CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

iswalnum — test for an alphanumeric wide-character code

SYNOPSIS

```
#include <wctype.h>

int iswalnum(wint_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *iswalnum*( ) function shall test whether *wc* is a wide-character code representing a character of class **alpha** or **digit** in the program's current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale.

The *wc* argument is a **wint_t**, the value of which the application shall ensure is a wide-character code corresponding to a valid character in the current locale, or equal to the value of the macro WEOF. If the argument has any other value, the behavior is undefined. |

RETURN VALUE

The *iswalnum*( ) function shall return non-zero if *wc* is an alphanumeric wide-character code; otherwise, it shall return 0.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

To ensure applications portability, especially across natural languages, only this function and those listed in the SEE ALSO section should be used for classification of wide-character codes.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

iswalpha( ), *iswcntrl*( ), *iswctype*( ), *iswdigit*( ), *iswgraph*( ), *iswlower*( ), *iswprint*( ), *iswpunct*( ), *iswspace*( ), *iswupper*( ), *iswxdigit*( ), *setlocale*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<wctype.h>**, **<wchar.h>**, **<stdio.h>**, the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale

CHANGE HISTORY

First released as a World-wide Portability Interface in Issue 4.

Issue 5

The following change has been made in this issue for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E):

- The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

iswalpha — test for an alphabetic wide-character code

SYNOPSIS

```
#include <wctype.h>

int iswalpha(wint_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *iswalpha*( ) function shall test whether *wc* is a wide-character code representing a character of class **alpha** in the program's current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale.

The *wc* argument is a **wint_t**, the value of which the application shall ensure is a wide-character | code corresponding to a valid character in the current locale, or equal to the value of the macro WEOF. If the argument has any other value, the behavior is undefined.

RETURN VALUE

The *iswalpha*( ) function shall return non-zero if *wc* is an alphabetic wide-character code; otherwise, it shall return 0.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

iswblank — test for a blank wide-character code

SYNOPSIS

```
#include <wctype.h>

int iswblank(wint_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *iswblank*( ) function shall test whether *wc* is a wide-character code representing a character of class **blank** in the program's current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale.

The *wc* argument is a **wint_t**, the value of which the application shall ensure is a wide-character code corresponding to a valid character in the current locale, or equal to the value of the macro WEOF. If the argument has any other value, the behavior is undefined. |

RETURN VALUE

The *iswblank*( ) function shall return non-zero if *wc* is a blank wide-character code; otherwise, it shall return 0. |

ERRORS

No errors are defined.

EXAMPLES

None.

CHANGE HISTORY

First released in Issue 6. Derived from the ISO/IEC 9899:1999 standard.

NAME

iswcntrl — test for a control wide-character code

SYNOPSIS

```
#include <wctype.h>

int iswcntrl(wint_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *iswcntrl*( ) function shall test whether *wc* is a wide-character code representing a character of class **cntrl** in the program's current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale. |

The *wc* argument is a **wint_t**, the value of which the application shall ensure is a wide-character code corresponding to a valid character in the current locale, or equal to the value of the macro WEOF. If the argument has any other value, the behavior is undefined. |

RETURN VALUE

The *iswcntrl*( ) function shall return non-zero if *wc* is a control wide-character code; otherwise, it shall return 0.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

To ensure applications portability, especially across natural languages, only this function and those listed in the SEE ALSO section should be used for classification of wide-character codes.

RATIONALE

CHANGE HISTORY

First released in Issue 4.

Issue 5

The following change has been made in this issue for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E):

- The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

iswctype — test character for a specified class

SYNOPSIS

```
#include <wctype.h>

int iswctype(wint_t wc, wctype_t charclass);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *iswctype*( ) function shall determine whether the wide-character code *wc* has the character class *charclass*, returning true or false. The *iswctype*( ) function is defined on WEOF and wide-character codes corresponding to the valid character encodings in the current locale. If the *wc* argument is not in the domain of the function, the result is undefined. If the value of *charclass* is invalid (that is, not obtained by a call to *wctype*( ) or *charclass* is invalidated by a subsequent call to *setlocale*( ) that has affected category *LC_CTYPE*) the result is unspecified.

RETURN VALUE

The *iswctype*( ) function shall return non-zero (true) if and only if *wc* has the property described by *charclass*. CX If *charclass* is 0, *iswctype*( ) shall return 0.

ERRORS

No errors are defined.

EXAMPLES

Testing for a Valid Character

```
#include <wctype.h>
...
int yes_or_no;
wint_t wc;
wctype_t valid_class;
...
if ((valid_class=wctype("vowel")) == (wctype_t)0)
    /* Invalid character class. */
yes_or_no=iswctype(wc,valid_class);
```

APPLICATION USAGE

The twelve strings `"alnum"`, `"alpha"`, `"blank"`, `"cntrl"`, `"digit"`, `"graph"`, `"lower"`, `"print"`, `"punct"`, `"space"`, `"upper"`, and `"xdigit"` are reserved for the standard character classes. In the table below, the functions in the left column are equivalent to the functions in the right column.

```
iswalnum(wc)    iswctype(wc, wctype("alnum"))
iswalpha(wc)    iswctype(wc, wctype("alpha"))
iswblank(wc)    iswctype(wc, wctype("blank"))
iswcntrl(wc)    iswctype(wc, wctype("cntrl"))
iswdigit(wc)    iswctype(wc, wctype("digit"))
iswgraph(wc)    iswctype(wc, wctype("graph"))
iswlower(wc)    iswctype(wc, wctype("lower"))
iswprint(wc)    iswctype(wc, wctype("print"))
iswpunct(wc)    iswctype(wc, wctype("punct"))
iswspace(wc)    iswctype(wc, wctype("space"))
```

```
iswupper(wc)    iswctype(wc, wctype("upper"))
iswxdigit(wc)   iswctype(wc, wctype("xdigit"))
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

iswalnum( ), *iswalpha*( ), *iswcntrl*( ), *iswdigit*( ), *iswgraph*( ), *iswlower*( ), *iswprint*( ), