hardware may be able to support may be a configurable value, or it may change based on hardware implementations. The addition of the _SC_PAGESIZE parameter to the *sysconf*( ) function is provided for determining the mapping page size at runtime.

Shared Memory Functions

Implementations may support the Shared Memory Objects option without supporting a general Memory Mapped Files option. Shared memory objects are named regions of storage that may be independent of the file system and can be mapped into the address space of one or more processes to allow them to share the associated memory.

- Requirements

  Shared memory is used to share data among several processes, each potentially running at different priority levels, responding to different inputs, or performing separate tasks. Shared memory is not just simply providing common access to data, it is providing the fastest possible communication between the processes. With one memory write operation, a process can pass information to as many processes as have the memory region mapped.

  As a result, shared memory provides a mechanism that can be used for all other interprocess communications facilities. It may also be used by an application for implementing more sophisticated mechanisms than semaphores and message queues.

  The need for a shared memory interface is obvious for virtual memory systems, where the operating system is directly preventing processes from accessing each other's data. However, in unprotected systems, such as those found in some embedded controllers, a shared memory interface is needed to provide a portable mechanism to allocate a region of memory to be shared and then to communicate the address of that region to other processes.

  This, then, provides the minimum functionality that a shared memory interface must have in order to support realtime applications: to allocate and name an object to be mapped into memory for potential sharing (*open*( ) or *shm_open*( )), and to make the memory object available within the address space of a process (*mmap*( )). To complete the interface, a mechanism to release the claim of a process on a shared memory object (*munmap*( )) is also needed, as well as a mechanism for deleting the name of a sharable object that was previously created (*unlink*( ) or *shm_unlink*( )).

  After a mapping has been established, an implementation should not have to provide services to maintain that mapping. All memory writes into that area will appear immediately in the memory mapping of that region by any other processes.

  Thus, requirements include:

  — Support creation of sharable memory objects and the mapping of these objects into the address space of a process.

  — Sharable memory objects should be accessed by global names accessible from all processes.

  — Support the mapping of specific sections of physical address space (such as a memory mapped device) into the address space of a process. This should not be done by the process specifying the actual address, but again by an implementation-defined global name (such as a special device name) dedicated to this purpose.

  — Support the mapping of discrete portions of these memory objects.

- — Support for minimum hardware configurations that contain no physical media on which to store shared memory contents permanently.
- — The ability to preallocate the entire shared memory region so that minimum hardware configurations without virtual memory support can guarantee contiguous space.
- — The maximizing of performance by not requiring functionality that would require implementation interaction above creating the shared memory area and returning the mapping.

Note that the above requirements do not preclude:

- — The sharable memory object from being implemented using actual files on an actual file system.
- — The global name that is accessible from all processes being restricted to a file system area that is dedicated to handling shared memory.
- — An implementation not providing implementation-defined global names for the purpose of physical address mapping.

- Shared Memory Objects Usage

If the Shared Memory Objects option is supported, a shared memory object may be created, or opened if it already exists, with the *shm_open*( ) function. If the shared memory object is created, it has a length of zero. The *ftruncate*( ) function can be used to set the size of the shared memory object after creation. The *shm_unlink*( ) function removes the name for a shared memory object created by *shm_open*( ).

- Shared Memory Overview

The shared memory facility defined by IEEE Std 1003.1-200x usually results in memory locations being added to the address space of the process. The implementation returns the address of the new space to the application by means of a pointer. This works well in languages like C. However, in languages without pointer types it will not work. In the bindings for such a language, either a special COMMON section will need to be defined (which is unlikely), or the binding will have to allow existing structures to be mapped. The implementation will likely have to place restrictions on the size and alignment of such structures or will have to map a suitable region of the address space of the process into the memory object, and thus into other processes. These are issues for that particular language binding. For IEEE Std 1003.1-200x, however, the practice will not be forbidden, merely undefined.

Two potentially different name spaces are used for naming objects that may be mapped into process address spaces. When the Memory Mapped Files option is supported, files may be accessed via *open*( ). When the Shared Memory Objects option is supported, sharable memory objects that might not be files may be accessed via the *shm_open*( ) function. These options are not mutually-exclusive.

Some implementations supporting the Shared Memory Objects option may choose to implement the shared memory object name space as part of the file system name space. There are several reasons for this:

- — It allows applications to prevent name conflicts by use of the directory structure.
- — It uses an existing mechanism for accessing global objects and prevents the creation of a new mechanism for naming global objects.

In such implementations, memory objects can be implemented using regular files, if that is what the implementation chooses. The *shm_open*( ) function can be implemented as an *open*( )

call in a fixed directory followed by a call to *fcntl*( ) to set FD_CLOEXEC. The *shm_unlink*( ) function can be implemented as an *unlink*( ) call.

On the other hand, it is also expected that small embedded systems that support the Shared Memory Objects option may wish to implement shared memory without having any file systems present. In this case, the implementations may choose to use a simple string valued name space for shared memory regions. The *shm_open*( ) function permits either type of implementation.

Some implementations have hardware that supports protection of mapped data from certain classes of access and some do not. Systems that supply this functionality can support the Memory Protection option.

Some implementations restrict size, alignment, and protections to be on *page*-size boundaries. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size. Applications on implementations that do support larger pages must be cognizant of the page size since this is the alignment and protection boundary.

Simple embedded implementations may have a 1-byte page size and only support the Shared Memory Objects option. This provides simple shared memory between processes without requiring mapping hardware.

IEEE Std 1003.1-200x specifically allows a memory object to remain referenced after a close because that is existing practice for the *mmap*( ) function.

Typed Memory Functions

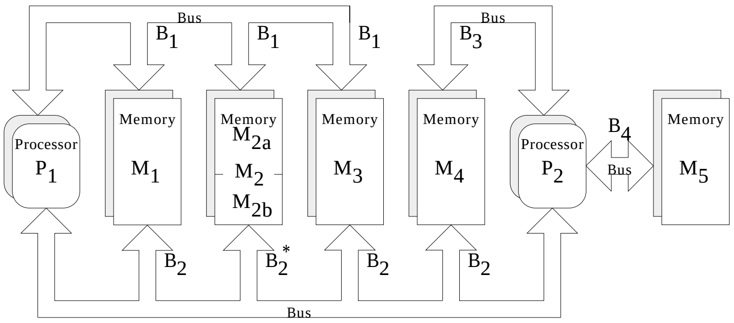
Implementations may support the Typed Memory Objects option without supporting either the Shared Memory option or the Memory Mapped Files option. Typed memory objects are pools of specialized storage, different from the main memory resource normally used by a processor to hold code and data, that can be mapped into the address space of one or more processes.

- Model

  Realtime systems conforming to one of the POSIX.13 realtime profiles are expected (and desired) to be supported on systems with more than one type or pool of memory (for example, SRAM, DRAM, ROM, EPROM, EEPROM), where each type or pool of memory may be accessible by one or more processors via one or more busses (ports). Memory mapped files, shared memory objects, and the language-specific storage allocation operators (*malloc*( ) for the ISO C standard, *new* for ISO Ada) fail to provide application program interfaces versatile enough to allow applications to control their utilization of such diverse memory resources. The typed memory interfaces *posix_typed_mem_open*( ), *posix_mem_offset*( ), *posix_typed_mem_get_info*( ), *mmap*( ), and *munmap*( ) defined herein support the model of typed memory described below.

  For purposes of this model, a system comprises several processors (for example, P1 and P2), several physical memory pools (for example, M1, M2, M2a, M2b, M3, M4, and M5), and several busses or ‘‘ports’’ (for example, B1, B2, B3, and B4) interconnecting the various processors and memory pools in some system-specific way. Notice that some memory pools may be contained in others (for example, M2a and M2b are contained in M2).

  Figure B-1 (on page 3412) shows an example of such a model. In a system like this, an application should be able to perform the following operations:



* All addresses in pool M_2 (comprising pools M_{2a} and M_{2b}) accessible via port B_1.
Addresses in pool M_{2b} are also accessible via port B_2.
Addresses in pool M_{2a} are *not* accessible via port B_2.

Figure B-1 Example of a System with Typed Memory

— Typed Memory Allocation

An application should be able to allocate memory dynamically from the desired pool using the desired bus, and map it into a process' address space. For example, processor P1 can allocate some portion of memory pool M1 through port B1, treating all unmapped subareas of M1 as a heap-storage resource from which memory may be allocated. This portion of memory is mapped into the process' address space, and subsequently deallocated when unmapped from all processes.

— Using the Same Storage Region from Different Busses

An application process with a mapped region of storage that is accessed from one bus should be able to map that same storage area at another address (subject to page size restrictions detailed in *mmap*( )), to allow it to be accessed from another bus. For example, processor P1 may wish to access the same region of memory pool M2b both through ports B1 and B2.

— Sharing Typed Memory Regions

Several application processes running on the same or different processors may wish to share a particular region of a typed memory pool. Each process or processor may wish to access this region through different busses. For example, processor P1 may want to share a region of memory pool M4 with processor P2, and they may be required to use busses B2 and B3, respectively, to minimize bus contention. A problem arises here when a process allocates and maps a portion of fragmented memory and then wants to share this region of memory with another process, either in the same processor or different processors. The solution adopted is to allow the first process to find out the memory map (offsets and lengths) of all the different fragments of memory that were mapped into its address space, by repeatedly calling *posix_mem_offset*( ). Then, this process can pass the offsets and lengths obtained to the second process, which can then map the same memory fragments into its address space.

— Contiguous Allocation

The problem of finding the memory map of the different fragments of the memory pool that were mapped into logically contiguous addresses of a given process, can be solved by requesting contiguous allocation. For example, a process in P1 can allocate 10 Kbytes of physically contiguous memory from M3-B1, and obtain the offset (within pool M3) of this block of memory. Then, it can pass this offset (and the length) to a process in P2 using some interprocess communication mechanism. The second process can map the same block of memory by using the offset transferred and specifying M3-B2.

— Unallocated Mapping

Any subarea of a memory pool that is mapped to a process, either as the result of an allocation request or an explicit mapping, is normally unavailable for allocation. Special processes such as debuggers, however, may need to map large areas of a typed memory pool, yet leave those areas available for allocation.

Typed memory allocation and mapping has to coexist with storage allocation operators like *malloc*( ), but systems are free to choose how to implement this coexistence. For example, it may be system configuration-dependent if all available system memory is made part of one of the typed memory pools or if some part will be restricted to conventional allocation operators. Equally system configuration-dependent may be the availability of operators like *malloc*( ) to allocate storage from certain typed memory pools. It is not excluded to configure a system such that a given named pool, P1, is in turn split into non-overlapping named subpools. For example, M1-B1, M2-B1, and M3-B1 could also be accessed as one common pool M123-B1. A call to *malloc*( ) on P1 could work on such a larger pool while full optimization of memory usage by P1 would require typed memory allocation at the subpool level.

- Existing Practice

OS-9 provides for the naming (numbering) and prioritization of memory types by a system administrator. It then provides APIs to request memory allocation of typed (colored) memory by number, and to generate a bus address from a mapped memory address (translate). When requesting colored memory, the user can specify type 0 to signify allocation from the first available type in priority order.

HP-RT presents interfaces to map different kinds of storage regions that are visible through a VME bus, although it does not provide allocation operations. It also provides functions to perform address translation between VME addresses and virtual addresses. It represents a VME-bus unique solution to the general problem.

The PSOS approach is similar (that is, based on a pre-established mapping of bus address ranges to specific memories) with a concept of segments and regions (regions dynamically allocated from a heap which is a special segment). Therefore, PSOS does not fully address the general allocation problem either. PSOS does not have a ‘‘process’’-based model, but more of a ‘‘thread’’-only-based model of multi-tasking. So mapping to a process address space is not an issue.

QNX (a Canadian OS vendor specializing in realtime embedded systems on 80x86-based processors) uses the System V approach of opening specially named devices (shared memory segments) and using *mmap*( ) to then gain access from the process. They do not address allocation directly, but once typed shared memory can be mapped, an ‘‘allocation manager’’ process could be written to handle requests for allocation.

The System V approach also included allocation, implemented by opening yet other special ‘‘devices’’ which allocate, rather than appearing as a whole memory object.

The Orkid realtime kernel interface definition has operations to manage memory ‘‘regions’’ and ‘‘pools’’, which are areas of memory that may reflect the differing physical nature of the memory. Operations to allocate memory from these regions and pools are also provided.

- Requirements

  Existing practice in SVID-derived UNIX systems relies on functionality similar to *mmap*( ) and its related interfaces to achieve mapping and allocation of typed memory. However, the issue of sharing typed memory (allocated or mapped) and the complication of multiple ports are not addressed in any consistent way by existing UNIX system practice. Part of this functionality is existing practice in specialized realtime operating systems. In order to solidify the capabilities implied by the model above, the following requirements are imposed on the interface:

  — Identification of Typed Memory Pools and Ports

  All processes (running in all processors) in the system shall be able to identify a particular (system configured) typed memory pool accessed through a particular (system configured) port by a name. That name shall be a member of a name space common to all these processes, but need not be the same name space as that containing ordinary filenames. The association between memory pools/ports and corresponding names is typically established when the system is configured. The ''open'' operation for typed memory objects should be distinct from the *open*( ) function, for consistency with other similar services, but implementable on top of *open*( ). This implies that the handle for a typed memory object will be a file descriptor.

  — Allocation and Mapping of Typed Memory

  Once a typed memory object has been identified by a process, it shall be possible to both map user-selected subareas of that object into process address space and to map system-selected (that is, dynamically allocated) subareas of that object, with user-specified length, into process address space. It shall also be possible to determine the maximum length of memory allocation that may be requested from a given typed memory object.

  — Sharing Typed Memory

  Two or more processes shall be able to share portions of typed memory, either user-selected or dynamically allocated. This requirement applies also to dynamically allocated regions of memory that are composed of several non-contiguous pieces.

  — Contiguous Allocation

  For dynamic allocation, it shall be the user's option whether the system is required to allocate a contiguous subarea within the typed memory object, or whether it is permitted to allocate discontiguous fragments which appear contiguous in the process mapping. Contiguous allocation simplifies the process of sharing allocated typed memory, while discontiguous allocation allows for potentially better recovery of deallocated typed memory.

  — Accessing Typed Memory Through Different Ports

  Once a subarea of a typed memory object has been mapped, it shall be possible to determine the location and length corresponding to a user-selected portion of that object within the memory pool. This location and length can then be used to remap that portion of memory for access from another port. If the referenced portion of typed memory was allocated discontiguously, the length thus determined may be shorter than anticipated, and the user code shall adapt to the value returned.

  — Deallocation

  When a previously mapped subarea of typed memory is no longer mapped by any process in the system—as a result of a call or calls to *munmap*( )—that subarea shall become potentially reusable for dynamic allocation; actual reuse of the subarea is a function of the dynamic typed memory allocation policy.

— Unallocated Mapping

It shall be possible to map user-selected subareas of a typed memory object without marking that subarea as unavailable for allocation. This option is not the default behavior, and shall require appropriate privilege.

- Scenario

The following scenario will serve to clarify the use of the typed memory interfaces.

Process A running on P1 (see Figure B-1 (on page 3412)) wants to allocate some memory from memory pool M2, and it wants to share this portion of memory with process B running on P2. Since P2 only has access to the lower part of M2, both processes will use the memory pool named M2b which is the part of M2 that is accessible both from P1 and P2. The operations that both processes need to perform are shown below:

— Allocating Typed Memory

Process A calls *posix_typed_mem_open*( ) with the name **/typed.m2b-b1** and a *tflag* of POSIX_TYPED_MEM_ALLOCATE to get a file descriptor usable for allocating from pool M2b accessed through port B1. It then calls *mmap*( ) with this file descriptor requesting a length of 4 096 bytes. The system allocates two discontiguous blocks of sizes 1 024 and 3 072 bytes within M2b. The *mmap*( ) function returns a pointer to a 4 096 byte array in process A's logical address space, mapping the allocated blocks contiguously. Process A can then utilize the array, and store data in it.

— Determining the Location of the Allocated Blocks

Process A can determine the lengths and offsets (relative to M2b) of the two blocks allocated, by using the following procedure: First, process A calls *posix_mem_offset*( ) with the address of the first element of the array and length 4 096. Upon return, the offset and length (1 024 bytes) of the first block are returned. A second call to *posix_mem_offset*( ) is then made using the address of the first element of the array plus 1 024 (the length of the first block), and a new length of 4 096–1 024. If there were more fragments allocated, this procedure could have been continued within a loop until the offsets and lengths of all the blocks were obtained. Notice that this relatively complex procedure can be avoided if contiguous allocation is requested (by opening the typed memory object with the *tflag* POSIX_TYPED_MEM_ALLOCATE_CONTIG).

— Sharing Data Across Processes

Process A passes the two offset values and lengths obtained from the *posix_mem_offset*( ) calls to process B running on P2, via some form of interprocess communication. Process B can gain access to process A's data by calling *posix_typed_mem_open*( ) with the name **/typed.m2b-b2** and a *tflag* of zero, then using two *mmap*( ) calls on the resulting file descriptor to map the two subareas of that typed memory object to its own address space.

- Rationale for no *mem_alloc*( ) and *mem_free*( )

The standard developers had originally proposed a pair of new flags to *mmap*( ) which, when applied to a typed memory object descriptor, would cause *mmap*( ) to allocate dynamically from an unallocated and unmapped area of the typed memory object. Deallocation was similarly accomplished through the use of *munmap*( ). This was rejected by the ballot group because it excessively complicated the (already rather complex) *mmap*( ) interface and introduced semantics useful only for typed memory, to a function which must also map shared memory and files. They felt that a memory allocator should be built on top of *mmap*( ) instead of being incorporated within the same interface, much as the ISO C standard libraries build *malloc*( ) on top of the virtual memory mapping functions *brk*( ) and *sbrk*( ). This would eliminate the complicated semantics involved with unmapping only part of an allocated block of typed memory.

To attempt to achieve ballot group consensus, typed memory allocation and deallocation was first migrated from *mmap*( ) and *munmap*( ) to a pair of complementary functions modeled on the ISO C standard *malloc*( ) and *free*( ). The *mem_alloc*( ) function specified explicitly the typed memory object (typed memory pool/access port) from which allocation takes place, unlike *malloc*( ) where the memory pool and port are unspecified. The *mem_free*( ) function handled deallocation. These new semantics still met all of the requirements detailed above without modifying the behavior of *mmap*( ) except to allow it to map specified areas of typed memory objects. An implementation would have been free to implement *mem_alloc*( ) and *mem_free*( ) over *mmap*( ), through *mmap*( ), or independently but cooperating with *mmap*( ).

The ballot group was queried to see if this was an acceptable alternative, and while there was some agreement that it achieved the goal of removing the complicated semantics of allocation from the *mmap*( ) interface, several balloters realized that it just created two additional functions that behaved, in great part, like *mmap*( ). These balloters proposed an alternative which has been implemented here in place of a separate *mem_alloc*( ) and *mem_free*( ). This alternative is based on four specific suggestions:

1. The *posix_typed_mem_open*( ) function should provide a flag which specifies ‘‘allocate on *mmap*( )’’ (otherwise, *mmap*( ) just maps the underlying object). This allows things roughly similar to **/dev/zero** *versus* **/dev/swap**. Two such flags have been implemented, one of which forces contiguous allocation.

2. The *posix_mem_offset*( ) function is acceptable because it can be applied usefully to mapped objects in general. It should return the file descriptor of the underlying object.

3. The *mem_get_info*( ) function in an earlier draft should be renamed *posix_typed_mem_get_info*( ) because it is not generally applicable to memory objects. It should probably return the file descriptor's allocation attribute. We have implemented the renaming of the function, but reject having it return a piece of information which is readily known by an application without this function. Its whole purpose is to query the typed memory object for attributes that are not user-specified, but determined by the implementation.

4. There should be no separate *mem_alloc*( ) or *mem_free*( ) functions. Instead, using *mmap*( ) on a typed memory object opened with an ‘‘allocate on *mmap*( )’’ flag should be used to force allocation. These are precisely the semantics defined in the current draft.

- Rationale for no Typed Memory Access Management

The working group had originally defined an additional interface (and an additional kind of object: typed memory master) to establish and dissolve mappings to typed memory on behalf of devices or processors which were independent of the operating system and had no inherent capability to directly establish mappings on their own. This was to have provided functionality similar to device driver interfaces such as *physio*( ) and their underlying bus-specific interfaces (for example, *mballoc*( )) which serve to set up and break down DMA pathways, and derive mapped addresses for use by hardware devices and processor cards.

The ballot group felt that this was beyond the scope of POSIX.1 and its amendments. Furthermore, the removal of interrupt handling interfaces from a preceding amendment (the IEEE Std 1003.1d-1999) during its balloting process renders these typed memory access management interfaces an incomplete solution to portable device management from a user process; it would be possible to initiate a device transfer to/from typed memory, but impossible to handle the transfer-complete interrupt in a portable way.

To achieve ballot group consensus, all references to typed memory access management capabilities were removed. The concept of portable interfaces from a device driver to both operating system and hardware is being addressed by the Uniform Driver Interface (UDI) industry forum, with formal standardization deferred until proof of concept and industry-wide acceptance and implementation.

B.2.8.4 Process Scheduling

IEEE PASC Interpretation 1003.1 #96 has been applied, adding the *pthread_setschedprio*( ) function. This was added since previously there was no way for a thread to lower its own priority without going to the tail of the threads list for its new priority. This capability is necessary to bound the duration of priority inversion encountered by a thread.

The following portion of the rationale presents models, requirements, and standardization issues relevant to process scheduling; see also Section B.2.9.4 (on page 3456).

In an operating system supporting multiple concurrent processes, the system determines the order in which processes execute to meet implementation-defined goals. For time-sharing systems, the goal is to enhance system throughput and promote fairness; the application is provided little or no control over this sequencing function. While this is acceptable and desirable behavior in a time-sharing system, it is inappropriate in a realtime system; realtime applications must specifically control the execution sequence of their concurrent processes in order to meet externally defined response requirements.

In IEEE Std 1003.1-200x, the control over process sequencing is provided using a concept of scheduling policies. These policies, described in detail in this section, define the behavior of the system whenever processor resources are to be allocated to competing processes. Only the behavior of the policy is defined; conforming implementations are free to use any mechanism desired to achieve the described behavior.

- Models

  In an operating system supporting multiple concurrent processes, the system determines the order in which processes execute and might force long-running processes to yield to other processes at certain intervals. Typically, the scheduling code is executed whenever an event occurs that might alter the process to be executed next.

  The simplest scheduling strategy is a ‘‘first-in, first-out’’ (FIFO) dispatcher. Whenever a process becomes runnable, it is placed on the end of a ready list. The process at the front of the ready list is executed until it exits or becomes blocked, at which point it is removed from the list. This scheduling technique is also known as ‘‘run-to-completion’’ or ‘‘run-to-block’’.

  A natural extension to this scheduling technique is the assignment of a ‘‘non-migrating priority’’ to each process. This policy differs from strict FIFO scheduling in only one respect: whenever a process becomes runnable, it is placed at the end of the list of processes runnable at that priority level. When selecting a process to run, the system always selects the first process from the highest priority queue with a runnable process. Thus, when a process becomes unblocked, it will preempt a running process of lower priority without otherwise altering the ready list. Further, if a process elects to alter its priority, it is removed from the ready list and reinserted, using its new priority, according to the policy above.

  While the above policy might be considered unfriendly in a time-sharing environment in which multiple users require more balanced resource allocation, it could be ideal in a realtime environment for several reasons. The most important of these is that it is deterministic: the highest-priority process is always run and, among processes of equal priority, the process that has been runnable for the longest time is executed first. Because of this determinism, cooperating processes can implement more complex scheduling simply by altering their priority. For instance, if processes at a single priority were to reschedule themselves at fixed time intervals, a time-slice policy would result.

In a dedicated operating system in which all processes are well-behaved realtime applications, non-migrating priority scheduling is sufficient. However, many existing implementations provide for more complex scheduling policies.

IEEE Std 1003.1-200x specifies a linear scheduling model. In this model, every process in the system has a priority. The system scheduler always dispatches a process that has the highest (generally the most time-critical) priority among all runnable processes in the system. As long as there is only one such process, the dispatching policy is trivial. When multiple processes of equal priority are eligible to run, they are ordered according to a strict run-to-completion (FIFO) policy.

The priority is represented as a positive integer and is inherited from the parent process. For processes running under a fixed priority scheduling policy, the priority is never altered except by an explicit function call.

It was determined arbitrarily that larger integers correspond to ‘‘higher priorities’’.

Certain implementations might impose restrictions on the priority ranges to which processes can be assigned. There also can be restrictions on the set of policies to which processes can be set.

- Requirements

Realtime processes require that scheduling be fast and deterministic, and that it guarantees to preempt lower priority processes.

Thus, given the linear scheduling model, realtime processes require that they be run at a priority that is higher than other processes. Within this framework, realtime processes are free to yield execution resources to each other in a completely portable and implementation-defined manner.

As there is a generally perceived requirement for processes at the same priority level to share processor resources more equitably, provisions are made by providing a scheduling policy (that is, SCHED_RR) intended to provide a timeslice-like facility.

Note: The following topics assume that low numeric priority implies low scheduling criticality and *vice versa.*

- Rationale for New Interface

Realtime applications need to be able to determine when processes will run in relation to each other. It must be possible to guarantee that a critical process will run whenever it is runnable; that is, whenever it wants to for as long as it needs. SCHED_FIFO satisfies this requirement. Additionally, SCHED_RR was defined to meet a realtime requirement for a well-defined time-sharing policy for processes at the same priority.

It would be possible to use the BSD *setpriority*( ) and *getpriority*( ) functions by redefining the meaning of the ‘‘nice’’ parameter according to the scheduling policy currently in use by the process. The System V *nice*( ) interface was felt to be undesirable for realtime because it specifies an adjustment to the ‘‘nice’’ value, rather than setting it to an explicit value. Realtime applications will usually want to set priority to an explicit value. Also, System V *nice*( ) does not allow for changing the priority of another process.

With the POSIX.1b interfaces, the traditional ‘‘nice’’ value does not affect the SCHED_FIFO or SCHED_RR scheduling policies. If a ‘‘nice’’ value is supported, it is implementation-defined whether it affects the SCHED_OTHER policy.

An important aspect of IEEE Std 1003.1-200x is the explicit description of the queuing and preemption rules. It is critical, to achieve deterministic scheduling, that such rules be stated clearly in IEEE Std 1003.1-200x.

IEEE Std 1003.1-200x does not address the interaction between priority and swapping. The issues involved with swapping and virtual memory paging are extremely implementation-defined and would be nearly impossible to standardize at this point. The proposed scheduling paradigm, however, fully describes the scheduling behavior of runnable processes, of which one criterion is that the working set be resident in memory. Assuming the existence of a portable interface for locking portions of a process in memory, paging behavior need not affect the scheduling of realtime processes.

IEEE Std 1003.1-200x also does not address the priorities of ‘‘system’’ processes. In general, these processes should always execute in low-priority ranges to avoid conflict with other realtime processes. Implementations should document the priority ranges in which system processes run.

The default scheduling policy is not defined. The effect of I/O interrupts and other system processing activities is not defined. The temporary lending of priority from one process to another (such as for the purposes of affecting freeing resources) by the system is not addressed. Preemption of resources is not addressed. Restrictions on the ability of a process to affect other processes beyond a certain level (influence levels) is not addressed.

The rationale used to justify the simple time-quantum scheduler is that it is common practice to depend upon this type of scheduling to assure ‘‘fair’’ distribution of processor resources among portions of the application that must interoperate in a serial fashion. Note that IEEE Std 1003.1-200x is silent with respect to the setting of this time quantum, or whether it is a system-wide value or a per-process value, although it appears that the prevailing realtime practice is for it to be a system-wide value.

In a system with N processes at a given priority, all processor-bound, in which the time quantum is equal for all processes at a specific priority level, the following assumptions are made of such a scheduling policy:

1. A time quantum Q exists and the current process will own control of the processor for at least a duration of Q and will have the processor for a duration of Q.
2. The Nth process at that priority will control a processor within a duration of $(N-1) \times Q$.

These assumptions are necessary to provide equal access to the processor and bounded response from the application.

The assumptions hold for the described scheduling policy only if no system overhead, such as interrupt servicing, is present. If the interrupt servicing load is non-zero, then one of the two assumptions becomes fallacious, based upon how Q is measured by the system.

If Q is measured by clock time, then the assumption that the process obtains a duration Q processor time is false if interrupt overhead exists. Indeed, a scenario can be constructed with N processes in which a single process undergoes complete processor starvation if a peripheral device, such as an analog-to-digital converter, generates significant interrupt activity periodically with a period of $N \times Q$.

If Q is measured as actual processor time, then the assumption that the Nth process runs in within the duration $(N-1) \times Q$ is false.

It should be noted that SCHED_FIFO suffers from interrupt-based delay as well. However, for SCHED_FIFO, the implied response of the system is ‘‘as soon as possible’’, so that the interrupt load for this case is a vendor selection and not a compliance issue.

With this in mind, it is necessary either to complete the definition by including bounds on the interrupt load, or to modify the assumptions that can be made about the scheduling policy.

Since the motivation of inclusion of the policy is common usage, and since current applications do not enjoy the luxury of bounded interrupt load, item (2) above is sufficient to express existing application needs and is less restrictive in the standard definition. No difference in interface is necessary.

In an implementation in which the time quantum is equal for all processes at a specific priority, our assumptions can then be restated as:

- A time quantum Q exists, and a processor-bound process will be rescheduled after a duration of, at most, Q. Time quantum Q may be defined in either wall clock time or execution time.
- In general, the Nth process of a priority level should wait no longer than $(N-1) \times Q$ time to execute, assuming no processes exist at higher priority levels.
- No process should wait indefinitely.

For implementations supporting per-process time quanta, these assumptions can be readily extended.

Sporadic Server Scheduling Policy

The sporadic server is a mechanism defined for scheduling aperiodic activities in time-critical realtime systems. This mechanism reserves a certain bounded amount of execution capacity for processing aperiodic events at a high priority level. Any aperiodic events that cannot be processed within the bounded amount of execution capacity are executed in the background at a low priority level. Thus, a certain amount of execution capacity can be guaranteed to be available for processing periodic tasks, even under burst conditions in the arrival of aperiodic processing requests (that is, a large number of requests in a short time interval). The sporadic server also simplifies the schedulability analysis of the realtime system, because it allows aperiodic processes or threads to be treated as if they were periodic. The sporadic server was first described by Sprunt, et al.

The key concept of the sporadic server is to provide and limit a certain amount of computation capacity for processing aperiodic events at their assigned normal priority, during a time interval called the *replenishment period*. Once the entity controlled by the sporadic server mechanism is initialized with its period and execution-time budget attributes, it preserves its execution capacity until an aperiodic request arrives. The request will be serviced (if there are no higher priority activities pending) as long as there is execution capacity left. If the request is completed, the actual execution time used to service it is subtracted from the capacity, and a replenishment of this amount of execution time is scheduled to happen one replenishment period after the arrival of the aperiodic request. If the request is not completed, because there is no execution capacity left, then the aperiodic process or thread is assigned a lower background priority. For each portion of consumed execution capacity the execution time used is replenished after one replenishment period. At the time of replenishment, if the sporadic server was executing at a background priority level, its priority is elevated to the normal level. Other similar replenishment policies have been defined, but the one presented here represents a compromise between efficiency and implementation complexity.

The interface that appears in this section defines a new scheduling policy for threads and processes that behaves according to the rules of the sporadic server mechanism. Scheduling attributes are defined and functions are provided to allow the user to set and get the parameters that control the scheduling behavior of this mechanism, namely the normal and low priority, the replenishment period, the maximum number of pending replenishment operations, and the initial execution-time budget.

- Scheduling Aperiodic Activities

  Virtually all realtime applications are required to process aperiodic activities. In many cases, there are tight timing constraints that the response to the aperiodic events must meet. Usual timing requirements imposed on the response to these events are:

  — The effects of an aperiodic activity on the response time of lower priority activities must be controllable and predictable.

  — The system must provide the fastest possible response time to aperiodic events.

  — It must be possible to take advantage of all the available processing bandwidth not needed by time-critical activities to enhance average-case response times to aperiodic events.

  Traditional methods for scheduling aperiodic activities are background processing, polling tasks, and direct event execution:

  — Background processing consists of assigning a very low priority to the processing of aperiodic events. It utilizes all the available bandwidth in the system that has not been consumed by higher priority threads. However, it is very difficult, or impossible, to meet requirements on average-case response time, because the aperiodic entity has to wait for the execution of all other entities which have higher priority.

  — Polling consists of creating a periodic process or thread for servicing aperiodic requests. At regular intervals, the polling entity is started and it services accumulated pending aperiodic requests. If no aperiodic requests are pending, the polling entity suspends itself until its next period. Polling allows the aperiodic requests to be processed at a higher priority level. However, worst and average-case response times of polling entities are a direct function of the polling period, and there is execution overhead for each polling period, even if no event has arrived. If the deadline of the aperiodic activity is short compared to the inter-arrival time, the polling frequency must be increased to guarantee meeting the deadline. For this case, the increase in frequency can dramatically reduce the efficiency of the system and, therefore, its capacity to meet all deadlines. Yet, polling represents a good way to handle a large class of practical problems because it preserves system predictability, and because the amortized overhead drops as load increases.

  — Direct event execution consists of executing the aperiodic events at a high fixed-priority level. Typically, the aperiodic event is processed by an interrupt service routine as soon as it arrives. This technique provides predictable response times for aperiodic events, but makes the response times of all lower priority activities completely unpredictable under burst arrival conditions. Therefore, if the density of aperiodic event arrivals is unbounded, it may be a dangerous technique for time-critical systems. Yet, for those cases in which the physics of the system imposes a bound on the event arrival rate, it is probably the most efficient technique.

  — The sporadic server scheduling algorithm combines the predictability of the polling approach with the short response times of the direct event execution. Thus, it allows systems to meet an important class of application requirements that cannot be met by using the traditional approaches. Multiple sporadic servers with different attributes can be applied to the scheduling of multiple classes of aperiodic events, each with different kinds of timing requirements, such as individual deadlines, average response times, and so on. It also has many other interesting applications for realtime, such as scheduling producer/consumer tasks in time-critical systems, limiting the effects of faults on the estimation of task execution-time requirements, and so on.

- Existing Practice

  The sporadic server has been used in different kinds of applications, including military avionics, robot control systems, industrial automation systems, and so on. There are examples of many systems that cannot be successfully scheduled using the classic approaches, such as direct event execution, or polling, and are schedulable using a sporadic server scheduler. The sporadic server algorithm itself can successfully schedule all systems scheduled with direct event execution or polling.

  The sporadic server scheduling policy has been implemented as a commercial product in the run-time system of the Verdix Ada compiler. There are also many applications that have used a much less efficient application-level sporadic server. These real-time applications would benefit from a sporadic server scheduler implemented at the scheduler level.

- Library-Level *versus* Kernel-Level Implementation

  The sporadic server interface described in this section requires the sporadic server policy to be implemented at the same level as the scheduler. This means that the process sporadic server shall be implemented at the kernel level and the thread sporadic server policy shall be implemented at the same level as the thread scheduler; that is, kernel or library level.

  In an earlier interface for the sporadic server, this mechanism was implementable at a different level than the scheduler. This feature allowed the implementer to choose between an efficient scheduler-level implementation, or a simpler user or library-level implementation. However, the working group considered that this interface made the use of sporadic servers more complex, and that library-level implementations would lack some of the important functionality of the sporadic server, namely the limitation of the actual execution time of aperiodic activities. The working group also felt that the interface described in this chapter does not preclude library-level implementations of threads intended to provide efficient low-overhead scheduling for those threads that are not scheduled under the sporadic server policy.

- Range of Scheduling Priorities

  Each of the scheduling policies supported in IEEE Std 1003.1-200x has an associated range of priorities. The priority ranges for each policy might or might not overlap with the priority ranges of other policies. For time-critical realtime applications it is usual for periodic and aperiodic activities to be scheduled together in the same processor. Periodic activities will usually be scheduled using the SCHED_FIFO scheduling policy, while aperiodic activities may be scheduled using SCHED_SPORADIC. Since the application developer will require complete control over the relative priorities of these activities in order to meet his timing requirements, it would be desirable for the priority ranges of SCHED_FIFO and SCHED_SPORADIC to overlap completely. Therefore, although IEEE Std 1003.1-200x does not require any particular relationship between the different priority ranges, it is recommended that these two ranges should coincide.

- Dynamically Setting the Sporadic Server Policy

  Several members of the working group requested that implementations should not be required to support dynamically setting the sporadic server scheduling policy for a thread. The reason is that this policy may have a high overhead for library-level implementations of threads, and if threads are allowed to dynamically set this policy, this overhead can be experienced even if the thread does not use that policy. By disallowing the dynamic setting of the sporadic server scheduling policy, these implementations can accomplish efficient scheduling for threads using other policies. If a strictly conforming application needs to use the sporadic server policy, and is therefore willing to pay the overhead, it must set this policy at the time of thread creation.

- Limitation of the Number of Pending Replenishments

  The number of simultaneously pending replenishment operations must be limited for each sporadic server for two reasons: an unlimited number of replenishment operations would need an unlimited number of system resources to store all the pending replenishment operations; on the other hand, in some implementations each replenishment operation will represent a source of priority inversion (just for the duration of the replenishment operation) and thus, the maximum amount of replenishments must be bounded to guarantee bounded response times. The way in which the number of replenishments is bounded is by lowering the priority of the sporadic server to *sched_ss_low_priority* when the number of pending replenishments has reached its limit. In this way, no new replenishments are scheduled until the number of pending replenishments decreases.

  In the sporadic server scheduling policy defined in IEEE Std 1003.1-200x, the application can specify the maximum number of pending replenishment operations for a single sporadic server, by setting the value of the *sched_ss_max_repl* scheduling parameter. This value must be between one and {SS_REPL_MAX}, which is a maximum limit imposed by the implementation. The limit {SS_REPL_MAX} must be greater than or equal to {_POSIX_SS_REPL_MAX}, which is defined to be four in IEEE Std 1003.1-200x. The minimum limit of four was chosen so that an application can at least guarantee that four different aperiodic events can be processed during each interval of length equal to the replenishment period.

B.2.8.5 Clocks and Timers

- Clocks

  IEEE Std 1003.1-200x and the ISO C standard both define functions for obtaining system time. Implicit behind these functions is a mechanism for measuring passage of time. This specification makes this mechanism explicit and calls it a clock. The CLOCK_REALTIME clock required by IEEE Std 1003.1-200x is a higher resolution version of the clock that maintains POSIX.1 system time. This is a ‘‘system-wide’’ clock, in that it is visible to all processes and, were it possible for multiple processes to all read the clock at the same time, they would see the same value.

  An extensible interface was defined, with the ability for implementations to define additional clocks. This was done because of the observation that many realtime platforms support multiple clocks, and it was desired to fit this model within the standard interface. But implementation-defined clocks need not represent actual hardware devices, nor are they necessarily system-wide.

- Timers

  Two timer types are required for a system to support realtime applications:

  1. One-shot

     A one-shot timer is a timer that is armed with an initial expiration time, either relative to the current time or at an absolute time (based on some timing base, such as time in seconds and nanoseconds since the Epoch). The timer expires once and then is disarmed. With the specified facilities, this is accomplished by setting the *it_value* member of the *value* argument to the desired expiration time and the *it_interval* member to zero.

  2. Periodic

     A periodic timer is a timer that is armed with an initial expiration time, again either relative or absolute, and a repetition interval. When the initial expiration occurs, the timer is reloaded with the repetition interval and continues counting. With the specified facilities, this is accomplished by setting the *it_value* member of the *value* argument to the desired initial expiration time and the *it_interval* member to the desired repetition interval.

For both of these types of timers, the time of the initial timer expiration can be specified in two ways:

1. Relative (to the current time)
2. Absolute

- Examples of Using Realtime Timers

  In the diagrams below, *S* indicates a program schedule, *R* shows a schedule method request, and *E* suggests an internal operating system event.

  — Periodic Timer: Data Logging

  During an experiment, it might be necessary to log realtime data periodically to an internal buffer or to a mass storage device. With a periodic scheduling method, a logging module can be started automatically at fixed time intervals to log the data.

  Program schedule is requested every 10 seconds.

```
    R         S         S         S         S         S
----+----+----+----+----+----+----+----+----+----+----+--->
    5   10   15   20   25   30   35   40   45   50   55
```

  [Time (in Seconds)]

  To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to *timer_settime*( ) with the TIMER_ABSTIME flag reset, and with an initial expiration value and a repetition interval of 10 seconds.

  — One-shot Timer (Relative Time): Device Initialization

  In an emission test environment, large sample bags are used to capture the exhaust from a vehicle. The exhaust is purged from these bags before each and every test. With a one-shot timer, a module could initiate the purge function and then suspend itself for a predetermined period of time while the sample bags are prepared.

  Program schedule requested 20 seconds after call is issued.

```
    R                   S
----+----+----+----+----+----+----+----+----+----+----+--->
    5   10   15   20   25   30   35   40   45   50   55
```

  [Time (in Seconds)]

  To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to *timer_settime*( ) with the TIMER_ABSTIME flag reset, and with an initial expiration value of 20 seconds and a repetition interval of zero.

  Note that if the program wishes merely to suspend itself for the specified interval, it could more easily use *nanosleep*( ).

  — One-shot Timer (Absolute Time): Data Transmission

The results from an experiment are often moved to a different system within a network for postprocessing or archiving. With an absolute one-shot timer, a module that moves data from a test-cell computer to a host computer can be automatically scheduled on a daily basis.

Program schedule requested for 2:30 a.m.

```
         R                                     S
-----+-----+-----+-----+-----+-----+-----+-----+-----+----->
   23:00 23:30 24:00 00:30 01:00 01:30 02:00 02:30 03:00
```

[Time of Day]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to *timer_settime*( ) with the TIMER_ABSTIME flag set, and an initial expiration value equal to 2:30 a.m. of the next day.

- Periodic Timer (Relative Time): Signal Stabilization

Some measurement devices, such as emission analyzers, do not respond instantaneously to an introduced sample. With a periodic timer with a relative initial expiration time, a module that introduces a sample and records the average response could suspend itself for a predetermined period of time while the signal is stabilized and then sample at a fixed rate.

Program schedule requested 15 seconds after call is issued and every 2 seconds thereafter.

```
   R              S S S S S S S S S S S S S S S S S S S S
----+----+----+----+----+----+----+----+----+----+----+--->
    5   10   15   20   25   30   35   40   45   50   55
```

[Time (in Seconds)]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to *timer_settime*( ) with TIMER_ABSTIME flag reset, and with an initial expiration value of 15 seconds and a repetition interval of 2 seconds.

- Periodic Timer (Absolute Time): Work Shift-related Processing

Resource utilization data is useful when time to perform experiments is being scheduled at a facility. With a periodic timer with an absolute initial expiration time, a module can be scheduled at the beginning of a work shift to gather resource utilization data throughout the shift. This data can be used to allocate resources effectively to minimize bottlenecks and delays and maximize facility throughput.

Program schedule requested for 2:00 a.m. and every 15 minutes thereafter.

```
         R                               S  S  S  S  S  S
-----+-----+-----+-----+-----+-----+-----+-----+-----+----->
   23:00 23:30 24:00 00:30 01:00 01:30 02:00 02:30 03:00
```

[Time of Day]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID CLOCK_REALTIME. Then the timer would be armed via a call to *timer_settime*( ) with TIMER_ABSTIME flag set, and with an initial expiration value equal to 2:00 a.m. and a repetition interval equal to 15 minutes.

- Relationship of Timers to Clocks

  The relationship between clocks and timers armed with an absolute time is straightforward: a timer expiration signal is requested when the associated clock reaches or exceeds the specified time. The relationship between clocks and timers armed with a relative time (an interval) is less obvious, but not unintuitive. In this case, a timer expiration signal is requested when the specified interval, *as measured by the associated clock*, has passed. For the required CLOCK_REALTIME clock, this allows timer expiration signals to be requested at specified ‘‘wall clock’’ times (absolute), or when a specified interval of ‘‘realtime’’ has passed (relative). For an implementation-defined clock—say, a process virtual time clock—timer expirations could be requested when the process has used a specified total amount of virtual time (absolute), or when it has used a specified *additional* amount of virtual time (relative).

  The interfaces also allow flexibility in the implementation of the functions. For example, an implementation could convert all absolute times to intervals by subtracting the clock value at the time of the call from the requested expiration time and ‘‘counting down’’ at the supported resolution. Or it could convert all relative times to absolute expiration time by adding in the clock value at the time of the call and comparing the clock value to the expiration time at the supported resolution. Or it might even choose to maintain absolute times as absolute and compare them to the clock value at the supported resolution for absolute timers, and maintain relative times as intervals and count them down at the resolution supported for relative timers. The choice will be driven by efficiency considerations and the underlying hardware or software clock implementation.

- Data Definitions for Clocks and Timers

  IEEE Std 1003.1-200x uses a time representation capable of supporting nanosecond resolution timers for the following reasons:

  — To enable IEEE Std 1003.1-200x to represent those computer systems already using nanosecond or submicrosecond resolution clocks.

  — To accommodate those per-process timers that might need nanoseconds to specify an absolute value of system-wide clocks, even though the resolution of the per-process timer may only be milliseconds, or *vice versa*.

  — Because the number of nanoseconds in a second can be represented in 32 bits.

  Time values are represented in the **timespec** structure. The *tv_sec* member is of type **time_t** so that this member is compatible with time values used by POSIX.1 functions and the ISO C standard. The *tv_nsec* member is a **signed long** in order to simplify and clarify code that decrements or finds differences of time values. Note that because 1 billion (number of nanoseconds per second) is less than half of the value representable by a signed 32-bit value, it is always possible to add two valid fractional seconds represented as integral nanoseconds without overflowing the signed 32-bit value.

  A maximum allowable resolution for the CLOCK_REALTIME clock of 20 ms (1/50 seconds) was chosen to allow line frequency clocks in European countries to be conforming. 60 Hz clocks in the U.S. will also be conforming, as will finer granularity clocks, although a Strictly Conforming Application cannot assume a granularity of less than 20 ms (1/50 seconds).

  The minimum allowable maximum time allowed for the CLOCK_REALTIME clock and the function *nanosleep*( ), and timers created with *clock_id*=CLOCK_REALTIME, is determined by the fact that the *tv_sec* member is of type **time_t**.

  IEEE Std 1003.1-200x specifies that timer expirations shall not be delivered early, nor shall *nanosleep*( ) return early due to quantization error. IEEE Std 1003.1-200x discusses the various implementations of *alarm*( ) in the rationale and states that implementations that do not allow alarm signals to occur early are the most appropriate, but refrained from mandating this behavior. Because of the importance of predictability to realtime applications, IEEE Std 1003.1-200x takes a stronger stance.

The developers of IEEE Std 1003.1-200x considered using a time representation that differs from POSIX.1b in the second 32 bit of the 64-bit value. Whereas POSIX.1b defines this field as a fractional second in nanoseconds, the other methodology defines this as a binary fraction of one second, with the radix point assumed before the most significant bit.

POSIX.1b is a software, source-level standard and most of the benefits of the alternate representation are enjoyed by hardware implementations of clocks and algorithms. It was felt that mandating this format for POSIX.1b clocks and timers would unnecessarily burden the application writer with writing, possibly non-portable, multiple precision arithmetic packages to perform conversion between binary fractions and integral units such as nanoseconds, milliseconds, and so on.

Rationale for the Monotonic Clock

For those applications that use time services to achieve realtime behavior, changing the value of the clock on which these services rely may cause erroneous timing behavior. For these applications, it is necessary to have a monotonic clock which cannot run backwards, and which has a maximum clock jump that is required to be documented by the implementation. Additionally, it is desirable (but not required by IEEE Std 1003.1-200x) that the monotonic clock increases its value uniformly. This clock should not be affected by changes to the system time; for example, to synchronize the clock with an external source or to account for leap seconds. Such changes would cause errors in the measurement of time intervals for those time services that use the absolute value of the clock.

One could argue that by defining the behavior of time services when the value of a clock is changed, deterministic realtime behavior can be achieved. For example, one could specify that relative time services should be unaffected by changes in the value of a clock. However, there are time services that are based upon an absolute time, but that are essentially intended as relative time services. For example, *pthread_cond_timedwait*( ) uses an absolute time to allow it to wake up after the required interval despite spurious wakeups. Although sometimes the *pthread_cond_timedwait*( ) timeouts are absolute in nature, there are many occasions in which they are relative, and their absolute value is determined from the current time plus a relative time interval. In this latter case, if the clock changes while the thread is waiting, the wait interval will not be the expected length. If a *pthread_cond_timedwait*( ) function were created that would take a relative time, it would not solve the problem because to retain the intended ‘‘deadline’’ a thread would need to compensate for latency due to the spurious wakeup, and preemption between wakeup and the next wait.

The solution is to create a new monotonic clock, whose value does not change except for the regular ticking of the clock, and use this clock for implementing the various relative timeouts that appear in the different POSIX interfaces, as well as allow *pthread_cond_timedwait*( ) to choose this new clock for its timeout. A new *clock_nanosleep*( ) function is created to allow an application to take advantage of this newly defined clock. Notice that the monotonic clock may be implemented using the same hardware clock as the system clock.

Relative timeouts for *sigtimedwait*( ) and *aio_suspend*( ) have been redefined to use the monotonic clock, if present. The *alarm*( ) function has not been redefined, because the same effect but with better resolution can be achieved by creating a timer (for which the appropriate clock may be chosen).

The *pthread_cond_timedwait*( ) function has been treated in a different way, compared to other functions with absolute timeouts, because it is used to wait for an event, and thus it may have a deadline, while the other timeouts are generally used as an error recovery mechanism, and for them the use of the monotonic clock is not so important. Since the desired timeout for the *pthread_cond_timedwait*( ) function may either be a relative interval, or an absolute time of day deadline, a new initialization attribute has been created for condition variables, to specify the clock that shall be used for measuring the timeout in a call to *pthread_cond_timedwait*( ). In this way, if a relative timeout is desired, the monotonic clock will be used; if an absolute deadline is required instead, the CLOCK_REALTIME or another appropriate clock may be used. This capability has not been added to other functions with absolute timeouts because for those functions the expected use of the timeout is mostly to prevent errors, and not so often to meet precise deadlines. As a consequence, the complexity of adding this capability is not justified by its perceived application usage.

The *nanosleep*( ) function has not been modified with the introduction of the monotonic clock. Instead, a new *clock_nanosleep*( ) function has been created, in which the desired clock may be specified in the function call.

- History of Resolution Issues

  Due to the shift from relative to absolute timeouts in IEEE Std 1003.1d-1999, the amendments to the *sem_timedwait*( ), *pthread_mutex_timedlock*( ), *mq_timedreceive*( ), and *mq_timedsend*( ) functions of that standard have been removed. Those amendments specified that CLOCK_MONOTONIC would be used for the (relative) timeouts if the Monotonic Clock option was supported.

  Having these functions continue to be tied solely to CLOCK_MONOTONIC would not work. Since the absolute value of a time value obtained from CLOCK_MONOTONIC is unspecified, under the absolute timeouts interface, applications would behave differently depending on whether the Monotonic Clock option was supported or not (because the absolute value of the clock would have different meanings in either case).

  Two options were considered:

  1. Leave the current behavior unchanged, which specifies the CLOCK_REALTIME clock for these (absolute) timeouts, to allow portability of applications between implementations supporting or not the Monotonic Clock option.

  2. Modify these functions in the way that *pthread_cond_timedwait*( ) was modified to allow a choice of clock, so that an application could use CLOCK_REALTIME when it is trying to achieve an absolute timeout and CLOCK_MONOTONIC when it is trying to achieve a relative timeout.

  It was decided that the features of CLOCK_MONOTONIC are not as critical to these functions as they are to *pthread_cond_timedwait*( ). The *pthread_cond_timedwait*( ) function is given a relative timeout; the timeout may represent a deadline for an event. When these functions are given relative timeouts, the timeouts are typically for error recovery purposes and need not be so precise.

  Therefore, it was decided that these functions should be tied to CLOCK_REALTIME and not complicated by being given a choice of clock.

Execution Time Monitoring

- Introduction

The main goals of the execution time monitoring facilities defined in this chapter are to measure the execution time of processes and threads and to allow an application to establish CPU time limits for these entities.

The analysis phase of time-critical realtime systems often relies on the measurement of execution times of individual threads or processes to determine whether the timing requirements will be met. Also, performance analysis techniques for soft deadline realtime systems rely heavily on the determination of these execution times. The execution time monitoring functions provide application developers with the ability to measure these execution times online and open the possibility of dynamic execution-time analysis and system reconfiguration, if required.

The second goal of allowing an application to establish execution time limits for individual processes or threads and detecting when they overrun allows program robustness to be increased by enabling online checking of the execution times.

If errors are detected—possibly because of erroneous program constructs, the existence of errors in the analysis phase, or a burst of event arrivals—online detection and recovery is possible in a portable way. This feature can be extremely important for many time-critical applications. Other applications require trapping CPU-time errors as a normal way to exit an algorithm; for instance, some realtime artificial intelligence applications trigger a number of independent inference processes of varying accuracy and speed, limit how long they can run, and pick the best answer available when time runs out. In many periodic systems, overrun processes are simply restarted in the next resource period, after necessary end-of-period actions have been taken. This allows algorithms that are inherently data-dependent to be made predictable.

The interface that appears in this chapter defines a new type of clock, the CPU-time clock, which measures execution time. Each process or thread can invoke the clock and timer functions defined in POSIX.1 to use them. Functions are also provided to access the CPU-time clock of other processes or threads to enable remote monitoring of these clocks. Monitoring of threads of other processes is not supported, since these threads are not visible from outside of their own process with the interfaces defined in POSIX.1.

- Execution Time Monitoring Interface

The clock and timer interface defined in POSIX.1 historically only defined one clock, which measures wall-clock time. The requirements for measuring execution time of processes and threads, and setting limits to their execution time by detecting when they overrun, can be accomplished with that interface if a new kind of clock is defined. These new clocks measure execution time, and one is associated with each process and with each thread. The clock functions currently defined in POSIX.1 can be used to read and set these CPU-time clocks, and timers can be created using these clocks as their timing base. These timers can then be used to send a signal when some specified execution time has been exceeded. The CPU-time clocks of each process or thread can be accessed by using the symbols CLOCK_PROCESS_CPUTIME_ID or CLOCK_THREAD_CPUTIME_ID.

The clock and timer interface defined in POSIX.1 and extended with the new kind of CPU-time clock would only allow processes or threads to access their own CPU-time clocks. However, many realtime systems require the possibility of monitoring the execution time of processes or threads from independent monitoring entities. In order to allow applications to construct independent monitoring entities that do not require cooperation from or modification of the monitored entities, two functions have been added: *clock_getcpuclockid*( ), for accessing CPU-time clocks of other processes, and *pthread_getcpuclockid*( ), for accessing CPU-time clocks of other threads. These functions return the clock identifier associated with the process or thread specified in the call. These clock IDs can then be used in the rest of the clock function calls.

The clocks accessed through these functions could also be used as a timing base for the creation of timers, thereby allowing independent monitoring entities to limit the CPU-time consumed by other entities. However, this possibility would imply additional complexity and overhead because of the need to maintain a timer queue for each process or thread, to store the different expiration times associated with timers created by different processes or threads. The working group decided this additional overhead was not justified by application requirements. Therefore, creation of timers attached to the CPU-time clocks of other processes or threads has been specified as implementation-defined.

- Overhead Considerations

  The measurement of execution time may introduce additional overhead in the thread scheduling, because of the need to keep track of the time consumed by each of these entities. In library-level implementations of threads, the efficiency of scheduling could be somehow compromised because of the need to make a kernel call, at each context switch, to read the process CPU-time clock. Consequently, a thread creation attribute called *cpu-clock-requirement* was defined, to allow threads to disconnect their respective CPU-time clocks. However, the Ballot Group considered that this attribute itself introduced some overhead, and that in current implementations it was not worth the effort. Therefore, the attribute was deleted, and thus thread CPU-time clocks are required for all threads if the Thread CPU-Time Clocks option is supported.

- Accuracy of CPU-time Clocks

  The mechanism used to measure the execution time of processes and threads is specified in IEEE Std 1003.1-200x as implementation-defined. The reason for this is that both the underlying hardware and the implementation architecture have a very strong influence on the accuracy achievable for measuring CPU time. For some implementations, the specification of strict accuracy requirements would represent very large overheads, or even the impossibility of being implemented.

  Since the mechanism for measuring execution time is implementation-defined, realtime applications will be able to take advantage of accurate implementations using a portable interface. Of course, strictly conforming applications cannot rely on any particular degree of accuracy, in the same way as they cannot rely on a very accurate measurement of wall clock time. There will always exist applications whose accuracy or efficiency requirements on the implementation are more rigid than the values defined in IEEE Std 1003.1-200x or any other standard.

  In any case, there is a minimum set of characteristics that realtime applications would expect from most implementations. One such characteristic is that the sum of all the execution times of all the threads in a process equals the process execution time, when no CPU-time clocks are disabled. This need not always be the case because implementations may differ in how they account for time during context switches. Another characteristic is that the sum of the execution times of all processes in a system equals the number of processors, multiplied by the elapsed time, assuming that no processor is idle during that elapsed time. However, in some implementations it might not be possible to relate CPU-time to elapsed time. For example, in a heterogeneous multi-processor system in which each processor runs at a different speed, an implementation may choose to define each ‘‘second’’ of CPU-time to be a certain number of ‘‘cycles’’ that a CPU has executed.

- Existing Practice

  Measuring and limiting the execution time of each concurrent activity are common features of most industrial implementations of realtime systems. Almost all critical realtime systems are currently built upon a cyclic executive. With this approach, a regular timer interrupt kicks off the next sequence of computations. It also checks that the current sequence has completed. If it has not, then some error recovery action can be undertaken (or at least an overrun is avoided). Current software engineering principles and the increasing complexity of software are driving application developers to implement these systems on multi-threaded or multi-process operating systems. Therefore, if a POSIX operating system is to be used for this type of application, then it must offer the same level of protection.

  Execution time clocks are also common in most UNIX implementations, although these clocks usually have requirements different from those of realtime applications. The POSIX.1 *times*( ) function supports the measurement of the execution time of the calling process, and its terminated child processes. This execution time is measured in clock ticks and is supplied as two different values with the user and system execution times, respectively. BSD supports the function *getrusage*( ), which allows the calling process to get information about the resources used by itself and/or all of its terminated child processes. The resource usage includes user and system CPU time. Some UNIX systems have options to specify high resolution (up to one microsecond) CPU time clocks using the *times*( ) or the *getrusage*( ) functions.

  The *times*( ) and *getrusage*( ) interfaces do not meet important realtime requirements, such as the possibility of monitoring execution time from a different process or thread, or the possibility of detecting an execution time overrun. The latter requirement is supported in some UNIX implementations that are able to send a signal when the execution time of a process has exceeded some specified value. For example, BSD defines the functions *getitimer*( ) and *setitimer*( ), which can operate either on a realtime clock (wall-clock), or on virtual-time or profile-time clocks which measure CPU time in two different ways. These functions do not support access to the execution time of other processes.

  IBM's MVS operating system supports per-process and per-thread execution time clocks. It also supports limiting the execution time of a given process.

  Given all this existing practice, the working group considered that the POSIX.1 clocks and timers interface was appropriate to meet most of the requirements that realtime applications have for execution time clocks. Functions were added to get the CPU time clock IDs, and to allow/disallow the thread CPU time clocks (in order to preserve the efficiency of some implementations of threads).

- Clock Constants

  The definition of the manifest constants CLOCK_PROCESS_CPUTIME_ID and CLOCK_THREAD_CPUTIME_ID allows processes or threads, respectively, to access their own execution-time clocks. However, given a process or thread, access to its own execution-time clock is also possible if the clock ID of this clock is obtained through a call to *clock_getcpuclockid*( ) or *pthread_getcpuclockid*( ). Therefore, these constants are not necessary and could be deleted to make the interface simpler. Their existence saves one system call in the first access to the CPU-time clock of each process or thread. The working group considered this issue and decided to leave the constants in IEEE Std 1003.1-200x because they are closer to the POSIX.1b use of clock identifiers.

- Library Implementations of Threads

  In library implementations of threads, kernel entities and library threads can coexist. In this case, if the CPU-time clocks are supported, most of the clock and timer functions will need to have two implementations: one in the thread library, and one in the system calls library. The main difference between these two implementations is that the thread library implementation will have to deal with clocks and timers that reside in the thread space, while the kernel implementation will operate on timers and clocks that reside in kernel space. In the library implementation, if the clock ID refers to a clock that resides in the kernel, a kernel call will have to be made. The correct version of the function can be chosen by specifying the appropriate order for the libraries during the link process.

- History of Resolution Issues: Deletion of the *enable* Attribute

In the draft corresponding to the first balloting round, CPU-time clocks had an attribute called *enable*. This attribute was introduced by the working group to allow implementations to avoid the overhead of measuring execution time for those processes or threads for which this measurement was not required. However, the *enable* attribute got several ballot objections. The main reason was that processes are already required to measure execution time by the POSIX.1 *times*( ) function. Consequently, the enable attribute was considered unnecessary, and was deleted from the draft.

Rationale Relating to Timeouts

- Requirements for Timeouts

Realtime systems which must operate reliably over extended periods without human intervention are characteristic in embedded applications such as avionics, machine control, and space exploration, as well as more mundane applications such as cable TV, security systems, and plant automation. A multi-tasking paradigm, in which many independent and/or cooperating software functions relinquish the processor(s) while waiting for a specific stimulus, resource, condition, or operation completion, is very useful in producing well engineered programs for such systems. For such systems to be robust and fault-tolerant, expected occurrences that are unduly delayed or that never occur must be detected so that appropriate recovery actions may be taken. This is difficult if there is no way for a task to regain control of a processor once it has relinquished control (blocked) awaiting an occurrence which, perhaps because of corrupted code, hardware malfunction, or latent software bugs, will not happen when expected. Therefore, the common practice in realtime operating systems is to provide a capability to timeout such blocking services. Although there are several methods to achieve this already defined by POSIX, none are as reliable or efficient as initiating a timeout simultaneously with initiating a blocking service. This is especially critical in hard-realtime embedded systems because the processors typically have little time reserve, and allowed fault recovery times are measured in milliseconds rather than seconds.

The working group largely agreed that such timeouts were necessary and ought to become part of IEEE Std 1003.1-200x, particularly vendors of realtime operating systems whose customers had already expressed a strong need for timeouts. There was some resistance to inclusion of timeouts in IEEE Std 1003.1-200x because the desired effect, fault tolerance, could, in theory, be achieved using existing facilities and alternative software designs, but there was no compelling evidence that realtime system designers would embrace such designs at the sacrifice of performance and/or simplicity.

- Which Services should be Timed Out?

Originally, the working group considered the prospect of providing timeouts on all blocking services, including those currently existing in POSIX.1, POSIX.1b, and POSIX.1c, and future interfaces to be defined by other working groups, as sort of a general policy. This was rather quickly rejected because of the scope of such a change, and the fact that many of those services would not normally be used in a realtime context. More traditional timesharing solutions to timeout would suffice for most of the POSIX.1 interfaces, while others had asynchronous alternatives which, while more complex to utilize, would be adequate for some realtime and all non-realtime applications.

The list of potential candidates for timeouts was narrowed to the following for further consideration:

- POSIX.1b
  - *sem_wait*( )
  - *mq_receive*( )
  - *mq_send*( )
  - *lio_listio*( )
  - *aio_suspend*( )
  - *sigwait*( ) (timeout already implemented by *sigtimedwait*( ))
- POSIX.1c
  - *pthread_mutex_lock*( )
  - *pthread_join*( )
  - *pthread_cond_wait*( ) (timeout already implemented by *pthread_cond_timedwait*( ))
- POSIX.1
  - *read*( )
  - *write*( )

After further review by the working group, the *lio_listio*( ), *read*( ), and *write*( ) functions (all forms of blocking synchronous I/O) were eliminated from the list because of the following:

- Asynchronous alternatives exist
- Timeouts can be implemented, albeit non-portably, in device drivers
- A strong desire not to introduce modifications to POSIX.1 interfaces

The working group ultimately rejected *pthread_join*( ) since both that interface and a timed variant of that interface are non-minimal and may be implemented as a function. See below for a library implementation of *pthread_join*( ).

Thus, there was a consensus among the working group members to add timeouts to 4 of the remaining 5 functions (the timeout for *aio_suspend*( ) was ultimately added directly to POSIX.1b, while the others were added by POSIX.1d). However, *pthread_mutex_lock*( ) remained contentious.

Many feel that *pthread_mutex_lock*( ) falls into the same class as the other functions; that is, it is desirable to timeout a mutex lock because a mutex may fail to be unlocked due to errant or corrupted code in a critical section (looping or branching outside of the unlock code), and therefore is equally in need of a reliable, simple, and efficient timeout. In fact, since mutexes are intended to guard small critical sections, most *pthread_mutex_lock*( ) calls would be expected to obtain the lock without blocking nor utilizing any kernel service, even in implementations of threads with global contention scope; the timeout alternative need only be considered after it is determined that the thread must block.

Those opposed to timing out mutexes feel that the very simplicity of the mutex is compromised by adding a timeout semantic, and that to do so is senseless. They claim that if a timed mutex is really deemed useful by a particular application, then it can be constructed from the facilities already in POSIX.1b and POSIX.1c. The following two C-language library implementations of mutex locking with timeout represent the solutions offered (in both implementations, the timeout parameter is specified as absolute time, not relative time as in the proposed POSIX.1c interfaces).

- Spinlock Implementation

```
#include <pthread.h>
#include <time.h>
#include <errno.h>

int pthread_mutex_timedlock(pthread_mutex_t *mutex,
        const struct timespec *timeout)
    {
    struct timespec timenow;

    while (pthread_mutex_trylock(mutex) == EBUSY)
        {
        clock_gettime(CLOCK_REALTIME, &timenow);
        if (timespec_cmp(&timenow,timeout) >= 0)
            {
            return ETIMEDOUT;
        }
        pthread_yield();
        }
    return 0;
    }
```

The Spinlock implementation is generally unsuitable for any application using priority-based thread scheduling policies such as SCHED_FIFO or SCHED_RR, since the mutex could currently be held by a thread of lower priority within the same allocation domain, but since the waiting thread never blocks, only threads of equal or higher priority will ever run, and the mutex cannot be unlocked. Setting priority inheritance or priority ceiling protocol on the mutex does not solve this problem, since the priority of a mutex owning thread is only boosted if higher priority threads are blocked waiting for the mutex; clearly not the case for this spinlock.

- Condition Wait Implementation

```
#include <pthread.h>
#include <time.h>
#include <errno.h>

struct timed_mutex
    {
    int locked;
    pthread_mutex_t mutex;
    pthread_cond_t cond;
    };
typedef struct timed_mutex timed_mutex_t;

int timed_mutex_lock(timed_mutex_t *tm,
        const struct timespec *timeout)
    {
    int timedout=FALSE;
    int error_status;
```

```
    pthread_mutex_lock(&tm->mutex);
    while (tm->locked && !timedout)
        {
        if ((error_status=pthread_cond_timedwait(&tm->cond,
            &tm->mutex,
            timeout))!=0)
        {
        if (error_status==ETIMEDOUT) timedout = TRUE;
        }
    }
    if(timedout)
        {
        pthread_mutex_unlock(&tm->mutex);
        return ETIMEDOUT;
        }
    else
        {
        tm->locked = TRUE;
        pthread_mutex_unlock(&tm->mutex);
        return 0;
        }
    }
void timed_mutex_unlock(timed_mutex_t *tm)
    {
    pthread_mutex_lock(&tm->mutex); / for case assignment not atomic /
    tm->locked = FALSE;
    pthread_mutex_unlock(&tm->mutex);
    pthread_cond_signal(&tm->cond);
    }
```

The Condition Wait implementation effectively substitutes the *pthread_cond_timedwait*( ) function (which is currently timed out) for the desired *pthread_mutex_timedlock*( ). Since waits on condition variables currently do not include protocols which avoid priority inversion, this method is generally unsuitable for realtime applications because it does not provide the same priority inversion protection as the untimed *pthread_mutex_lock*( ). Also, for any given implementations of the current mutex and condition variable primitives, this library implementation has a performance cost at least 2.5 times that of the untimed *pthread_mutex_lock*( ) even in the case where the timed mutex is readily locked without blocking (the interfaces required for this case are shown in bold). Even in uniprocessors or where assignment is atomic, at least an additional *pthread_cond_signal*( ) is required. *pthread_mutex_timedlock*( ) could be implemented at effectively no performance penalty in this case because the timeout parameters need only be considered after it is determined that the mutex cannot be locked immediately.

Thus it has not yet been shown that the full semantics of mutex locking with timeout can be efficiently and reliably achieved using existing interfaces. Even if the existence of an acceptable library implementation were proven, it is difficult to justify why the interface itself should not be made portable, especially considering approval for the other four timeouts.

- Rationale for Library Implementation of *pthread_timedjoin*( )

Library implementation of *pthread_timedjoin*( ):

```
/*
 * Construct a thread variety entirely from existing functions
 * with which a join can be done, allowing the join to time out.
 */
#include <pthread.h>
#include <time.h>

struct timed_thread {
    pthread_t t;
    pthread_mutex_t m;
    int exiting;
    pthread_cond_t exit_c;
    void *(*start_routine)(void *arg);
    void *arg;
    void *status;
};

typedef struct timed_thread *timed_thread_t;
static pthread_key_t timed_thread_key;
static pthread_once_t timed_thread_once = PTHREAD_ONCE_INIT;

static void timed_thread_init()
{
    pthread_key_create(&timed_thread_key, NULL);
}

static void *timed_thread_start_routine(void *args)

/*
 * Routine to establish thread-specific data value and run the actual
 * thread start routine which was supplied to timed_thread_create().
 */
{
    timed_thread_t tt = (timed_thread_t) args;

    pthread_once(&timed_thread_once, timed_thread_init);
    pthread_setspecific(timed_thread_key, (void *)tt);
    timed_thread_exit((tt->start_routine)(tt->arg));
}

int timed_thread_create(timed_thread_t ttp, const pthread_attr_t *attr,
    void *(*start_routine)(void *), void *arg)

/*
 * Allocate a thread which can be used with timed_thread_join().
 */
{
    timed_thread_t tt;
    int result;

    tt = (timed_thread_t) malloc(sizeof(struct timed_thread));
    pthread_mutex_init(&tt->m,NULL);
    tt->exiting = FALSE;
    pthread_cond_init(&tt->exit_c,NULL);
    tt->start_routine = start_routine;
```

```
        tt->arg = arg;
        tt->status = NULL;

        if ((result = pthread_create(&tt->t, attr,
            timed_thread_start_routine, (void *)tt)) != 0) {
            free(tt);
            return result;
        }

        pthread_detach(tt->t);
        ttp = tt;
        return 0;
    }

    int timed_thread_join(timed_thread_t tt,
        struct timespec *timeout,
        void **status)
    {
        int result;

        pthread_mutex_lock(&tt->m);
        result = 0;
        /*
         * Wait until the thread announces that it is exiting,
         * or until timeout.
         */
        while (result == 0 && ! tt->exiting) {
            result = pthread_cond_timedwait(&tt->exit_c, &tt->m, timeout);
        }
        pthread_mutex_unlock(&tt->m);
        if (result == 0 && tt->exiting) {
            *status = tt->status;
            free((void *)tt);
            return result;
        }
        return result;
    }

    void timed_thread_exit(void *status)
    {
        timed_thread_t tt;
        void *specific;

        if ((specific=pthread_getspecific(timed_thread_key)) == NULL){
            /*
             * Handle cases which won’t happen with correct usage.
             */
            pthread_exit( NULL);
        }
        tt = (timed_thread_t) specific;
        pthread_mutex_lock(&tt->m);
        /*
         * Tell a joiner that we’re exiting.
         */
        tt->status = status;
```

```
        tt->exiting = TRUE;
        pthread_cond_signal(&tt->exit_c);
        pthread_mutex_unlock(&tt->m);
        /*
         * Call pthread exit() to call destructors and really
         * exit the thread.
         */
        pthread_exit(NULL);
}
```

The *pthread_join*( ) C-language example shown above demonstrates that it is possible, using existing pthread facilities, to construct a variety of thread which allows for joining such a thread, but which allows the join operation to time out. It does this by using a *pthread_cond_timedwait*( ) to wait for the thread to exit. A **timed_thread_t** descriptor structure is used to pass parameters from the creating thread to the created thread, and from the exiting thread to the joining thread. This implementation is roughly equivalent to what a normal *pthread_join*( ) implementation would do, with the single change being that *pthread_cond_timedwait*( ) is used in place of a simple *pthread_cond_wait*( ).

Since it is possible to implement such a facility entirely from existing pthread interfaces, and with roughly equal efficiency and complexity to an implementation which would be provided directly by a pthreads implementation, it was the consensus of the working group members that any *pthread_timedjoin*( ) facility would be unnecessary, and should not be provided.

- Form of the Timeout Interfaces

The working group considered a number of alternative ways to add timeouts to blocking services. At first, a system interface which would specify a one-shot or persistent timeout to be applied to subsequent blocking services invoked by the calling process or thread was considered because it allowed all blocking services to be timed out in a uniform manner with a single additional interface; this was rather quickly rejected because it could easily result in the wrong services being timed out.

It was suggested that a timeout value might be specified as an attribute of the object (semaphore, mutex, message queue, and so on), but there was no consensus on this, either on a case-by-case basis or for all timeouts.

Looking at the two existing timeouts for blocking services indicates that the working group members favor a separate interface for the timed version of a function. However, *pthread_cond_timedwait*( ) utilizes an absolute timeout value while *sigtimedwait*( ) uses a relative timeout value. The working group members agreed that relative timeout values are appropriate where the timeout mechanism's primary use was to deal with an unexpected or error situation, but they are inappropriate when the timeout must expire at a particular time, or before a specific deadline. For the timeouts being introduced in IEEE Std 1003.1-200x, the working group considered allowing both relative and absolute timeouts as is done with POSIX.1b timers, but ultimately favored the simpler absolute timeout form.

An absolute time measure can be easily implemented on top of an interface that specifies relative time, by reading the clock, calculating the difference between the current time and the desired wake-up time, and issuing a relative timeout call. But there is a race condition with this approach because the thread could be preempted after reading the clock, but before making the timed out call; in this case, the thread would be awakened later than it should and, thus, if the wake up time represented a deadline, it would miss it.

There is also a race condition when trying to build a relative timeout on top of an interface that specifies absolute timeouts. In this case, we would have to read the clock to calculate the absolute wake-up time as the sum of the current time plus the relative timeout interval. In this case, if the thread is preempted after reading the clock but before making the timed out call, the thread would be awakened earlier than desired.

But the race condition with the absolute timeouts interface is not as bad as the one that happens with the relative timeout interface, because there are simple workarounds. For the absolute timeouts interface, if the timing requirement is a deadline, we can still meet this deadline because the thread woke up earlier than the deadline. If the timeout is just used as an error recovery mechanism, the precision of timing is not really important. If the timing requirement is that between actions A and B a minimum interval of time must elapse, we can safely use the absolute timeout interface by reading the clock after action A has been started. It could be argued that, since the call with the absolute timeout is atomic from the application point of view, it is not possible to read the clock after action A, if this action is part of the timed out call. But if we look at the nature of the calls for which we specify timeouts (locking a mutex, waiting for a semaphore, waiting for a message, or waiting until there is space in a message queue), the timeouts that an application would build on these actions would not be triggered by these actions themselves, but by some other external action. For example, if we want to wait for a message to arrive to a message queue, and wait for at least 20 milliseconds, this time interval would start to be counted from some event that would trigger both the action that produces the message, as well as the action that waits for the message to arrive, and not by the wait-for-message operation itself. In this case, we could use the workaround proposed above.

For these reasons, the absolute timeout is preferred over the relative timeout interface.

B.2.9 Threads

Threads will normally be more expensive than subroutines (or functions, routines, and so on) if specialized hardware support is not provided. Nevertheless, threads should be sufficiently efficient to encourage their use as a medium to fine-grained structuring mechanism for parallelism in an application. Structuring an application using threads then allows it to take immediate advantage of any underlying parallelism available in the host environment. This means implementors are encouraged to optimize for fast execution at the possible expense of efficient utilization of storage. For example, a common thread creation technique is to cache appropriate thread data structures. That is, rather than releasing system resources, the implementation retains these resources and reuses them when the program next asks to create a new thread. If this reuse of thread resources is to be possible, there has to be very little unique state associated with each thread, because any such state has to be reset when the thread is reused.

Thread Creation Attributes

Attributes objects are provided for threads, mutexes, and condition variables as a mechanism to support probable future standardization in these areas without requiring that the interface itself be changed. Attributes objects provide clean isolation of the configurable aspects of threads. For example, ‘‘stack size’’ is an important attribute of a thread, but it cannot be expressed portably. When porting a threaded program, stack sizes often need to be adjusted. The use of attributes objects can help by allowing the changes to be isolated in a single place, rather than being spread across every instance of thread creation.

Attributes objects can be used to set up *classes* of threads with similar attributes; for example, ‘‘threads with large stacks and high priority’’ or ‘‘threads with minimal stacks’’. These classes can be defined in a single place and then referenced wherever threads need to be created.

Changes to ‘‘class’’ decisions become straightforward, and detailed analysis of each *pthread_create*( ) call is not required.

The attributes objects are defined as opaque types as an aid to extensibility. If these objects had been specified as structures, adding new attributes would force recompilation of all multi-threaded programs when the attributes objects are extended; this might not be possible if different program components were supplied by different vendors.

Additionally, opaque attributes objects present opportunities for improving performance. Argument validity can be checked once when attributes are set, rather than each time a thread is created. Implementations will often need to cache kernel objects that are expensive to create. Opaque attributes objects provide an efficient mechanism to detect when cached objects become invalid due to attribute changes.

Because assignment is not necessarily defined on a given opaque type, implementation-dependent default values cannot be defined in a portable way. The solution to this problem is to allow attribute objects to be initialized dynamically by attributes object initialization functions, so that default values can be supplied automatically by the implementation.

The following proposal was provided as a suggested alternative to the supplied attributes:

1. Maintain the style of passing a parameter formed by the bitwise-inclusive OR of flags to the initialization routines (*pthread_create*( ), *pthread_mutex_init*( ), *pthread_cond_init*( )). The parameter containing the flags should be an opaque type for extensibility. If no flags are set in the parameter, then the objects are created with default characteristics. An implementation may specify implementation-defined flag values and associated behavior.
2. If further specialization of mutexes and condition variables is necessary, implementations may specify additional procedures that operate on the **pthread_mutex_t** and **pthread_cond_t** objects (instead of on attributes objects).

The difficulties with this solution are:

1. A bitmask is not opaque if bits have to be set into bit-vector attributes objects using explicitly-coded bitwise-inclusive OR operations. If the set of options exceeds an **int**, application programmers need to know the location of each bit. If bits are set or read by encapsulation (that is, *get**( ) or *set**( ) functions), then the bitmask is merely an implementation of attributes objects as currently defined and should not be exposed to the programmer.
2. Many attributes are not Boolean or very small integral values. For example, scheduling policy may be placed in 3 bits or 4 bits, but priority requires 5 bits or more, thereby taking up at least 8 bits out of a possible 16 bits on machines with 16-bit integers. Because of this, the bitmask can only reasonably control whether particular attributes are set or not, and it cannot serve as the repository of the value itself. The value needs to be specified as a function parameter (which is non-extensible), or by setting a structure field (which is non-opaque), or by *get**( ) and *set**( ) functions (making the bitmask a redundant addition to the attributes objects).

Stack size is defined as an optional attribute because the very notion of a stack is inherently machine-dependent. Some implementations may not be able to change the size of the stack, for example, and others may not need to because stack pages may be discontiguous and can be allocated and released on demand.

The attribute mechanism has been designed in large measure for extensibility. Future extensions to the attribute mechanism or to any attributes object defined in IEEE Std 1003.1-200x has to be done with care so as not to affect binary-compatibility.

Attribute objects, even if allocated by means of dynamic allocation functions such as *malloc*( ), may have their size fixed at compile time. This means, for example, a *pthread_create*( ) in an implementation with extensions to the **pthread_attr_t** cannot look beyond the area that the binary application assumes is valid. This suggests that implementations should maintain a size field in the attributes object, as well as possibly version information, if extensions in different directions (possibly by different vendors) are to be accommodated.

Thread Implementation Models

There are various thread implementation models. At one end of the spectrum is the ''library-thread model''. In such a model, the threads of a process are not visible to the operating system kernel, and the threads are not kernel scheduled entities. The process is the only kernel scheduled entity. The process is scheduled onto the processor by the kernel according to the scheduling attributes of the process. The threads are scheduled onto the single kernel scheduled entity (the process) by the runtime library according to the scheduling attributes of the threads. A problem with this model is that it constrains concurrency. Since there is only one kernel scheduled entity (namely, the process), only one thread per process can execute at a time. If the thread that is executing blocks on I/O, then the whole process blocks.

At the other end of the spectrum is the ''kernel-thread model''. In this model, all threads are visible to the operating system kernel. Thus, all threads are kernel scheduled entities, and all threads can concurrently execute. The threads are scheduled onto processors by the kernel according to the scheduling attributes of the threads. The drawback to this model is that the creation and management of the threads entails operating system calls, as opposed to subroutine calls, which makes kernel threads heavier weight than library threads.

Hybrids of these two models are common. A hybrid model offers the speed of library threads and the concurrency of kernel threads. In hybrid models, a process has some (relatively small) number of kernel scheduled entities associated with it. It also has a potentially much larger number of library threads associated with it. Some library threads may be bound to kernel scheduled entities, while the other library threads are multiplexed onto the remaining kernel scheduled entities. There are two levels of thread scheduling:

1. The runtime library manages the scheduling of (unbound) library threads onto kernel scheduled entities.

2. The kernel manages the scheduling of kernel scheduled entities onto processors.

For this reason, a hybrid model is referred to as a *two-level threads scheduling model*. In this model, the process can have multiple concurrently executing threads; specifically, it can have as many concurrently executing threads as it has kernel scheduled entities.

Thread-Specific Data

Many applications require that a certain amount of context be maintained on a per-thread basis across procedure calls. A common example is a multi-threaded library routine that allocates resources from a common pool and maintains an active resource list for each thread. The thread-specific data interface provided to meet these needs may be viewed as a two-dimensional array of values with keys serving as the row index and thread IDs as the column index (although the implementation need not work this way).

- Models

  Three possible thread-specific data models were considered:

  1. No Explicit Support

A standard thread-specific data interface is not strictly necessary to support applications that require per-thread context. One could, for example, provide a hash function that converted a **pthread_t** into an integer value that could then be used to index into a global array of per-thread data pointers. This hash function, in conjunction with *pthread_self*( ), would be all the interface required to support a mechanism of this sort. Unfortunately, this technique is cumbersome. It can lead to duplicated code as each set of cooperating modules implements their own per-thread data management schemes.

2. Single (**void** *) Pointer

   Another technique would be to provide a single word of per-thread storage and a pair of functions to fetch and store the value of this word. The word could then hold a pointer to a block of per-thread memory. The allocation, partitioning, and general use of this memory would be entirely up to the application. Although this method is not as problematic as technique 1, it suffers from interoperability problems. For example, all modules using the per-thread pointer would have to agree on a common usage protocol.

3. Key / Value Mechanism

   This method associates an opaque key (for example, stored in a variable of type **pthread_key_t**) with each per-thread datum. These keys play the role of identifiers for per-thread data. This technique is the most generic and avoids the problems noted above, albeit at the cost of some complexity.

The primary advantage of the third model is its information hiding properties. Modules using this model are free to create and use their own key(s) independent of all other such usage, whereas the other models require that all modules that use thread-specific context explicitly cooperate with all other such modules. The data-independence provided by the third model is worth the additional interface.

- Requirements

It is important that it be possible to implement the thread-specific data interface without the use of thread private memory. To do otherwise would increase the weight of each thread, thereby limiting the range of applications for which the threads interfaces provided by IEEE Std 1003.1-200x is appropriate.

The values that one binds to the key via *pthread_setspecific*( ) may, in fact, be pointers to shared storage locations available to all threads. It is only the key / value bindings that are maintained on a per-thread basis, and these can be kept in any portion of the address space that is reserved for use by the calling thread (for example, on the stack). Thus, no per-thread MMU state is required to implement the interface. On the other hand, there is nothing in the interface specification to preclude the use of a per-thread MMU state if it is available (for example, the key values returned by *pthread_key_create*( ) could be thread private memory addresses).

- Standardization Issues

Thread-specific data is a requirement for a usable thread interface. The binding described in this section provides a portable thread-specific data mechanism for languages that do not directly support a thread-specific storage class. A binding to IEEE Std 1003.1-200x for a language that does include such a storage class need not provide this specific interface.

If a language were to include the notion of thread-specific storage, it would be desirable (but *not* required) to provide an implementation of the pthreads thread-specific data interface based on the language feature. For example, assume that a compiler for a C-like language supports a *private* storage class that provides thread-specific storage. Something similar to the following macros might be used to effect a compatible implementation:

```
#define pthread_key_t                      private void *
#define pthread_key_create(key)            /* no-op */
#define pthread_setspecific(key,value)     (key)=(value)
#define pthread_getspecific(key)           (key)
```

Note: For the sake of clarity, this example ignores destructor functions. A correct implementation would have to support them.

Barriers

- Background

Barriers are typically used in parallel DO/FOR loops to ensure that all threads have reached a particular stage in a parallel computation before allowing any to proceed to the next stage. Highly efficient implementation is possible on machines which support a ‘‘Fetch and Add’’ operation as described in the referenced Almasi and Gottlieb (1989).

The use of return value PTHREAD_BARRIER_SERIAL_THREAD is shown in the following example:

```
if ( (status=pthread_barrier_wait(&barrier)) ==
    PTHREAD_BARRIER_SERIAL_THREAD) {
    ...serial section
    }
        else if (status != 0) {
        ...error processing
    }
status=pthread_barrier_wait(&barrier);
...
```

This behavior allows a serial section of code to be executed by one thread as soon as all threads reach the first barrier. The second barrier prevents the other threads from proceeding until the serial section being executed by the one thread has completed.

Although barriers can be implemented with mutexes and condition variables, the referenced Almasi and Gottlieb (1989) provides ample illustration that such implementations are significantly less efficient than is possible. While the relative efficiency of barriers may well vary by implementation, it is important that they be recognized in the IEEE Std 1003.1-200x to facilitate application portability while providing the necessary freedom to implementors.

- Lack of Timeout Feature

Alternate versions of most blocking routines have been provided to support watchdog timeouts. No alternate interface of this sort has been provided for barrier waits for the following reasons:

- Multiple threads may use different timeout values, some of which may be indefinite. It is not clear which threads should break through the barrier with a timeout error if and when these timeouts expire.

- The barrier may become unusable once a thread breaks out of a *pthread_barrier_wait*( ) with a timeout error. There is, in general, no way to guarantee the consistency of a barrier’s internal data structures once a thread has timed out of a *pthread_barrier_wait*( ). Even the inclusion of a special barrier reinitialization function would not help much since it is not clear how this function would affect the behavior of threads that reach the barrier between the original timeout and the call to the reinitialization function.

Spin Locks

- Background

  Spin locks represent an extremely low-level synchronization mechanism suitable primarily for use on shared memory multi-processors. It is typically an atomically modified Boolean value that is set to one when the lock is held and to zero when the lock is freed.

  When a caller requests a spin lock that is already held, it typically spins in a loop testing whether the lock has become available. Such spinning wastes processor cycles so the lock should only be held for short durations and not across sleep / block operations. Callers should unlock spin locks before calling sleep operations.

  Spin locks are available on a variety of systems. The functions included in IEEE Std 1003.1-200x are an attempt to standardize that existing practice.

- Lack of Timeout Feature

  Alternate versions of most blocking routines have been provided to support watchdog timeouts. No alternate interface of this sort has been provided for spin locks for the following reasons:

  - It is impossible to determine appropriate timeout intervals for spin locks in a portable manner. The amount of time one can expect to spend spin-waiting is inversely proportional to the degree of parallelism provided by the system.

    It can vary from a few cycles when each competing thread is running on its own processor, to an indefinite amount of time when all threads are multiplexed on a single processor (which is why spin locking is not advisable on uniprocessors).

  - When used properly, the amount of time the calling thread spends waiting on a spin lock should be considerably less than the time required to set up a corresponding watchdog timer. Since the primary purpose of spin locks is to provide a low-overhead synchronization mechanism for multi-processors, the overhead of a timeout mechanism was deemed unacceptable.

  It was also suggested that an additional *count* argument be provided (on the *pthread_spin_lock*( ) call) in *lieu* of a true timeout so that a spin lock call could fail gracefully if it was unable to apply the lock after *count* attempts. This idea was rejected because it is not existing practice. Furthermore, the same effect can be obtained with *pthread_spin_trylock*( ), as illustrated below:

```
int n = MAX_SPIN;

while ( −−n >= 0 )
{
    if ( !pthread_spin_try_lock(...) )
        break;
}
if ( n >= 0 )
{
    /* Successfully acquired the lock */
}
else
{
    /* Unable to acquire the lock */
}
```

- *process-shared* Attribute

  The initialization functions associated with most POSIX synchronization objects (for example, mutexes, barriers, and read-write locks) take an attributes object with a *process-shared* attribute that specifies whether or not the object is to be shared across processes. In the draft corresponding to the first balloting round, two separate initialization functions are provided for spin locks, however: one for spin locks that were to be shared across processes (*spin_init*( )), and one for locks that were only used by multiple threads within a single process (*pthread_spin_init*( )). This was done so as to keep the overhead associated with spin waiting to an absolute minimum. However, the balloting group requested that, since the overhead associated to a bit check was small, spin locks should be consistent with the rest of the synchronization primitives, and thus the *process-shared* attribute was introduced for spin locks.

- Spin Locks *versus* Mutexes

  It has been suggested that mutexes are an adequate synchronization mechanism and spin locks are not necessary. Locking mechanisms typically must trade off the processor resources consumed while setting up to block the thread and the processor resources consumed by the thread while it is blocked. Spin locks require very little resources to set up the blocking of a thread. Existing practice is to simply loop, repeating the atomic locking operation until the lock is available. While the resources consumed to set up blocking of the thread are low, the thread continues to consume processor resources while it is waiting.

  On the other hand, mutexes may be implemented such that the processor resources consumed to block the thread are large relative to a spin lock. After detecting that the mutex lock is not available, the thread must alter its scheduling state, add itself to a set of waiting threads, and, when the lock becomes available again, undo all of this before taking over ownership of the mutex. However, while a thread is blocked by a mutex, no processor resources are consumed.

  Therefore, spin locks and mutexes may be implemented to have different characteristics. Spin locks may have lower overall overhead for very short-term blocking, and mutexes may have lower overall overhead when a thread will be blocked for longer periods of time. The presence of both interfaces allows implementations with these two different characteristics, both of which may be useful to a particular application.

  It has also been suggested that applications can build their own spin locks from the *pthread_mutex_trylock*( ) function:

```
    while (pthread_mutex_trylock(&mutex));
```

The apparent simplicity of this construct is somewhat deceiving, however. While the actual wait is quite efficient, various guarantees on the integrity of mutex objects (for example, priority inheritance rules) may add overhead to the successful path of the trylock operation that is not required of spin locks. One could, of course, add an attribute to the mutex to bypass such overhead, but the very act of finding and testing this attribute represents more overhead than is found in the typical spin lock.

The need to hold spin lock overhead to an absolute minimum also makes it impossible to provide guarantees against starvation similar to those provided for mutexes or read-write locks. The overhead required to implement such guarantees (for example, disabling preemption before spinning) may well exceed the overhead of the spin wait itself by many orders of magnitude. If a ‘‘safe’’ spin wait seems desirable, it can always be provided (albeit at some performance cost) via appropriate mutex attributes.

XSI Supported Functions

On XSI-conformant systems, the following symbolic constants are always defined:

_POSIX_READER_WRITER_LOCKS
_POSIX_THREAD_ATTR_STACKADDR
_POSIX_THREAD_ATTR_STACKSIZE
_POSIX_THREAD_PROCESS_SHARED
_POSIX_THREADS

Therefore, the following threads functions are always supported:

pthread_atfork( )
pthread_attr_destroy( )
pthread_attr_getdetachstate( )
pthread_attr_getguardsize( )
pthread_attr_getschedparam( )
pthread_attr_getstack( )
pthread_attr_getstackaddr( )
pthread_attr_getstacksize( )
pthread_attr_init( )
pthread_attr_setdetachstate( )
pthread_attr_setguardsize( )
pthread_attr_setschedparam( )
pthread_attr_setstack( )
pthread_attr_setstackaddr( )
pthread_attr_setstacksize( )
pthread_cancel( )
pthread_cleanup_pop( )
pthread_cleanup_push( )
pthread_cond_broadcast( )
pthread_cond_destroy( )
pthread_cond_init( )
pthread_cond_signal( )
pthread_cond_timedwait( )
pthread_cond_wait( )
pthread_condattr_destroy( )
pthread_key_create( )
pthread_key_delete( )
pthread_kill( )
pthread_mutex_destroy( )
pthread_mutex_init( )
pthread_mutex_lock( )
pthread_mutex_trylock( )
pthread_mutex_unlock( )
pthread_mutexattr_destroy( )
pthread_mutexattr_getpshared( )
pthread_mutexattr_gettype( )
pthread_mutexattr_init( )
pthread_mutexattr_setpshared( )
pthread_mutexattr_settype( )
pthread_once( )
pthread_rwlock_destroy( )
pthread_rwlock_init( )
pthread_rwlock_rdlock( )
pthread_rwlock_tryrdlock( )
pthread_rwlock_trywrlock( )
pthread_rwlock_unlock( )
pthread_rwlock_wrlock( )
pthread_rwlockattr_destroy( )
pthread_rwlockattr_getpshared( )
pthread_rwlockattr_init( )

pthread_condattr_getpshared( )
pthread_condattr_init( )
pthread_condattr_setpshared( )
pthread_create( )
pthread_detach( )
pthread_equal( )
pthread_exit( )
pthread_getconcurrency( )
pthread_getspecific( )
pthread_join( )
pthread_rwlockattr_setpshared( )
pthread_self( )
pthread_setcancelstate( )
pthread_setcanceltype( )
pthread_setconcurrency( )
pthread_setspecific( )
pthread_sigmask( )
pthread_testcancel( )
sigwait( )

On XSI-conformant systems, the symbolic constant _POSIX_THREAD_SAFE_FUNCTIONS is always defined. Therefore, the following functions are always supported:

asctime_r( )
ctime_r( )
flockfile( )
ftrylockfile( )
funlockfile( )
getc_unlocked( )
getchar_unlocked( )
getgrgid_r( )
getgrnam_r( )
getpwnam_r( )
getpwuid_r( )
gmtime_r( )
localtime_r( )
putc_unlocked( )
putchar_unlocked( )
rand_r( )
readdir_r( )
strerror_r( )
strtok_r( )

The following threads functions are only supported on XSI-conformant systems if the Realtime Threads Option Group is supported :

pthread_attr_getinheritsched( )
pthread_attr_getschedpolicy( )
pthread_attr_getscope( )
pthread_attr_setinheritsched( )
pthread_attr_setschedpolicy( )
pthread_attr_setscope( )
pthread_getschedparam( )
pthread_mutex_getprioceiling( )
pthread_mutex_setprioceiling( )
pthread_mutexattr_getprioceiling( )
pthread_mutexattr_getprotocol( )
pthread_mutexattr_setprioceiling( )
pthread_mutexattr_setprotocol( )
pthread_setschedparam( )

XSI Threads Extensions

The following XSI extensions to POSIX.1c are now supported in IEEE Std 1003.1-200x as part of the alignment with the Single UNIX Specification:

- Extended mutex attribute types
- Read-write locks and attributes (also introduced by IEEE Std 1003.1j-2000 amendment)
- Thread concurrency level
- Thread stack guard size
- Parallel I/O

A total of 19 new functions were added.

These extensions carefully follow the threads programming model specified in POSIX.1c. As with POSIX.1c, all the new functions return zero if successful; otherwise, an error number is returned to indicate the error.

The concept of attribute objects was introduced in POSIX.1c to allow implementations to extend IEEE Std 1003.1-200x without changing the existing interfaces. Attribute objects were defined for threads, mutexes, and condition variables. Attributes objects are defined as implementation-defined opaque types to aid extensibility, and functions are defined to allow attributes to be set or retrieved. This model has been followed when adding the new type attribute of **pthread_mutexattr_t** or the new read-write lock attributes object **pthread_rwlockattr_t**.

- Extended Mutex Attributes

  POSIX.1c defines a mutex attributes object as an implementation-defined opaque object of type **pthread_mutexattr_t**, and specifies a number of attributes which this object must have and a number of functions which manipulate these attributes. These attributes include *detachstate*, *inheritsched*, *schedparm*, *schedpolicy*, *contentionscope*, *stackaddr*, and *stacksize*.

  The System Interfaces volume of IEEE Std 1003.1-200x specifies another mutex attribute called *type*. The *type* attribute allows applications to specify the behavior of mutex locking operations in situations where the POSIX.1c behavior is undefined. The OSF DCE threads implementation, based on Draft 4 of POSIX.1c, specified a similar attribute. Note that the names of the attributes have changed somewhat from the OSF DCE threads implementation.

  The System Interfaces volume of IEEE Std 1003.1-200x also extends the specification of the following POSIX.1c functions which manipulate mutexes:

  pthread_mutex_lock( )
  pthread_mutex_trylock( )
  pthread_mutex_unlock( )

  to take account of the new mutex attribute type and to specify behavior which was declared as undefined in POSIX.1c. How a calling thread acquires or releases a mutex now depends upon the mutex *type* attribute.

  The *type* attribute can have the following values:

  PTHREAD_MUTEX_NORMAL
  Basic mutex with no specific error checking built in. Does not report a deadlock error.

  PTHREAD_MUTEX_RECURSIVE
  Allows any thread to recursively lock a mutex. The mutex must be unlocked an equal number of times to release the mutex.

  PTHREAD_MUTEX_ERRORCHECK
  Detects and reports simple usage errors; that is, an attempt to unlock a mutex that is not locked by the calling thread or that is not locked at all, or an attempt to relock a mutex the thread already owns.

  PTHREAD_MUTEX_DEFAULT
  The default mutex type. May be mapped to any of the above mutex types or may be an implementation-defined type.

  Normal mutexes do not detect deadlock conditions; for example, a thread will hang if it tries to relock a normal mutex that it already owns. Attempting to unlock a mutex locked by another thread, or unlocking an unlocked mutex, results in undefined behavior. Normal mutexes will usually be the fastest type of mutex available on a platform but provide the least error checking.

  Recursive mutexes are useful for converting old code where it is difficult to establish clear boundaries of synchronization. A thread can relock a recursive mutex without first unlocking it. The relocking deadlock which can occur with normal mutexes cannot occur with this type of mutex. However, multiple locks of a recursive mutex require the same number of unlocks to release the mutex before another thread can acquire the mutex. Furthermore, this type of mutex maintains the concept of an owner. Thus, a thread attempting to unlock a recursive mutex which another thread has locked returns with an error. A thread attempting to unlock a recursive mutex that is not locked shall return with an error. Never use a recursive mutex with condition variables because the implicit unlock performed by *pthread_cond_wait*( ) or *pthread_cond_timedwait*( ) will not actually release the mutex if it had been locked multiple times.

Errorcheck mutexes provide error checking and are useful primarily as a debugging aid. A thread attempting to relock an errorcheck mutex without first unlocking it returns with an error. Again, this type of mutex maintains the concept of an owner. Thus, a thread attempting to unlock an errorcheck mutex which another thread has locked returns with an error. A thread attempting to unlock an errorcheck mutex that is not locked also returns with an error. It should be noted that errorcheck mutexes will almost always be much slower than normal mutexes due to the extra state checks performed.

The *default* mutex type provides implementation-defined error checking. The default mutex may be mapped to one of the other defined types or may be something entirely different. This enables each vendor to provide the mutex semantics which the vendor feels will be most useful to their target users. Most vendors will probably choose to make normal mutexes the default so as to give applications the benefit of the fastest type of mutexes available on their platform. Check your implementation's documentation.

An application developer can use any of the mutex types almost interchangeably as long as the application does not depend upon the implementation detecting (or failing to detect) any particular errors. Note that a recursive mutex can be used with condition variable waits as long as the application never recursively locks the mutex.

Two functions are provided for manipulating the *type* attribute of a mutex attributes object. This attribute is set or returned in the *type* parameter of these functions. The *pthread_mutexattr_settype*( ) function is used to set a specific type value while *pthread_mutexattr_gettype*( ) is used to return the type of the mutex. Setting the *type* attribute of a mutex attributes object affects only mutexes initialized using that mutex attributes object. Changing the *type* attribute does not affect mutexes previously initialized using that mutex attributes object.

- Read-Write Locks and Attributes

  The read-write locks introduced have been harmonized with those in IEEE Std 1003.1j-2000; see also Section B.2.9.6 (on page 3464).

  Read-write locks (also known as reader-writer locks) allow a thread to exclusively lock some shared data while updating that data, or allow any number of threads to have simultaneous read-only access to the data.

  Unlike a mutex, a read-write lock distinguishes between reading data and writing data. A mutex excludes all other threads. A read-write lock allows other threads access to the data, providing no thread is modifying the data. Thus, a read-write lock is less primitive than either a mutex-condition variable pair or a semaphore.

  Application developers should consider using a read-write lock rather than a mutex to protect data that is frequently referenced but seldom modified. Most threads (readers) will be able to read the data without waiting and will only have to block when some other thread (a writer) is in the process of modifying the data. Conversely a thread that wants to change the data is forced to wait until there are no readers. This type of lock is often used to facilitate parallel access to data on multi-processor platforms or to avoid context switches on single processor platforms where multiple threads access the same data.

If a read-write lock becomes unlocked and there are multiple threads waiting to acquire the write lock, the implementation's scheduling policy determines which thread shall acquire the read-write lock for writing. If there are multiple threads blocked on a read-write lock for both read locks and write locks, it is unspecified whether the readers or a writer acquire the lock first. However, for performance reasons, implementations often favor writers over readers to avoid potential writer starvation.

A read-write lock object is an implementation-defined opaque object of type **pthread_rwlock_t** as defined in **<pthread.h>**. There are two different sorts of locks associated with a read-write lock: a *read lock* and a *write lock*.

The *pthread_rwlockattr_init*( ) function initializes a read-write lock attributes object with the default value for all the attributes defined in the implementation. After a read-write lock attributes object has been used to initialize one or more read-write locks, changes to the read-write lock attributes object, including destruction, do not affect previously initialized read-write locks.

Implementations must provide at least the read-write lock attribute *process-shared*. This attribute can have the following values:

PTHREAD_PROCESS_SHARED
Any thread of any process that has access to the memory where the read-write lock resides can manipulate the read-write lock.

PTHREAD_PROCESS_PRIVATE
Only threads created within the same process as the thread that initialized the read-write lock can manipulate the read-write lock. This is the default value.

The *pthread_rwlockattr_setpshared*( ) function is used to set the *process-shared* attribute of an initialized read-write lock attributes object while the function *pthread_rwlockattr_getpshared*( ) obtains the current value of the *process-shared* attribute.

A read-write lock attributes object is destroyed using the *pthread_rwlockattr_destroy*( ) function. The effect of subsequent use of the read-write lock attributes object is undefined.

A thread creates a read-write lock using the *pthread_rwlock_init*( ) function. The attributes of the read-write lock can be specified by the application developer; otherwise, the default implementation-defined read-write lock attributes are used if the pointer to the read-write lock attributes object is NULL. In cases where the default attributes are appropriate, the PTHREAD_RWLOCK_INITIALIZER macro can be used to initialize statically allocated read-write locks.

A thread which wants to apply a read lock to the read-write lock can use either *pthread_rwlock_rdlock*( ) or *pthread_rwlock_tryrdlock*( ). If *pthread_rwlock_rdlock*( ) is used, the thread acquires a read lock if a writer does not hold the write lock and there are no writers blocked on the write lock. If a read lock is not acquired, the calling thread blocks until it can acquire a lock. However, if *pthread_rwlock_tryrdlock*( ) is used, the function returns immediately with the error [EBUSY] if any thread holds a write lock or there are blocked writers waiting for the write lock.

A thread which wants to apply a write lock to the read-write lock can use either of two functions: *pthread_rwlock_wrlock*( ) or *pthread_rwlock_trywrlock*( ). If *pthread_rwlock_wrlock*( ) is used, the thread acquires the write lock if no other reader or writer threads hold the read-write lock. If the write lock is not acquired, the thread blocks until it can acquire the write lock. However, if *pthread_rwlock_trywrlock*( ) is used, the function returns immediately with the error [EBUSY] if any thread is holding either a read or a write lock.

The *pthread_rwlock_unlock*( ) function is used to unlock a read-write lock object held by the calling thread. Results are undefined if the read-write lock is not held by the calling thread. If there are other read locks currently held on the read-write lock object, the read-write lock object shall remain in the read locked state but without the current thread as one of its owners. If this function releases the last read lock for this read-write lock object, the read-write lock object shall be put in the unlocked read state. If this function is called to release a write lock for this read-write lock object, the read-write lock object shall be put in the unlocked state.

- Thread Concurrency Level

  On threads implementations that multiplex user threads onto a smaller set of kernel execution entities, the system attempts to create a reasonable number of kernel execution entities for the application upon application startup.

  On some implementations, these kernel entities are retained by user threads that block in the kernel. Other implementations do not *timeslice* user threads so that multiple compute-bound user threads can share a kernel thread. On such implementations, some applications may use up all the available kernel execution entities before its user-space threads are used up. The process may be left with user threads capable of doing work for the application but with no way to schedule them.

  The *pthread_setconcurrency*( ) function enables an application to request more kernel entities; that is, specify a desired concurrency level. However, this function merely provides a hint to the implementation. The implementation is free to ignore this request or to provide some other number of kernel entities. If an implementation does not multiplex user threads onto a smaller number of kernel execution entities, the *pthread_setconcurrency*( ) function has no effect.

  The *pthread_setconcurrency*( ) function may also have an effect on implementations where the kernel mode and user mode schedulers cooperate to ensure that ready user threads are not prevented from running by other threads blocked in the kernel.

  The *pthread_getconcurrency*( ) function always returns the value set by a previous call to *pthread_setconcurrency*( ). However, if *pthread_setconcurrency*( ) was not previously called, this function shall return zero to indicate that the threads implementation is maintaining the concurrency level.

- Thread Stack Guard Size

  DCE threads introduced the concept of a *thread stack guard size*. Most thread implementations add a region of protected memory to a thread's stack, commonly known as a *guard region*, as a safety measure to prevent stack pointer overflow in one thread from corrupting the contents of another thread's stack. The default size of the guard regions attribute is {PAGESIZE} bytes and is implementation-defined.

  Some application developers may wish to change the stack guard size. When an application creates a large number of threads, the extra page allocated for each stack may strain system resources. In addition to the extra page of memory, the kernel's memory manager has to keep track of the different protections on adjoining pages. When this is a problem, the application developer may request a guard size of 0 bytes to conserve system resources by eliminating stack overflow protection.

  Conversely an application that allocates large data structures such as arrays on the stack may wish to increase the default guard size in order to detect stack overflow. If a thread allocates two pages for a data array, a single guard page provides little protection against thread stack overflows since the thread can corrupt adjoining memory beyond the guard page.

The System Interfaces volume of IEEE Std 1003.1-200x defines a new attribute of a thread attributes object; that is, the *guardsize* attribute which allows applications to specify the size of the guard region of a thread's stack.

Two functions are provided for manipulating a thread's stack guard size. The *pthread_attr_setguardsize*( ) function sets the thread *guardsize* attribute, and the *pthread_attr_getguardsize*( ) function retrieves the current value.

An implementation may round up the requested guard size to a multiple of the configurable system variable {PAGESIZE}. In this case, *pthread_attr_getguardsize*( ) returns the guard size specified by the previous *pthread_attr_setguardsize*( ) function call and not the rounded up value.

If an application is managing its own thread stacks using the *stackaddr* attribute, the *guardsize* attribute is ignored and no stack overflow protection is provided. In this case, it is the responsibility of the application to manage stack overflow along with stack allocation.

- Parallel I/O

  Suppose two or more threads independently issue read requests on the same file. To read specific data from a file, a thread must first call *lseek*( ) to seek to the proper offset in the file, and then call *read*( ) to retrieve the required data. If more than one thread does this at the same time, the first thread may complete its seek call, but before it gets a chance to issue its read call a second thread may complete its seek call, resulting in the first thread accessing incorrect data when it issues its read call. One workaround is to lock the file descriptor while seeking and reading or writing, but this reduces parallelism and adds overhead.

  Instead, the System Interfaces volume of IEEE Std 1003.1-200x provides two functions to make seek/read and seek/write operations atomic. The file descriptor's current offset is unchanged, thus allowing multiple read and write operations to proceed in parallel. This improves the I/O performance of threaded applications. The *pread*( ) function is used to do an atomic read of data from a file into a buffer. Conversely, the *pwrite*( ) function does an atomic write of data from a buffer to a file.

B.2.9.1 Thread-Safety

All functions required by IEEE Std 1003.1-200x need to be thread-safe. Implementations have to provide internal synchronization when necessary in order to achieve this goal. In certain cases—for example, most floating-point implementations—context switch code may have to manage the writable shared state.

While a read from a pipe of {PIPE_MAX}*2 bytes may not generate a single atomic and thread-safe stream of bytes, it should generate ''several'' (individually atomic) thread-safe streams of bytes. Similarly, while reading from a terminal device may not generate a single atomic and thread-safe stream of bytes, it should generate some finite number of (individually atomic) and thread-safe streams of bytes. That is, concurrent calls to read for a pipe, FIFO, or terminal device are not allowed to result in corrupting the stream of bytes or other internal data. However, *read*( ), in these cases, is not required to return a single contiguous and atomic stream of bytes.

It is not required that all functions provided by IEEE Std 1003.1-200x be either async-cancel-safe or async-signal-safe.

As it turns out, some functions are inherently not thread-safe; that is, their interface specifications preclude reentrancy. For example, some functions (such as *asctime*( )) return a pointer to a result stored in memory space allocated by the function on a per-process basis. Such a function is not thread-safe, because its result can be overwritten by successive invocations.

Other functions, while not inherently non-thread-safe, may be implemented in ways that lead to them not being thread-safe. For example, some functions (such as *rand*( )) store state information (such as a seed value, which survives multiple function invocations) in memory space allocated by the function on a per-process basis. The implementation of such a function is not thread-safe if the implementation fails to synchronize invocations of the function and thus fails to protect the state information. The problem is that when the state information is not protected, concurrent invocations can interfere with one another (for example, see the same seed value).

Thread-Safety and Locking of Existing Functions

Originally, POSIX.1 was not designed to work in a multi-threaded environment, and some implementations of some existing functions will not work properly when executed concurrently. To provide routines that will work correctly in an environment with threads (''thread-safe''), two problems need to be solved:

1. Routines that maintain or return pointers to static areas internal to the routine (which may now be shared) need to be modified. The routines *ttyname*( ) and *localtime*( ) are examples.
2. Routines that access data space shared by more than one thread need to be modified. The *malloc*( ) function and the *stdio* family routines are examples.

There are a variety of constraints on these changes. The first is compatibility with the existing versions of these functions—non-thread-safe functions will continue to be in use for some time, as the original interfaces are used by existing code. Another is that the new thread-safe versions of these functions represent as small a change as possible over the familiar interfaces provided by the existing non-thread-safe versions. The new interfaces should be independent of any particular threads implementation. In particular, they should be thread-safe without depending on explicit thread-specific memory. Finally, there should be minimal performance penalty due to the changes made to the functions.

It is intended that the list of functions from POSIX.1 that cannot be made thread-safe and for which corrected versions are provided be complete.

Thread-Safety and Locking Solutions

Many of the POSIX.1 functions were thread-safe and did not change at all. However, some functions (for example, the math functions typically found in **libm**) are not thread-safe because of writable shared global state. For instance, in IEEE Std 754-1985 floating-point implementations, the computation modes and flags are global and shared.

Some functions are not thread-safe because a particular implementation is not reentrant, typically because of a non-essential use of static storage. These require only a new implementation.

Thread-safe libraries are useful in a wide range of parallel (and asynchronous) programming environments, not just within pthreads. In order to be used outside the context of pthreads, however, such libraries still have to use some synchronization method. These could either be independent of the pthread synchronization operations, or they could be a subset of the pthread interfaces. Either method results in thread-safe library implementations that can be used without the rest of pthreads.

Some functions, such as the *stdio* family interface and dynamic memory allocation functions such as *malloc*( ), are interdependent routines that share resources (for example, buffers) across related calls. These require synchronization to work correctly, but they do not require any change to their external (user-visible) interfaces.

In some cases, such as *getc*( ) and *putc*( ), adding synchronization is likely to create an unacceptable performance impact. In this case, slower thread-safe synchronized functions are to be provided, but the original, faster (but unsafe) functions (which may be implemented as macros) are retained under new names. Some additional special-purpose synchronization facilities are necessary for these macros to be usable in multi-threaded programs. This also requires changes in **<stdio.h>**.

The other common reason that functions are unsafe is that they return a pointer to static storage, making the functions non-thread-safe. This has to be changed, and there are three natural choices:

1. Return a pointer to thread-specific storage

   This could incur a severe performance penalty on those architectures with a costly implementation of the thread-specific data interface.

   A variation on this technique is to use *malloc*( ) to allocate storage for the function output and return a pointer to this storage. This technique may also have an undesirable performance impact, however, and a simplistic implementation requires that the user program explicitly free the storage object when it is no longer needed. This technique is used by some existing POSIX.1 functions. With careful implementation for infrequently used functions, there may be little or no performance or storage penalty, and the maintenance of already-standardized interfaces is a significant benefit.

2. Return the actual value computed by the function

   This technique can only be used with functions that return pointers to structures—routines that return character strings would have to wrap their output in an enclosing structure in order to return the output on the stack. There is also a negative performance impact inherent in this solution in that the output value has to be copied twice before it can be used by the calling function: once from the called routine's local buffers to the top of the stack, then from the top of the stack to the assignment target. Finally, many older compilers cannot support this technique due to a historical tendency to use internal static buffers to deliver the results of structure-valued functions.

3. Have the caller pass the address of a buffer to contain the computed value

   The only disadvantage of this approach is that extra arguments have to be provided by the calling program. It represents the most efficient solution to the problem, however, and, unlike the *malloc*( ) technique, it is semantically clear.

There are some routines (often groups of related routines) whose interfaces are inherently non-thread-safe because they communicate across multiple function invocations by means of static memory locations. The solution is to redesign the calls so that they are thread-safe, typically by passing the needed data as extra parameters. Unfortunately, this may require major changes to the interface as well.

A floating-point implementation using IEEE Std 754-1985 is a case in point. A less problematic example is the *rand48* family of pseudo-random number generators. The functions *getgrgid*( ), *getgrnam*( ), *getpwnam*( ), and *getpwuid*( ) are another such case.

The problems with *errno* are discussed in **Alternative Solutions for Per-Thread errno** (on page 3382).

Some functions can be thread-safe or not, depending on their arguments. These include the *tmpnam*( ) and *ctermid*( ) functions. These functions have pointers to character strings as arguments. If the pointers are not NULL, the functions store their results in the character string; however, if the pointers are NULL, the functions store their results in an area that may be static and thus subject to overwriting by successive calls. These should only be called by multi-thread applications when their arguments are non-NULL.

Asynchronous Safety and Thread-Safety

A floating-point implementation has many modes that effect rounding and other aspects of computation. Functions in some math library implementations may change the computation modes for the duration of a function call. If such a function call is interrupted by a signal or cancelation, the floating-point state is not required to be protected.

There is a significant cost to make floating-point operations async-cancel-safe or async-signal-safe; accordingly, neither form of async safety is required.

Functions Returning Pointers to Static Storage

For those functions that are not thread-safe because they return values in fixed size statically allocated structures, alternate ''_r'' forms are provided that pass a pointer to an explicit result structure. Those that return pointers into library-allocated buffers have forms provided with explicit buffer and length parameters.

For functions that return pointers to library-allocated buffers, it makes sense to provide ''_r'' versions that allow the application control over allocation of the storage in which results are returned. This allows the state used by these functions to be managed on an application-specific basis, supporting per-thread, per-process, or other application-specific sharing relationships.

Early proposals had provided ''_r'' versions for functions that returned pointers to variable-size buffers without providing a means for determining the required buffer size. This would have made using such functions exceedingly clumsy, potentially requiring iteratively calling them with increasingly larger guesses for the amount of storage required. Hence, *sysconf*( ) variables have been provided for such functions that return the maximum required buffer size.

Thus, the rule that has been followed by IEEE Std 1003.1-200x when adapting single-threaded non-thread-safe functions is as follows: all functions returning pointers to library-allocated storage should have ''_r'' versions provided, allowing the application control over the storage allocation. Those with variable-sized return values accept both a buffer address and a length parameter. The *sysconf*( ) variables are provided to supply the appropriate buffer sizes when required. Implementors are encouraged to apply the same rule when adapting their own existing functions to a pthreads environment.

B.2.9.2 Thread IDs

Separate programs should communicate through well-defined interfaces and should not depend on each other's implementation. For example, if a programmer decides to rewrite the *sort* program using multiple threads, it should be easy to do this so that the interface to the *sort* program does not change. Consider that if the user causes SIGINT to be generated while the *sort* program is running, keeping the same interface means that the entire sort program is killed, not just one of its threads. As another example, consider a realtime program that manages a reactor. Such a program may wish to allow other programs to control the priority at which it watches the control rods. One technique to accomplish this is to write the ID of the thread watching the control rods into a file and allow other programs to change the priority of that thread as they see fit. A simpler technique is to have the reactor process accept IPCs (Inter-Process Communication messages) from other processes, telling it at a semantic level what priority the program should assign to watching the control rods. This allows the programmer greater flexibility in the implementation. For example, the programmer can change the implementation from having one thread per rod to having one thread watching all of the rods without changing the interface. Having threads live inside the process means that the implementation of a process is invisible to outside processes (excepting debuggers and system management tools).

Threads do not provide a protection boundary. Every thread model allows threads to share memory with other threads and encourages this sharing to be widespread. This means that one thread can wipe out memory that is needed for the correct functioning of other threads that are sharing its memory. Consequently, providing each thread with its own user and/or group IDs would not provide a protection boundary between threads sharing memory.

B.2.9.3 *Thread Mutexes*

There is no additional rationale provided for this section.

B.2.9.4 *Thread Scheduling*

- Scheduling Implementation Models

  The following scheduling implementation models are presented in terms of threads and ‘‘kernel entities’’. This is to simplify exposition of the models, and it does not imply that an implementation actually has an identifiable ‘‘kernel entity’’.

  A kernel entity is not defined beyond the fact that it has scheduling attributes that are used to resolve contention with other kernel entities for execution resources. A kernel entity may be thought of as an envelope that holds a thread or a separate kernel thread. It is not a conventional process, although it shares with the process the attribute that it has a single thread of control; it does not necessarily imply an address space, open files, and so on. It is better thought of as a primitive facility upon which conventional processes and threads may be constructed.

  — System Thread Scheduling Model

  This model consists of one thread per kernel entity. The kernel entity is solely responsible for scheduling thread execution on one or more processors. This model schedules all threads against all other threads in the system using the scheduling attributes of the thread.

  — Process Scheduling Model

  A generalized process scheduling model consists of two levels of scheduling. A threads library creates a pool of kernel entities, as required, and schedules threads to run on them using the scheduling attributes of the threads. Typically, the size of the pool is a function of the simultaneously runnable threads, not the total number of threads. The kernel then schedules the kernel entities onto processors according to their scheduling attributes, which are managed by the threads library. This set model potentially allows a wide range of mappings between threads and kernel entities.

- System and Process Scheduling Model Performance

  There are a number of important implications on the performance of applications using these scheduling models. The process scheduling model potentially provides lower overhead for making scheduling decisions, since there is no need to access kernel-level information or functions and the set of schedulable entities is smaller (only the threads within the process).

  On the other hand, since the kernel is also making scheduling decisions regarding the system resources under its control (for example, CPU(s), I/O devices, memory), decisions that do not take thread scheduling parameters into account can result in unspecified delays for realtime application threads, causing them to miss maximum response time limits. |

- Rate Monotonic Scheduling

  Rate monotonic scheduling was considered, but rejected for standardization in the context of pthreads. A sporadic server policy is included.

- Scheduling Options

  In IEEE Std 1003.1-200x, the basic thread scheduling functions are defined under the Threads option, so that they are required of all threads implementations. However, there are no specific scheduling policies required by this option to allow for conforming thread implementations that are not targeted to realtime applications.

  Specific standard scheduling policies are defined to be under the Thread Execution Scheduling option, and they are specifically designed to support realtime applications by providing predictable resource sharing sequences. The name of this option was chosen to emphasize that this functionality is defined as appropriate for realtime applications that require simple priority-based scheduling.

  It is recognized that these policies are not necessarily satisfactory for some multi-processor implementations, and work is ongoing to address a wider range of scheduling behaviors. The interfaces have been chosen to create abundant opportunity for future scheduling policies to be implemented and standardized based on this interface. In order to standardize a new scheduling policy, all that is required (from the standpoint of thread scheduling attributes) is to define a new policy name, new members of the thread attributes object, and functions to set these members when the scheduling policy is equal to the new value.

Scheduling Contention Scope

In order to accommodate the requirement for realtime response, each thread has a scheduling contention scope attribute. Threads with a system scheduling contention scope have to be scheduled with respect to all other threads in the system. These threads are usually bound to a single kernel entity that reflects their scheduling attributes and are directly scheduled by the kernel.

Threads with a process scheduling contention scope need be scheduled only with respect to the other threads in the process. These threads may be scheduled within the process onto a pool of kernel entities. The implementation is also free to bind these threads directly to kernel entities and let them be scheduled by the kernel. Process scheduling contention scope allows the implementation the most flexibility and is the default if both contention scopes are supported and none is specified.

Thus, the choice by implementors to provide one or the other (or both) of these scheduling models is driven by the need of their supported application domains for worst-case (that is, realtime) response, or average-case (non-realtime) response.

Scheduling Allocation Domain

The SCHED_FIFO and SCHED_RR scheduling policies take on different characteristics on a multi-processor. Other scheduling policies are also subject to changed behavior when executed on a multi-processor. The concept of scheduling allocation domain determines the set of processors on which the threads of an application may run. By considering the application's processor scheduling allocation domain for its threads, scheduling policies can be defined in terms of their behavior for varying processor scheduling allocation domain values. It is conceivable that not all scheduling allocation domain sizes make sense for all scheduling policies on all implementations. The concept of scheduling allocation domain, however, is a useful tool for the description of multi-processor scheduling policies.

The ‘‘process control’’ approach to scheduling obtains significant performance advantages from dynamic scheduling allocation domain sizes when it is applicable.

Non-Uniform Memory Access (NUMA) multi-processors may use a system scheduling structure that involves reassignment of threads among scheduling allocation domains. In NUMA machines, a natural model of scheduling is to match scheduling allocation domains to clusters of processors. Load balancing in such an environment requires changing the scheduling allocation domain to which a thread is assigned.

Scheduling Documentation

Implementation-provided scheduling policies need to be completely documented in order to be useful. This documentation includes a description of the attributes required for the policy, the scheduling interaction of threads running under this policy and all other supported policies, and the effects of all possible values for processor scheduling allocation domain. Note that for the implementor wishing to be minimally-compliant, it is (minimally) acceptable to define the behavior as undefined.

Scheduling Contention Scope Attribute

The scheduling contention scope defines how threads compete for resources. Within IEEE Std 1003.1-200x, scheduling contention scope is used to describe only how threads are scheduled in relation to one another in the system. That is, either they are scheduled against all other threads in the system (‘‘system scope’’) or only against those threads in the process (‘‘process scope’’). In fact, scheduling contention scope may apply to additional resources, including virtual timers and profiling, which are not currently considered by IEEE Std 1003.1-200x.

Mixed Scopes

If only one scheduling contention scope is supported, the scheduling decision is straightforward. To perform the processor scheduling decision in a mixed scope environment, it is necessary to map the scheduling attributes of the thread with process-wide contention scope to the same attribute space as the thread with system-wide contention scope.

Since a conforming implementation has to support one and may support both scopes, it is useful to discuss the effects of such choices with respect to example applications. If an implementation supports both scopes, mixing scopes provides a means of better managing system-level (that is, kernel-level) and library-level resources. In general, threads with system scope will require the resources of a separate kernel entity in order to guarantee the scheduling semantics. On the other hand, threads with process scope can share the resources of a kernel entity while maintaining the scheduling semantics.

The application is free to create threads with dedicated kernel resources, and other threads that multiplex kernel resources. Consider the example of a window server. The server allocates two threads per widget: one thread manages the widget user interface (including drawing), while the other thread takes any required application action. This allows the widget to be ‘‘active’’ while the application is computing. A screen image may be built from thousands of widgets. If each of these threads had been created with system scope, then most of the kernel-level resources might be wasted, since only a few widgets are active at any one time. In addition, mixed scope is particularly useful in a window server where one thread with high priority and system scope handles the mouse so that it tracks well. As another example, consider a database server. For each of the hundreds or thousands of clients supported by a large server, an equivalent number of threads will have to be created. If each of these threads were system, the consequences would be the same as for the window server example above. However, the server could be constructed so that actual retrieval of data is done by several dedicated threads. Dedicated threads that do work for all clients frequently justify the added expense of system scope. If it were not permissible to mix system and process threads in the same process, this type of solution would not be possible.

Dynamic Thread Scheduling Parameters Access

In many time-constrained applications, there is no need to change the scheduling attributes dynamically during thread or process execution, since the general use of these attributes is to reflect directly the time constraints of the application. Since these time constraints are generally imposed to meet higher-level system requirements, such as accuracy or availability, they frequently should remain unchanged during application execution.

However, there are important situations in which the scheduling attributes should be changed. Generally, this will occur when external environmental conditions exist in which the time constraints change. Consider, for example, a space vehicle major mode change, such as the change from ascent to descent mode, or the change from the space environment to the atmospheric environment. In such cases, the frequency with which many of the sensors or acutators need to be read or written will change, which will necessitate a priority change. In other cases, even the existence of a time constraint might be temporary, necessitating not just a priority change, but also a policy change for ongoing threads or processes. For this reason, it is critical that the interface should provide functions to change the scheduling parameters dynamically, but, as with many of the other realtime functions, it is important that applications use them properly to avoid the possibility of unnecessarily degrading performance.

In providing functions for dynamically changing the scheduling behavior of threads, there were two options: provide functions to get and set the individual scheduling parameters of threads, or provide a single interface to get and set all the scheduling parameters for a given thread simultaneously. Both approaches have merit. Access functions for individual parameters allow simpler control of thread scheduling for simple thread scheduling parameters. However, a single function for setting all the parameters for a given scheduling policy is required when first setting that scheduling policy. Since the single all-encompassing functions are required, it was decided to leave the interface as minimal as possible. Note that simpler functions (such as *pthread_setprio*( ) for threads running under the priority-based schedulers) can be easily defined in terms of the all-encompassing functions.

If the *pthread_setschedparam*( ) function executes successfully, it will have set all of the scheduling parameter values indicated in *param*; otherwise, none of the scheduling parameters will have been modified. This is necessary to ensure that the scheduling of this and all other threads continues to be consistent in the presence of an erroneous scheduling parameter.

The [EPERM] error value is included in the list of possible *pthread_setschedparam*( ) error returns as a reflection of the fact that the ability to change scheduling parameters increases risks to the implementation and application performance if the scheduling parameters are changed improperly. For this reason, and based on some existing practice, it was felt that some implementations would probably choose to define specific permissions for changing either a thread's own or another thread's scheduling parameters. IEEE Std 1003.1-200x does not include portable methods for setting or retrieving permissions, so any such use of permissions is completely unspecified .

Mutex Initialization Scheduling Attributes

In a priority-driven environment, a direct use of traditional primitives like mutexes and condition variables can lead to unbounded priority inversion, where a higher priority thread can be blocked by a lower priority thread, or set of threads, for an unbounded duration of time. As a result, it becomes impossible to guarantee thread deadlines. Priority inversion can be bounded and minimized by the use of priority inheritance protocols. This allows thread deadlines to be guaranteed even in the presence of synchronization requirements.

Two useful but simple members of the family of priority inheritance protocols are the basic priority inheritance protocol and the priority ceiling protocol emulation. Under the Basic Priority

Inheritance protocol (governed by the Thread Priority Inheritance option), a thread that is blocking higher priority threads executes at the priority of the highest priority thread that it blocks. This simple mechanism allows priority inversion to be bounded by the duration of critical sections and makes timing analysis possible.

Under the Priority Ceiling Protocol Emulation protocol (governed by the Thread Priority Protection option), each mutex has a priority ceiling, usually defined as the priority of the highest priority thread that can lock the mutex. When a thread is executing inside critical sections, its priority is unconditionally increased to the highest of the priority ceilings of all the mutexes owned by the thread. This protocol has two very desirable properties in uni-processor systems. First, a thread can be blocked by a lower priority thread for at most the duration of one single critical section. Furthermore, when the protocol is correctly used in a single processor, and if threads do not become blocked while owning mutexes, mutual deadlocks are prevented.

The priority ceiling emulation can be extended to multiple processor environments, in which case the values of the priority ceilings will be assigned depending on the kind of mutex that is being used: local to only one processor, or global, shared by several processors. Local priority ceilings will be assigned the usual way, equal to the priority of the highest priority thread that may lock that mutex. Global priority ceilings will usually be assigned a priority level higher than all the priorities assigned to any of the threads that reside in the involved processors to avoid the effect called remote blocking.

Change the Priority Ceiling of a Mutex

In order for the priority protect protocol to exhibit its desired properties of bounding priority inversion and avoidance of deadlock, it is critical that the ceiling priority of a mutex be the same as the priority of the highest thread that can ever hold it, or higher. Thus, if the priorities of the threads using such mutexes never change dynamically, there is no need ever to change the priority ceiling of a mutex.

However, if a major system mode change results in an altered response time requirement for one or more application threads, their priority has to change to reflect it. It will occasionally be the case that the priority ceilings of mutexes held also need to change. While changing priority ceilings should generally be avoided, it is important that IEEE Std 1003.1-200x provide these interfaces for those cases in which it is necessary.

B.2.9.5 *Thread Cancelation*

Many existing threads packages have facilities for canceling an operation or canceling a thread. These facilities are used for implementing user requests (such as the CANCEL button in a window-based application), for implementing OR parallelism (for example, telling the other threads to stop working once one thread has found a forced mate in a parallel chess program), or for implementing the ABORT mechanism in Ada.

POSIX programs traditionally have used the signal mechanism combined with either *longjmp*( ) or polling to cancel operations. Many POSIX programmers have trouble using these facilities to solve their problems efficiently in a single-threaded process. With the introduction of threads, these solutions become even more difficult to use.

The main issues with implementing a cancelation facility are specifying the operation to be canceled, cleanly releasing any resources allocated to that operation, controlling when the target notices that it has been canceled, and defining the interaction between asynchronous signals and cancelation.

Specifying the Operation to Cancel

Consider a thread that calls through five distinct levels of program abstraction and then, inside the lowest-level abstraction, calls a function that suspends the thread. (An abstraction boundary is a layer at which the client of the abstraction sees only the service being provided and can remain ignorant of the implementation. Abstractions are often layered, each level of abstraction being a client of the lower-level abstraction and implementing a higher-level abstraction.) Depending on the semantics of each abstraction, one could imagine wanting to cancel only the call that causes suspension, only the bottom two levels, or the operation being done by the entire thread. Canceling operations at a finer grain than the entire thread is difficult because threads are active and they may be run in parallel on a multi-processor. By the time one thread can make a request to cancel an operation, the thread performing the operation may have completed that operation and gone on to start another operation whose cancelation is not desired. Thread IDs are not reused until the thread has exited, and either it was created with the *Attr detachstate* attribute set to PTHREAD_CREATE_DETACHED or the *pthread_join*( ) or *pthread_detach*( ) function has been called for that thread. Consequently, a thread cancelation will never be misdirected when the thread terminates. For these reasons, the canceling of operations is done at the granularity of the thread. Threads are designed to be inexpensive enough so that a separate thread may be created to perform each separately cancelable operation; for example, each possibly long running user request.

For cancelation to be used in existing code, cancelation scopes and handlers will have to be established for code that needs to release resources upon cancelation, so that it follows the programming discipline described in the text.

A Special Signal Versus a Special Interface

Two different mechanisms were considered for providing the cancelation interfaces. The first was to provide an interface to direct signals at a thread and then to define a special signal that had the required semantics. The other alternative was to use a special interface that delivered the correct semantics to the target thread.

The solution using signals produced a number of problems. It required the implementation to provide cancelation in terms of signals whereas a perfectly valid (and possibly more efficient) implementation could have both layered on a low-level set of primitives. There were so many exceptions to the special signal (it cannot be used with kill, no POSIX.1 interfaces can be used with it) that it was clearly not a valid signal. Its semantics on delivery were also completely different from any existing POSIX.1 signal. As such, a special interface that did not mandate the implementation and did not confuse the semantics of signals and cancelation was felt to be the better solution.

Races Between Cancelation and Resuming Execution

Due to the nature of cancelation, there is generally no synchronization between the thread requesting the cancelation of a blocked thread and events that may cause that thread to resume execution. For this reason, and because excess serialization hurts performance, when both an event that a thread is waiting for has occurred and a cancelation request has been made and cancelation is enabled, IEEE Std 1003.1-200x explicitly allows the implementation to choose between returning from the blocking call or acting on the cancelation request.

Interaction of Cancelation with Asynchronous Signals

A typical use of cancelation is to acquire a lock on some resource and to establish a cancelation cleanup handler for releasing the resource when and if the thread is canceled.

A correct and complete implementation of cancelation in the presence of asynchronous signals requires considerable care. An implementation has to push a cancelation cleanup handler on the cancelation cleanup stack while maintaining the integrity of the stack data structure. If an asynchronously generated signal is posted to the thread during a stack operation, the signal handler cannot manipulate the cancelation cleanup stack. As a consequence, asynchronous signal handlers may not cancel threads or otherwise manipulate the cancelation state of a thread. Threads may, of course, be canceled by another thread that used a *sigwait*( ) function to wait synchronously for an asynchronous signal.

In order for cancelation to function correctly, it is required that asynchronous signal handlers not change the cancelation state. This requires that some elements of existing practice, such as using *longjmp*( ) to exit from an asynchronous signal handler implicitly, be prohibited in cases where the integrity of the cancelation state of the interrupt thread cannot be ensured.

Thread Cancelation Overview

- Cancelability States

  The three possible cancelability states (disabled, deferred, and asynchronous) are encoded into two separate bits ((disable, enable) and (deferred, asynchronous)) to allow them to be changed and restored independently. For instance, short code sequences that will not block sometimes disable cancelability on entry and restore the previous state upon exit. Likewise, long or unbounded code sequences containing no convenient explicit cancelation points will sometimes set the cancelability type to asynchronous on entry and restore the previous value upon exit.

- Cancelation Points

  Cancelation points are points inside of certain functions where a thread has to act on any pending cancelation request when cancelability is enabled, if the function would block. As with checking for signals, operations need only check for pending cancelation requests when the operation is about to block indefinitely.

  The idea was considered of allowing implementations to define whether blocking calls such as *read*( ) should be cancelation points. It was decided that it would adversely affect the design of conforming applications if blocking calls were not cancelation points because threads could be left blocked in an uncancelable state.

  There are several important blocking routines that are specifically not made cancelation points:

  — *pthread_mutex_lock*( )

    If *pthread_mutex_lock*( ) were a cancelation point, every routine that called it would also become a cancelation point (that is, any routine that touched shared state would automatically become a cancelation point). For example, *malloc*( ), *free*( ), and *rand*( ) would become cancelation points under this scheme. Having too many cancelation points makes programming very difficult, leading to either much disabling and restoring of cancelability or much difficulty in trying to arrange for reliable cleanup at every possible place.

    Since *pthread_mutex_lock*( ) is not a cancelation point, threads could result in being blocked uninterruptibly for long periods of time if mutexes were used as a general synchronization mechanism. As this is normally not acceptable, mutexes should only be used to protect resources that are held for small fixed lengths of time where not being able to be canceled will not be a problem. Resources that need to be held exclusively for long periods of time should be protected with condition variables.

— *barrier_wait*( )

Canceling a barrier wait will render a barrier unusable. Similar to a barrier timeout (which the standard developers rejected), there is no way to guarantee the consistency of a barrier's internal data structures if a barrier wait is canceled.

— *pthread_spin_lock*( )

As with mutexes, spin locks should only be used to protect resources that are held for small fixed lengths of time where not being cancelable will not be a problem.

Every library routine should specify whether or not it includes any cancelation points. Typically, only those routines that may block or compute indefinitely need to include cancelation points.

Correctly coded routines only reach cancelation points after having set up a cancelation cleanup handler to restore invariants if the thread is canceled at that point. Being cancelable only at specified cancelation points allows programmers to keep track of actions needed in a cancelation cleanup handler more easily. A thread should only be made asynchronously cancelable when it is not in the process of acquiring or releasing resources or otherwise in a state from which it would be difficult or impossible to recover.

- Thread Cancelation Cleanup Handlers

The cancelation cleanup handlers provide a portable mechanism, easy to implement, for releasing resources and restoring invariants. They are easier to use than signal handlers because they provide a stack of cancelation cleanup handlers rather than a single handler, and because they have an argument that can be used to pass context information to the handler.

The alternative to providing these simple cancelation cleanup handlers (whose only use is for cleaning up when a thread is canceled) is to define a general exception package that could be used for handling and cleaning up after hardware traps and software detected errors. This was too far removed from the charter of providing threads to handle asynchrony. However, it is an explicit goal of IEEE Std 1003.1-200x to be compatible with existing exception facilities and languages having exceptions.

The interaction of this facility and other procedure-based or language-level exception facilities is unspecified in this version of IEEE Std 1003.1-200x. However, it is intended that it be possible for an implementation to define the relationship between these cancelation cleanup handlers and Ada, C++, or other language-level exception handling facilities.

It was suggested that the cancelation cleanup handlers should also be called when the process exits or calls the *exec* function. This was rejected partly due to the performance problem caused by having to call the cancelation cleanup handlers of every thread before the operation could continue. The other reason was that the only state expected to be cleaned up by the cancelation cleanup handlers would be the intraprocess state. Any handlers that are to clean up the interprocess state would be registered with *atexit*( ). There is the orthogonal problem that the *exec* functions do not honor the *atexit*( ) handlers, but resolving this is beyond the scope of IEEE Std 1003.1-200x.

- Async-Cancel Safety

  A function is said to be *async-cancel safe* if it is written in such a way that entering the function with asynchronous cancelability enabled will not cause any invariants to be violated, even if a cancelation request is delivered at any arbitrary instruction. Functions that are async-cancel-safe are often written in such a way that they need to acquire no resources for their operation and the visible variables that they may write are strictly limited.

  Any routine that gets a resource as a side-effect cannot be made async-cancel-safe (for example, *malloc*( )). If such a routine were called with asynchronous cancelability enabled, it might acquire the resource successfully, but as it was returning to the client, it could act on a cancelation request. In such a case, the application would have no way of knowing whether the resource was acquired or not.

  Indeed, because many interesting routines cannot be made async-cancel-safe, most library routines in general are not async-cancel-safe. Every library routine should specify whether or not it is async-cancel safe so that programmers know which routines can be called from code that is asynchronously cancelable.

B.2.9.6 Thread Read-Write Locks

Background

Read-write locks are often used to allow parallel access to data on multi-processors, to avoid context switches on uni-processors when multiple threads access the same data, and to protect data structures that are frequently accessed (that is, read) but rarely updated (that is, written). The in-core representation of a file system directory is a good example of such a data structure. One would like to achieve as much concurrency as possible when searching directories, but limit concurrent access when adding or deleting files.

Although read-write locks can be implemented with mutexes and condition variables, such implementations are significantly less efficient than is possible. Therefore, this synchronization primitive is included in IEEE Std 1003.1-200x for the purpose of allowing more efficient implementations in multi-processor systems.

Queuing of Waiting Threads

The *pthread_rwlock_unlock*( ) function description states that one writer or one or more readers shall acquire the lock if it is no longer held by any thread as a result of the call. However, the function does not specify which thread(s) acquire the lock, unless the Thread Execution Scheduling option is supported.

The standard developers considered the issue of scheduling with respect to the queuing of threads blocked on a read-write lock. The question turned out to be whether IEEE Std 1003.1-200x should require priority scheduling of read-write locks for threads whose execution scheduling policy is priority-based (for example, SCHED_FIFO or SCHED_RR). There are tradeoffs between priority scheduling, the amount of concurrency achievable among readers, and the prevention of writer and/or reader starvation.

For example, suppose one or more readers hold a read-write lock and the following threads request the lock in the listed order:

```
pthread_rwlock_wrlock() - Low priority thread writer_a
pthread_rwlock_rdlock() - High priority thread reader_a
pthread_rwlock_rdlock() - High priority thread reader_b
pthread_rwlock_rdlock() - High priority thread reader_c
```

When the lock becomes available, should *writer_a* block the high priority readers? Or, suppose a read-write lock becomes available and the following are queued:

```
pthread_rwlock_rdlock() - Low priority thread reader_a
pthread_rwlock_rdlock() - Low priority thread reader_b
pthread_rwlock_rdlock() - Low priority thread reader_c
pthread_rwlock_wrlock() - Medium priority thread writer_a
pthread_rwlock_rdlock() - High priority thread reader_d
```

If priority scheduling is applied then *reader_d* would acquire the lock and *writer_a* would block the remaining readers. But should the remaining readers also acquire the lock to increase concurrency? The solution adopted takes into account that when the Thread Execution Scheduling option is supported, high priority threads may in fact starve low priority threads (the application developer is responsible in this case to design the system in such a way that this starvation is avoided). Therefore, IEEE Std 1003.1-200x specifies that high priority readers take precedence over lower priority writers. However, to prevent writer starvation from threads of the same or lower priority, writers take precedence over readers of the same or lower priority.

Priority inheritance mechanisms are non-trivial in the context of read-write locks. When a high priority writer is forced to wait for multiple readers, for example, it is not clear which subset of the readers should inherit the writer's priority. Furthermore, the internal data structures that record the inheritance must be accessible to all readers, and this implies some sort of serialization that could negate any gain in parallelism achieved through the use of multiple readers in the first place. Finally, existing practice does not support the use of priority inheritance for read-write locks. Therefore, no specification of priority inheritance or priority ceiling is attempted. If reliable priority-scheduled synchronization is absolutely required, it can always be obtained through the use of mutexes.

Comparison to fcntl() Locks

The read-write locks and the *fcntl*() locks in IEEE Std 1003.1-200x share a common goal: increasing concurrency among readers, thus increasing throughput and decreasing delay.

However, the read-write locks have two features not present in the *fcntl*() locks. First, under priority scheduling, read-write locks are granted in priority order. Second, also under priority scheduling, writer starvation is prevented by giving writers preference over readers of equal or lower priority.

Also, read-write locks can be used in systems lacking a file system, such as those conforming to the minimal realtime system profile of IEEE Std 1003.13-1998.

History of Resolution Issues

Based upon some balloting objections, the draft specified the behavior of threads waiting on a read-write lock during the execution of a signal handler, as if the thread had not called the lock operation. However, this specified behavior would require implementations to establish internal signal handlers even though this situation would be rare, or never happen for many programs. This would introduce an unacceptable performance hit in comparison to the little additional functionality gained. Therefore, the behavior of read-write locks and signals was reverted back to its previous mutex-like specification.

B.2.9.7 *Thread Interactions with Regular File Operations*

There is no additional rationale provided for this section.

B.2.10 Sockets

The base document for the sockets interfaces in IEEE Std 1003.1-200x is the XNS, Issue 5.2 specification. This was primarily chosen as it aligns with IPv6. Additional material has been added from IEEE Std 1003.1g-2000, notably socket concepts, raw sockets, the *pselect*( ) function, and the **<sys/select.h>** header.

B.2.10.1 *Address Families*

There is no additional rationale provided for this section.

B.2.10.2 *Addressing*

There is no additional rationale provided for this section.

B.2.10.3 *Protocols*

There is no additional rationale provided for this section.

B.2.10.4 *Routing*

There is no additional rationale provided for this section.

B.2.10.5 *Interfaces*

There is no additional rationale provided for this section.

B.2.10.6 *Socket Types*

The type **socklen_t** was invented to cover the range of implementations seen in the field. The intent of **socklen_t** is to be the type for all lengths that are naturally bounded in size; that is, that they are the length of a buffer which cannot sensibly become of massive size: network addresses, host names, string representations of these, ancillary data, control messages, and socket options are examples. Truly boundless sizes are represented by **size_t** as in *read*( ), *write*( ), and so on.

All **socklen_t** types were originally (in BSD UNIX) of type **int**. During the development of IEEE Std 1003.1-200x, it was decided to change all buffer lengths to **size_t**, which appears at face value to make sense. When dual mode 32/64-bit systems came along, this choice unnecessarily complicated system interfaces because **size_t** (with **long**) was a different size under ILP32 and LP64 models. Reverting to **int** would have happened except that some implementations had already shipped 64-bit-only interfaces. The compromise was a type which could be defined to be any size by the implementation: **socklen_t**.

B.2.10.7 *Socket I/O Mode*

There is no additional rationale provided for this section.

B.2.10.8 *Socket Owner*

There is no additional rationale provided for this section.

B.2.10.9 *Socket Queue Limits*

There is no additional rationale provided for this section.

B.2.10.10 *Pending Error*

There is no additional rationale provided for this section.

B.2.10.11 *Socket Receive Queue*

There is no additional rationale provided for this section.

B.2.10.12 *Socket Out-of-Band Data State*

There is no additional rationale provided for this section.

B.2.10.13 *Connection Indication Queue*

There is no additional rationale provided for this section.

B.2.10.14 *Signals*

There is no additional rationale provided for this section.

B.2.10.15 *Asynchronous Errors*

There is no additional rationale provided for this section.

B.2.10.16 *Use of Options*

There is no additional rationale provided for this section.

B.2.10.17 *Use of Sockets for Local UNIX Connections*

There is no additional rationale provided for this section.

B.2.10.18 *Use of Sockets over Internet Protocols*

A raw socket allows privileged users direct access to a protocol; for example, raw access to the IP and ICMP protocols is possible through raw sockets. Raw sockets are intended for knowledgeable applications that wish to take advantage of some protocol feature not directly accessible through the other sockets interfaces.

B.2.10.19 *Use of Sockets over Internet Protocols Based on IPv4*

There is no additional rationale provided for this section.

B.2.10.20 *Use of Sockets over Internet Protocols Based on IPv6*

There is no additional rationale provided for this section.

B.2.11 Tracing

The organization of the tracing rationale differs from the traditional rationale in that this tracing rationale text is written against the trace interface as a whole, rather than against the individual components of the trace interface or the normative section in which those components are defined. Therefore the sections below do not parallel the sections of normative text in IEEE Std 1003.1-200x.

B.2.11.1 Objectives

The intended uses of tracing are application-system debugging during system development, as a ‘‘flight recorder’’ for maintenance of fielded systems, and as a performance measurement tool. In all of these intended uses, the vendor-supplied computer system and its software are, for this discussion, assumed error-free; the intent being to debug the user-written and/or third-party application code, and their interactions. Clearly, problems with the vendor-supplied system and its software will be uncovered from time to time, but this is a byproduct of the primary activity, debugging user code.

Another need for defining a trace interface in POSIX stems from the objective to provide an efficient portable way to perform benchmarks. Existing practice shows that such interfaces are commonly used in a variety of systems but with little commonality. As part of the benchmarking needs, we must consider two aspects within the trace interface.

The first, and perhaps more important one, is the qualitative aspect.

The second is the quantitative aspect.

- Qualitative Aspect

  To better understand this aspect, let us consider an example. Suppose that you want to organize a number of actions to be performed during the day. Some of these actions are known at the beginning of the day. Some others, which may be more or less important, will be triggered by reading your mail. During the day you will make some phone calls and synchronously receive some more information. Finally you will receive asynchronous phone calls that also will trigger actions. If you, or somebody else, examines your day at work, you, or he, can discover that you have not efficiently organized your work. For instance, relative to the phone calls you made, would it be preferable to make some of these early in the morning? Or to delay some others until the end of the day? Relative to the phone calls you have received, you might find that somebody you called in the morning has called you 10 times while you were performing some important work. To examine, afterwards, your day at work, you record in sequence all the trace events relative to your work. This should give you a chance of organizing your next day at work.

  This is the qualitative aspect of the trace interface. The user of a system needs to keep a trace of particular points the application passes through, so that he can eventually make some changes in the application and/or system configuration, to give the application a chance of running more efficiently.

- Quantitative Aspect

  This aspect concerns primarily realtime applications, where missed deadlines can be undesirable. Although there are, in IEEE Std 1003.1-200x, some interfaces useful for such applications (timeouts, execution time monitoring, and so on), there are no APIs to aid in the tuning of a realtime application’s behavior (**timespec** in timeouts, length of message queues, duration of driver interrupt service routine, and so on). The tuning of an application needs a means of recording timestamped important trace events during execution in order to analyze offline, and eventually, to tune some realtime features (redesign the system with less functionalities, readjust timeouts, redesign driver interrupts, and so on).

Detailed Objectives

Objectives were defined to build the trace interface and are kept for historical interest. Although some objectives are not fully respected in this trace interface, the concept of the POSIX trace interface assumes the following points:

1. It shall be possible to trace both system and user trace events concurrently.
2. It must be possible to trace per-process trace events and also to trace system trace events which are unrelated to any particular process. A per-process trace event is either user-initiated or system-initiated.
3. It must be possible to control tracing on a per process basis from either inside or outside the process.
4. It must be possible to control tracing on a per-thread basis from inside the enclosing process.
5. Trace points shall be controllable by trace event type ID from inside and outside of the process. Multiple trace points can have the same trace event type ID, and will be controlled jointly.
6. Recording of trace events is dependent on both trace event type ID and the process/thread. Both must be enabled in order to record trace events. System trace events may or may not be handled differently.
7. The API shall not mandate the ability to control tracing for more than one process at the same time.
8. There is no objective for trace control on anything bigger than a process; for example, group or session.
9. Trace propagation and control:
   a. Trace propagation across fork is optional; the default is to not trace a child process.
   b. Trace control shall span *thread_create* operations; that is, if a process is being traced, any thread will be traced as well if this thread allows tracing. The default is to allow tracing.
10. Trace control shall not span *exec* or *spawn* operations.
11. A triggering API is not required. The triggering API is the ability to command or stop tracing based on the occurrence of specific trace event other than a POSIX_TRACE_START trace event or a POSIX_TRACE_STOP trace event.
12. Trace log entries shall have timestamps of implementation-defined resolution. Implementations are exhorted to support at least microsecond resolution. When a trace log entry is retrieved, it shall have timestamp, PC address, PID, and TID of the entity that generated the trace event.
13. Independently developed code should be able to use trace facilities without coordination and without conflict.
14. Even if the trace points in the trace calls are not unique, the trace log entries (after any processing) shall be uniquely identified as to trace point.
15. There shall be a standard API to read the trace stream.

16. The format of the trace stream and the trace log is opaque and unspecified.
17. It shall be possible to read a completed trace, if recorded on some suitable non-volatile storage, even subsequent to a power cycle or subsequent cold boot of the system.
18. Support of analysis of a trace log while it is being formed is implementation-defined.
19. The API shall allow the application to write trace stream identification information into the trace stream and to be able to retrieve it, without it being overwritten by trace entries, even if the trace stream is full.
20. It must be possible to specify the destination of trace data produced by trace events.
21. It must be possible to have different trace streams, and for the tracing enabled by one trace stream to be completely independent of the tracing of another trace stream.
22. It must be possible to trace events from threads in different CPUs.
23. The API shall support one or more trace streams per-system, and one or more trace streams per-process, up to an implementation-defined set of per-system and per-process maximums.
24. It shall be possible to determine the order in which the trace events happened, without necessarily depending on the clock, up to an implementation-defined time resolution.
25. For performance reasons, the trace event point call(s) shall be implementable as a macro (see the ISO POSIX-1: 1996 standard, 1.3.4, Statement 2).
26. IEEE Std 1003.1-200x must not define the trace points which a conforming system must implement, except for trace points used in the control of tracing.
27. The APIs shall be thread-safe, and trace points should be lock-free (that is shall not require a lock to gain exclusive access to some resource).
28. The user-provided information associated with a trace event is variable-sized, up to some maximum size.
29. Bounds on record and trace stream sizes:
    a. The API must permit the application to declare the upper bounds on the length of an application data record. The system shall return the limit it used. The limit used may be smaller than requested.
    b. The API must permit the application to declare the upper bounds on the size of trace streams. The system shall return the limit it used. The limit used may be different, either larger or smaller, than requested.
30. The API must be able to pass any fundamental data type, and a structured data type composed only of fundamental types. The API must be able to pass data by reference, given only as an address and a length. Fundamental types are the POSIX.1 types (see the **<sys/types.h>** header) plus those defined in the ISO C standard.
31. The API shall apply the POSIX notions of ownership and permission to recorded trace data, corresponding to the sources of that data.

Comments on Objectives

Note: In the following comments, numbers in square brackets refer to the above objectives.

It is necessary to be able to obtain a trace stream for a complete activity. This means we need to be able to trace both application and system trace events. A per-process trace event is either user-initiated, like the *write*( ) POSIX call, or system-initiated, like a timer expiration. We also need to be able to trace an entire process's activity even when it has threads in multiple CPUs. To avoid excess trace activity, it is necessary to be able to control tracing on a trace event type basis.
[Objectives 1,2,5,22]

We need to be able to control tracing on a per-process basis, both from inside and outside the process; that is, a process can start a trace activity on itself or any other process. We also see the need to allow the definition of a maximum number trace streams per system.
[Objectives 3,23]

From within a process, it is necessary to be able to control tracing on a per-thread basis. This provides an additional filtering capability to keep the amount of traced data to a minimum. It also allows for less ambiguity as to the origin of trace events. It is recognized that thread-level control is only valid from within the process itself. It is also desirable to know the maximum number of trace streams per process that can be started. We do not want the API to require thread synchronization or to mandate priority inversions that would cause the thread to block. However, the API must be thread-safe.
[Objectives 4,23,24,27]

We see no objective to control tracing on anything larger than a process; for example, a group or session. Also, the ability to start or stop a trace activity on multiple processes atomically may be very difficult or cumbersome in some implementations.
[Objectives 6,8]

It is also necessary to be able to control tracing by trace event type identifier, sometimes called a trace hook ID. However, there is no mandated set of system trace events, since such trace points are very system-dependent. The API must not require from the operating system facilities that are not standard (POSIX).
[Objectives 6,26]

Trace control must span *fork*( ) and *pthread_create*( ). If not, there will be no way to ensure that a program's activity is entirely traced. The newly forked child would not be able to turn on its tracing until after it obtained control after the fork, and trace control externally would be even more problematic.
[Objective 9]

Since *exec*( ) and *spawn*( ) represent a complete change in the execution of a task (a new program), trace control need not persist over an *exec*( ) or *spawn*( ).
[Objective 10]

Where trace activities are started on multiple processes, these trace activities should not interfere with each other.
[Objective 21]

There is no need for a triggering objective, primarily for performance reasons; see also Section B.2.11.8 (on page 3491), rationale on triggering.
[Objective 11]

It must be possible to determine the origin of each traced event. We need the process and thread identifiers for each trace event. We also saw the need for a user-specifiable origin, but felt this would create too much overhead.
[Objectives 12,14]

We must allow for trace points to come embedded in software components from several different sources and vendors without requiring coordination.
[Objective 13]

We need to be able to uniquely identify trace points that may have the same trace stream identifier. We only need to be able to do this when a trace report is produced.
[Objectives 12,14]

Tracing is a very performance-sensitive activity, and will therefore likely be implemented at a low level within the system. Hence the interface shall not mandate any particular buffering or storage method. Therefore, we will need a standard API to read a trace stream. Also the interface shall not mandate the format of the trace data, and the interface shall not assume a trace storage method. Due to the possibility of a monolithic kernel and the possible presence of multiple processes capable of running trace activities, the two kinds of trace events may be stored in two separate streams for performance reasons. A mandatory dump mechanism, common in some existing practice, has been avoided to allow the implementation of this set of functions on small realtime profiles for which the concept of a file system is not defined. The trace API calls should be implemented as macros.
[Objectives 15,16,25,30]

Since a trace facility is a valuable service tool, the output (or log) of a completed trace stream that is written to permanent storage must be readable on other systems of the type that produced the trace log. Note that there is no objective to be able to interpret a trace log that was not successfully completed.
[Objectives 17,18,19]

For trace streams written to permanent storage, a way to specify the destination of the trace stream is needed.
[Objective 20]

We need to be able to depend on the ordering of trace events up to some implementation-defined time interval. For example, we need to know the time period which, if trace events are closer together, their ordering is unspecified. Events that occur within an interval smaller than this resolution may or may not be read back in the correct order.
[Objective 24]

The application should be able to know how much data can be traced. When trace event types can be filtered, the application should be able to specify the approximate maximum amount of data that will be traced in a trace event so resources can be more efficiently allocated.
[Objectives 28,29]

Users should not be able to trace data to which they would not normally have access to. System trace events corresponding to a process / thread should be associated with the ownership of that process / thread.
[Objective 31]

B.2.11.2 Trace Model

Introduction

The model is based on two base entities: the ‘‘Trace Stream’’ and the ‘‘Trace Log’’ , and a recorded unit called the ‘‘Trace Event’’. The possibility of using Trace Streams and Trace Logs separately gives us two use dimensions and solves both the performance issue and the full-information system issue. In the case of a trace stream without log, specific information, although reduced in quantity, is required to be registered, in a possibly small realtime system, with as little overhead as possible. The Trace Log option has been added for small realtime systems. In the case of a trace stream with log, considerable complex application-specific information needs to be collected.

Trace Model Description

The trace model can be examined for three different subfunctions: Application Instrumentation, Trace Operation Control, and Trace Analysis.

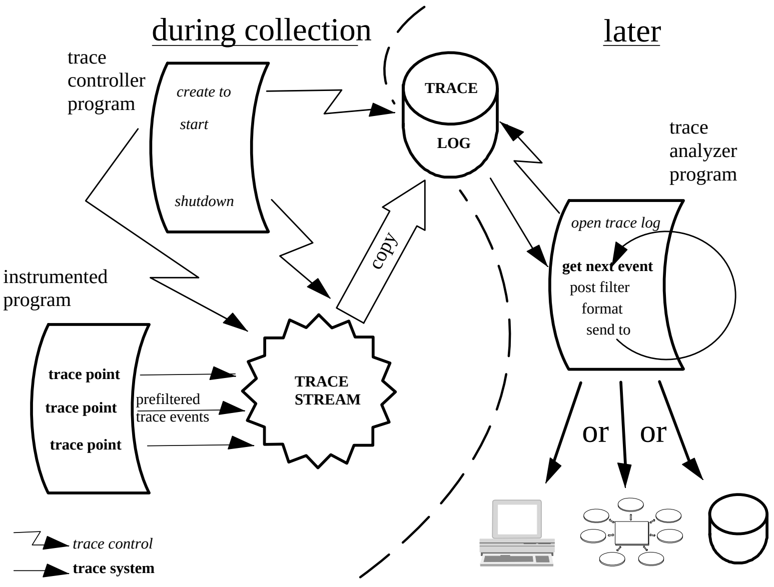


Figure B-2 Trace System Overview: for Offline Analysis

Each of these subfunctions requires specific characteristics of the trace mechanism API.

- Application Instrumentation

  When instrumenting an application, the programmer has no concern about the future utilization of the trace events in trace stream or trace log, the full policy of trace stream, or the eventual pre-filtering of trace events. But he is concerned about the correct determination of specific trace event type identifier, regardless of how many independent libraries are used in the same user application; see Figure B-2 and Figure B-3 (on page 3475).

This trace API shall provide the necessary operations to accomplish this subfunction. This is done by providing functions to associate a programmer-defined name with an implementation-defined trace event type identifier; see the *posix_trace_eventid_open*( ) function), and to send this trace event into a potential trace stream (see the *posix_trace_event*( ) function).

- Trace Operation Control

  When controlling the recording of trace events in a trace stream, the programmer is concerned with the correct initialization of the trace mechanism (that is, the sizing of the trace stream), the correct retention of trace events in a permanent storage, the correct dynamic recording of trace events, and so on.

  This trace API shall provide the necessary material to permit this efficiently. This is done by providing functions to initialize a new trace stream, and optionally a trace log:

  — Trace Stream Attributes Object Initialization (see *posix_trace_attr_init*( ))

  — Functions to Retrieve or Set Information About a Trace Stream (see *posix_trace_attr_getgenversion*( ))

  — Functions to Retrieve or Set the Behavior of a Trace Stream (see *posix_trace_attr_getinherited*( ))

  — Functions to Retrieve or Set Trace Stream Size Attributes (see *posix_trace_attr_getmaxusereventsize*( ))

  — Trace Stream Initialization, Flush, and Shutdown from a Process (see *posix_trace_create*( ))

  — Clear Trace Stream and Trace Log (see *posix_trace_clear*( ))

  To select the trace event types that are to be traced:

  — Manipulate Trace Event Type Identifier (see *posix_trace_trid_eventid_open*( ))

  — Iterate over a Mapping of Trace Event Type (see *posix_trace_eventtypelist_getnext_id*( ))

  — Manipulate Trace Event Type Sets (see *posix_trace_eventset_empty*( ))

  — Set Filter of an Initialized Trace Stream (see *posix_trace_set_filter*( ))

  To control the execution of an active trace stream:

  — Trace Start and Stop (see *posix_trace_start*( ))

  — Functions to Retrieve the Trace Attributes or Trace Statuses (see *posix_trace_get_attr*( ))

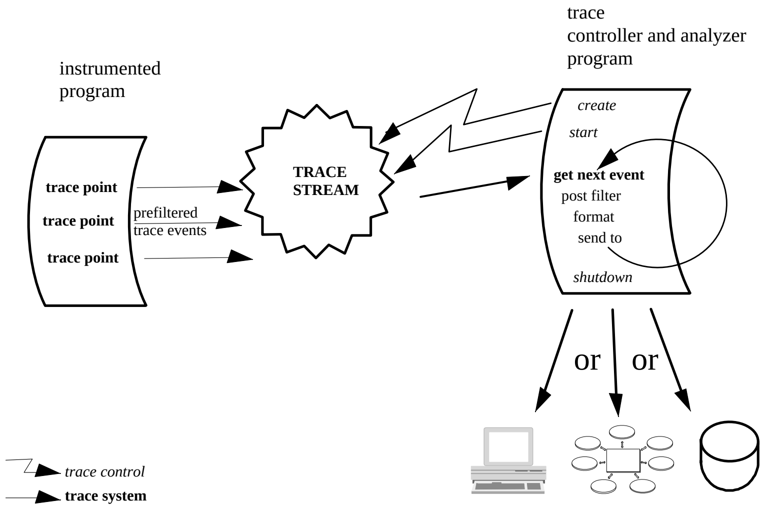

Figure B-3 Trace System Overview: for Online Analysis

- Trace Analysis

  Once correctly recorded, on permanent storage or not, an ultimate activity consists of the analysis of the recorded information. If the recorded data is on permanent storage, a specific open operation is required to associate a trace stream to a trace log.

  The first intent of the group was to request the presence of a system identification structure in the trace stream attribute. This was, for the application, to allow some portable way to process the recorded information. However, there is no requirement that the **utsname** structure, on which this system identification was based, be portable from one machine to another, so the contents of the attribute cannot be interpreted correctly by an application conforming to IEEE Std 1003.1-200x.

  Draft 6 incorporates this modification and requests that some unspecified information be recorded in the trace log in order to fail opening it if the analysis process and the controller process were running in different types of machine, but does not request that this information be accessible to the application. This modification has implied a modification in the *posix_trace_open*( ) function error code returns.

  This trace API shall provide functions to:

  — Extract trace stream identification attributes (see *posix_trace_attr_getgenversion*( ))

  — Extract trace stream behavior attributes (see *posix_trace_attr_getinherited*( ))

  — Extract trace event, stream, and log size attributes (see *posix_trace_attr_getmaxusereventsize*( ))

  — Look up trace event type names (see *posix_trace_eventid_get_name*( ))

- Iterate over trace event type identifiers (see *posix_trace_eventtypelist_getnext_id*( ))
- Open, rewind, and close a trace log (see *posix_trace_open*( ))
- Read trace stream attributes and status (see *posix_trace_get_attr*( ))
- Read trace events (see *posix_trace_getnext_event*( ))

Due to the following two reasons:

1. The requirement that the trace system must not add unacceptable overhead to the traced process and so that the trace event point execution must be fast
2. The traced application does not care about tracing errors

the trace system cannot return any internal error to the application. Internal error conditions can range from unrecoverable errors that will force the active trace stream to abort, to small errors that can affect the quality of tracing without aborting the trace stream. The group decided to define a system trace event to report to the analysis process such internal errors. It is not the intention of IEEE Std 1003.1-200x to require an implementation to report an internal error that corrupts or terminates tracing operation. The implementor is free to decide which internal documented errors, if any, the trace system is able to report.

States of a Trace Stream

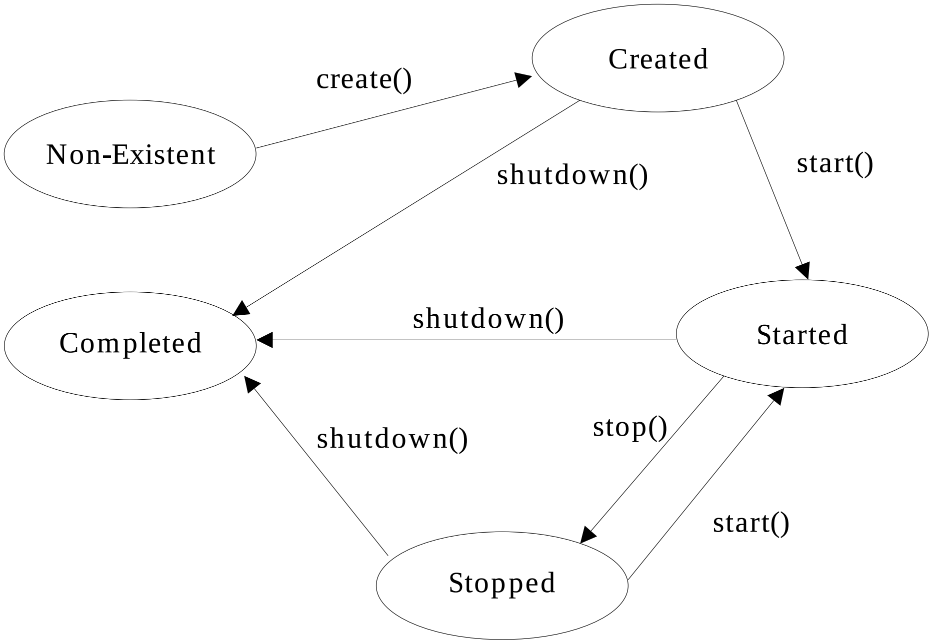

Figure B-4 Trace System Overview: States of a Trace Stream

Figure B-4 shows the different states an active trace stream passes through. After the *posix_trace_create*( ) function call, a trace stream becomes CREATED and a trace stream is associated for the future collection of trace events. The status of the trace stream is POSIX_TRACE_SUSPENDED. The state becomes STARTED after a call to the *posix_trace_start*( ) function, and the status becomes POSIX_TRACE_RUNNING. In this state, all trace events that are not filtered out shall be stored into the trace stream. After a call to *posix_trace_stop*( ), the trace stream becomes STOPPED (and the status POSIX_TRACE_SUSPENDED). In this state, no new trace events will be recorded in the trace stream, but previously recorded trace events may continue to be read.

After a call to *posix_trace_shutdown*( ), the trace stream is in the state COMPLETED. The trace stream no longer exists but, if the Trace Log option is supported, all the information contained in it has been logged. If a log object has not been associated with the trace stream at the creation, it is the responsibility of the trace controller process to not shut the trace stream down while trace events remain to be read in the stream.

Tracing All Processes

Some implementations have a tracing subsystem with the ability to trace all processes. This is useful to debug some types of device drivers such as those for ATM or X25 adapters. These types of adapters are used by several independent processes, that are not issued from the same process.

The POSIX trace interface does not define any constant or option to create a trace stream tracing all processes. But the POSIX trace interface does not prevent this type of implementation and the implementor is free to add this capability. Nevertheless, the POSIX trace interface allows to trace all the system trace events and all the processes issued from the same process.

If such a tracing system capability has to be implemented, when a trace stream is created, it is recommended that a constant named POSIX_TRACE_ALLPROC be used instead of the process identifier in the argument of the function *posix_trace_create*( ) or *posix_trace_create_withlog*( ). A possible value for POSIX_TRACE_ALLPROC may be −1 instead of a real process identifier.

The implementor has to be aware that there is some impact on the tracing behavior as defined in the POSIX trace interface. For example:

- If the default value for the inheritance attribute is to set to POSIX_TRACE_CLOSE_FOR_CHILD, the implementation has to stop tracing for the child process.
- The trace controller which is creating this type of trace stream must have the appropriate privilege to trace all the processes.

Trace Storage

The model is based on two types of trace events: system trace events and user-defined trace events. The internal representation of trace events is implementation-defined, and so the implementor is free to choose the more suitable, practical, and efficient way to design the internal management of trace events. For the timestamping operation, the model does not impose the CLOCK_REALTIME or any other clock. The buffering allocation and operation follow the same principle. The implementor is free to use one or more buffers to record trace events; the interface assumes only a logical trace stream of sequentially recorded trace events. Regarding flushing of trace events, the interface allows the definition of a trace log object which typically can be a file. But the group was also aware of defining functions to permit the use of this interface in small realtime systems, which may not have general file system capabilities. For instance, the three functions *posix_trace_getnext_event*( ) (blocking), *posix_trace_timedgetnext_event*( ) (blocking with timeout), and *posix_trace_trygetnext_event*( ) (non-blocking) are proposed to read the recorded trace events.

The policy to be used when the trace stream becomes full also relies on common practice:

- For an active trace stream, the POSIX_TRACE_LOOP trace stream policy permits automatic overrun (overwrite of oldest trace events) while waiting for some user-defined condition to cause tracing to stop. By contrast, the POSIX_TRACE_UNTIL_FULL trace stream policy requires the system to stop tracing when the trace stream is full. However, if the trace stream that is full is at least partially emptied by a call to the *posix_trace_flush*( ) function or by calls to *posix_trace_getnext_event*( ) function, the trace system will automatically resume tracing.

If the Trace Log option is supported the operation of the POSIX_TRACE_FLUSH policy is an extension of the POSIX_TRACE_UNTIL_FULL policy. The automatic free operation (by flushing to the associated trace log) is added.

- If a log is associated with the trace stream and this log is a regular file, these policies also apply for the log. One more policy, POSIX_TRACE_APPEND, is defined to allow indefinite extension of the log. Since the log destination can be any device or pseudo-device, the implementation may not be able to manipulate the destination as required by IEEE Std 1003.1-200x. For this reason, the behavior of the log full policy may be unspecified depending of the trace log type.

  The current trace interface does not define a service to preallocate space for a trace log file, because this space can be preallocated by means of a call to the *posix_fallocate*( ) function. This function could be called after the file has been opened, but before the trace stream is created. The *posix_fallocate*( ) function ensures that any required storage for regular file data is allocated on the file system storage media. If *posix_fallocate*( ) returns successfully, subsequent writes to the specified file data shall not fail due to the lack of free space on the file system storage media. Besides trace events, a trace stream also includes trace attributes and the mapping from trace event names to trace event type identifiers. The implementor is free to choose how to store the trace attributes and the trace event type map, but must ensure that this information is not lost when a trace stream overrun occurs.

B.2.11.3 Trace Programming Examples

Several programming examples are presented to show the code of the different possible subfunctions using a trace subsystem. All these programs need to include the **<trace.h>** header. In the examples shown, error checking is omitted for more simplicity.

Trace Operation Control

These examples show the creation of a trace stream for another process; one which is already trace instrumented. All the default trace stream attributes are used to simplify programming in the first example. The second example shows more possibilities.

First Example

```
/* Caution. Error checks omitted */
{
    trace_attr_t attr;
    pid_t pid = traced_process_pid;
    int fd;
    trace_id_t trid;

    - - - - - -
    /* Initialize trace stream attributes */
    posix_trace_attr_init(&attr);
    /* Open a trace log */
    fd=open("/tmp/mytracelog",...);
    /*
     * Create a new trace associated with a log
     * and with default attributes
     */
```

```
        posix_trace_create_withlog(pid, &attr, fd, &trid);
        /* Trace attribute structure can now be destroyed */
        posix_trace_attr_destroy(&attr);
        /* Start of trace event recording */
        posix_trace_start(trid);
        - - - - - -
        - - - - - -
        /* Duration of tracing */
        - - - - - -
        - - - - - -
        /* Stop and shutdown of trace activity */
        posix_trace_shutdown(trid);
        - - - - - -
    }
```

Second Example

Between the initialization of the trace stream attributes and the creation of the trace stream, these trace stream attributes may be modified; see **Trace Stream Attribute Manipulation** (on page 3483) for specific programming example. Between the creation and the start of the trace stream, the event filter may be set; after the trace stream is started, the event filter may be changed. The setting of an event set and the change of a filter is shown in **Create a Trace Event Type Set and Change the Trace Event Type Filter** (on page 3483).

```
    /* Caution. Error checks omitted */
    {
        trace_attr_t attr;
        pid_t pid = traced_process_pid;
        int fd;
        trace_id_t trid;
        - - - - - -
        /* Initialize trace stream attributes */
        posix_trace_attr_init(&attr);
        /* Attr default may be changed at this place; see example */
        - - - - - -
        /* Create and open a trace log with R/W user access */
        fd=open("/tmp/mytracelog",O_WRONLY|O_CREAT,S_IRUSR|S_IWUSR);
        /* Create a new trace associated with a log */
        posix_trace_create_withlog(pid, &attr, fd, &trid);
        /*
         * If the Trace Filter option is supported
         * trace event type filter default may be changed at this place;
         * see example about changing the trace event type filter
         */
        posix_trace_start(trid);
        - - - - - -

        /*
         * If you have an uninteresting part of the application
         * you can stop temporarily.
         *
         * posix_trace_stop(trid);
         * - - - - - -
```

```
         * - - - - - -
         * posix_trace_start(trid);
         */
        - - - - - -
        /*
         * If the Trace Filter option is supported
         * the current trace event type filter can be changed
         * at any time (see example about how to set
         * a trace event type filter
         */
        - - - - - -

        /* Stop the recording of trace events */
        posix_trace_stop(trid);
        /* Shutdown the trace stream */
        posix_trace_shutdown(trid);
        /*
         * Destroy trace stream attributes; attr structure may have
         * been used during tracing to fetch the attributes
         */
        posix_trace_attr_destroy(&attr);
        - - - - - -
}
```

Application Instrumentation

This example shows an instrumented application. The code is included in a block of instructions, perhaps a function from a library. Possibly in an initialization part of the instrumented application, two user trace events names are mapped to two trace event type identifiers (function *posix_trace_eventid_open*( )). Then two trace points are programmed.

```
/* Caution. Error checks omitted */
{
    trace_event_id_t eventid1, eventid2;
    - - - - - -
    /* Initialization of two trace event type ids */
    posix_trace_eventid_open("my_first_event",&eventid1);
    posix_trace_eventid_open("my_second_event",&eventid2);
    - - - - - -
    - - - - - -
    - - - - - -
    /* Trace point */
    posix_trace_event(eventid1,NULL,0);
    - - - - - -
    /* Trace point */
    posix_trace_event(eventid2,NULL,0);
    - - - - - -
}
```

Trace Analyzer

This example shows the manipulation of a trace log resulting from the dumping of a completed trace stream. All the default attributes are used to simplify programming, and data associated with a trace event are not shown in the first example. The second example shows more possibilities.

First Example

```
/* Caution. Error checks omitted */
{
    int fd;
    trace_id_t trid;
    posix_trace_event_info trace_event;
    char trace_event_name[TRACE_EVENT_NAME_MAX];
    int return_value;
    size_t returndatasize;
    int lost_event_number;

    - - - - - -

    /* Open an existing trace log */
    fd=open("/tmp/tracelog", O_RDONLY);
    /* Open a trace stream on the open log */
    posix_trace_open(fd, &trid);
    /* Read a trace event */
    posix_trace_getnext_event(trid, &trace_event,
        NULL, 0, &returndatasize,&return_value);

    /* Read and print all trace event names out in a loop */
    while (return_value == NULL)
    {
        /*
         * Get the name of the trace event associated
         * with trid trace ID
         */
        posix_trace_eventid_get_name(trid, trace_event.event_id,
            trace_event_name);
        /* Print the trace event name out */
        printf("%s\n",trace_event_name);
        /* Read a trace event */
        posix_trace_getnext_event(trid, &trace_event,
            NULL, 0, &returndatasize,&return_value);
    }

    /* Close the trace stream */
    posix_trace_close(trid);
    /* Close the trace log */
    close(fd);
}
```

Second Example

The complete example includes the two other examples in **Retrieve Information from a Trace Log** (on page 3484) and in **Retrieve the List of Trace Event Types Used in a Trace Log** (on page 3485). For example, the *maxdatasize* variable is set in **Retrieve the List of Trace Event Types Used in a Trace Log** (on page 3485).

```
/* Caution. Error checks omitted */
{
    int fd;
    trace_id_t trid;
    posix_trace_event_info trace_event;
    char trace_event_name[TRACE_EVENT_NAME_MAX];
    char * data;
    size_t maxdatasize=1024, returndatasize;
    int return_value;
    - - - - - -

    /* Open an existing trace log */
    fd=open("/tmp/tracelog", O_RDONLY);
    /* Open a trace stream on the open log */
    posix_trace_open( fd, &trid);
    /*
     * Retrieve information about the trace stream which
     * was dumped in this trace log (see example)
     */
    - - - - - -

    /* Allocate a buffer for trace event data */
    data=(char *)malloc(maxdatasize);
    /*
     * Retrieve the list of trace event used in this
     * trace log (see example)
     */
    - - - - - -

    /* Read and print all trace event names and data out in a loop */
    while (1)
    {
    posix_trace_getnext_event(trid, &trace_event,
        data, maxdatasize, &returndatasize,&return_value);
        if (return_value != NULL) break;
        /*
         * Get the name of the trace event type associated
         * with trid trace ID
         */
        posix_trace_eventid_get_name(trid, trace_event.event_id,
            trace_event_name);
        {
        int i;

        /* Print the trace event name out */
        printf("%s: ", trace_event_name);
        /* Print the trace event data out */
        for (i=0; i<returndatasize, i++) printf("%02.2X",
```

```
                (unsigned char)data[i]);
            printf("\n");
            }
        }
        /* Close the trace stream */
        posix_trace_close(trid);
        /* The buffer data is deallocated */
        free(data);
        /* Now the file can be closed */
        close(fd);
    }
```

Several Programming Manipulations

The following examples show some typical sets of operations needed in some contexts.

Trace Stream Attribute Manipulation

This example shows the manipulation of a trace stream attribute object in order to change the default value provided by a previous *posix_trace_attr_init*( ) call.

```
/* Caution. Error checks omitted */
{
    trace_attr_t attr;
    size_t logsize=100000;
    - - - - - -
    /* Initialize trace stream attributes */
    posix_trace_attr_init(&attr);
    /* Set the trace name in the attributes structure */
    posix_trace_attr_setname(&attr, "my_trace");
    /* Set the trace full policy */
    posix_trace_attr_setstreamfullpolicy(&attr, POSIX_TRACE_LOOP);
    /* Set the trace log size */
    posix_trace_attr_setlogsize(&attr, logsize);
    - - - - - -
}
```

Create a Trace Event Type Set and Change the Trace Event Type Filter

This example is valid only if the Trace Event Filter option is supported. This example shows the manipulation of a trace event type set in order to change the trace event type filter for an existing active trace stream, which may be just-created, running, or suspended. Some sets of trace event types are well-known, such as the set of trace event types not associated with a process, some trace event types are just-built trace event types for this trace stream; one trace event type is the predefined trace event error type which is deleted from the trace event type set.

```
/* Caution. Error checks omitted */
{
    trace_id_t trid = existing_trace;
    trace_event_set_t set;
    trace_event_id_t trace_event1, trace_event2;
    - - - - - -
    /* Initialize to an empty set of trace event types */
```

```
    /* (not strictly required because posix_trace_event_set_fill() */
    /* will ignore the prior contents of the event set.) */
    posix_trace_eventset_emptyset(&set);
    /*
     * Fill the set with all system trace events
     * not associated with a process
     */
    posix_trace_eventset_fill(&set, POSIX_TRACE_WOPID_EVENTS);

    /*
     * Get the trace event type identifier of the known trace event name
     * my_first_event for the trid trace stream
     */
    posix_trace_trid_eventid_open(trid, "my_first_event", &trace_event1);
    /* Add the set with this trace event type identifier */
    posix_trace_eventset_add_event(trace_event1, &set);
    /*
     * Get the trace event type identifier of the known trace event name
     * my_second_event for the trid trace stream
     */

    posix_trace_trid_eventid_open(trid, "my_second_event", &trace_event2);
    /* Add the set with this trace event type identifier */
    posix_trace_eventset_add_event(trace_event2, &set);
    - - - - - -
    /* Delete the system trace event POSIX_TRACE_ERROR from the set */
    posix_trace_eventset_del_event(POSIX_TRACE_ERROR, &set);
    - - - - - -

    /* Modify the trace stream filter making it equal to the new set */
    posix_trace_set_filter(trid, &set, POSIX_TRACE_SET_EVENTSET);
    - - - - - -
    /*
     * Now trace_event1, trace_event2, and all system trace event types
     * not associated with a process, except for the POSIX_TRACE_ERROR
     * system trace event type, are filtered out of (not recorded in) the
     * existing trace stream.
     */
}
```

Retrieve Information from a Trace Log

This example shows how to extract information from a trace log, the dump of a trace stream. This code:

- Asks if the trace stream has lost trace events
- Extracts the information about the version of the trace subsystem which generated this trace log
- Retrieves the maximum size of trace event data; this may be used to dynamically allocate an array for extracting trace event data from the trace log without overflow

```
/* Caution. Error checks omitted */
{
    struct posix_trace_status_info statusinfo;
```

```
        trace_attr_t attr;
        trace_id_t trid = existing_trace;
        size_t maxdatasize;
        char genversion[TRACE_NAME_MAX];
        - - - - - -
        /* Get the trace stream status */
        posix_trace_get_status(trid, &statusinfo);
        /* Detect an overrun condition */
        if (statusinfo.posix_stream_overrun_status == POSIX_TRACE_OVERRUN)
            printf("trace events have been lost\n");

        /* Get attributes from the trid trace stream */
        posix_trace_get_attr(trid, &attr);
        /* Get the trace generation version from the attributes */
        posix_trace_attr_getgenversion(&attr, genversion);
        /* Print the trace generation version out */
        printf("Information about Trace Generator:%s\n",genversion);

        /* Get the trace event max data size from the attributes */
        posix_trace_attr_getmaxdatasize(&attr, &maxdatasize);
        /* Print the trace event max data size out */
        printf("Maximum size of associated data:%d\n",maxdatasize);
        /* Destroy the trace stream attributes */
        posix_trace_attr_destroy(&attr);
    }
```

Retrieve the List of Trace Event Types Used in a Trace Log

This example shows the retrieval of a trace stream's trace event type list. This operation may be very useful if you are interested only in tracking the type of trace events in a trace log.

```
/* Caution. Error checks omitted */
{
    trace_id_t trid = existing_trace;
    trace_event_id_t event_id;
    char event_name[TRACE_EVENT_NAME_MAX];
    int return_value;
    - - - - - -

    /*
     * In a loop print all existing trace event names out
     * for the trid trace stream
     */
    while (1)
    {
        posix_trace_eventtypelist_getnext_id(trid, &event_id
            &return_value);
        if (return_value != NULL) break;
        /*
         * Get the name of the trace event associated
         * with trid trace ID
         */
        posix_trace_eventid_get_name(trid, event_id, event_name);
        /* Print the name out */
```

```
                printf("%s\n", event_name);
            }
        }
```

B.2.11.4 Rationale on Trace for Debugging

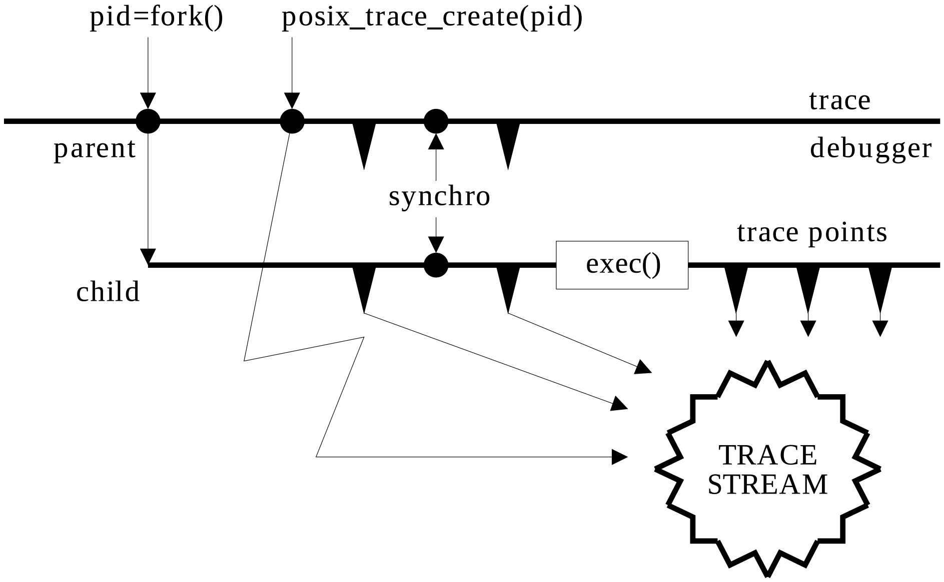

Figure B-5 Trace Another Process

Among the different possibilities offered by the trace interface defined in IEEE Std 1003.1-200x, the debugging of an application is the most interesting one. Typical operations in the controlling debugger process are to filter trace event types, to get trace events from the trace stream, to stop the trace stream when the debugged process is executing uninteresting code, to start the trace stream when some interesting point is reached, and so on. The interface defined in IEEE Std 1003.1-200x should define all the necessary base functions to allow this dynamic debug handling.

Figure B-5 shows an example in which the trace stream is created after the call to the *fork*( ) function. If the user does not want to lose trace events some synchronization mechanism (represented in the figure) may be needed before calling the *exec*( ) function, to give the parent a chance to create the trace stream before the child begins the execution of its trace points.

B.2.11.5 Rationale on Trace Event Type Name Space

At first, the working group was in favor of the representation of a trace event type by an integer (*event_name*). It seems that existing practice shows the weakness of such a representation. The collision of trace event types is the main problem that cannot be simply resolved using this sort of representation. Suppose, for example, that a third party designs an instrumented library. The user does not have the source of this library and wants to trace his application which uses in some part the third-party library. There is no means for him to know what are the trace event types used in the instrumented library so he has some chance of duplicating some of them and thus to obtain a contaminated tracing of his application.

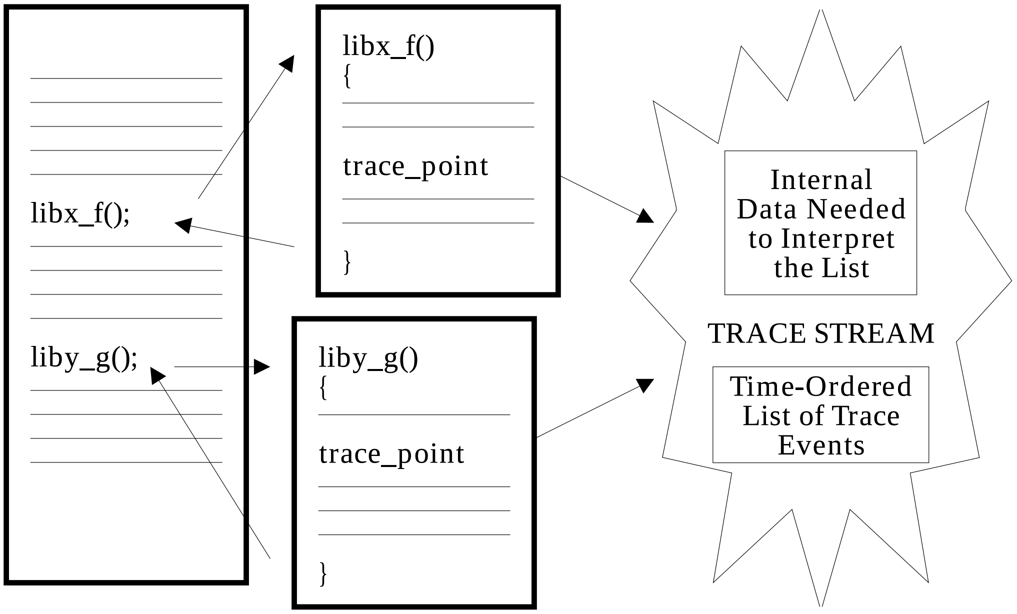

Figure B-6 Trace Name Space Overview: With Third-Party Library

We have requirements to allow program images containing pieces from various vendors to be traced without also requiring those or any other vendors to coordinate their uses of the trace facility, and especially the naming of their various trace event types and trace point IDs. The chosen solution is to provide a very large name space, large enough so that the individual vendors can give their trace types and tracepoint IDs sufficiently long and descriptive names making the occurrence of collisions quite unlikely. The probability of collision is thus made sufficiently low so that the problem may, as a practical matter, be ignored. By requirement, the consequence of collisions will be a slight ambiguity in the trace streams; tracing will continue in spite of collisions and ambiguities. ‘‘The show must go on’’. The *posix_prog_address* member of the **posix_trace_event_info** structure is used to allow trace streams to be unambiguously interpreted, despite the fact that trace event types and trace event names need not be unique.

The *posix_trace_eventid_open*( ) function is required to allow the instrumented third-party library to get a valid trace event type identifier for its trace event names. This operation is, somehow, an allocation, and the group was aware of proposing some deallocation mechanism which the instrumented application could use to recover the resources used by a trace event type identifier. This would have given the instrumented application the benefit of being capable of reusing a possible minimum set of trace event type identifiers, but also the inconvenience to have, possibly in the same trace stream, one trace event type identifier identifying two different trace event types. After some discussions the group decided to not define such a function which would make this API thicker for little benefit, the user having always the possibility of adding identification information in the data member of the trace event structure.

The set of the trace event type identifiers the controlling process wants to filter out is initialized in the trace mechanism using the function *posix_trace_set_filter*( ), setting the arguments according to the definitions explained in *posix_trace_set_filter*( ). This operation can be done statically (when the trace is in the STOPPED state) or dynamically (when the trace is in the STARTED state). The preparation of the filter is normally done using the function defined in *posix_trace_eventtypelist_getnext_id*( ) and eventually the function *posix_trace_eventtypelist_rewind*( ) in order to know (before the recording) the list of the potential set of trace event types that can be recorded. In the case of an active trace stream, this list may not be exhaustive. Actually, the target process may not have yet called the function *posix_trace_eventid_open*( ). But it is a common practice, for a controlling process, to prepare the filtering of a future trace stream before its start. Therefore the user must have a way to get the trace event type identifier corresponding to a well-known trace event name before its future association by the pre-cited function. This is done by calling the *posix_trace_trid_eventid_open*( ) function, given the trace stream identifier and the trace name, and described hereafter. Because this trace event type identifier is associated with a trace stream identifier, where a unique process has initialized two or more traces, the implementation is expected to return the same trace event type identifier for successive calls to *posix_trace_trid_eventid_open*( ) with different trace stream identifiers. The *posix_trace_eventid_get_name*( ) function is used by the controller process to identify, by the name, the trace event type returned by a call to the *posix_trace_eventtypelist_getnext_id*( ) function.

Afterwards, the set of trace event types is constructed using the functions defined in *posix_trace_eventset_empty*( ), *posix_trace_eventset_fill*( ), *posix_trace_eventset_add*( ), and *posix_trace_eventset_del*( ).

A set of functions is provided devoted to the manipulation of the trace event type identifier and names for an active trace stream. All these functions require the trace stream identifier argument as the first parameter. The opacity of the trace event type identifier implies that the user cannot associate directly its well-known trace event name with the system associated trace event type identifier.

The *posix_trace_trid_eventid_open*( ) function allows the application to get the system trace event type identifier back from the system, given its well-known trace event name. This function is useful only when a controlling process needs to specify specific events to be filtered. |

The *posix_trace_eventid_get_name*( ) function allows the application to obtain a trace event name given its trace event type identifier. One possible use of this function is to identify the type of a trace event retrieved from the trace stream, and print it. The easiest way to implement this requirement, is to use a single trace event type map for all the processes whose maps are required to be identical. A more difficult way is to attempt to keep multiple maps identical at every call to *posix_trace_eventid_open*( ) and *posix_trace_trid_eventid_open*( ).

B.2.11.6 Rationale on Trace Events Type Filtering

The most basic rationale for runtime and pre-registration filtering (selection/rejection) of trace event types is to prevent choking of the trace collection facility, and/or overloading of the computer system. Any worthwhile trace facility can bring even the largest computer to its knees. Otherwise, we would record everything, and filter after the fact; it would be much simpler, but impractical.

To achieve debugging, measurement, or whatever the purpose of tracing, the filtering of trace event types is an important part of trace analysis. Due to the fact that the trace events are put into a trace stream and probably logged afterwards into a file, different levels of filtering—that is, rejection of trace event types—are possible.

Filtering of Trace Event Types Before Tracing

This function, represented by the *posix_trace_set_filter*( ) function in IEEE Std 1003.1-200x (see *posix_trace_set_filter*( )), selects, before or during tracing, the set of trace event types to be filtered out. It should be possible also (as OSF suggested in their ETAP trace specifications) to select the kernel trace event types to be traced in a system-wide fashion. These two functionalities are called the pre-filtering of trace event types.

The restriction on the actual type used for the **trace_event_set_t** type is intended to guarantee that these objects can always be assigned, have their address taken, and be passed by value as parameters. It is not intended that this type be a structure including pointers to other data structures, as that could impact the portability of applications performing such operations. A reasonable implementation could be a structure containing an array of integer types.

Filtering of Trace Event Types at Runtime

Using this API, this functionality may be built, a privileged process or a privileged thread can get trace events from the trace stream of another process or thread, and thus specify the type of trace events to record into a file, using methods and interfaces out of the scope of IEEE Std 1003.1-200x. This functionality, called inline filtering of trace event types, is used for runtime analysis of trace streams.

Post-Mortem Filtering of Trace Event Types

The word *post-mortem* is used here to indicate that some unanticipated situation occurs during execution that does not permit a pre or inline filtering of trace events and that it is necessary to record all trace event types, to have a chance to discover the problem afterwards. When the program stops, all the trace events recorded previously can be analyzed in order to find the solution. This functionality could be named the post-filtering of trace event types.

Discussions about Trace Event Type-Filtering

After long discussions with the parties involved in the process of defining the trace interface, it seems that the sensitivity to the filtering problem is different, but everybody agrees that the level of the overhead introduced during the tracing operation depends on the filtering method elected. If the time that it takes the trace event to be recorded can be neglected, the overhead introduced by the filtering process can be classified as follows:

Pre-filtering	System and process / thread-level overhead
Inline-filtering	Process / thread-level overhead
Post-filtering	No overhead; done offline

The pre-filtering could be named *critical realtime* filtering in the sense that the filtering of trace event type is manageable at the user level so the user can lower to a minimum the filtering overhead at some user selected level of priority for the inline filtering, or delay the filtering to after execution for the post-filtering. The counterpart of this solution is that the size of the trace stream must be sufficient to record all the trace events. The advantage of the pre-filtering is that the utilization of the trace stream is optimized.

Only pre-filtering is defined by IEEE Std 1003.1-200x. However, great care must be taken in specifying pre-filtering, so that it does not impose unacceptable overhead. Moreover, it is necessary to isolate all the functionality relative to the pre-filtering.

The result of this rationale is to define a new option, the Trace Event Filter option, not necessarily implemented in small realtime systems, where system overhead is minimized to the extent possible.

B.2.11.7 *Tracing, pthread API*

The objective to be able to control tracing for individual threads may be in conflict with the efficiency expected in threads with a contentionscope attribute of PTHREAD_SCOPE_PROCESS. For these threads, context switches from one thread that has tracing enabled to another thread that has tracing disabled may require a kernel call to inform the kernel whether it has to trace system events executed by that thread or not. For this reason, it was proposed that the ability to enable or disable tracing for PTHREAD_SCOPE_PROCESS threads be made optional, through the introduction of a Trace Scope Process option. A trace implementation which did not implement the Trace Scope Process option would not honor the tracing-state attribute of a thread with PTHREAD_SCOPE_PROCESS; it would, however, honor the tracing-state attribute of a thread with PTHREAD_SCOPE_SYSTEM. This proposal was rejected as:

1. Removing desired functionality (per-thread trace control)
2. Introducing counter-intuitive behavior for the tracing-state attribute
3. Mixing logically orthogonal ideas (thread scheduling and thread tracing) [Objective 4]

Finally, to solve this complex issue, this API does not provide *pthread_gettracingstate*( ), *pthread_settracingstate*( ), *pthread_attr_gettracingstate*( ), and *pthread_attr_settracingstate*( ) interfaces. These interfaces force the thread implementation to add to the weight of the thread and cause a revision of the threads libraries, just to support tracing. Worse yet, *posix_trace_userevent*( ) must always test this per-thread variable even in the common case where it is not used at all. Per-thread tracing is easy to implement using existing interfaces where necessary; see the following example.

Example

```
/* Caution. Error checks omitted */
static pthread_key_t my_key;
static trace_event_id_t my_event_id;
static pthread_once_t my_once = PTHREAD_ONCE_INIT;

void my_init(void)
{
    (void) pthread_key_create(&my_key, NULL);
    (void) posix_trace_eventid_open("my", &my_event_id);
}

int get_trace_flag(void)
{
    pthread_once(&my_once, my_init);
    return (pthread_getspecific(my_key) != NULL);
}

void set_trace_flag(int f)
{
    pthread_once(&my_once, my_init);
    pthread_setspecific(my_key, f? &my_event_id: NULL);
}

fn()
{
    if (get_trace_flag())
```

```
        posix_trace_event(my_event_id, ...)
}
```

The above example does not implement third-party state setting, but it is also implementable with some more work, yet the extra functionality is rarely needed.

Lastly, per-thread tracing works poorly for threads with PTHREAD_SCOPE_PROCESS contention scope. These ‘‘library’’ threads have minimal interaction with the kernel and would have to explicitly set the attributes whenever they are context switched to a new kernel thread in order to trace system events. Such state was explicitly avoided in POSIX threads to keep PTHREAD_SCOPE_PROCESS threads lightweight.

The reason that keeping PTHREAD_SCOPE_PROCESS threads lightweight is important is that such threads can be used not just for simple multi-processors but also for coroutine style programming (such as discrete event simulation) without inventing a new threads paradigm. Adding extra runtime cost to thread context switches will make using POSIX threads less attractive in these situations.

B.2.11.8 Rationale on Triggering

The ability to start or stop tracing based on the occurrence of specific trace event types has been proposed as a parallel to similar functionality appearing in logic analyzers. Such triggering, in order to be very useful, should be based not only on the trace event type, but on trace event-specific data, including tests of user-specified fields for matching or threshold values.

Such a facility is unnecessary where the buffering of the stream is not a constraint, since such checks can be performed offline during post-mortem analysis.

For example, a large system could incorporate a daemon utility to collect the trace records from memory buffers and spool them to secondary storage for later analysis. In the instances where resources are truly limited, such as embedded applications, the application incorporation of application code to test the circumstances of a trace event and call the trace point only if needed is usually straightforward.

For performance reasons, the *posix_trace_event*( ) function should be implemented using a macro, so if the trace is inactive, the trace event point calls are latent code and must cost no more than a scalar test.

The API proposed in IEEE Std 1003.1-200x does not include any triggering functionality.

B.2.11.9 Rationale on Timestamp Clock

It has been suggested that the tracing mechanism should include the possibility of specifying the clock to be used in timestamping the trace events. When application trace events must be correlated to remote trace events, such a facility could provide a global time reference not available from a local clock. Further, the application may be driven by timers based on a clock different from that used for the timestamp, and the correlation of the trace to those untraced timer activities could be an important part of the analysis of the application.

However, the tracing mechanism needs to be fast and just the provision of such an option can materially affect its performance. Leaving aside the performance costs of reading some clocks, this notion is also ill-defined when kernel trace events are to be traced by two applications making use of different tracing clocks. This can even happen within a single application where different parts of the application are served by different clocks. Another complication can occur when a clock is maintained strictly at the user level and is unavailable at the kernel level.

It is felt that the benefits of a selectable trace clock do not match its costs. Applications that wish to correlate clocks other than the default tracing clock can include trace events with sample values of those other clocks, allowing correlation of timestamps from the various independent clocks. In any case, such a technique would be required when applications are sensitive to multiple clocks.

B.2.11.10 Rationale on Different Overrun Conditions

The analysis of the dynamic behavior of the trace mechanism shows that different overrun conditions may occur. The API must provide a means to manage such conditions in a portable way.

Overrun in Trace Streams Initialized with POSIX_TRACE_LOOP Policy

In this case, the user of the trace mechanism is interested in using the trace stream with POSIX_TRACE_LOOP policy to record trace events continuously, but ideally without losing any trace events. The online analyzer process must get the trace events at a mean speed equivalent to the recording speed. Should the trace stream become full, a trace stream overrun occurs. This condition is detected by getting the status of the active trace stream (function *posix_trace_get_status*( )) and looking at the member *posix_stream_overrun_status* of the read **posix_stream_status** structure. In addition, two predefined trace event types are defined:

1. The beginning of a trace overflow, to locate the beginning of an overflow when reading a trace stream
2. The end of a trace overflow, to locate the end of an overflow, when reading a trace stream

As a timestamp is associated with these predefined trace events, it is possible to know the duration of the overflow.

Overrun in Dumping Trace Streams into Trace Logs

The user lets the trace mechanism dump the trace stream initialized with POSIX_TRACE_FLUSH policy automatically into a trace log. If the dump operation is slower than the recording of trace events, the trace stream can overrun. This condition is detected by getting the status of the active trace stream (function *posix_trace_get_status*( )) and looking at the member *posix_log_overrun_status* of the read **posix_stream_status** structure. This overrun indicates that the trace mechanism is not able to operate in this mode at this speed. It is the responsibility of the user to modify one of the trace parameters (the stream size or the trace event type filter, for instance) to avoid such overrun conditions, if overruns are to be prevented. The same already predefined trace event types (see **Overrun in Trace Streams Initialized with POSIX_TRACE_LOOP Policy**) are used to detect and to know the duration of an overflow.

Reading an Active Trace Stream

Although this trace API allows one to read an active trace stream with log while it is tracing, this feature can lead to false overflow origin interpretation: the trace log or the reader of the trace stream. Reading from an active trace stream with log is thus non-portable, and has been left unspecified.

B.2.12 Data Types

The requirement that additional types defined in this section end in ‘‘_t’’ was prompted by the problem of name space pollution. It is difficult to define a type (where that type is not one defined by IEEE Std 1003.1-200x) in one header file and use it in another without adding symbols to the name space of the program. To allow implementors to provide their own types, all conforming applications are required to avoid symbols ending in ‘‘_t’’, which permits the implementor to provide additional types. Because a major use of types is in the definition of structure members, which can (and in many cases must) be added to the structures defined in IEEE Std 1003.1-200x, the need for additional types is compelling.

The types, such as **ushort** and **ulong**, which are in common usage, are not defined in IEEE Std 1003.1-200x (although **ushort_t** would be permitted as an extension). They can be added to **<sys/types.h>** using a feature test macro (see Section B.2.2.1 (on page 3375)). A suggested symbol for these is _SYSIII. Similarly, the types like **u_short** would probably be best controlled by _BSD.

Some of these symbols may appear in other headers; see Section B.2.2.2 (on page 3376).

dev_t	This type may be made large enough to accommodate host-locality considerations of networked systems. This type must be arithmetic. Earlier proposals allowed this to be non-arithmetic (such as a structure) and provided a *samefile*( ) function for comparison.
gid_t	Some implementations had separated **gid_t** from **uid_t** before POSIX.1 was completed. It would be difficult for them to coalesce them when it was unnecessary. Additionally, it is quite possible that user IDs might be different from group IDs because the user ID might wish to span a heterogeneous network, where the group ID might not. For current implementations, the cost of having a separate **gid_t** will be only lexical.
mode_t	This type was chosen so that implementations could choose the appropriate integral type, and for compatibility with the ISO C standard. 4.3 BSD uses **unsigned short** and the SVID uses **ushort**, which is the same. Historically, only the low-order sixteen bits are significant.
nlink_t	This type was introduced in place of **short** for *st_nlink* (see the **<sys/stat.h>** header) in response to an objection that **short** was too small.
off_t	This type is used only in *lseek*( ), *fcntl*( ), and **<sys/stat.h>**. Many implementations would have difficulties if it were defined as anything other than **long**. Requiring an integral type limits the capabilities of *lseek*( ) to four gigabytes. The ISO C standard supplies routines that use larger types; see *fgetpos*( ) and *fsetpos*( ). XSI-conformant systems provide the *fseeko*( ) and *lseeko*( ) functions that use larger types.
pid_t	The inclusion of this symbol was controversial because it is tied to the issue of the representation of a process ID as a number. From the point of view of a conforming application, process IDs should be ‘‘magic cookies’’[1] that are produced

---

[1] An historical term meaning: ‘‘An opaque object, or token, of determinate size, whose significance is known only to the entity which created it. An entity receiving such a token from the generating entity may only make such use of the ‘cookie’ as is defined and permitted by the supplying entity.’’

by calls such as *fork*( ), used by calls such as *waitpid*( ) or *kill*( ), and not otherwise analyzed (except that the sign is used as a flag for certain operations).

The concept of a {PID_MAX} value interacted with this in early proposals. Treating process IDs as an opaque type both removes the requirement for {PID_MAX} and allows systems to be more flexible in providing process IDs that span a large range of values, or a small one.

Since the values in **uid_t**, **gid_t**, and **pid_t** will be numbers generally, and potentially both large in magnitude and sparse, applications that are based on arrays of objects of this type are unlikely to be fully portable in any case. Solutions that treat them as magic cookies will be portable.

{CHILD_MAX} precludes the possibility of a ‘‘toy implementation’’, where there would only be one process.

ssize_t This is intended to be a signed analog of **size_t**. The wording is such that an implementation may either choose to use a longer type or simply to use the signed version of the type that underlies **size_t**. All functions that return **ssize_t** (*read*( ) and *write*( )) describe as ‘‘implementation-defined’’ the result of an input exceeding {SSIZE_MAX}. It is recognized that some implementations might have **int**s that are smaller than **size_t**. A conforming application would be constrained not to perform I/O in pieces larger than {SSIZE_MAX}, but a conforming application using extensions would be able to use the full range if the implementation provided an extended range, while still having a single type-compatible interface.

The symbols **size_t** and **ssize_t** are also required in **<unistd.h>** to minimize the changes needed for calls to *read*( ) and *write*( ). Implementors are reminded that it must be possible to include both **<sys/types.h>** and **<unistd.h>** in the same program (in either order) without error.

uid_t Before the addition of this type, the data types used to represent these values varied throughout early proposals. The **<sys/stat.h>** header defined these values as type **short**, the **<passwd.h>** file (now **<pwd.h>** and **<grp.h>**) used an **int**, and *getuid*( ) returned an **int**. In response to a strong objection to the inconsistent definitions, all the types to were switched to **uid_t**.

In practice, those historical implementations that use varying types of this sort can typedef **uid_t** to **short** with no serious consequences.

The problem associated with this change concerns object compatibility after structure size changes. Since most implementations will define **uid_t** as a short, the only substantive change will be a reduction in the size of the **passwd** structure. Consequently, implementations with an overriding concern for object compatibility can pad the structure back to its current size. For that reason, this problem was not considered critical enough to warrant the addition of a separate type to POSIX.1.

The types **uid_t** and **gid_t** are magic cookies. There is no {UID_MAX} defined by POSIX.1, and no structure imposed on **uid_t** and **gid_t** other than that they be positive arithmetic types. (In fact, they could be **unsigned char**.) There is no maximum or minimum specified for the number of distinct user or group IDs.

B.3 System Interfaces

See the RATIONALE sections on the individual reference pages.

B.3.1 Examples for Spawn

The following long examples are provided in the Rationale (Informative) volume of IEEE Std 1003.1-200x as a supplement to the reference page for *spawn*( ).

Example Library Implementation of Spawn

The *posix_spawn*( ) or *posix_spawnp*( ) functions provide the following:

- Simply start a process executing a process image. This is the simplest application for process creation, and it may cover most executions of POSIX *fork*( ).
- Support I/O redirection, including pipes.
- Run the child under a user and group ID in the domain of the parent.
- Run the child at any priority in the domain of the parent.

The *posix_spawn*( ) or *posix_spawnp*( ) functions do not cover every possible use of the *fork*( ) function, but they do span the common applications: typical use by a shell and a login utility.

The price for an application is that before it calls *posix_spawn*( ) or *posix_spawnp*( ), the parent must adjust to a state that *posix_spawn*( ) or *posix_spawnp*( ) can map to the desired state for the child. Environment changes require the parent to save some of its state and restore it afterwards. The effective behavior of a successful invocation of *posix_spawn*( ) is as if the operation were implemented with POSIX operations as follows:

```
#include <sys/types.h>
#include <stdlib.h>
#include <stdio.h>
#include <unistd.h>
#include <sched.h>
#include <fcntl.h>
#include <signal.h>
#include <errno.h>
#include <string.h>
#include <signal.h>

/* #include <spawn.h>*/

int posix_spawnattr_destroy(posix_spawnattr_t *attr)
    {
    /* No action needed */
    return 0;
    }

int posix_spawnattr_getflags(const posix_spawnattr_t *attr,
        short *flags)
    {
    *flags=attr->posix_attr_flags;
    return 0;
    }
```

```
int posix_spawnattr_setflags(posix_spawnattr_t *attr, short flags)
    {
    attr->posix_attr_flags=flags;
    return 0;
    }

int posix_spawnattr_getpgroup(const posix_spawnattr_t *attr,
        pid_t *pgroup)
    {
    *pgroup=attr->posix_attr_pgroup;
    return 0;
    }

int posix_spawnattr_setpgroup(posix_spawnattr_t *attr, pid_t pgroup)
    {
    attr->posix_attr_pgroup=pgroup;
    return 0;
    }

int posix_spawnattr_getschedpolicy(const posix_spawnattr_t *attr,
        int *schedpolicy)
    {
    *schedpolicy=attr->posix_attr_schedpolicy;
    return 0;
    }

int posix_spawnattr_setschedpolicy(posix_spawnattr_t *attr,
        int schedpolicy)
    {
    attr->posix_attr_schedpolicy=schedpolicy;
    return 0;
    }

int posix_spawnattr_getschedparam(const posix_spawnattr_t *attr,
        struct sched_param *schedparam)
    {
    *schedparam=attr->posix_attr_schedparam;
    return 0;
    }

int posix_spawnattr_setschedparam(posix_spawnattr_t *attr,
        const struct sched_param *schedparam)
    {
    attr->posix_attr_schedparam=*schedparam;
    return 0;
    }

int posix_spawnattr_getsigmask(const posix_spawnattr_t *attr,
        sigset_t *sigmask)
    {
    *sigmask=attr->posix_attr_sigmask;
    return 0;
    }

int posix_spawnattr_setsigmask(posix_spawnattr_t *attr,
        const sigset_t *sigmask)
```

```
        {
        attr->posix_attr_sigmask=*sigmask;
        return 0;
        }
    int posix_spawnattr_getsigdefault(const posix_spawnattr_t *attr,
            sigset_t *sigdefault)
        {
        *sigdefault=attr->posix_attr_sigdefault;
        return 0;
        }
    int posix_spawnattr_setsigdefault(posix_spawnattr_t *attr,
            const sigset_t *sigdefault)
        {
        attr->posix_attr_sigdefault=*sigdefault;
        return 0;
        }
```

I/O Redirection with Spawn

I/O redirection with *posix_spawn*( ) or *posix_spawnp*( ) is accomplished by crafting a *file_actions* argument to effect the desired redirection. Such a redirection follows the general outline of the following example:

```
/* To redirect new standard output (fd 1) to a file, */
/* and redirect new standard input (fd 0) from my fd socket_pair[1], */
/* and close my fd socket_pair[0] in the new process. */
posix_spawn_file_actions_t file_actions;
posix_spawn_file_actions_init(&file_actions);
posix_spawn_file_actions_addopen(&file_actions, 1, "newout", ...);
posix_spawn_file_actions_dup2(&file_actions, socket_pair[1], 0);
posix_spawn_file_actions_close(&file_actions, socket_pair[0]);
posix_spawn_file_actions_close(&file_actions, socket_pair[1]);
posix_spawn(..., &file_actions, ...);
posix_spawn_file_actions_destroy(&file_actions);
```

Spawning a Process Under a New User ID

Spawning a process under a new user ID follows the outline shown in the following example:

```
Save = getuid();
setuid(newid);
posix_spawn(...);
setuid(Save);
```

Rationale (Informative)

Part C:

Shell and Utilities

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

Appendix C

Rationale for Shell and Utilities

C.1 Introduction

C.1.1 Scope

Refer to Section A.1.1 (on page 3293).

C.1.2 Conformance

Refer to Section A.2 (on page 3299).

C.1.3 Normative References

There is no additional rationale provided for this section.

C.1.4 Change History

The change history is provided as an informative section, to track changes from previous issues of IEEE Std 1003.1-200x.

The following sections describe changes made to the Shell and Utilities volume of IEEE Std 1003.1-200x since Issue 5 of the base document. The CHANGE HISTORY section for each utility describes technical changes made to that utility since Issue 5. Changes between earlier issues of the base document and Issue 5 are not included.

The change history between Issue 5 and Issue 6 also lists the changes since the ISO POSIX-2: 1993 standard.

Changes from Issue 5 to Issue 6 (IEEE Std 1003.1-200x)

The following list summarizes the major changes that were made in the Shell and Utilities volume of IEEE Std 1003.1-200x from Issue 5 to Issue 6:

- This volume of IEEE Std 1003.1-200x is extensively revised so it can be both an IEEE POSIX Standard and an Open Group Technical Standard.
- The terminology has been reworked to meet the style requirements.
- Shading notation and margin codes are introduced for identification of options within the volume.
- This volume of IEEE Std 1003.1-200x is updated to mandate support of FIPS 151-2. The following changes were made:
    - Support is mandated for the capabilities associated with the following symbolic constants:

      _POSIX_CHOWN_RESTRICTED
      _POSIX_JOB_CONTROL
      _POSIX_SAVED_IDS

    - In the environment for the login shell, the environment variables *LOGNAME* and *HOME* shall be defined and have the properties described in the Base Definitions volume of

IEEE Std 1003.1-200x, Chapter 7, Locale.

- This volume of IEEE Std 1003.1-200x is updated to align with some features of the Single UNIX Specification.
- A new section on Utility Limits is added.
- A section on the Relationships to Other Documents is added.
- Concepts and definitions have been moved to a separate volume.
- A RATIONALE section is added to each reference page.
- The *c99* utility is added as a replacement for *c89*, which is withdrawn in this issue.
- IEEE Std 1003.2d-1994 is incorporated, adding the *qalter*, *qdel*, *qhold*, *qmove*, *qmsg*, *qrerun*, *qrls*, *qselect*, *qsig*, *qstat*, and *qsub* utilities.
- IEEE P1003.2b draft standard is incorporated, making extensive updates and adding the *iconv* utility.
- IEEE PASC Interpretations are applied.
- The Open Groups corrigenda and resolutions are applied.

New Features in Issue 6

The following table lists the new utilities introduced since the ISO POSIX-2:1993 standard (as modified by IEEE Std 1003.2d-1994). These are all part of the XSI extension.

New Utilities in Issue 6

admin	*fuser*	*link*	*tsort*	*uustat*
cal	*gencat*	*m4*	*ulimit*	*uux*
cflow	*get*	*nl*	*uncompress*	*val*
compress	*hash*	*prs*	*unget*	*what*
cxref	*ipcrm*	*sact*	*unlink*	*zcat*
delta	*ipcs*	*sccs*	*uucp*	

C.1.5 Terminology

Refer to Section A.1.4 (on page 3295).

C.1.6 Definitions

Refer to Section A.3 (on page 3302).

C.1.7 Relationship to Other Documents

C.1.7.1 System Interfaces

It has been pointed out that the Shell and Utilities volume of IEEE Std 1003.1-200x assumes that a great deal of functionality from the System Interfaces volume of IEEE Std 1003.1-200x is present, but never states exactly how much (and strictly does not need to since both are mandated on a conforming system). This section is an attempt to clarify the assumptions.

C.1.7.2 Concepts Derived from the ISO C Standard

This section was introduced to address the issue that there was insufficient detail presented by such utilities as *awk* or *sh* about their procedural control statements and their methods of performing arithmetic functions.

The ISO C standard was selected as a model because most historical implementations of the standard utilities were written in C. Thus, it was more likely that they would act in the desired manner without modification.

Using the ISO C standard is primarily a notational convenience so that the many procedural languages in the Shell and Utilities volume of IEEE Std 1003.1-200x would not have to be rigorously described in every aspect. Its selection does not require that the standard utilities be written in Standard C; they could be written in Common Usage C, Ada, Pascal, assembler language, or anything else.

The sizes of the various numeric values refer to C-language data types that are allowed to be different sizes by the ISO C standard. Thus, like a C-language application, a shell application cannot rely on their exact size. However, it can rely on their minimum sizes expressed in the ISO C standard, such as {LONG_MAX} for a **long** type.

C.1.8 Portability

Refer to Section A.1.5 (on page 3298).

C.1.8.1 Codes

Refer to Section A.1.5.1 (on page 3298).

C.1.9 Utility Limits

This section grew out of an idea that originated with the original POSIX.1, in the tables of system limits for the *sysconf*( ) and *pathconf*( ) functions. The idea being that a conforming application can be written to use the most restrictive values that a minimal system can provide, but it should not have to. The values provided represent compromises so that some vendors can use historically limited versions of UNIX system utilities. They are the highest values that a strictly conforming application can assume, given no other information.

However, by using the *getconf* utility or the *sysconf*( ) function, the elegant application can be tailored to more liberal values on some of the specific instances of specific implementations.

There is no explicitly stated requirement that an implementation provide finite limits for any of these numeric values; the implementation is free to provide essentially unbounded capabilities (where it makes sense), stopping only at reasonable points such as {ULONG_MAX} (from the ISO C standard). Therefore, applications desiring to tailor themselves to the values on a particular implementation need to be ready for possibly huge values; it may not be a good idea to allocate blindly a buffer for an input line based on the value of {LINE_MAX}, for instance. However, unlike the System Interfaces volume of IEEE Std 1003.1-200x, there is no set of limits that return a special indication meaning ''unbounded''. The implementation should always return an actual number, even if the number is very large.

The statement:

> ''It is not guaranteed that the application ...''

is an indication that many of these limits are designed to ensure that implementors design their utilities without arbitrary constraints related to unimaginative programming. There are certainly conditions under which combinations of options can cause failures that would not render an implementation non-conforming. For example, {EXPR_NEST_MAX} and {ARG_MAX} could collide when expressions are large; combinations of {BC_SCALE_MAX} and {BC_DIM_MAX} could exceed virtual memory.

In the Shell and Utilities volume of IEEE Std 1003.1-200x, the notion of a limit being guaranteed for the process lifetime, as it is in the System Interfaces volume of IEEE Std 1003.1-200x, is not as useful to a shell script. The *getconf* utility is probably a process itself, so the guarantee would be without value. Therefore, the Shell and Utilities volume of IEEE Std 1003.1-200x requires the guarantee to be for the session lifetime. This will mean that many vendors will either return very conservative values or possibly implement *getconf* as a built-in.

It may seem confusing to have limits that apply only to a single utility grouped into one global section. However, the alternative, which would be to disperse them out into their utility description sections, would cause great difficulty when *sysconf*( ) and *getconf* were described. Therefore, the standard developers chose the global approach.

Each language binding could provide symbol names that are slightly different from those shown here. For example, the C-Language Binding option adds a leading underscore to the symbols as a prefix.

The following comments describe selection criteria for the symbols and their values:

{ARG_MAX}
This is defined by the System Interfaces volume of IEEE Std 1003.1-200x. Unfortunately, it is very difficult for a conforming application to deal with this value, as it does not know how much of its argument space is being consumed by the environment variables of the user.

{BC_BASE_MAX}
{BC_DIM_MAX}
{BC_SCALE_MAX}
These were originally one value, {BC_SCALE_MAX}, but it was unreasonable to link all three concepts into one limit.

{CHILD_MAX}
This is defined by the System Interfaces volume of IEEE Std 1003.1-200x.

{COLL_WEIGHTS_MAX}
The weights assigned to **order** can be considered as ‘‘passes’’ through the collation algorithm.

{EXPR_NEST_MAX}
The value for expression nesting was borrowed from the ISO C standard.

{LINE_MAX}
This is a global limit that affects all utilities, unless otherwise noted. The {MAX_CANON} value from the System Interfaces volume of IEEE Std 1003.1-200x may further limit input lines from terminals. The {LINE_MAX} value was the subject of much debate and is a compromise between those who wished to have unlimited lines and those who understood that many historical utilities were written with fixed buffers. Frequently, utility writers selected the UNIX system constant BUFSIZ to allocate these buffers; therefore, some utilities were limited to 512 bytes for I/O lines, while others achieved 4 096 bytes or greater.

It should be noted that {LINE_MAX} applies only to input line length; there is no requirement in IEEE Std 1003.1-200x that limits the length of output lines. Utilities such as *awk*, *sed*, and *paste* could theoretically construct lines longer than any of the input lines they received, depending on the options used or the instructions from the application. They are not required to truncate their output to {LINE_MAX}. It is the responsibility of the application to deal with this. If the output of one of those utilities is to be piped into another of the standard utilities, line length restrictions will have to be considered; the *fold* utility, among others, could be used to ensure that only reasonable line lengths reach utilities or applications.

{LINK_MAX}
This is defined by the System Interfaces volume of IEEE Std 1003.1-200x.

{MAX_CANON}
{MAX_INPUT}
{NAME_MAX}
{NGROUPS_MAX}
{OPEN_MAX}
{PATH_MAX}
{PIPE_BUF}
These limits are defined by the System Interfaces volume of IEEE Std 1003.1-200x. Note that the byte lengths described by some of these values continue to represent bytes, even if the applicable character set uses a multi-byte encoding.

{RE_DUP_MAX}
The value selected is consistent with historical practice. Although the name implies that it applies to all REs, only BREs use the interval notation **\{***m*,*n***\}** addressed by this limit.

{POSIX2_SYMLINKS}
The {POSIX2_SYMLINKS} variable indicates that the underlying operating system supports the creation of symbolic links in specific directories. Many of the utilities defined in IEEE Std 1003.1-200x that deal with symbolic links do not depend on this value. For example, a utility that follows symbolic links (or does not, as the case may be) will only be affected by a symbolic link if it encounters one. Presumably, a file system that does not support symbolic links will not contain any. This variable does affect such utilities as *ln* −**s** and *pax* that attempt to create symbolic links.

{POSIX2_SYMLINKS} was developed even though there is no comparable configuration value for the system interfaces.

There are different limits associated with command lines and input to utilities, depending on the method of invocation. In the case of a C program *exec*-ing a utility, {ARG_MAX} is the underlying limit. In the case of the shell reading a script and *exec*-ing a utility, {LINE_MAX} limits the length of lines the shell is required to process, and {ARG_MAX} will still be a limit. If a user is entering a command on a terminal to the shell, requesting that it invoke the utility, {MAX_INPUT} may restrict the length of the line that can be given to the shell to a value below {LINE_MAX}.

When an option is supported, *getconf* returns a value of 1. For example, when C development is supported:

```
if [ "$(getconf POSIX2_C_DEV)" −eq 1 ]; then
    echo C supported
fi
```

The *sysconf*( ) function in the C-Language Binding option would return 1.

The following comments describe selection criteria for the symbols and their values:

POSIX2_C_BIND
POSIX2_C_DEV
POSIX2_FORT_DEV
POSIX2_FORT_RUN

POSIX2_SW_DEV
POSIX2_UPE

It is possible for some (usually privileged) operations to remove utilities that support these options or otherwise to render these options unsupported. The header files, the *sysconf*( ) function, or the *getconf* utility will not necessarily detect such actions, in which case they should not be considered as rendering the implementation non-conforming. A test suite should not attempt tests such as:

```
rm /usr/bin/c99
getconf POSIX2_C_DEV
```

POSIX2_LOCALEDEF

This symbol was introduced to allow implementations to restrict supported locales to only those supplied by the implementation.

C.1.10 Grammar Conventions

There is no additional rationale provided for this section.

C.1.11 Utility Description Defaults

This section is arranged with headings in the same order as all the utility descriptions. It is a collection of related and unrelated information concerning

1. The default actions of utilities
2. The meanings of notations used in IEEE Std 1003.1-200x that are specific to individual utility sections

Although this material may seem out of place here, it is important that this information appear before any of the utilities to be described later.

NAME

There is no additional rationale provided for this section.

SYNOPSIS

There is no additional rationale provided for this section.

DESCRIPTION

There is no additional rationale provided for this section.

OPTIONS

Although it has not always been possible, the standard developers tried to avoid repeating information to reduce the risk that duplicate explanations could each be modified differently.

The need to recognize −− is required because conforming applications need to shield their operands from any arbitrary options that the implementation may provide as an extension. For example, if the standard utility *foo* is listed as taking no options, and the application needed to give it a pathname with a leading hyphen, it could safely do it as:

```
foo −− −myfile
```

and avoid any problems with −**m** used as an extension.

OPERANDS

The usage of – is never shown in the SYNOPSIS. Similarly, the usage of – – is never shown.

The requirement for processing operands in command-line order is to avoid a ‘‘WeirdNIX’’ utility that might choose to sort the input files alphabetically, by size, or by directory order. Although this might be acceptable for some utilities, in general the programmer has a right to know exactly what order will be chosen.

Some of the standard utilities take multiple *file* operands and act as if they were processing the concatenation of those files. For example:

```
asa file1 file2
```

and:

```
cat file1 file2 | asa
```

have similar results when questions of file access, errors, and performance are ignored. Other utilities such as *grep* or *wc* have completely different results in these two cases. This latter type of utility is always identified in its DESCRIPTION or OPERANDS sections, whereas the former is not. Although it might be possible to create a general assertion about the former case, the following points must be addressed:

- Access times for the files might be different in the operand case *versus* the *cat* case.
- The utility may have error messages that are cognizant of the input filename, and this added value should not be suppressed. (As an example, *awk* sets a variable with the filename at each file boundary.)

STDIN

There is no additional rationale provided for this section.

INPUT FILES

A conforming application cannot assume the following three commands are equivalent:

```
tail –n +2 file
(sed –n 1q; cat) < file
cat file | (sed –n 1q; cat)
```

The second command is equivalent to the first only when the file is seekable. In the third command, if the file offset in the open file description were not unspecified, *sed* would have to be implemented so that it read from the pipe 1 byte at a time or it would have to employ some method to seek backwards on the pipe. Such functionality is not defined currently in POSIX.1 and does not exist on all historical systems. Other utilities, such as *head*, *read*, and *sh*, have similar properties, so the restriction is described globally in this section.

The definition of *text file* is strictly enforced for input to the standard utilities; very few of them list exceptions to the undefined results called for here. (Of course, ‘‘undefined’’ here does not mean that historical implementations necessarily have to change to start indicating error conditions. Conforming applications cannot rely on implementations succeeding or failing when non-text files are used.)

The utilities that allow line continuation are generally those that accept input languages, rather than pure data. It would be unusual for an input line of this type to exceed {LINE_MAX} bytes and unreasonable to require that the implementation allow unlimited accumulation of multiple lines, each of which could reach {LINE_MAX}. Thus, for a conforming application the total of all the continued lines in a set cannot exceed {LINE_MAX}.

The format description is intended to be sufficiently rigorous to allow other applications to generate these input files. However, since <blank>s can legitimately be included in some of the fields described by the standard utilities, particularly in locales other than the POSIX locale, this intent is not always realized.

ENVIRONMENT VARIABLES

There is no additional rationale provided for this section.

ASYNCHRONOUS EVENTS

Because there is no language prohibiting it, a utility is permitted to catch a signal, perform some additional processing (such as deleting temporary files), restore the default signal action (or action inherited from the parent process), and resignal itself.

STDOUT

The format description is intended to be sufficiently rigorous to allow post-processing of output by other programs, particularly by an *awk* or *lex* parser.

STDERR

This section does not describe error messages that refer to incorrect operation of the utility. Consider a utility that processes program source code as its input. This section is used to describe messages produced by a correctly operating utility that encounters an error in the program source code on which it is processing. However, a message indicating that the utility had insufficient memory in which to operate would not be described.

Some utilities have traditionally produced warning messages without returning a non-zero exit status; these are specifically noted in their sections. Other utilities shall not write to standard error if they complete successfully, unless the implementation provides some sort of extension to increase the verbosity or debugging level.

The format descriptions are intended to be sufficiently rigorous to allow post-processing of output by other programs.

OUTPUT FILES

The format description is intended to be sufficiently rigorous to allow post-processing of output by other programs, particularly by an *awk* or *lex* parser.

Receipt of the SIGQUIT signal should generally cause termination (unless in some debugging mode) that would bypass any attempted recovery actions.

EXTENDED DESCRIPTION

There is no additional rationale provided for this section.

EXIT STATUS

Note the additional discussion of exit values in *Exit Status for Commands* in the *sh* utility. It describes requirements for returning exit values greater than 125.

A utility may list zero as a successful return, 1 as a failure for a specific reason, and greater than 1 as ‘‘an error occurred’’. In this case, unspecified conditions may cause a 2 or 3, or other value, to be returned. A strictly conforming application should be written so that it tests for successful exit status values (zero in this case), rather than relying upon the single specific error value listed in IEEE Std 1003.1-200x. In that way, it will have maximum portability, even on implementations with extensions.

The standard developers are aware that the general non-enumeration of errors makes it difficult to write test suites that test the *incorrect* operation of utilities. There are some historical implementations that have expended effort to provide detailed status messages and a helpful environment to bypass or explain errors, such as prompting, retrying, or ignoring unimportant syntax errors; other implementations have not. Since there is no realistic way to mandate system behavior in cases of undefined application actions or system problems—in a manner acceptable to all cultures and environments—attention has been limited to the correct operation of utilities by the conforming application. Furthermore, the conforming application does not need detailed information concerning errors that it caused through incorrect usage or that it cannot correct.

There is no description of defaults for this section because all of the standard utilities specify something (or explicitly state ''Unspecified'') for exit status.

CONSEQUENCES OF ERRORS

Several actions are possible when a utility encounters an error condition, depending on the severity of the error and the state of the utility. Included in the possible actions of various utilities are: deletion of temporary or intermediate work files; deletion of incomplete files; and validity checking of the file system or directory.

The text about recursive traversing is meant to ensure that utilities such as *find* process as many files in the hierarchy as they can. They should not abandon all of the hierarchy at the first error and resume with the next command-line operand, but should attempt to keep going.

APPLICATION USAGE

This section provides additional caveats, issues, and recommendations to the developer.

EXAMPLES

This section provides sample usage.

RATIONALE

There is no additional rationale provided for this section.

FUTURE DIRECTIONS

FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in the future, and often cautions the developer to architect the code to account for a change in this area. Note that a future directions statement should not be taken as a commitment to adopt a feature or interface in the future.

SEE ALSO

There is no additional rationale provided for this section.

CHANGE HISTORY

There is no additional rationale provided for this section.

C.1.12 Considerations for Utilities in Support of Files of Arbitrary Size

This section is intended to clarify the requirements for utilities in support of large files.

The utilities listed in this section are utilities which are used to perform administrative tasks such as to create, move, copy, remove, change the permissions, or measure the resources of a file. They are useful both as end-user tools and as utilities invoked by applications during software installation and operation.

The *chgrp*, *chmod*, *chown*, *ln*, and *rm* utilities probably require use of large file capable versions of *stat*( ), *lstat*( ), *ftw*( ), and the **stat** structure.

The *cat*, *cksum*, *cmp*, *cp*, *dd*, *mv*, *sum*, and *touch* utilities probably require use of large file capable versions of *creat*( ), *open*( ), and *fopen*( ).

The *cat*, *cksum*, *cmp*, *dd*, *df*, *du*, *ls*, and *sum* utilities may require writing large integer values. For example:

- The *cat* utility might have a **−n** option which counts <newline>s.
- The *cksum* and *ls* utilities report file sizes.
- The *cmp* utility reports the line number at which the first difference occurs, and also has a **−l** option which reports file offsets.
- The *dd*, *df*, *du*, *ls*, and *sum* utilities report block counts.

The *dd*, *find*, and *test* utilities may need to interpret command arguments that contain 64-bit values. For *dd*, the arguments include *skip*=*n*, *seek*=*n*, and *count*=*n*. For *find*, the arguments include **−size***n*. For *test*, the arguments are those associated with algebraic comparisons.

The *df* utility might need to access large file systems with *statvfs*( ).

The *ulimit* utility will need to use large file capable versions of *getrlimit*( ) and *setrlimit*( ) and be able to read and write large integer values.

C.1.13 Built-In Utilities

All of these utilities can be *exec*-ed. There is no requirement that these utilities are actually built into the shell itself, but many shells need the capability to do so because the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.9.1.1, Command Search and Execution requires that they be found prior to the *PATH* search. The shell could satisfy its requirements by keeping a list of the names and directly accessing the file-system versions regardless of *PATH*. Providing all of the required functionality for those such as *cd* or *read* would be more difficult.

There were originally three justifications for allowing the omission of *exec*-able versions:

1. It would require wasting space in the file system, at the expense of very small systems. However, it has been pointed out that all 16 utilities in the table can be provided with 16 links to a single-line shell script:

   ```
   $0 "$@"
   ```

2. It is not logical to require invocation of utilities such as *cd* because they have no value outside the shell environment or cannot be useful in a child process. However, counter-examples always seemed to be available for even the most unusual cases:

```
find . −type d −exec cd {} \; −exec foo {} \;
```

(which invokes ''foo'' on accessible directories)

```
ps ... | sed ... | xargs kill
```

```
find . −exec true \; −a ...
```

(where ''true'' is used for temporary debugging)

3. It is confusing to have a utility such as *kill* that can easily be in the file system in the base standard, but that requires built-in status for the UPE (for the % job control job ID notation). It was decided that it was more appropriate to describe the required functionality (rather than the implementation) to the system implementors and let them decide how to satisfy it.

On the other hand, it was realized that any distinction like this between utilities was not useful to applications, and that the cost to correct it was small. These arguments were ultimately the most effective.

There were varying reasons for including utilities in the table of built-ins:

alias, *fc*, *unalias*
The functionality of these utilities is performed more simply within the shell itself and that is the model most historical implementations have used.

bg, *fg*, *jobs*
All of the job control-related utilities are eligible for built-in status because that is the model most historical implementations have used.

cd, *getopts*, *newgrp*, *read*, *umask*, *wait*
The functionality of these utilities is performed more simply within the context of the current process. An example can be taken from the usage of the *cd* utility. The purpose of the utility is to change the working directory for subsequent operations. The actions of *cd* affect the process in which *cd* is executed and all subsequent child processes of that process. Based on the ISO POSIX-1 standard p1 process model, changes in the process environment of a child process have no effect on the parent process. If the *cd* utility were executed from a child process, the working directory change would be effective only in the child process. Child processes initiated subsequent to the child process that executed the *cd* utility would not have a changed working directory relative to the parent process.

command
This utility was placed in the table primarily to protect scripts that are concerned about their *PATH* being manipulated. The ''secure'' shell script example in the *command* utility in the Shell and Utilities volume of IEEE Std 1003.1-200x would not be possible if a *PATH* change retrieved an alien version of *command*. (An alternative would have been to implement *getconf* as a built-in, but the standard developers considered that it carried too many changing configuration strings to require in the shell.)

kill
Since *kill* provides optional job control functionality using shell notation (`%1`, `%2`, and so on), some implementations would find it extremely difficult to provide this outside the shell.

true, *false*
These are in the table as a courtesy to programmers who wish to use the ''**while** \ *true*'' shell construct without protecting *true* from *PATH* searches. (It is acknowledged that ''**while** \ :'' also works, but the idiom with *true* is historically pervasive.)

All utilities, including those in the table, are accessible via the *system*( ) and *popen*( ) functions in the System Interfaces volume of IEEE Std 1003.1-200x. There are situations where the return functionality of *system*( ) and *popen*( ) is not desirable. Applications that require the exit status of the invoked utility will not be able to use *system*( ) or *popen*( ), since the exit status returned is that of the command language interpreter rather than that of the invoked utility. The alternative for such applications is the use of the *exec* family.

C.2 Shell Command Language

C.2.1 Shell Introduction

The System V shell was selected as the starting point for the Shell and Utilities volume of IEEE Std 1003.1-200x. The BSD C shell was excluded from consideration for the following reasons:

- Most historically portable shell scripts assume the Version 7 Bourne shell, from which the System V shell is derived.
- The majority of tutorial materials on shell programming assume the System V shell.

The construct `"#!"` is reserved for implementations wishing to provide that extension. If it were not reserved, the Shell and Utilities volume of IEEE Std 1003.1-200x would disallow it by forcing it to be a comment. As it stands, a strictly conforming application must not use `"#!"` as the first two characters of the file.

C.2.2 Quoting

There is no additional rationale provided for this section.

C.2.2.1 Escape Character (Backslash)

There is no additional rationale provided for this section.

C.2.2.2 Single-Quotes

A backslash cannot be used to escape a single-quote in a single-quoted string. An embedded quote can be created by writing, for example: `"'a'\''b'"`, which yields `"a'b"`. (See the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.6.5, Field Splitting for a better understanding of how portions of words are either split into fields or remain concatenated.) A single token can be made up of concatenated partial strings containing all three kinds of quoting or escaping, thus permitting any combination of characters.

C.2.2.3 Double-Quotes

The escaped <newline> used for line continuation is removed entirely from the input and is not replaced by any white space. Therefore, it cannot serve as a token separator.

In double-quoting, if a backslash is immediately followed by a character that would be interpreted as having a special meaning, the backslash is deleted and the subsequent character is taken literally. If a backslash does not precede a character that would have a special meaning, it is left in place unmodified and the character immediately following it is also left unmodified. Thus, for example:

```
"\$"   →   $
"\a"   →   \a
```

It would be desirable to include the statement ‘‘The characters from an enclosed `"${"` to the matching `’}’` shall not be affected by the double quotes’’, similar to the one for `"$()"`. However, historical practice in the System V shell prevents this.

The requirement that double-quotes be matched inside `"${...}"` within double-quotes and the rule for finding the matching `’}’` in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.6.2, Parameter Expansion eliminate several subtle inconsistencies in expansion for historical shells in rare cases; for example:

```
"${foo-bar"}
```

yields **bar** when **foo** is not defined, and is an invalid substitution when **foo** is defined, in many historical shells. The differences in processing the `"${...}"` form have led to inconsistencies between historical systems. A consequence of this rule is that single-quotes cannot be used to quote the `’}’` within `"${...}"`; for example:

```
unset bar
foo="${bar–’}’}"
```

is invalid because the `"${...}"` substitution contains an unpaired unescaped single-quote. The backslash can be used to escape the `’}’` in this example to achieve the desired result:

```
unset bar
foo="${bar–\}}"
```

The differences in processing the `"${...}"` form have led to inconsistencies between the historical System V shell, BSD, and KornShells, and the text in the Shell and Utilities volume of IEEE Std 1003.1-200x is an attempt to converge them without breaking too many applications. The only alternative to this compromise between shells would be to make the behavior unspecified whenever the literal characters `’’’`, `’{’`, `’}’`, and `’"’` appear within `"${...}"`. To write a portable script that uses these values, a user would have to assign variables; for example:

```
squote=\’ dquote=\" lbrace=’{’ rbrace=’}’
${foo–$squote$rbrace$squote}
```

rather than:

```
${foo–"’}’"}
```

Some implementations have allowed the end of the word to terminate the backquoted command substitution, such as in:

```
"‘echo hello"
```

This usage is undefined; the matching backquote is required by the Shell and Utilities volume of IEEE Std 1003.1-200x. The other undefined usage can be illustrated by the example:

```
sh –c ’‘ echo "foo‘’
```

The description of the recursive actions involving command substitution can be illustrated with an example. Upon recognizing the introduction of command substitution, the shell parses input (in a new context), gathering the source for the command substitution until an unbalanced `’)’` or `’‘’` is located. For example, in the following:

```
echo "$(date; echo "
    one" )"
```

the double-quote following the *echo* does not terminate the first double-quote; it is part of the command substitution script. Similarly, in:

```
echo "$(echo *)"
```

the asterisk is not quoted since it is inside command substitution; however:

```
echo "$(echo "*")"
```

is quoted (and represents the asterisk character itself).

C.2.3 Token Recognition

The `"(("` and `"))"` symbols are control operators in the KornShell, used for an alternative syntax of an arithmetic expression command. A conforming application cannot use `"(("` as a single token (with the exception of the `"$(("` form for shell arithmetic).

On some implementations, the symbol `"(("` is a control operator; its use produces unspecified results. Applications that wish to have nested subshells, such as:

```
((echo Hello);(echo World))
```

shall separate the `"(("` characters into two tokens by including white space between them. Some systems may treat these as invalid arithmetic expressions instead of subshells.

Certain combinations of characters are invalid in portable scripts, as shown in the grammar. Implementations may use these combinations (such as `"|&"`) as valid control operators. Portable scripts cannot rely on receiving errors in all cases where this volume of IEEE Std 1003.1-200x indicates that a syntax is invalid.

The (3) rule about combining characters to form operators is not meant to preclude systems from extending the shell language when characters are combined in otherwise invalid ways. Conforming applications cannot use invalid combinations, and test suites should not penalize systems that take advantage of this fact. For example, the unquoted combination `"|&"` is not valid in a POSIX script, but has a specific KornShell meaning.

The (10) rule about `'#'` as the current character is the first in the sequence in which a new token is being assembled. The `'#'` starts a comment only when it is at the beginning of a token. This rule is also written to indicate that the search for the end-of-comment does not consider escaped <newline> specially, so that a comment cannot be continued to the next line.

C.2.3.1 Alias Substitution

The alias capability was added in the UPE because it is widely used in historical implementations by interactive users.

The definition of *alias name* precludes an alias name containing a slash character. Since the text applies to the command words of simple commands, reserved words (in their proper places) cannot be confused with aliases.

The placement of alias substitution in token recognition makes it clear that it precedes all of the word expansion steps.

An example concerning trailing <blank>s and reserved words follows. If the user types:

```
$ alias foo="/bin/ls "
$ alias while="/"
```

The effect of executing:

```
$ while true
> do
> echo "Hello, World"
> done
```

is a never-ending sequence of `"Hello, World"` strings to the screen. However, if the user types:

```
$ foo while
```

the result is an *ls* listing of **/**. Since the alias substitution for **foo** ends in a <space>, the next word is checked for alias substitution. The next word, **while**, has also been aliased, so it is substituted as well. Since it is not in the proper position as a command word, it is not recognized as a reserved word.

If the user types:

```
$ foo; while
```

while retains its normal reserved-word properties.

C.2.4 Reserved Words

All reserved words are recognized syntactically as such in the contexts described. However, note that **in** is the only meaningful reserved word after a **case** or **for**; similarly, **in** is not meaningful as the first word of a simple command.

Reserved words are recognized only when they are delimited (that is, meet the definition of the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.435, Word), whereas operators are themselves delimiters. For instance, `'('` and `')'` are control operators, so that no <space> is needed in (*list*). However, `'{'` and `'}'` are reserved words in { *list*;}, so that in this case the leading <space> and semicolon are required.

The list of unspecified reserved words is from the KornShell, so conforming applications cannot use them in places a reserved word would be recognized. This list contained **time** in early proposals, but it was removed when the *time* utility was selected for the Shell and Utilities volume of IEEE Std 1003.1-200x.

There was a strong argument for promoting braces to operators (instead of reserved words), so they would be syntactically equivalent to subshell operators. Concerns about compatibility outweighed the advantages of this approach. Nevertheless, conforming applications should consider quoting `'{'` and `'}'` when they represent themselves.

The restriction on ending a name with a colon is to allow future implementations that support named labels for flow control; see the RATIONALE for the *break* built-in utility .

It is possible that a future version of the Shell and Utilities volume of IEEE Std 1003.1-200x may require that `'{'` and `'}'` be treated individually as control operators, although the token `"{}"` will probably be a special-case exemption from this because of the often-used *find*{} construct.

C.2.5 Parameters and Variables

C.2.5.1 Positional Parameters

There is no additional rationale provided for this section.

C.2.5.2 Special Parameters

Most historical implementations implement subshells by forking; thus, the special parameter `'$'` does not necessarily represent the process ID of the shell process executing the commands since the subshell execution environment preserves the value of `'$'`.

If a subshell were to execute a background command, the value of `"$!"` for the parent would not change. For example:

```
(
date &
echo $!
)
echo $!
```

would echo two different values for `"$!"`.

The `"$–"` special parameter can be used to save and restore *set* options:

```
Save=$(echo $– | sed 's/[ics]//g')
...
set +aCefnuvx
if [ –n "$Save" ]; then
    set –$Save
fi
```

The three options are removed using *sed* in the example because they may appear in the value of `"$–"` (from the *sh* command line), but are not valid options to *set*.

The descriptions of parameters `'*'` and `'@'` assume the reader is familiar with the field splitting discussion in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.6.5, Field Splitting and understands that portions of the word remain concatenated unless there is some reason to split them into separate fields.

Some examples of the `'*'` and `'@'` properties, including the concatenation aspects:

```
set "abc" "def ghi" "jkl"

echo $*     => "abc" "def" "ghi" "jkl"
echo "$*"   => "abc def ghi jkl"
echo $@     => "abc" "def" "ghi" "jkl"
```

but:

```
echo "$@"       => "abc" "def ghi" "jkl"
echo "xx$@yy"   => "xxabc" "def ghi" "jklyy"
echo "$@$@"     => "abc" "def ghi" "jklabc" "def ghi" "jkl"
```

In the preceding examples, the double-quote characters that appear after the `"=>"` do not appear in the output and are used only to illustrate word boundaries.

The following example illustrates the effect of setting *IFS* to a null string:

```
$ IFS=''
$ set foo bar bam
$ echo "$@"
foo bar bam
$ echo "$*"
foobarbam
$ unset IFS
$ echo "$*"
foo bar bam
```

C.2.5.3 *Shell Variables*

See the discussion of *IFS* in Section C.2.6.5 (on page 3529).

The prohibition on *LC_CTYPE* changes affecting lexical processing protects the shell implementor (and the shell programmer) from the ill effects of changing the definition of <blank> or the set of alphabetic characters in the current environment. It would probably not be feasible to write a compiled version of a shell script without this rule. The rule applies only to the current invocation of the shell and its subshells—invoking a shell script or performing *exec sh* would subject the new shell to the changes in *LC_CTYPE*.

Other common environment variables used by historical shells are not specified by the Shell and Utilities volume of IEEE Std 1003.1-200x, but they should be reserved for the historical uses.

Tilde expansion for components of the *PATH* in an assignment such as:

```
PATH=˜hlj/bin:˜dwc/bin:$PATH
```

is a feature of some historical shells and is allowed by the wording of the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.6.1, Tilde Expansion. Note that the tildes are expanded during the assignment to *PATH*, not when *PATH* is accessed during command search.

The following entries represent additional information about variables included in the Shell and Utilities volume of IEEE Std 1003.1-200x, or rationale for common variables in use by shells that have been excluded:

_	(Underscore.) While underscore is historical practice, its overloaded usage in the KornShell is confusing, and it has been omitted from the Shell and Utilities volume of IEEE Std 1003.1-200x.
ENV	This variable can be used to set aliases and other items local to the invocation of a shell. The file referred to by *ENV* differs from **$HOME/.profile** in that **.profile** is typically executed at session start-up, whereas the *ENV* file is executed at the beginning of each shell invocation. The *ENV* value is interpreted in a manner similar to a dot script, in that the commands are executed in the current environment and the file needs to be readable, but not executable. However, unlike dot scripts, no *PATH* searching is performed. This is used as a guard against Trojan Horse security breaches.
ERRNO	This variable was omitted from the Shell and Utilities volume of IEEE Std 1003.1-200x because the values of error numbers are not defined in IEEE Std 1003.1-200x in a portable manner.
FCEDIT	Since this variable affects only the *fc* utility, it has been omitted from this more global place. The value of *FCEDIT* does not affect the command line editing mode in the shell; see the description of *set* −**o** *vi* in the *set* built-in utility.

PS1 This variable is used for interactive prompts. Historically, the ‘‘superuser’’ has had a prompt of `'#'`. Since privileges are not required to be monolithic, it is difficult to define which privileges should cause the alternate prompt. However, a sufficiently powerful user should be reminded of that power by having an alternate prompt.

PS3 This variable is used by the KornShell for the *select* command. Since the POSIX shell does not include *select*, *PS3* was omitted.

PS4 This variable is used for shell debugging. For example, the following script:

```
PS4='[${LINENO}]+ '
set −x
echo Hello
```

writes the following to standard error:

```
[3]+ echo Hello
```

RANDOM This pseudo-random number generator was not seen as being useful to interactive users.

SECONDS Although this variable is sometimes used with *PS1* to allow the display of the current time in the prompt of the user, it is not one that would be manipulated frequently enough by an interactive user to include in the Shell and Utilities volume of IEEE Std 1003.1-200x.

C.2.6 Word Expansions

Step (2) refers to the ‘‘portions of fields generated by step (1)’’. For example, if the word being expanded were `"$x+$y"` and *IFS*=+, the word would be split only if `"$x"` or `"$y"` contained `'+'`; the `'+'` in the original word was not generated by step (1).

IFS is used for performing field splitting on the results of parameter and command substitution; it is not used for splitting all fields. Previous versions of the shell used it for splitting all fields during field splitting, but this has severe problems because the shell can no longer parse its own script. There are also important security implications caused by this behavior. All useful applications of *IFS* use it for parsing input of the *read* utility and for splitting the results of parameter and command substitution.

The rule concerning expansion to a single field requires that if **foo**=**abc** and **bar**=**def**, that:

```
"$foo""$bar"
```

expands to the single field:

```
abcdef
```

The rule concerning empty fields can be illustrated by:

```
$    unset foo
$    set $foo bar ’’ xyz "$foo" abc
$    for i
>    do
>        echo "-$i-"
>    done
-bar-
--
-xyz-
--
-abc-
```

Step (1) indicates that parameter expansion, command substitution, and arithmetic expansion are all processed simultaneously as they are scanned. For example, the following is valid arithmetic:

```
x=1
echo $(( $(echo 3)+$x ))
```

An early proposal stated that tilde expansion preceded the other steps, but this is not the case in known historical implementations; if it were, and if a referenced home directory contained a '$' character, expansions would result within the directory name.

C.2.6.1 Tilde Expansion

Tilde expansion generally occurs only at the beginning of words, but an exception based on historical practice has been included:

```
PATH=/posix/bin:˜dgk/bin
```

This is eligible for tilde expansion because tilde follows a colon and none of the relevant characters is quoted. Consideration was given to prohibiting this behavior because any of the following are reasonable substitutes:

```
PATH=$(printf %s ˜karels/bin : ˜bostic/bin)
```

```
for Dir in ˜maart/bin ˜srb/bin ...
do
    PATH=${PATH:+$PATH:}$Dir
done
```

In the first command, explicit colons are used for each directory. In all cases, the shell performs tilde expansion on each directory because all are separate words to the shell.

Note that expressions in operands such as:

```
make -k mumble LIBDIR=˜chet/lib
```

do not qualify as shell variable assignments, and tilde expansion is not performed (unless the command does so itself, which *make* does not).

Because of the requirement that the word is not quoted, the following are not equivalent; only the last causes tilde expansion:

```
\˜hlj/   ~h\lj/   ~"hlj"/   ~hlj\/   ~hlj/
```

In an early proposal, tilde expansion occurred following any unquoted equals sign or colon, but this was removed because of its complexity and to avoid breaking commands such as:

```
rcp hostname:˜marc/.profile .
```

A suggestion was made that the special sequence "$˜" should be allowed to force tilde expansion anywhere. Since this is not historical practice, it has been left for future implementations to evaluate. (The description in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.2, Quoting requires that a dollar sign be quoted to represent itself, so the "$˜" combination is already unspecified.)

The results of giving tilde with an unknown login name are undefined because the KornShell "˜+" and "˜−" constructs make use of this condition, but in general it is an error to give an incorrect login name with tilde. The results of having *HOME* unset are unspecified because some historical shells treat this as an error.

C.2.6.2 *Parameter Expansion*

The rule for finding the closing '}' in "${...}" is the one used in the KornShell and is upwardly-compatible with the Bourne shell, which does not determine the closing '}' until the word is expanded. The advantage of this is that incomplete expansions, such as:

```
${foo
```

can be determined during tokenization, rather than during expansion.

The string length and substring capabilities were included because of the demonstrated need for them, based on their usage in other shells, such as C shell and KornShell.

Historical versions of the KornShell have not performed tilde expansion on the word part of parameter expansion; however, it is more consistent to do so.

C.2.6.3 *Command Substitution*

The "$()" form of command substitution solves a problem of inconsistent behavior when using backquotes. For example:

Command	Output
`echo '\$x'`	`\$x`
``echo `echo '\$x'` ``	`$x`
`echo $(echo '\$x')`	`\$x`

Additionally, the backquoted syntax has historical restrictions on the contents of the embedded command. While the newer "$()" form can process any kind of valid embedded script, the backquoted form cannot handle some valid scripts that include backquotes. For example, these otherwise valid embedded scripts do not work in the left column, but do work on the right:

```
echo `                         echo $(
cat <<\eof                     cat <<\eof
a here-doc with `              a here-doc with )
eof                            eof
`                              )

echo `                         echo $(
echo abc # a comment with `    echo abc # a comment with )
`                              )

echo `                         echo $(
echo '`'                       echo ')'
`                              )
```

Because of these inconsistent behaviors, the backquoted variety of command substitution is not recommended for new applications that nest command substitutions or attempt to embed complex scripts.

The KornShell feature:

> If *command* is of the form <*word*, *word* is expanded to generate a pathname, and the value of the command substitution is the contents of this file with any trailing <newline>s deleted.

was omitted from the Shell and Utilities volume of IEEE Std 1003.1-200x because $(*cat word*) is an appropriate substitute. However, to prevent breaking numerous scripts relying on this feature, it is unspecified to have a script within `"$()"` that has only redirections.

The requirement to separate `"$("` and `'('` when a single subshell is command-substituted is to avoid any ambiguities with arithmetic expansion.

C.2.6.4 *Arithmetic Expansion*

The `"(())"` form of KornShell arithmetic in early proposals was omitted. The standard developers concluded that there was a strong desire for some kind of arithmetic evaluator to replace *expr*, and that relating it to `'$'` makes it work well with the standard shell language, and it provides access to arithmetic evaluation in places where accessing a utility would be inconvenient.

The syntax and semantics for arithmetic were changed for the ISO/IEC 9945-2:1993 standard. The language is essentially a pure arithmetic evaluator of constants and operators (excluding assignment) and represents a simple subset of the previous arithmetic language (which was derived from the KornShell `"(())"` construct). The syntax was changed from that of a command denoted by ((*expression*)) to an expansion denoted by $((*expression*)). The new form is a dollar expansion (`'$'`) that evaluates the expression and substitutes the resulting value. Objections to the previous style of arithmetic included that it was too complicated, did not fit in well with the use of variables in the shell, and its syntax conflicted with subshells. The justification for the new syntax is that the shell is traditionally a macro language, and if a new feature is to be added, it should be accomplished by extending the capabilities presented by the current model of the shell, rather than by inventing a new one outside the model; adding a new dollar expansion was perceived to be the most intuitive and least destructive way to add such a new capability.

In early proposals, a form $[*expression*] was used. It was functionally equivalent to the `"$(())"` of the current text, but objections were lodged that the 1988 KornShell had already implemented `"$(())"` and there was no compelling reason to invent yet another syntax. Furthermore, the `"$[]"` syntax had a minor incompatibility involving the patterns in **case** statements.

The portion of the ISO C standard arithmetic operations selected corresponds to the operations historically supported in the KornShell.

It was concluded that the *test* command (**[**) was sufficient for the majority of relational arithmetic tests, and that tests involving complicated relational expressions within the shell are rare, yet could still be accommodated by testing the value of `"$(())"` itself. For example:

```
# a complicated relational expression
while [ $(( (($x + $y)/($a * $b)) < ($foo*$bar) )) −ne 0 ]
```

or better yet, the rare script that has many complex relational expressions could define a function like this:

```
val() {
    return $((!$1))
}
```

and complicated tests would be less intimidating:

```
while val $(( (($x + $y)/($a * $b)) < ($foo*$bar) ))
do
    # some calculations
done
```

A suggestion that was not adopted was to modify *true* and *false* to take an optional argument, and *true* would exit true only if the argument was non-zero, and *false* would exit false only if the argument was non-zero:

```
while true $(($x > 5 && $y <= 25))
```

There is a minor portability concern with the new syntax. The example $((2+2)) could have been intended to mean a command substitution of a utility named 2+2 in a subshell. The standard developers considered this to be obscure and isolated to some KornShell scripts (because `"$()"` command substitution existed previously only in the KornShell). The text on command substitution requires that the `"$("` and `'('` be separate tokens if this usage is needed.

An example such as:

```
echo $((echo hi);(echo there))
```

should not be misinterpreted by the shell as arithmetic because attempts to balance the parentheses pairs would indicate that they are subshells. However, as indicated by the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.112, Control Operator, a conforming application must separate two adjacent parentheses with white space to indicate nested subshells.

Although the ISO/IEC 9899:1999 standard now requires support for **long long** and allows extended integer types with higher ranks, IEEE Std 1003.1-200x only requires arithmetic expansions to support **signed long** integer arithmetic. Implementations are encouraged to support signed integer values at least as large as the size of the largest file allowed on the implementation.

Implementations are also allowed to perform floating-point evaluations as long as an application won't see different results for expressions that would not overflow **signed long** integer expression evaluation. (This includes appropriate truncation of results to integer values.)

Changes made in response to IEEE PASC Interpretation 1003.2 #208 removed the requirement that the integer constant suffixes `l` and `L` had to be recognized. The ISO POSIX-2:1993 standard didn't require the `u`, `ul`, `uL`, `U`, `Ul`, `UL`, `lu`, `lU`, `Lu`, and `LU` suffixes since only signed integer arithmetic was required. Since all arithmetic expressions were treated as handling **signed long** integer types anyway, the `l` and `L` suffixes were redundant. No known scripts used them and some historic shells didn't support them. When the ISO/IEC 9899:1999 standard was used as the basis for the description of arithmetic processing, the `ll` and `LL` suffixes and combinations were also not required. Implementations are still free to accept any or all of these suffices, but are not required to do so.

There was also some confusion as to whether the shell was required to recognize character constants. Syntactically, character constants were required to be recognized, but the requirements for the handling of backslash (`"\\"`) and quote (`'\''`) characters (needed to specify character constants) within an arithmetic expansion were ambiguous. Furthermore, no known shells supported them. Changes made in response to IEEE PASC Interpretation 1003.2

#208 removed the requirement to support them (if they were indeed required before). IEEE Std 1003.1-200x clearly does not require support for character constants.

C.2.6.5 *Field Splitting*

The operation of field splitting using *IFS*, as described in early proposals, was based on the way the KornShell splits words, but it is incompatible with other common versions of the shell. However, each has merit, and so a decision was made to allow both. If the *IFS* variable is unset or is <space><tab><newline>, the operation is equivalent to the way the System V shell splits words. Using characters outside the <space><tab><newline> set yields the KornShell behavior, where each of the non-<space><tab><newline>s is significant. This behavior, which affords the most flexibility, was taken from the way the original *awk* handled field splitting.

Rule (3) can be summarized as a pseudo-ERE:

```
(s*ns*|s+)
```

where *s* is an *IFS* white space character and *n* is a character in the *IFS* that is not white space. Any string matching that ERE delimits a field, except that the *s*+ form does not delimit fields at the beginning or the end of a line. For example, if *IFS* is <space>/<comma>/<tab>, the string:

```
<space><space>red<space><space>,<space>white<space>blue
```

yields the three colors as the delimited fields.

C.2.6.6 *Pathname Expansion*

There is no additional rationale provided for this section.

C.2.6.7 *Quote Removal*

There is no additional rationale provided for this section.

C.2.7 Redirection

In the System Interfaces volume of IEEE Std 1003.1-200x, file descriptors are integers in the range 0–({OPEN_MAX}–1). The file descriptors discussed in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.7, Redirection are that same set of small integers.

Having multi-digit file descriptor numbers for I/O redirection can cause some obscure compatibility problems. Specifically, scripts that depend on an example command:

```
echo 22>/dev/null
```

echoing 2 to standard error or 22 to standard output are no longer portable. However, the file descriptor number still must be delimited from the preceding text. For example:

```
cat file2>foo
```

writes the contents of **file2**, not the contents of **file**.

The `">|"` format of output redirection was adopted from the KornShell. Along with the *noclobber* option, *set* −**C**, it provides a safety feature to prevent inadvertent overwriting of existing files. (See the RATIONALE for the *pathchk* utility for why this step was taken.) The restriction on regular files is historical practice.

The System V shell and the KornShell have differed historically on pathname expansion of *word*; the former never performed it, the latter only when the result was a single field (file). As a compromise, it was decided that the KornShell functionality was useful, but only as a shorthand device for interactive users. No reasonable shell script would be written with a command such as:

```
cat foo > a*
```

Thus, shell scripts are prohibited from doing it, while interactive users can select the shell with which they are most comfortable.

The construct 2>&1 is often used to redirect standard error to the same file as standard output. Since the redirections take place beginning to end, the order of redirections is significant. For example:

```
ls > foo 2>&1
```

directs both standard output and standard error to file **foo**. However:

```
ls 2>&1 > foo
```

only directs standard output to file **foo** because standard error was duplicated as standard output before standard output was directed to file **foo**.

The "<>" operator could be useful in writing an application that worked with several terminals, and occasionally wanted to start up a shell. That shell would in turn be unable to run applications that run from an ordinary controlling terminal unless it could make use of "<>" redirection. The specific example is a historical version of the pager *more*, which reads from standard error to get its commands, so standard input and standard output are both available for their usual usage. There is no way of saying the following in the shell without "<>":

```
cat food | more – >/dev/tty03 2<>/dev/tty03
```

Another example of "<>" is one that opens **/dev/tty** on file descriptor 3 for reading and writing:

```
exec 3<> /dev/tty
```

An example of creating a lock file for a critical code region:

```
set –C
until    2> /dev/null > lockfile
do       sleep 30
done
set +C
perform critical function
rm lockfile
```

Since **/dev/null** is not a regular file, no error is generated by redirecting to it in *noclobber* mode.

Tilde expansion is not performed on a here-document because the data is treated as if it were enclosed in double quotes.

C.2.7.1 Redirecting Input

There is no additional rationale provided for this section.

C.2.7.2 Redirecting Output

There is no additional rationale provided for this section.

C.2.7.3 Appending Redirected Output

Note that when a file is opened (even with the O_APPEND flag set), the initial file offset for that file is set to the beginning of the file. Some historic shells set the file offset to the current end-of-file when append mode shell redirection was used, but this is not allowed by IEEE Std 1003.1-200x.

C.2.7.4 Here-Document

There is no additional rationale provided for this section.

C.2.7.5 Duplicating an Input File Descriptor

There is no additional rationale provided for this section.

C.2.7.6 Duplicating an Output File Descriptor

There is no additional rationale provided for this section.

C.2.7.7 Open File Descriptors for Reading and Writing

There is no additional rationale provided for this section.

C.2.8 Exit Status and Errors

C.2.8.1 Consequences of Shell Errors

There is no additional rationale provided for this section.

C.2.8.2 Exit Status for Commands

There is a historical difference in *sh* and *ksh* non-interactive error behavior. When a command named in a script is not found, some implementations of *sh* exit immediately, but *ksh* continues with the next command. Thus, the Shell and Utilities volume of IEEE Std 1003.1-200x says that the shell ‘‘may’’ exit in this case. This puts a small burden on the programmer, who has to test for successful completion following a command if it is important that the next command not be executed if the previous command was not found. If it is important for the command to have been found, it was probably also important for it to complete successfully. The test for successful completion would not need to change.

Historically, shells have returned an exit status of $128+n$, where n represents the signal number. Since signal numbers are not standardized, there is no portable way to determine which signal caused the termination. Also, it is possible for a command to exit with a status in the same range of numbers that the shell would use to report that the command was terminated by a signal. Implementations are encouraged to choose exit values greater than 256 to indicate programs that terminate by a signal so that the exit status cannot be confused with an exit status generated by a normal termination.

Historical shells make the distinction between ‘‘utility not found’’ and ‘‘utility found but cannot execute’’ in their error messages. By specifying two seldomly used exit status values for these cases, 127 and 126 respectively, this gives an application the opportunity to make use of this distinction without having to parse an error message that would probably change from locale to locale. The *command*, *env*, *nohup*, and *xargs* utilities in the Shell and Utilities volume of IEEE Std 1003.1-200x have also been specified to use this convention.

When a command fails during word expansion or redirection, most historical implementations exit with a status of 1. However, there was some sentiment that this value should probably be much higher so that an application could distinguish this case from the more normal exit status values. Thus, the language ‘‘greater than zero’’ was selected to allow either method to be implemented.

C.2.9 Shell Commands

A description of an ‘‘empty command’’ was removed from an early proposal because it is only relevant in the cases of *sh* −**c** `""`, *system*(`""`), or an empty shell-script file (such as the implementation of *true* on some historical systems). Since it is no longer mentioned in the Shell and Utilities volume of IEEE Std 1003.1-200x, it falls into the silently unspecified category of behavior where implementations can continue to operate as they have historically, but conforming applications do not construct empty commands. (However, note that *sh* does explicitly state an exit status for an empty string or file.) In an interactive session or a script with other commands, extra <newline>s or semicolons, such as;

```
$ false
$
$ echo $?
1
```

would not qualify as the empty command described here because they would be consumed by other parts of the grammar.

C.2.9.1 Simple Commands

The enumerated list is used only when the command is actually going to be executed. For example, in:

```
true || $foo *
```

no expansions are performed.

The following example illustrates both how a variable assignment without a command name affects the current execution environment, and how an assignment with a command name only affects the execution environment of the command:

```
$ x=red
$ echo $x
red
$ export x
$ sh −c ’echo $x’
red
$ x=blue sh −c ’echo $x’
blue
$ echo $x
red
```

This next example illustrates that redirections without a command name are still performed:

```
$ ls foo
ls: foo: no such file or directory
$ > foo
$ ls foo
foo
```

A command without a command name, but one that includes a command substitution, has an exit status of the last command substitution that the shell performed. For example:

```
if      x=$(command)
then    ...
fi
```

An example of redirections without a command name being performed in a subshell shows that the here-document does not disrupt the standard input of the **while** loop:

```
IFS=:
while    read a b
do       echo $a
         <<−eof
         Hello
         eof
done </etc/passwd
```

Some examples of commands without command names in AND-OR lists:

```
> foo || {
    echo "error: foo cannot be created" >&2
    exit 1
}

# set saved if /vmunix.save exists
test −f /vmunix.save && saved=1
```

Command substitution and redirections without command names both occur in subshells, but they are not necessarily the same ones. For example, in:

```
exec 3> file
var=$(echo foo >&3) 3>&1
```

it is unspecified whether **foo** is echoed to the file or to standard output.

Command Search and Execution

This description requires that the shell can execute shell scripts directly, even if the underlying system does not support the common `"#!"` interpreter convention. That is, if file **foo** contains shell commands and is executable, the following executes **foo**:

```
./foo
```

The command search shown here does not match all historical implementations. A more typical sequence has been:

- Any built-in (special or regular)
- Functions
- Path search for executable files

But there are problems with this sequence. Since the programmer has no idea in advance which utilities might have been built into the shell, a function cannot be used to override portably a utility of the same name. (For example, a function named *cd* cannot be written for many historical systems.) Furthermore, the *PATH* variable is partially ineffective in this case, and only a pathname with a slash can be used to ensure a specific executable file is invoked.

After the *execve*( ) failure described, the shell normally executes the file as a shell script. Some implementations, however, attempt to detect whether the file is actually a script and not an executable from some other architecture. The method used by the KornShell is allowed by the text that indicates non-text files may be bypassed.

The sequence selected for the Shell and Utilities volume of IEEE Std 1003.1-200x acknowledges that special built-ins cannot be overridden, but gives the programmer full control over which versions of other utilities are executed. It provides a means of suppressing function lookup (via the *command* utility) for the user's own functions and ensures that any regular built-ins or functions provided by the implementation are under the control of the path search. The mechanisms for associating built-ins or functions with executable files in the path are not specified by the Shell and Utilities volume of IEEE Std 1003.1-200x, but the wording requires that if either is implemented, the application is not able to distinguish a function or built-in from an executable (other than in terms of performance, presumably). The implementation ensures that all effects specified by the Shell and Utilities volume of IEEE Std 1003.1-200x resulting from the invocation of the regular built-in or function (interaction with the environment, variables, traps, and so on) are identical to those resulting from the invocation of an executable file.

Examples

Consider three versions of the *ls* utility:

1. The application includes a shell function named *ls*.
2. The user writes a utility named *ls* and puts it in **/fred/bin**.
3. The example implementation provides *ls* as a regular shell built-in that is invoked (either by the shell or directly by *exec*) when the path search reaches the directory **/posix/bin**.

If *PATH*=**/posix/bin**, various invocations yield different versions of *ls*:

Invocation	**Version of *ls***
ls (from within application script)	(1) function
command ls (from within application script)	(3) built-in
ls (from within makefile called by application)	(3) built-in
system("*ls*")	(3) built-in
PATH="**/fred/bin**:$*PATH*" *ls*	(2) user's version

C.2.9.2 Pipelines

Because pipeline assignment of standard input or standard output or both takes place before redirection, it can be modified by redirection. For example:

```
$ command1 2>&1 | command2
```

sends both the standard output and standard error of *command1* to the standard input of *command2*.

The reserved word **!** allows more flexible testing using AND and OR lists.

It was suggested that it would be better to return a non-zero value if any command in the pipeline terminates with non-zero status (perhaps the bitwise-inclusive OR of all return values). However, the choice of the last-specified command semantics are historical practice and would cause applications to break if changed. An example of historical behavior:

```
$ sleep 5 | (exit 4)
$ echo $?
4
$ (exit 4) | sleep 5
$ echo $?
0
```

C.2.9.3 Lists

The equal precedence of "&&" and "||" is historical practice. The standard developers evaluated the model used more frequently in high-level programming languages, such as C, to allow the shell logical operators to be used for complex expressions in an unambiguous way, but they could not allow historical scripts to break in the subtle way unequal precedence might cause. Some arguments were posed concerning the "{}" or "()" groupings that are required historically. There are some disadvantages to these groupings:

- The "()" can be expensive, as they spawn other processes on some implementations. This performance concern is primarily an implementation issue.
- The "{}" braces are not operators (they are reserved words) and require a trailing space after each '{', and a semicolon before each '}'. Most programmers (and certainly interactive users) have avoided braces as grouping constructs because of the problematic syntax required. Braces were not changed to operators because that would generate compatibility issues even greater than the precedence question; braces appear outside the context of a keyword in many shell scripts.

IEEE PASC Interpretation 1003.2 #204 is applied, clarifying that the operators "&&" and "||" are evaluated with left associativity.

Asynchronous Lists

The grammar treats a construct such as:

```
foo & bar & bam &
```

as one ‘‘asynchronous list’’, but since the status of each element is tracked by the shell, the term ‘‘element of an asynchronous list’’ was introduced to identify just one of the **foo**, **bar**, or **bam** portions of the overall list.

Unless the implementation has an internal limit, such as {CHILD_MAX}, on the retained process IDs, it would require unbounded memory for the following example:

```
while true
do      foo & echo $!
done
```

The treatment of the signals SIGINT and SIGQUIT with asynchronous lists is described in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.11, Signals and Error Handling.

Since the connection of the input to the equivalent of **/dev/null** is considered to occur before redirections, the following script would produce no output:

```
exec < /etc/passwd
cat <&0 &
wait
```

Sequential Lists

There is no additional rationale provided for this section.

AND Lists

There is no additional rationale provided for this section.

OR Lists

There is no additional rationale provided for this section.

C.2.9.4 *Compound Commands*

Grouping Commands

The semicolon shown in {*compound-list*;} is an example of a control operator delimiting the **}** reserved word. Other delimiters are possible, as shown in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.10, Shell Grammar; <newline> is frequently used.

A proposal was made to use the **<do-done>** construct in all cases where command grouping in the current process environment is performed, identifying it as a construct for the grouping commands, as well as for shell functions. This was not included because the shell already has a grouping construct for this purpose (`"{}"`), and changing it would have been counter-productive.

For Loop

The format is shown with generous usage of <newline>s. See the grammar in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.10, Shell Grammar for a precise description of where <newline>s and semicolons can be interchanged.

Some historical implementations support `'{'` and `'}'` as substitutes for **do** and **done**. The standard developers chose to omit them, even as an obsolescent feature. (Note that these substitutes were only for the **for** command; the **while** and **until** commands could not use them historically because they are followed by compound-lists that may contain `"{...}"` grouping commands themselves.)

The reserved word pair **do** ... **done** was selected rather than **do** ... **od** (which would have matched the spirit of **if** ... **fi** and **case** ... **esac**) because *od* is already the name of a standard utility.

PASC Interpretation 1003.2 #169 has been applied changing the grammar.

Case Conditional Construct

An optional left parenthesis before *pattern* was added to allow numerous historical KornShell scripts to conform. At one time, using the leading parenthesis was required if the **case** statement was to be embedded within a `"$()"` command substitution; this is no longer the case with the POSIX shell. Nevertheless, many historical scripts use the left parenthesis, if only because it makes matching-parenthesis searching easier in *vi* and other editors. This is a relatively simple implementation change that is upward-compatible for all scripts.

Consideration was given to requiring *break* inside the *compound-list* to prevent falling through to the next pattern action list. This was rejected as being nonexisting practice. An interesting undocumented feature of the KornShell is that using `";&"` instead of `";;"` as a terminator causes the exact opposite behavior—the flow of control continues with the next *compound-list*.

The pattern `'*'`, given as the last pattern in a **case** construct, is equivalent to the default case in a C-language **switch** statement.

The grammar shows that reserved words can be used as patterns, even if one is the first word on a line. Obviously, the reserved word **esac** cannot be used in this manner.

If Conditional Construct

The precise format for the command syntax is described in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.10, Shell Grammar.

While Loop

The precise format for the command syntax is described in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.10, Shell Grammar.

Until Loop

The precise format for the command syntax is described in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.10, Shell Grammar.

C.2.9.5 Function Definition Command

The description of functions in an early proposal was based on the notion that functions should behave like miniature shell scripts; that is, except for sharing variables, most elements of an execution environment should behave as if they were a new execution environment, and changes to these should be local to the function. For example, traps and options should be reset on entry to the function, and any changes to them do not affect the traps or options of the caller. There were numerous objections to this basic idea, and the opponents asserted that functions were intended to be a convenient mechanism for grouping common commands that were to be executed in the current execution environment, similar to the execution of the *dot* special built-in.

It was also pointed out that the functions described in that early proposal did not provide a local scope for everything a new shell script would, such as the current working directory, or *umask*, but instead provided a local scope for only a few select properties. The basic argument was that if a local scope is needed for the execution environment, the mechanism already existed: the application can put the commands in a new shell script and call that script. All historical shells that implemented functions, other than the KornShell, have implemented functions that operate in the current execution environment. Because of this, traps and options have a global scope within a shell script. Local variables within a function were considered and included in another early proposal (controlled by the special built-in *local*), but were removed because they do not fit the simple model developed for functions and because there was some opposition to adding yet another new special built-in that was not part of historical practice. Implementations should reserve the identifier *local* (as well as *typeset*, as used in the KornShell) in case this local variable mechanism is adopted in a future version of IEEE Std 1003.1-200x.

A separate issue from the execution environment of a function is the availability of that function to child shells. A few objectors maintained that just as a variable can be shared with child shells by exporting it, so should a function. In early proposals, the *export* command therefore had a **–f** flag for exporting functions. Functions that were exported were to be put into the environment as *name*( )=*value* pairs, and upon invocation, the shell would scan the environment for these and automatically define these functions. This facility was strongly opposed and was omitted. Some of the arguments against exportable functions were as follows:

- There was little historical practice. The Ninth Edition shell provided them, but there was controversy over how well it worked.

- There are numerous security problems associated with functions appearing in the environment of a user and overriding standard utilities or the utilities owned by the application.
- There was controversy over requiring *make* to import functions, where it has historically used an *exec* function for many of its command line executions.
- Functions can be big and the environment is of a limited size. (The counter-argument was that functions are no different from variables in terms of size: there can be big ones, and there can be small ones—and just as one does not export huge variables, one does not export huge functions. However, this might not apply to the average shell-function writer, who typically writes much larger functions than variables.)

As far as can be determined, the functions in the Shell and Utilities volume of IEEE Std 1003.1-200x match those in System V. Earlier versions of the KornShell had two methods of defining functions:

```
function fname { compound-list }
```

and:

```
fname() { compound-list }
```

The latter used the same definition as the Shell and Utilities volume of IEEE Std 1003.1-200x, but differed in semantics, as described previously. The current edition of the KornShell aligns the latter syntax with the Shell and Utilities volume of IEEE Std 1003.1-200x and keeps the former as is.

The name space for functions is limited to that of a *name* because of historical practice. Complications in defining the syntactic rules for the function definition command and in dealing with known extensions such as the `"@()"` usage in the KornShell prevented the name space from being widened to a *word*. Using functions to support synonyms such as the `"!!"` and `'%'` usage in the C shell is thus disallowed to conforming applications, but acceptable as an extension. For interactive users, the aliasing facilities in the Shell and Utilities volume of IEEE Std 1003.1-200x should be adequate for this purpose. It is recognized that the name space for utilities in the file system is wider than that currently supported for functions, if the portable filename character set guidelines are ignored, but it did not seem useful to mandate extensions in systems for so little benefit to conforming applications.

The `"()"` in the function definition command consists of two operators. Therefore, intermixing <blank>s with the *fname*, `'('`, and `')'` is allowed, but unnecessary.

An example of how a function definition can be used wherever a simple command is allowed:

```
# If variable i is equal to "yes",
# define function foo to be ls -l
#
[ "$i" = yes ] && foo() {
    ls -l
}
```

C.2.10 Shell Grammar

There are several subtle aspects of this grammar where conventional usage implies rules about the grammar that in fact are not true.

For *compound_list*, only the forms that end in a *separator* allow a reserved word to be recognized, so usually only a *separator* can be used where a compound list precedes a reserved word (such as **Then**, **Else**, **Do** and **Rbrace**). Explicitly requiring a separator would disallow such valid (if rare) statements as:

```
if (false) then (echo x) else (echo y) fi
```

See the Note under special grammar rule 1.

Concerning the third sentence of rule (1) (''Also, if the parser ...''):

- This sentence applies rather narrowly: when a compound list is terminated by some clear delimiter (such as the closing **fi** of an inner **if_clause**) then it would apply; where the compound list might continue (as in after a `';'`), rule (7a) (and consequently the first sentence of rule (1)) would apply. In many instances the two conditions are identical, but this part of rule (1) does not give license to treating a **WORD** as a reserved word unless it is in a place where a reserved word has to appear.
- The statement is equivalent to requiring that when the LR(1) lookahead set contains exactly one reserved word, it must be recognized if it is present. (Here ''LR(1)'' refers to the theoretical concepts, not to any real parser generator.)

  For example, in the construct below, and when the parser is at the point marked with `'^'`, the only next legal token is **then** (this follows directly from the grammar rules):

  ```
  if if...fi then ... fi
             ^
  ```

  At that point, the **then** must be recognized as a reserved word.

  (Depending on the parser generator actually used, ''extra'' reserved words may be in some lookahead sets. It does not really matter if they are recognized, or even if any possible reserved word is recognized in that state, because if it is recognized and is not in the (theoretical) LR(1) lookahead set, an error is ultimately detected. In the example above, if some other reserved word (for example, **while**) is also recognized, an error occurs later.

  This is approximately equivalent to saying that reserved words are recognized after other reserved words (because it is after a reserved word that this condition occurs), but avoids the ''except for ...'' list that would be required for **case**, **for**, and so on. (Reserved words are of course recognized anywhere a *simple_command* can appear, as well. Other rules take care of the special cases of non-recognition, such as rule (4) for **case** statements.)

Note that the body of here-documents are handled by token recognition (see the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.3, Token Recognition) and do not appear in the grammar directly. (However, the here-document I/O redirection operator is handled as part of the grammar.)

The start symbol of the grammar (**complete_command**) represents either input from the command line or a shell script. It is repeatedly applied by the interpreter to its input and represents a single ''chunk'' of that input as seen by the interpreter.

C.2.10.1 *Shell Grammar Lexical Conventions*

There is no additional rationale provided for this section.

C.2.10.2 *Shell Grammar Rules*

There is no additional rationale provided for this section.

C.2.11 Signals and Error Handling

There is no additional rationale provided for this section.

C.2.12 Shell Execution Environment

Some implementations have implemented the last stage of a pipeline in the current environment so that commands such as:

```
command | read foo
```

set variable **foo** in the current environment. This extension is allowed, but not required; therefore, a shell programmer should consider a pipeline to be in a subshell environment, but not depend on it.

In early proposals, the description of execution environment failed to mention that each command in a multiple command pipeline could be in a subshell execution environment. For compatibility with some historical shells, the wording was phrased to allow an implementation to place any or all commands of a pipeline in the current environment. However, this means that a POSIX application must assume each command is in a subshell environment, but not depend on it.

The wording about shell scripts is meant to convey the fact that describing ‘‘trap actions’’ can only be understood in the context of the shell command language. Outside of this context, such as in a C-language program, signals are the operative condition, not traps.

C.2.13 Pattern Matching Notation

Pattern matching is a simpler concept and has a simpler syntax than REs, as the former is generally used for the manipulation of filenames, which are relatively simple collections of characters, while the latter is generally used to manipulate arbitrary text strings of potentially greater complexity. However, some of the basic concepts are the same, so this section points liberally to the detailed descriptions in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 9, Regular Expressions.

C.2.13.1 *Patterns Matching a Single Character*

Both quoting and escaping are described here because pattern matching must work in three separate circumstances:

1. Calling directly upon the shell, such as in pathname expansion or in a **case** statement. All of the following match the string or file **abc**:

   ```
   abc "abc" a"b"c a\bc a[b]c a["b"]c a[\b]c a["\b"]c a?c a*c
   ```

   The following do not:

   ```
   "a?c" a\*c a\[b]c
   ```

2. Calling a utility or function without going through a shell, as described for *find* and the *fnmatch*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x.

3. Calling utilities such as *find*, *cpio*, *tar*, or *pax* through the shell command line. In this case, shell quote removal is performed before the utility sees the argument. For example, in:

   ```
   find /bin −name "e\c[\h]o" −print
   ```

   after quote removal, the backslashes are presented to *find* and it treats them as escape characters. Both precede ordinary characters, so the *c* and *h* represent themselves and *echo* would be found on many historical systems (that have it in **/bin**). To find a filename that contained shell special characters or pattern characters, both quoting and escaping are required, such as:

   ```
   pax −r ... "*a\(\?"
   ```

   to extract a filename ending with `"a(?"`.

Conforming applications are required to quote or escape the shell special characters (sometimes called metacharacters). If used without this protection, syntax errors can result or implementation extensions can be triggered. For example, the KornShell supports a series of extensions based on parentheses in patterns.

The restriction on a circumflex in a bracket expression is to allow implementations that support pattern matching using the circumflex as the negation character in addition to the exclamation mark. A conforming application must use something like `"[\^!]"` to match either character.

C.2.13.2 Patterns Matching Multiple Characters

Since each asterisk matches zero or more occurrences, the patterns `"a*b"` and `"a**b"` have identical functionality.

Examples

`a[bc]`	Matches the strings `"ab"` and `"ac"`.
`a*d`	Matches the strings `"ad"`, `"abd"`, and `"abcd"`, but not the string `"abc"`.
`a*d*`	Matches the strings `"ad"`, `"abcd"`, `"abcdef"`, `"aaaad"`, and `"adddd"`.
`*a*d`	Matches the strings `"ad"`, `"abcd"`, `"efabcd"`, `"aaaad"`, and `"adddd"`.

C.2.13.3 Patterns Used for Filename Expansion

The caveat about a slash within a bracket expression is derived from historical practice. The pattern `"a[b/c]d"` does not match such pathnames as **abd** or **a/d**. On some implementations (including those conforming to the Single UNIX Specification), it matched a pathname of literally `"a[b/c]d"`. On other systems, it produced an undefined condition (an unescaped `'['` used outside a bracket expression). In this version, the XSI behavior is now required.

Filenames beginning with a period historically have been specially protected from view on UNIX systems. A proposal to allow an explicit period in a bracket expression to match a leading period was considered; it is allowed as an implementation extension, but a conforming application cannot make use of it. If this extension becomes popular in the future, it will be considered for a future version of the Shell and Utilities volume of IEEE Std 1003.1-200x.

Historical systems have varied in their permissions requirements. To match **f*/bar** has required read permissions on the **f*** directories in the System V shell, but the Shell and Utilities volume of IEEE Std 1003.1-200x, the C shell, and KornShell require only search permissions.

C.2.14 Special Built-In Utilities

See the RATIONALE sections on the individual reference pages.

C.3 Batch Environment Services and Utilities

Scope of the Batch Environment Option

This section summarizes the deliberations of the IEEE P1003.15 (Batch Environment) working group in the development of the Batch Environment option, which covers a set of services and utilities defining a batch processing system.

This informative section contains historical information concerning the contents of the amendment and describes why features were included or discarded by the working group.

History of Batch Systems

The supercomputing technical committee began as a ‘‘Birds Of a Feather’’ (BOF) at the January 1987 Usenix meeting. There was enough general interest to form a supercomputing attachment to the /usr/group working groups. Several subgroups rapidly formed. Of those subgroups, the batch group was the most ambitious. The first early meetings were spent evaluating user needs and existing batch implementations.

To evaluate user needs, individuals from the supercomputing community came and presented their needs. Common requests were flexibility, interoperability, control of resources, and ease-of-use. Backwards-compatibility was not an issue. The working group then evaluated some existing systems. The following different systems were evaluated:

- PROD
- Convex Distributed Batch
- NQS
- CTSS
- MDQS from Ballistics Research Laboratory (BRL)

Finally, NQS was chosen as a model because it satisfied not only the most user requirements, but because it was public domain, already implemented on a variety of hardware platforms, and networked-based.

Historical Implementations of Batch Systems

Deferred processing of work under the control of a scheduler has been a feature of most proprietary operating systems from the earliest days of multi-user systems in order to maximize utilization of the computer.

The arrival of UNIX systems proved to be a dilemma to many hardware providers and users because it did not include the sophisticated batch facilities offered by the proprietary systems. This omission was rectified in 1986 by NASA Ames Research Center who developed the Network Queuing System (NQS) as a portable UNIX application that allowed the routing and processing of batch ‘‘jobs’’ in a network. To encourage its usage, the product was later put into the public domain. It was promptly picked up by UNIX hardware providers, and ported and developed for their respective hardware and UNIX implementations.

Many major vendors, who traditionally offer a batch-dominated environment, ported the public-domain product to their systems, customized it to support the capabilities of their systems, and added many customer-requested features.

Due to the strong hardware provider and customer acceptance of NQS, it was decided to use NQS as the basis for the POSIX Batch Environment amendment in 1987. Other batch systems considered at the time included CTSS, MDQS (a forerunner of NQS from the Ballistics Research Laboratory), and PROD (a Los Alamos Labs development). None were thought to have both the functionality and acceptability of NQS.

NQS Differences from the at utility

The base standard *at* and *batch* utilities are not sufficient to meet the batch processing needs in a supercomputing environment and additional functionality in the areas of resource management, job scheduling, system management, and control of output is required.

Batch Environment Option Definitions

The concept of a batch job is closely related to a session with a session leader. The main difference is that a batch job does not have a controlling terminal. There has been much debate over whether to use the term *request* or *job*. Job was the final choice because of the historical use of this term in the batch environment.

The current definition for job identifiers is not sufficient with the model of destinations. The current definition is:

```
sequence_number.originating_host
```

Using the model of destination, a host may include multiple batch nodes, the location of which is identified uniquely by a name or directory service. If the current definition is used, batch nodes running on the same host would have to coordinate their use of sequence numbers, as sequence numbers are assigned by the originating host. The alternative is to use the originating batch node name instead of the originating host name.

The reasons for wishing to run more than one batch system per host could be the following:

A test and production batch system are maintained on a single host. This is most likely in a development facility, but could also arise when a site is moving from one version to another. The new batch system could be installed as a test version that is completely separate from the production batch system, so that problems can be isolated to the test system. Requiring the batch nodes to coordinate their use of sequence numbers creates a dependency between the two nodes, and that defeats the purpose of running two nodes.

A site has multiple departments using a single host, with different management policies. An example of contention might be in job selection algorithms. One group might want a FIFO type of selection, while another group wishes to use a more complex algorithm based on resource availability. Again, requiring the batch nodes to coordinate is an unnecessary binding.

The proposal eventually accepted was to replace originating host with originating batch node. This supplies sufficient granularity to ensure unique job identifiers. If more than one batch node is on a particular host, they each have their own unique name.

The queue portion of a destination is not part of the job identifier as these are not required to be unique between batch nodes. For instance, two batch nodes may both have queues called small, medium, and large. It is only the batch node name that is uniquely identifiable throughout the batch system. The queue name has no additional function in this context.

Assume there are three batch nodes, each of which has its own name server. On batch node one, there are no queues. On batch node two, there are fifty queues. On batch node three, there are forty queues. The system administrator for batch node one does not have to configure queues, because there are none implemented. However, if a user wishes to send a job to either batch node two or three, the system administrator for batch node one must configure a destination that maps to the appropriate batch node and queue. If every queue is to be made accessible from batch node one, the system administrator has to configure ninety destinations.

To avoid requiring this, there should be a mechanism to allow a user to separate the destination into a batch node name and a queue name. Then, an implementation that is configured to get to all the batch nodes does not need any more configuration to allow a user to get to all of the queues on all of the batch nodes. The node name is used to locate the batch node, while the queue name is sent unchanged to that batch node.

The following are requirements that a destination identifier must be capable of providing:

- The ability to direct a job to a queue in a particular batch node.
- The ability to direct a job to a particular batch node.
- The ability to group at a higher level than just one queue. This includes grouping similar queues across multiple batch nodes (this is a pipe queue today).
- The ability to group batch nodes. This allows a user to submit a job to a group name with no knowledge of the batch node configuration. This also provides aliasing as a special case. Aliasing is a group containing only one batch node name. The group name is the alias.

In addition, the administrator has the following requirements:

- The ability to control access to the queues.
- The ability to control access to the batch nodes.
- The ability to control access to groups of queues (pipe queues).
- The ability to configure retry time intervals and durations.

The requirements of the user are met by destination as explained in the following:

The user has the ability to specify a queue name, which is known only to the batch node specified. There is no configuration of these queues required on the submitting node.

The user has the ability to specify a batch node whose name is network-unique. The configuration required is that the batch node be defined as an application, just as other applications such as FTP are configured.

Once a job reaches a queue, it can again become a user of the batch system. The batch node can choose to send the job to another batch node or queue or both. In other words, the routing is at an application level, and it is up to the batch system to choose where the job will be sent. Configuration is up to the batch node where the queue resides. This provides grouping of queues across batch nodes or within a batch node. The user submits the job to a queue, which by definition routes the job to other queues or nodes or both.

A node name may be given to a naming service, which returns multiple addresses as opposed to just one. This provides grouping at a batch node level. This is a local issue, meaning that the batch node must choose only one of these addresses. The list of addresses is not sent with the job, and once the job is accepted on another node, there is no connection between the list and the job. The requirements of the administrator are met by destination as explained in the following:

The control of queues is a batch system issue, and will be done using the batch administrative utilities.

The control of nodes is a network issue, and will be done through whatever network facilities are available.

The control of access to groups of queues (pipe queues) is covered by the control of any other queue. The fact that the job may then be sent to another destination is not relevant.

The propagation of a job across more than one point-to-point connection was dropped because of its complexity and because all of the issues arising from this capability could not be resolved. It could be provided as additional functionality at some time in the future.

The addition of *network* as a defined term was done to clarify the difference between a network of batch nodes as opposed to a network of hosts. A network of batch nodes is referred to as a batch system. The network refers to the actual host configuration. A single host may have multiple batch nodes.

In the absence of a standard network naming convention, this option establishes its own convention for the sake of consistency and expediency. This is subject to change, should a future working group develop a standard naming convention for network pathnames.

C.3.1 Batch General Concepts

During the development of the Batch Environment option, a number of topics were discussed at length which influenced the wording of the normative text but could not be included in the final text. The following items are some of the most significant terms and concepts of those discussed:

- Small and Consistent Command Set

  Often, conventional utilities from UNIX systems have a very complicated utility syntax and usage. This can often result in confusion and errors when trying to use them. The Batch Environment option utility set, on the other hand, has been paired to a small set of robust utilities with an orthogonal calling sequence.

- Checkpoint/Restart

  This feature permits an already executing process to checkpoint or save its contents. Some implementations permit this at both the batch utility level; for example, checkpointing this job upon its abnormal termination or from within the job itself via a system call. Support of checkpoint/restart is optional. A conscious, careful effort was made to make the *qsub* and *qmgr* utilities consistently refer to checkpoint/restart as optional functionality.

- Rerunability

  When a user submits a job for batch processing, they can designate it ''rerunnable'' in that it will automatically resume execution from the start of the job if the machine on which it was executing crashes for some reason. The decision on whether the job will be rerun or not is entirely up to the submitter of the job and no decisions will be made within the batch system. A job that is rerunnable and has been submitted with the proper checkpoint/restart switch will first be checkpointed and execution begun from that point. Furthermore, use of the implementation-defined checkpoint/restart feature will be not be defined in this context.

- Error Codes

  All utilities exit with error status zero (0) if successful, one (1) if a user error occurred, and two (2) for an internal Batch Environment option error.

- Level of Portability

  Portability is specified at both the user, operator, and administrator levels. A conforming batch implementation prevents identical functionality and behavior at all these levels. Additionally, portable batch shell scripts with embedded Batch Environment option utilities adds an additional level of portability.

- Resource Specification

  A small set of globally understood resources, such as memory and CPU time, is specified. All conforming batch implementations are able to process them in a manner consistent with the yet-to-be-developed resource management model. Resources not in this amendment set are ignored and passed along as part of the argument stream of the utility.

- Queue Position

  Queue position is the place a job occupies in a queue. It is dependent on a variety of factors such as submission time and priority. Since priority may be affected by the implementation of fair share scheduling, the definition of queue position is implementation-defined.

- Queue ID

  A numerical queue ID is an external requirement for purposes of accounting. The identification number was chosen over queue name for processing convenience.

- Job ID

  A common notion of ‘‘jobs’’ is a collection of processes whose process group cannot be altered and is used for resource management and accounting. This concept is implementation-defined and, as such, has been omitted from the batch amendment.

- Bytes *versus* Words

  Except for one case, bytes are used as the standard unit for memory size. Furthermore, the definition of a word varies from machine to machine. Therefore, bytes will be the default unit of memory size.

- Regular Expressions

  The standard definition of regular expressions is much too broad to be used in the batch utility syntax. All that is needed is a simple concept of ‘‘all’’; for example, delete all my jobs from the named queue. For this reason, regular expressions have been eliminated from the batch amendment.

- Display Privacy

  How much data should be displayed locally through functions? Local policy dictates the amount of privacy. Library functions must be used to create and enforce local policy. Network and local *qstat*s must reflect the policy of the server machine.

- Remote Host Naming Convention

  It was decided that host names would be a maximum of 255 characters in length, with at most 15 characters being shown in displays. The 255 character limit was chosen because it is consistent with BSD. The 15-character limit was an arbitrary decision.

- Network Administration

  Network administration is important, but is outside the scope of the batch amendment. Network administration could done with *rsh*. However, authentication becomes two-sided.

- Network Administration Philosophy

  Keep it simple. Centralized management should be possible. For example, Los Alamos needs a dumb set of CPUs to be managed by a central system *versus* several independently-managed systems as is the general case for the Batch Environment option.

- Operator Utility Defaults (that is, Default Host, User, Account, and so on)

  It was decided that usability would override orthogonality and syntactic consistency.

- The Batch System Manager and Operator Distinction

  The distinction between manager and operator is that operators can only control the flow of jobs. A manager can alter the batch system configuration in addition to job flow. POSIX makes a distinction between user and system administrator but goes no further. The concepts of manager and operator privileges fall under local policy. The distinction between manager and operator is historical in batch environments, and the Batch Environment option has continued that distinction.

- The Batch System Administrator

  An administrator is equivalent to a batch system manager.

C.3.2 Batch Services

This rationale is provided as informative rather than normative text, to avoid placing requirements on implementors regarding the use of symbolic constants, but at the same time to give implementors a preferred practice for assigning values to these constants to promote interoperability.

The *Checkpoint* and *Minimum_Cpu_Interval* attributes induce a variety of behavior depending upon their values. Some jobs cannot or should not be checkpointed. Other users will simply need to ensure job continuation across planned downtimes; for example, scheduled preventive maintenance. For users consuming expensive resources, or for jobs that run longer than the mean time between failures, however, periodic checkpointing may be essential. However, system administrators must be able to set minimum checkpoint intervals on a queue-by-queue basis to guard against; for example, naive users specifying interval values too small on memory intensive jobs. Otherwise, system overhead would adversely affect performance.

The use of symbolic constants, such as NO_CHECKPOINT, was introduced to lend a degree of formalism and portability to this option.

Support for checkpointing is optional for servers. However, clients must provide for the −**c** option, since in a distributed environment the job may run on a server that does provide such support, even if the host of the client does not support the checkpoint feature.

If the user does not specify the −**c** option, the default action is left unspecified by this option. Some implementations may wish to do checkpointing by default; others may wish to checkpoint only under an explicit request from the user.

The *Priority* attribute has been made non-optional. All clients already had been required to support the −**p** option. The concept of prioritization is common in historical implementations. The default priority is left to the server to establish.

The *Hold_Types* attribute has been modified to allow for implementation-defined hold types to be passed to a batch server.

It was the intent of the IEEE P1003.15 working group to mandate the support for the *Resource_List* attribute in this option by referring to another amendment, specifically P1003.1a. However, during the development of P1003.1a this was excluded. As such this requirement has been removed from the normative text.

The *Shell_Path* attribute has been modified to accept a list of shell paths that are associated with a host. The name of the attribute has been changed to *Shell_Path_List*.

C.3.3 Common Behavior for Batch Environment Utilities

This section was defined to meet the goal of a ‘‘Small and Consistent Command Set’’ for this option.

C.4 Utilities

For the utilities included in IEEE Std 1003.1-200x, see the RATIONALE sections on the individual reference pages.

Exclusion of Utilities

The set of utilities contained in IEEE Std 1003.1-200x is drawn from the base documents, with one addition: the *c99* utility. This section contains rationale for some of the deliberations that led to this set of utilities, and why certain utilities were excluded.

Many utilities were evaluated by the standard developers; more historical utilities were excluded from the base documents than included. The following list contains many common UNIX system utilities that were not included as mandatory utilities, in the UPE, in the XSI extension, or in one of the software development groups. It is logistically difficult for this rationale to distribute correctly the reasons for not including a utility among the various utility options. Therefore, this section covers the reasons for all utilities not included in IEEE Std 1003.1-200x.

This rationale is limited to a discussion of only those utilities actively or indirectly evaluated by the standard developers of the base documents, rather than the list of all known UNIX utilities from all its variants.

adb	The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool. Furthermore, many useful aspects of *adb* are very hardware-specific.
as	Assemblers are hardware-specific and are included implicitly as part of the compilers in IEEE Std 1003.1-200x.
banner	The only known use of this command is as part of the *lp* printer header pages. It was decided that the format of the header is implementation-defined, so this utility is superfluous to application portability.
calendar	This reminder service program is not useful to conforming applications.
cancel	The *lp* (line printer spooling) system specified is the most basic possible and did not need this level of application control.
chroot	This is primarily of administrative use, requiring superuser privileges.
col	No utilities defined in IEEE Std 1003.1-200x produce output requiring such a filter. The *nroff* text formatter is present on many historical systems and will continue to remain as an extension; *col* is expected to be shipped by all the systems that ship *nroff*.
cpio	This has been replaced by *pax*, for reasons explained in the rationale for that utility.
cpp	This is subsumed by *c99*.
cu	This utility is terminal-oriented and is not useful from shell scripts or typical application programs.

dc	The functionality of this utility can be provided by the *bc* utility; *bc* was selected because it was easier to use and had superior functionality. Although the historical versions of *bc* are implemented using *dc* as a base, IEEE Std 1003.1-200x prescribes the interface and not the underlying mechanism used to implement it.
dircmp	Although a useful concept, the historical output of this directory comparison program is not suitable for processing in application programs. Also, the *diff* **−r** command gives equivalent functionality.
dis	Disassemblers are hardware-specific.
emacs	The community of *emacs* editing enthusiasts was adamant that the full *emacs* editor not be included in the base documents because they were concerned that an attempt to standardize this very powerful environment would encourage vendors to ship versions conforming strictly to the standard, but lacking the extensibility required by the community. The author of the original *emacs* program also expressed his desire to omit the program. Furthermore, there were a number of historical UNIX systems that did not include *emacs*, or included it without supporting it, but there were very few that did not include and support *vi*.
ld	This is subsumed by *c99*.
line	The functionality of *line* can be provided with *read*.
lint	This technology is partially subsumed by *c99*. It is also hard to specify the degree of checking for possible error conditions in programs in any compiler, and specifying what *lint* would do in these cases is equally difficult. It is fairly easy to specify what a compiler does. It requires specifying the language, what it does with that language, and stating that the interpretation of any incorrect program is unspecified. Unfortunately, any description of *lint* is required to specify what to do with erroneous programs. Since the number of possible errors and questionable programming practices is infinite, one cannot require *lint* to detect all errors of any given class. Additionally, some vendors complained that since many compilers are distributed in a binary form without a *lint* facility (because the ISO C standard does not require one), implementing the standard as a stand-alone product will be much harder. Rather than being able to build upon a standard compiler component (simply by providing *c99* as an interface), source to that compiler would most likely need to be modified to provide the *lint* functionality. This was considered a major burden on system providers for a very small gain to developers (users).
login	This utility is terminal-oriented and is not useful from shell scripts or typical application programs.
lorder	This utility is an aid in creating an implementation-defined detail of object libraries that the standard developers did not feel required standardization.
lpstat	The *lp* system specified is the most basic possible and did not need this level of application control.
mail	This utility was omitted in favor of *mailx* because there was a considerable functionality overlap between the two.
mknod	This was omitted in favor of *mkfifo*, as *mknod* has too many implementation-defined functions.

news	This utility is terminal-oriented and is not useful from shell scripts or typical application programs.
pack	This compression program was considered inferior to *compress*.
passwd	This utility was proposed in a historical draft of the base documents but met with too many objections to be included. There were various reasons: • Changing a password should not be viewed as a command, but as part of the login sequence. Changing a password should only be done while a trusted path is in effect. • Even though the text in early drafts was intended to allow a variety of implementations to conform, the security policy for one site may differ from another site running with identical hardware and software. One site might use password authentication while the other did not. Vendors could not supply a *passwd* utility that would conform to IEEE Std 1003.1-200x for all sites using their system. • This is really a subject for a system administration working group or a security working group.
pcat	This compression program was considered inferior to *zcat*.
pg	This duplicated many of the features of the *more* pager, which was preferred by the standard developers.
prof	The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool.
RCS	RCS was originally considered as part of a version control utilities portion of the scope. However, this aspect was abandoned by the standard developers. SCCS is now included as an optional part of the XSI extension.
red	Restricted editor. This was not considered by the standard developers because it never provided the level of security restriction required.
rsh	Restricted shell. This was not considered by the standard developers because it does not provide the level of security restriction that is implied by historical documentation.
sdb	The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool. Furthermore, some useful aspects of *sdb* are very hardware-specific.
sdiff	The ‘‘side-by-side *diff*’’ utility from System V was omitted because it is used infrequently, and even less so by conforming applications. Despite being in System V, it is not in the SVID or XPG.
shar	Any of the numerous ‘‘shell archivers’’ were excluded because they did not meet the requirement of existing practice.
shl	This utility is terminal-oriented and is not useful from shell scripts or typical application programs. The job control aspects of the shell command language are generally more useful.
size	The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications.

	This utility is primarily a debugging tool.
spell	This utility is not useful from shell scripts or typical application programs. The *spell* utility was considered, but was omitted because there is no known technology that can be used to make it recognize general language for user-specified input without providing a complete dictionary along with the input file.
su	This utility is not useful from shell scripts or typical application programs. (There was also sentiment to avoid security-related utilities.)
sum	This utility was renamed *cksum*.
tar	This has been replaced by *pax*, for reasons explained in the rationale for that utility.
tsort	This utility is an aid in creating an implementation-defined detail of object libraries that the standard developers did not feel required standardization.
unpack	This compression program was considered inferior to *uncompress*.
wall	This utility is terminal-oriented and is not useful from shell scripts or typical application programs. It is generally used only by system administrators.

Rationale (Informative)

Part D:

Portability Considerations

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

Appendix D

Portability Considerations (Informative)

This section contains information to satisfy various international requirements:

- Section D.1 describes perceived user requirements.
- Section D.2 (on page 3558) indicates how the facilities of IEEE Std 1003.1-200x satisfy those requirements.
- Section D.3 (on page 3565) offers guidance to writers of profiles on how the configurable options, limits, and optional behavior of IEEE Std 1003.1-200x should be cited in profiles.

D.1 User Requirements

This section describes the user requirements that were perceived by the developers of IEEE Std 1003.1-200x. The primary source for these requirements was an analysis of historical practice in widespread use, as typified by the base documents listed in Section A.1.1 (on page 3293).

IEEE Std 1003.1-200x addresses the needs of users requiring open systems solutions for source code portability of applications. It currently addresses users requiring open systems solutions for source-code portability of applications involving multi-programming and process management (creating processes, signaling, and so on); access to files and directories in a hierarchy of file systems (opening, reading, writing, deleting files, and so on); access to asynchronous communications ports and other special devices; access to information about other users of the system; facilities supporting applications requiring bounded (realtime) response.

The following users are identified for IEEE Std 1003.1-200x:

- Those employing applications written in high-level languages, such as C, Ada, or FORTRAN.
- Users who desire conforming applications that do not necessarily require the characteristics of high-level languages (for example, the speed of execution of compiled languages or the relative security of source code intellectual property inherent in the compilation process).
- Users who desire conforming applications that can be developed quickly and can be modified readily without the use of compilers and other system components that may be unavailable on small systems or those without special application development capabilities.
- Users who interact with a system to achieve general-purpose time-sharing capabilities common to most business or government offices or academic environments: editing, filing, inter-user communications, printing, and so on.
- Users who develop applications for POSIX-conformant systems.
- Users who develop applications for UNIX systems.

An acknowledged restriction on applicable users is that they are limited to the group of individuals who are familiar with the style of interaction characteristic of historically-derived systems based on one of the UNIX operating systems (as opposed to other historical systems with different models, such as MS/DOS, Macintosh, VMS, MVS, and so on). Typical users would include program developers, engineers, or general-purpose time-sharing users.

The requirements of users of IEEE Std 1003.1-200x can be summarized as a single goal: *application source portability*. The requirements of the user are stated in terms of the requirements of portability of applications. This in turn becomes a requirement for a standardized set of syntax and semantics for operations commonly found on many operating systems.

The following sections list the perceived requirements for application portability.

D.1.1 Configuration Interrogation

An application must be able to determine whether and how certain optional features are provided and to identify the system upon which it is running, so that it may appropriately adapt to its environment.

Applications must have sufficient information to adapt to varying behaviors of the system.

D.1.2 Process Management

An application must be able to manage itself, either as a single process or as multiple processes. Applications must be able to manage other processes when appropriate.

Applications must be able to identify, control, create, and delete processes, and there must be communication of information between processes and to and from the system.

Applications must be able to use multiple flows of control with a process (threads) and synchronize operations between these flows of control.

D.1.3 Access to Data

Applications must be able to operate on the data stored on the system, access it, and transmit it to other applications. Information must have protection from unauthorized or accidental access or modification.

D.1.4 Access to the Environment

Applications must be able to access the external environment to communicate their input and results.

D.1.5 Access to Determinism and Performance Enhancements

Applications must have sufficient control of resource allocation to ensure the timeliness of interactions with external objects.

D.1.6 Operating System-Dependent Profile

The capabilities of the operating system may make certain optional characteristics of the base language in effect no longer optional, and this should be specified.

D.1.7 I/O Interaction

The interaction between the C language I/O subsystem (*stdio*) and the I/O subsystem of IEEE Std 1003.1-200x must be specified.

D.1.8 Internationalization Interaction

The effects of the environment of IEEE Std 1003.1-200x on the internationalization facilities of the C language must be specified.

D.1.9 C-Language Extensions

Certain functions in the C language must be extended to support the additional capabilities provided by IEEE Std 1003.1-200x.

D.1.10 Command Language

Users should be able to define procedures that combine simple tools and/or applications into higher-level components that perform to the specific needs of the user. The user should be able to store, recall, use, and modify these procedures. These procedures should employ a powerful command language that is used for recurring tasks in conforming applications (scripts) in the same way that it is used interactively to accomplish one-time tasks. The language and the utilities that it uses must be consistent between systems to reduce errors and retraining.

D.1.11 Interactive Facilities

Use the system to accomplish individual tasks at an interactive terminal. The interface should be consistent, intuitive, and offer usability enhancements to increase the productivity of terminal users, reduce errors, and minimize retraining costs. Online documentation or usage assistance should be available.

D.1.12 Accomplish Multiple Tasks Simultaneously

Access applications and interactive facilities from a single terminal without requiring serial execution: switch between multiple interactive tasks; schedule one-time or periodic background work; display the status of all work in progress or scheduled; influence the priority scheduling of work, when authorized.

D.1.13 Complex Data Manipulation

Manipulate data in files in complex ways: sort, merge, compare, translate, edit, format, pattern match, select subsets (strings, columns, fields, rows, and so on). These facilities should be available to both conforming applications and interactive users.

D.1.14 File Hierarchy Manipulation

Create, delete, move/rename, copy, backup/archive, and display files and directories. These facilities should be available to both conforming applications and interactive users.

D.1.15 Locale Configuration

Customize applications and interactive sessions for the cultural and language conventions of the user. Employ a wide variety of standard character encodings. These facilities should be available to both conforming applications and interactive users.

D.1.16 Inter-User Communication

Send messages or transfer files to other users on the same system or other systems on a network. These facilities should be available to both conforming applications and interactive users.

D.1.17 System Environment

Display information about the status of the system (activities of users and their interactive and background work, file system utilization, system time, configuration, and presence of optional facilities) and the environment of the user (terminal characteristics, and so on). Inform the system operator/administrator of problems. Control access to user files and other resources.

D.1.18 Printing

Output files on a variety of output device classes, accessing devices on local or network-connected systems. Control (or influence) the formatting, priority scheduling, and output distribution of work. These facilities should be available to both conforming applications and interactive users.

D.1.19 Software Development

Develop (create and manage source files, compile/interpret, debug) portable open systems applications and package them for distribution to, and updating of, other systems.

D.2 Portability Capabilities

This section describes the significant portability capabilities of IEEE Std 1003.1-200x and indicates how the user requirements listed in Section D.1 (on page 3555) are addressed. The capabilities are listed in the same format as the preceding user requirements; they are summarized below:

- Configuration Interrogation
- Process Management
- Access to Data
- Access to the Environment
- Access to Determinism and Performance Enhancements
- Operating System-Dependent Profile
- I/O Interaction
- Internationalization Interaction
- C-Language Extensions
- Command Language
- Interactive Facilities

- Accomplish Multiple Tasks Simultaneously
- Complex Data Manipulation
- File Hierarchy Manipulation
- Locale Configuration
- Inter-User Communication
- System Environment
- Printing
- Software Development

D.2.1 Configuration Interrogation

The *uname*( ) operation provides basic identification of the system. The *sysconf*( ), *pathconf*( ), and *fpathconf*( ) functions and the *getconf* utility provide means to interrogate the implementation to determine how to adapt to the environment in which it is running. These values can be either static (indicating that all instances of the implementation have the same value) or dynamic (indicating that different instances of the implementation have the different values, or that the value may vary for other reasons, such as reconfiguration).

Unsatisfied Requirements

None directly. However, as new areas are added, there will be a need for additional capability in this area.

D.2.2 Process Management

The *fork*( ), *exec* family, and *spawn*( ) functions provide for the creation of new processes or the insertion of new applications into existing processes. The *_Exit*( ), *_exit*( ), *exit*( ), and *abort*( ) functions allow for the termination of a process by itself. The *wait*( ) and *waitpid*( ) functions allow one process to deal with the termination of another.

The *times*( ) function allows for basic measurement of times used by a process. Various functions, including *fstat*( ), *getegid*( ), *geteuid*( ), *getgid*( ), *getgrgid*( ), *getgrnam*( ), *getlogin*( ), *getpid*( ), *getppid*( ), *getpwnam*( ), *getpwuid*( ), *getuid*( ), *lstat*( ), and *stat*( ), provide for access to the identifiers of processes and the identifiers and names of owners of processes (and files).

The various functions operating on environment variables provide for communication of information (primarily user-configurable defaults) from a parent to child processes.

The operations on the current working directory control and interrogate the directory from which relative filename searches start. The *umask*( ) function controls the default protections applied to files created by the process.

The *alarm*( ), *pause*( ), *sleep*( ), *ualarm*( ), and *usleep*( ) operations allow the process to suspend until a timer has expired or to be notified when a period of time has elapsed. The *time*( ) operation interrogates the current time and date.

The signal mechanism provides for communication of events either from other processes or from the environment to the application, and the means for the application to control the effect of these events. The mechanism provides for external termination of a process and for a process to suspend until an event occurs. The mechanism also provides for a value to be associated with an event.

Job control provides a means to group processes and control them as groups, and to control their access to the function between the user and the system (the *controlling terminal*). It also provides the means to suspend and resume processes.

The Process Scheduling option provides control of the scheduling and priority of a process.

The Message Passing option provides a means for interprocess communication involving small amounts of data.

The Memory Management facilities provide control of memory resources and for the sharing of memory. This functionality is mandatory on XSI-conformant systems.

The Threads facilities provide multiple flows of control with a process (threads), synchronization between threads, association of data with threads, and controlled cancelation of threads.

The XSI interprocess communications functionality provide an alternate set of facilities to manipulate semaphores, message queues, and shared memory. These are provided on XSI-conformant systems to support conforming applications developed to run on UNIX systems. |

D.2.3 Access to Data

The *open*( ), *close*( ), *fclose*( ), *fopen*( ), and *pipe*( ) functions provide for access to files and data. Such files may be regular files, interprocess data channels (pipes), or devices. Additional types of objects in the file system are permitted and are being contemplated for standardization.

The *access*( ), *chmod*( ), *chown*( ), *dup*( ), *dup2*( ), *fchmod*( ), *fcntl*( ), *fstat*( ), *ftruncate*( ), *lstat*( ), *readlink*( ), *realpath*( ), *stat*( ), and *utime*( ) functions allow for control and interrogation of file and file-related objects, (including symbolic links) and their ownership, protections, and timestamps.

The *fgetc*( ), *fputc*( ), *fread*( ), *fseek*( ), *fsetpos*( ), *fwrite*( ), *getc*( ), *getch*( ), *lseek*( ), *putchar*( ), *putc*( ), *read*( ), and *write*( ) functions provide for data transfer from the application to files (in all their forms).

The *closedir*( ), *link*( ), *mkdir*( ), *opendir*( ), *readdir*( ), *rename*( ), *rmdir*( ), *rewinddir*( ), and *unlink*( ) functions provide for a complete set of operations on directories. Directories can arbitrarily contain other directories, and a single file can be mentioned in more than one directory.

The file-locking mechanism provides for advisory locking (protection during transactions) of ranges of bytes (in effect, records) in a file.

The *confstr*( ), *fpathconf*( ), *pathconf*( ), and *sysconf*( ) functions provide for enquiry as to the behavior of the system where variability is permitted.

The Synchronized Input and Output option provides for assured commitment of data to media.

The Asynchronous Input and Output option provides for initiation and control of asynchronous data transfers.

D.2.4 Access to the Environment

The operations and types in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface are provided for access to asynchronous serial devices. The primary intended use for these is the controlling terminal for the application (the interaction point between the user and the system). They are general enough to be used to control any asynchronous serial device. The functions are also general enough to be used with many other device types as a user interface when some emulation is provided.

Less detailed access is provided for other device types, but in many instances an application need not know whether an object in the file system is a device or a regular file to operate correctly.

Unsatisfied Requirements

Detailed control of common device classes, specifically magnetic tape, is not provided.

D.2.5 Bounded (Realtime) Response

The Realtime Signals Extension provides queued signals and the prioritization of the handling of signals. The SCHED_FIFO, SCHED_SPORADIC, and SCHED_RR scheduling policies provide control over processor allocation. The Semaphores option provides high-performance synchronization. The Memory Management functions provide memory locking for control of memory allocation, file mapping for high-performance, and shared memory for high-performance interprocess communication. The Message Passing option provides for interprocess communication without being dependent on shared memory.

The Timers option provides a high resolution function called *nanosleep*( ) with a finer resolution than the *sleep*( ) function.

The Typed Memory Objects option, the Monotonic Clock option, and the Timeouts option provide further facilities for applications to use to obtain predictable bounded response.

D.2.6 Operating System-Dependent Profile

IEEE Std 1003.1-200x makes no distinction between text and binary files. The values of EXIT_SUCCESS and EXIT_FAILURE are further defined.

Unsatisfied Requirements

None known, but the ISO C standard may contain some additional options that could be specified.

D.2.7 I/O Interaction

IEEE Std 1003.1-200x defines how each of the ISO C standard *stdio* functions interact with the POSIX.1 operations, typically specifying the behavior in terms of POSIX.1 operations.

Unsatisfied Requirements

None.

D.2.8 Internationalization Interaction

The IEEE Std 1003.1-200x environment operations provide a means to define the environment for *setlocale*( ) and time functions such as *ctime*( ). The *tzset*( ) function is provided to set time conversion information.

The *nl_langinfo*( ) function is provided as an XSI extension to query locale-specific cultural settings.

Unsatisfied Requirements

None.

D.2.9 C-Language Extensions

The *setjmp*( ) and *longjmp*( ) functions are not defined to be cognizant of the signal masks defined for POSIX.1. The *sigsetjmp*( ) and *siglongjmp*( ) functions are provided to fill this gap.

The *_setjmp*( ) and *_longjmp*( ) functions are provided as XSI extensions to support historic practice.

Unsatisfied Requirements

None.

D.2.10 Command Language

The shell command language, as described in Shell and Utilities volume of IEEE Std 1003.1-200x, Chapter 2, Shell Command Language, is a common language useful in batch scripts, through an API to high-level languages (for the C-Language Binding option, *system*( ) and *popen*( )) and through an interactive terminal (see the *sh* utility). The shell language has many of the characteristics of a high-level language, but it has been designed to be more suitable for user terminal entry and includes interactive debugging facilities. Through the use of pipelining, many complex commands can be constructed from combinations of data filters and other common components. Shell scripts can be created, stored, recalled, and modified by the user with simple editors.

In addition to the basic shell language, the following utilities offer features that simplify and enhance programmatic access to the utilities and provide features normally found only in high-level languages: *basename*, *bc*, *command*, *dirname*, *echo*, *env*, *expr*, *false*, *printf*, *read*, *sleep*, *tee*, *test*, *time**,[2] *true*, *wait*, *xargs*, and all of the special built-in utilities in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.14, Special Built-In Utilities .

Unsatisfied Requirements

None.

D.2.11 Interactive Facilities

The utilities offer a common style of command-line interface through conformance to the Utility Syntax Guidelines (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines) and the common utility defaults (see the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 1.11, Utility Description Defaults). The *sh* utility offers an interactive command-line history and editing facility. The following utilities in the User Portability Utilities option have been customized for interactive use: *alias*, *ex*, *fc*, *mailx*, *more*, *talk*, *vi*, *unalias*, and *write*; the *man* utility offers online access to system documentation.

---

[2] The utilities listed with an asterisk here and later in this section are present only on systems which support the User Portability Utilities option. There may be further restrictions on the utilities offered with various configuration option combinations; see the individual utility descriptions.

Unsatisfied Requirements

The command line interface to individual utilities is as intuitive and consistent as historical practice allows. Work underway based on graphical user interfaces may be more suitable for novice or occasional users of the system.

D.2.12 Accomplish Multiple Tasks Simultaneously

The shell command language offers background processing through the asynchronous list command form; see the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.9, Shell Commands. The *nohup* utility makes background processing more robust and usable. The *kill* utility can terminate background jobs. When the User Portability Utilities option is supported, the following utilities allow manipulation of jobs: *bg*, *fg*, and *jobs*. Also, if the User Portability Utilities option is supported, the following can support periodic job scheduling, control, and display: *at*, *batch*, *crontab*, *nice*, *ps*, and *renice*.

Unsatisfied Requirements

Terminals with multiple windows may be more suitable for some multi-tasking interactive uses than the job control approach in IEEE Std 1003.1-200x. See the comments on graphical user interfaces in Section D.2.11 (on page 3562). The *nice* and *renice* utilities do not necessarily take advantage of complex system scheduling algorithms that are supported by the realtime options within IEEE Std 1003.1-200x.

D.2.13 Complex Data Manipulation

The following utilities address user requirements in this area: *asa*, *awk*, *bc*, *cmp*, *comm*, *csplit**, *cut*, *dd*, *diff*, *ed*, *ex**, *expand**, *expr*, *find*, *fold*, *grep*, *head*, *join*, *od*, *paste*, *pr*, *printf*, *sed*, *sort*, *split**, *tabs**, *tail*, *tr*, *unexpand**, *uniq*, *uudecode**, *uuencode**, and *wc*.

Unsatisfied Requirements

Sophisticated text formatting utilities, such as *troff* or *TeX*, are not included. Standards work in the area of SGML may satisfy this.

D.2.14 File Hierarchy Manipulation

The following utilities address user requirements in this area: *basename*, *cd*, *chgrp*, *chmod*, *chown*, *cksum*, *cp*, *dd*, *df**, *diff*, *dirname*, *du**, *find*, *ls*, *ln*, *mkdir*, *mkfifo*, *mv*, *patch**, *pathchk*, *pax*, *pwd*, *rm*, *rmdir*, *test*, and *touch*.

Unsatisfied Requirements

Some graphical user interfaces offer more intuitive file manager components that allow file manipulation through the use of icons for novice users.

D.2.15 Locale Configuration

The standard utilities are affected by the various *LC_* variables to achieve locale-dependent operation: character classification, collation sequences, regular expressions and shell pattern matching, date and time formats, numeric formatting, and monetary formatting. When the POSIX2_LOCALEDEF option is supported, applications can provide their own locale definition files. The following utilities address user requirements in this area: *date*, *ed*, *ex**, *find*, *grep*, *locale*, *localedef*, *more**, *sed*, *sh*, *sort*, *tr*, *uniq*, and *vi**.

The *iconv*( ), *iconv_close*( ), and *iconv_open*( ) functions are available to allow an application to convert character data between supported character sets.

The *gencat* utility and the *catopen*( ), *catclose*( ), and *catgets*( ) functions for message catalog manipulation are available on XSI-conformant systems.

Unsatisfied Requirements

Some aspects of multi-byte character and state-encoded character encodings have not yet been addressed. The C-language functions, such as *getopt*( ), are generally limited to single-byte characters. The effect of the *LC_MESSAGES* variable on message formats is only suggested at this time.

D.2.16 Inter-User Communication

The following utilities address user requirements in this area: *cksum*, *mailx**, *mesg**, *patch**, *pax*, *talk**, *uudecode**, *uuencode**, *who**, and *write**.

The historical UUCP utilities are included on XSI-conformant systems.

Unsatisfied Requirements

None.

D.2.17 System Environment

The following utilities address user requirements in this area: *chgrp*, *chmod*, *chown*, *df**, *du**, *env*, *getconf*, *id*, *logger*, *logname*, *mesg**, *newgrp**, *ps**, *stty*, *tput**, *tty*, *umask*, *uname*, and *who**.

The *closelog*( ), *openlog*( ), *setlogmask*( ), and *syslog*( ) functions provide System Logging facilities on XSI-conformant systems; these are analogous to the *logger* utility.

Unsatisfied Requirements

None.

D.2.18 Printing

The following utilities address user requirements in this area: *pr* and *lp*.

Unsatisfied Requirements

There are no features to control the formatting or scheduling of the print jobs.

D.2.19 Software Development

The following utilities address user requirements in this area: *ar*, *asa*, *awk*, *c99*, *ctags**, *fort77*, *getconf*, *getopts*, *lex*, *localedef*, *make*, *nm**, *od*, *patch**, *pax*, *strings**, *strip*, *time**, and *yacc*.

The *system*( ), *popen*( ), *pclose*( ), *regcomp*( ), *regexec*( ), *regerror*( ), *regfree*( ), *fnmatch*( ), *getopt*( ), *glob*( ), *globfree*( ), *wordexp*( ), and *wordfree*( ) functions allow C-language programmers to access some of the interfaces used by the utilities, such as argument processing, regular expressions, and pattern matching.

The SCCS source-code control system utilities are available on systems supporting the XSI Development option.

Unsatisfied Requirements

There are no language-specific development tools related to languages other than C and FORTRAN. The C tools are more complete and varied than the FORTRAN tools. There is no data dictionary or other CASE-like development tools.

D.2.20 Future Growth

It is arguable whether or not all functionality to support applications is potentially within the scope of IEEE Std 1003.1-200x. As a simple matter of practicality, it cannot be. Areas such as graphics, application domain-specific functionality, windowing, and so on, should be in unique standards. As such, they are properly ‘‘Unsatisfied Requirements’’ in terms of providing fully conforming applications, but ones which are outside the scope of IEEE Std 1003.1-200x.

However, as the standards evolve, certain functionality once considered ‘‘exotic’’ enough to be part of a separate standard become common enough to be included in a core standard such as this. Realtime and networking, for example, have both moved from separate standards (with much difficult cross-referencing) into IEEE Std 1003.1 over time, and although no specific areas have been identified for inclusion in future revisions, such inclusions seem likely.

D.3 Profiling Considerations

This section offers guidance to writers of profiles on how the configurable options, limits, and optional behavior of IEEE Std 1003.1-200x should be cited in profiles. Profile writers should consult the general guidance in POSIX.0 when writing POSIX Standardized Profiles.

The information in this section is an inclusive list of features that should be considered by profile writers. Subsetting of IEEE Std 1003.1-200x should follow the Base Definitions volume of IEEE Std 1003.1-200x, Section 2.1.5.1, Subprofiling Considerations. A set of profiling options is described in Appendix E (on page 3579).

D.3.1 Configuration Options

There are two set of options suggested by IEEE Std 1003.1-200x: those for POSIX-conforming systems and those for X/Open System Interface (XSI) conformance. The requirements for XSI conformance are documented in the Base Definitions volume of IEEE Std 1003.1-200x and not discussed further here, as they superset the POSIX conformance requirements.

D.3.2 Configuration Options (Shell and Utilities)

There are three broad optional configurations for the Shell and Utilities volume of IEEE Std 1003.1-200x: basic execution system, development system, and user portability interactive system. The options to support these, and other minor configuration options, are listed in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 2, Conformance. Profile writers should consult the following list and the comments concerning user requirements addressed by various components in Section D.2 (on page 3558).

POSIX2_UPE

The system supports the User Portability Utilities option.

This option is a requirement for a user portability interactive system. It is required frequently except for those systems, such as embedded realtime or dedicated application systems, that support little or no interactive time-sharing work by users or operators. XSI-conformant systems support this option.

POSIX2_SW_DEV

The system supports the Software Development Utilities option.

This option is required by many systems, even those in which actual software development does not occur. The *make* utility, in particular, is required by many application software packages as they are installed onto the system. If POSIX2_C_DEV is supported, POSIX2_SW_DEV is almost a mandatory requirement because of *ar* and *make*.

POSIX2_C_BIND

The system supports the C-Language Bindings option.

This option is required on some implementations developing complex C applications or on any system installing C applications in source form that require the functions in this option. The *system*( ) and *popen*( ) functions, in particular, are widely used by applications; the others are rather more specialized.

POSIX2_C_DEV

The system supports the C-Language Development Utilities option.

This option is required by many systems, even those in which actual C-language software development does not occur. The *c99* utility, in particular, is required by many application software packages as they are installed onto the system. The *lex* and *yacc* utilities are used less frequently.

POSIX2_FORT_DEV

The system supports the FORTRAN Development Utilities option

As with C, this option is needed on any system developing or installing FORTRAN applications in source form.

POSIX2_FORT_RUN

The system supports the FORTRAN Runtime Utilities option.

This option is required for some FORTRAN applications that need the *asa* utility to convert Hollerith printing statement output. It is unknown how frequently this occurs.

POSIX2_LOCALEDEF

The system supports the creation of locales.

This option is needed if applications require their own customized locale definitions to operate. It is presently unknown whether many applications are dependent on this. However, the option is virtually mandatory for systems in which internationalized applications are developed.

XSI-conformant systems support this option.

POSIX2_PBS

The system supports the Batch Environment option.

POSIX2_PBS_ACCOUNTING

The system supports the optional feature of accounting within the Batch Environment option. It will be required in servers that implement the optional feature of accounting.

POSIX2_PBS_CHECKPOINT

The systems supports the optional feature of checkpoint/restart within the Batch Environment option.

POSIX2_PBS_LOCATE

The system supports the optional feature of locating batch jobs within the Batch Environment option.

POSIX2_PBS_MESSAGE

The system supports the optional feature of sending messages to batch jobs within the Batch Environment option.

POSIX2_PBS_TRACK

The system supports the optional feature of tracking batch jobs within the Batch Environment option.

POSIX2_CHAR_TERM

The system supports at least one terminal type capable of all operations described in IEEE Std 1003.1-200x.

On systems with POSIX2_UPE, this option is almost always required. It was developed solely to allow certain specialized vendors and user applications to bypass the requirement for general-purpose asynchronous terminal support. For example, an application and system that was suitable for block-mode terminals, such as IBM 3270s, would not need this option.

XSI-conformant systems support this option.

D.3.3 Configurable Limits

Very few of the limits need to be increased for profiles. No profile can cite lower values.

{POSIX2_BC_BASE_MAX}
{POSIX2_BC_DIM_MAX}
{POSIX2_BC_SCALE_MAX}
{POSIX2_BC_STRING_MAX}

No increase is anticipated for any of these *bc* values, except for very specialized applications involving huge numbers.

{POSIX2_COLL_WEIGHTS_MAX}

Some natural languages with complex collation requirements require an increase from the default 2 to 4; no higher numbers are anticipated.

{POSIX2_EXPR_NEST_MAX}
No increase is anticipated.

{POSIX2_LINE_MAX}
This number is much larger than most historical applications have been able to use. At some future time, applications may be rewritten to take advantage of even larger values.

{POSIX2_RE_DUP_MAX}
No increase is anticipated.

{POSIX2_VERSION}
This is actually not a limit, but a standard version stamp. Generally, a profile should specify Shell and Utilities volume of IEEE Std 1003.1-200x, Chapter 2, Shell Command Language by name in the normative references section, not this value.

D.3.4 Configuration Options (System Interfaces)

{NGROUPS_MAX}
A non-zero value indicates that the implementation supports supplementary groups.

This option is needed where there is a large amount of shared use of files, but where a certain amount of protection is needed. Many profiles[3] are known to require this option; it should only be required if needed, but it should never be prohibited.

_POSIX_ADVISORY_INFO
The system provides advisory information for file management.

This option allows the application to specify advisory information that can be used to achieve better or even deterministic response time in file manager or input and output operations.

_POSIX_ASYNCHRONOUS_IO
The system provides concurrent process execution and input and output transfers.

This option was created to support historical systems that did not provide the feature. It should only be required if needed, but it should never be prohibited.

_POSIX_BARRIERS
The system supports barrier synchronization.

This option was created to allow efficient synchronization of multiple parallel threads in multi-processor systems in which the operation is supported in part by the hardware architecture.

_POSIX_CHOWN_RESTRICTED
The system restricts the right to ‘‘give away’’ files to other users.

This option should be carefully investigated before it is required. Some applications expect that they can change the ownership of files in this way. It is provided where either security or system account requirements cause this ability to be a problem. It is also known to be specified in many profiles.

---

[3] There are no formally approved profiles of IEEE Std 1003.1-200x at the time of publication; the reference here is to various profiles generated by private bodies or governments.

_POSIX_CLOCK_SELECTION

The system supports the Clock Selection option.

This option allows applications to request a high resolution sleep in order to suspend a thread during a relative time interval, or until an absolute time value, using the desired clock. It also allows the application to select the clock used in a *pthread_cond_timedwait*( ) function call.

_POSIX_CPUTIME

The system supports the Process CPU-Time Clocks option.

This option allows applications to use a new clock that measures the execution times of processes or threads, and the possibility to create timers based upon these clocks, for runtime detection (and treatment) of execution time overruns.

_POSIX_FSYNC

The system supports file synchronization requests.

This option was created to support historical systems that did not provide the feature. Applications that are expecting guaranteed completion of their input and output operations should require the _POSIX_SYNC_IO option. This option should never be prohibited.

XSI-conformant systems support this option.

_POSIX_IPV6

The system supports facilities related to Internet Protocol Version 6 (IPv6).

This option was created to allow systems to transition to IPv6.

_POSIX_JOB_CONTROL

Job control facilities are mandatory in IEEE Std 1003.1-200x.

The option was created primarily to support historical systems that did not provide the feature. Many existing profiles now require it; it should only be required if needed, but it should never be prohibited. Most applications that use it can run when it is not present, although with a degraded level of user convenience.

_POSIX_MAPPED_FILES

The system supports the mapping of regular files into the process address space.

XSI-conformant systems support this option.

Both this option and the Shared Memory Objects option provide shared access to memory objects in the process address space. The functions defined under this option provide the functionality of existing practice for mapping regular files. This functionality was deemed unnecessary, if not inappropriate, for embedded systems applications and, hence, is provided under this option. It should only be required if needed, but it should never be prohibited.

_POSIX_MEMLOCK

The system supports the locking of the address space.

This option was created to support historical systems that did not provide the feature. It should only be required if needed, but it should never be prohibited.

_POSIX_MEMLOCK_RANGE

The system supports the locking of specific ranges of the address space.

For applications that have well-defined sections that need to be locked and others that do not, IEEE Std 1003.1-200x supports an optional set of functions to lock or unlock a range of process addresses. The following are two reasons for having a means to lock down a specific range:

1. An asynchronous event handler function that must respond to external events in a deterministic manner such that page faults cannot be tolerated
2. An input/output ''buffer'' area that is the target for direct-to-process I/O, and the overhead of implicit locking and unlocking for each I/O call cannot be tolerated

It should only be required if needed, but it should never be prohibited.

_POSIX_MEMORY_PROTECTION
The system supports memory protection.

XSI-conformant systems support this option.

The provision of this option typically imposes additional hardware requirements. It should never be prohibited.

_POSIX_PRIORITIZED_IO
The system provides prioritization for input and output operations.

The use of this option may interfere with the ability of the system to optimize input and output throughput. It should only be required if needed, but it should never be prohibited.

_POSIX_MESSAGE_PASSING
The system supports the passing of messages between processes.

This option was created to support historical systems that did not provide the feature. The functionality adds a high-performance XSI interprocess communication facility for local communication. It should only be required if needed, but it should never be prohibited.

_POSIX_MONOTONIC_CLOCK
The system supports the Monotonic Clock option.

This option allows realtime applications to rely on a monotonically increasing clock that does not jump backwards, and whose value does not change except for the regular ticking of the clock.

_POSIX_PRIORITY_SCHEDULING
The system provides priority-based process scheduling.

Support of this option provides predictable scheduling behavior, allowing applications to determine the order in which processes that are ready to run are granted access to a processor. It should only be required if needed, but it should never be prohibited.

_POSIX_REALTIME_SIGNALS
The system provides prioritized, queued signals with associated data values.

This option was created to support historical systems that did not provide the features. It should only be required if needed, but it should never be prohibited.

_POSIX_REGEXP
Support for regular expression facilities are mandatory in IEEE Std 1003.1-200x.

_POSIX_SAVED_IDS
Support for this feature is mandatory in IEEE Std 1003.1-200x.

Certain classes of applications rely on it for proper operation, and there is no alternative short of giving the application root privileges on most implementations that did not provide _POSIX_SAVED_IDS.

_POSIX_SEMAPHORES

The system provides counting semaphores.

This option was created to support historical systems that did not provide the feature. It should only be required if needed, but it should never be prohibited.

_POSIX_SHARED_MEMORY_OBJECTS

The system supports the mapping of shared memory objects into the process address space.

Both this option and the Memory Mapped Files option provide shared access to memory objects in the process address space. The functions defined under this option provide the functionality of existing practice for shared memory objects. This functionality was deemed appropriate for embedded systems applications and, hence, is provided under this option. It should only be required if needed, but it should never be prohibited.

_POSIX_SHELL

Support for the *sh* utility command line interpreter is mandatory in IEEE Std 1003.1-200x.

_POSIX_SPAWN

The system supports the spawn option.

This option provides applications with an efficient mechanism to spawn execution of a new process.

_POSIX_SPINLOCKS

The system supports spin locks.

This option was created to support a simple and efficient synchronization mechanism for threads executing in multi-processor systems.

_POSIX_SPORADIC_SERVER

The system supports the sporadic server scheduling policy.

This option provides applications with a new scheduling policy for scheduling aperiodic processes or threads in hard realtime applications.

_POSIX_SYNCHRONIZED_IO

The system supports guaranteed file synchronization.

This option was created to support historical systems that did not provide the feature. Applications that are expecting guaranteed completion of their input and output operations should require this option, rather than the File Synchronization option. It should only be required if needed, but it should never be prohibited.

_POSIX_THREADS

The system supports multiple threads of control within a single process.

This option was created to support historical systems that did not provide the feature. Applications written assuming a multi-threaded environment would be expected to require this option. It should only be required if needed, but it should never be prohibited.

XSI-conformant systems support this option.

_POSIX_THREAD_ATTR_STACKADDR

The system supports specification of the stack address for a created thread.

Applications may take advantage of support of this option for performance benefits, but dependence on this feature should be minimized. This option should never be prohibited.

XSI-conformant systems support this option.

_POSIX_THREAD_ATTR_STACKSIZE

The system supports specification of the stack size for a created thread.

Applications may require this option in order to ensure proper execution, but such usage limits portability and dependence on this feature should be minimized. It should only be required if needed, but it should never be prohibited.

XSI-conformant systems support this option.

_POSIX_THREAD_PRIORITY_SCHEDULING

The system provides priority-based thread scheduling.

Support of this option provides predictable scheduling behavior, allowing applications to determine the order in which threads that are ready to run are granted access to a processor. It should only be required if needed, but it should never be prohibited.

_POSIX_THREAD_PRIO_INHERIT

The system provides mutual exclusion operations with priority inheritance.

Support of this option provides predictable scheduling behavior, allowing applications to determine the order in which threads that are ready to run are granted access to a processor. It should only be required if needed, but it should never be prohibited.

_POSIX_THREAD_PRIO_PROTECT

The system supports a priority ceiling emulation protocol for mutual exclusion operations.

Support of this option provides predictable scheduling behavior, allowing applications to determine the order in which threads that are ready to run are granted access to a processor. It should only be required if needed, but it should never be prohibited.

_POSIX_THREAD_PROCESS_SHARED

The system provides shared access among multiple processes to synchronization objects.

This option was created to support historical systems that did not provide the feature. It should only be required if needed, but it should never be prohibited.

XSI-conformant systems support this option.

_POSIX_THREAD_SAFE_FUNCTIONS

The system provides thread-safe versions of all of the POSIX.1 functions.

This option is required if the Threads option is supported. This is a separate option because thread-safe functions are useful in implementations providing other mechanisms for concurrency. It should only be required if needed, but it should never be prohibited.

XSI-conformant systems support this option.

_POSIX_THREAD_SPORADIC_SERVER

The system supports the thread sporadic server scheduling policy.

Support for this option provides applications with a new scheduling policy for scheduling aperiodic threads in hard realtime applications.

_POSIX_TIMEOUTS

The system provides timeouts for some blocking services.

This option was created to provide a timeout capability to system services, thus allowing applications to include better error detection, and recovery capabilities.

_POSIX_TIMERS

The system provides higher resolution clocks with multiple timers per process.

This option was created to support historical systems that did not provide the features. This option is appropriate for applications requiring higher resolution timestamps or needing to control the timing of multiple activities. It should only be required if needed, but it should never be prohibited.

_POSIX_TRACE
The system supports the trace option.

This option was created to allow applications to perform tracing.

_POSIX_TRACE_EVENT_FILTER
The system supports the trace event filter option.

This option is dependent on support of the Trace option.

_POSIX_TRACE_INHERIT
The system supports the trace inherit option.

This option is dependent on support of the Trace option.

_POSIX_TRACE_LOG
The system supports the trace log option.

This option is dependent on support of the Trace option.

_POSIX_TYPED_MEMORY_OBJECTS
The system supports typed memory objects.

This option was created to allow realtime applications to access different kinds of physical memory, and allow processes in these applications to share portions of this memory.

D.3.5 Configurable Limits

In general, the configurable limits in the **<limits.h>** header defined in the Base Definitions volume of IEEE Std 1003.1-200x have been set to minimal values; many applications or implementations may require larger values. No profile can cite lower values.

{AIO_LISTIO_MAX}
The current minimum is likely to be inadequate for most applications. It is expected that this value will be increased by profiles requiring support for list input and output operations.

{AIO_MAX}
The current minimum is likely to be inadequate for most applications. It is expected that this value will be increased by profiles requiring support for asynchronous input and output operations.

{AIO_PRIO_DELTA_MAX}
The functionality associated with this limit is needed only by sophisticated applications. It is not expected that this limit would need to be increased under a general-purpose profile.

{ARG_MAX}
The current minimum is likely to need to be increased for profiles, particularly as larger amounts of information are passed through the environment. Many implementations are believed to support larger values.

{CHILD_MAX}
The current minimum is suitable only for systems where a single user is not running applications in parallel. It is significantly too low for any system also requiring windows, and if _POSIX_JOB_CONTROL is specified, it should be raised.

{CLOCKRES_MIN}

It is expected that profiles will require a finer granularity clock, perhaps as fine as 1 µs, represented by a value of 1 000 for this limit.

{DELAYTIMER_MAX}

It is believed that most implementations will provide larger values.

{LINK_MAX}

For most applications and usage, the current minimum is adequate. Many implementations have a much larger value, but this should not be used as a basis for raising the value unless the applications to be used require it.

{LOGIN_NAME_MAX}

This is not actually a limit, but an implementation parameter. No profile should impose a requirement on this value.

{MAX_CANON}

For most purposes, the current minimum is adequate. Unless high-speed burst serial devices are used, it should be left as is.

{MAX_INPUT}

See {MAX_CANON}.

{MQ_OPEN_MAX}

The current minimum should be adequate for most profiles.

{MQ_PRIO_MAX}

The current minimum corresponds to the required number of process scheduling priorities. Many realtime practitioners believe that the number of message priority levels ought to be the same as the number of execution scheduling priorities.

{NAME_MAX}

Many implementations now support larger values, and many applications and users assume that larger names can be used. Many existing profiles also specify a larger value. Specifying this value will reduce the number of conforming implementations, although this might not be a significant consideration over time. Values greater than 255 should not be required.

{NGROUPS_MAX}

The value selected will typically be 8 or larger.

{OPEN_MAX}

The historically common value for this has been 20. Many implementations support larger values. If applications that use larger values are anticipated, an appropriate value should be specified.

{PAGESIZE}

This is not actually a limit, but an implementation parameter. No profile should impose a requirement on this value.

{PATH_MAX}

Historically, the minimum has been either 1 024 or indefinite, depending on the implementation. Few applications actually require values larger than 256, but some users may create file hierarchies that must be accessed with longer paths. This value should only be changed if there is a clear requirement.

{PIPE_BUF}

The current minimum is adequate for most applications. Historically, it has been larger. If applications that write single transactions larger than this are anticipated, it should be increased. Applications that write lines of text larger than this probably do not need it increased, as the text line is delimited by a newline.

{POSIX_VERSION}
This is actually not a limit, but a standard version stamp. Generally, a profile should specify IEEE Std 1003.1-200x by a name in the normative references section, not this value.

{PTHREAD_DESTRUCTOR_ITERATIONS}
It is unlikely that applications will need larger values to avoid loss of memory resources.

{PTHREAD_KEYS_MAX}
The current value should be adequate for most profiles.

{PTHREAD_STACK_MIN}
This should not be treated as an actual limit, but as an implementation parameter. No profile should impose a requirement on this value.

{PTHREAD_THREADS_MAX}
It is believed that most implementations will provide larger values.

{RTSIG_MAX}
The current limit was chosen so that the set of POSIX.1 signal numbers can fit within a 32-bit field. It is recognized that most existing implementations define many more signals than are specified in POSIX.1 and, in fact, many implementations have already exceeded 32 signals (including the ‘‘null signal’’). Support of {_POSIX_RTSIG_MAX} additional signals may push some implementations over the single 32-bit word line, but is unlikely to push any implementations that are already over that line beyond the 64 signal line.

{SEM_NSEMS_MAX}
The current value should be adequate for most profiles.

{SEM_VALUE_MAX}
The current value should be adequate for most profiles.

{SSIZE_MAX}
This limit reflects fundamental hardware characteristics (the size of an integer), and should not be specified unless it is clearly required. Extreme care should be taken to assure that any value that might be specified does not unnecessarily eliminate implementations because of accidents of hardware design.

{STREAM_MAX}
This limit is very closely related to {OPEN_MAX}. It should never be larger than {OPEN_MAX}, but could reasonably be smaller for application areas where most files are not accessed through *stdio*. Some implementations may limit {STREAM_MAX} to 20 but allow {OPEN_MAX} to be considerably larger. Such implementations should be allowed for if the applications permit.

{TIMER_MAX}
The current limit should be adequate for most profiles, but it may need to be larger for applications with a large number of asynchronous operations.

{TTY_NAME_MAX}
This is not actually a limit, but an implementation parameter. No profile should impose a requirement on this value.

{TZNAME_MAX}
The minimum has been historically adequate, but if longer timezone names are anticipated (particularly such values as UTC−1), this should be increased.

D.3.6 Optional Behavior

In IEEE Std 1003.1-200x, there are no instances of the terms unspecified, undefined, implementation-defined, or with the verbs ‘‘may’’ or ‘‘need not’’, that the developers of IEEE Std 1003.1-200x anticipate or sanction as suitable for profile or test method citation. All of these are merely warnings to conforming applications to avoid certain areas that can vary from system to system, and even over time on the same system. In many cases, these terms are used explicitly to support extensions, but profiles should not anticipate and require such extensions; future versions of IEEE Std 1003.1-200x may do so.

Rationale (Informative)

Part E:

Subprofiling Considerations

The Open Group
The Institute of Electrical and Electronics Engineers, Inc.

Appendix E

Subprofiling Considerations (Informative)

This section contains further information to satisfy the requirement that the project scope enable subprofiling of IEEE Std 1003.1-200x. The original intent was to have included a set of options similar to the ‘‘Units of Functionality’’ contained in IEEE Std 1003.13-1998. However, as the development of IEEE Std 1003.1-200x continued, the standard developers felt it premature to fix these in normative text. The approach instead has been to include a general requirement in normative text regarding subprofiling and to include an informative section (here) containing a proposed set of subprofiling options.

E.1 Subprofiling Option Groups

The following Option Groups[4] are defined to support profiling. Systems claiming support to IEEE Std 1003.1-200x need not implement these options apart from the requirements stated in the Base Definitions volume of IEEE Std 1003.1-200x, Section 2.1.3, POSIX Conformance. These Option Groups allow profiles to subset the System Interfaces volume of IEEE Std 1003.1-200x by collecting sets of related functions.
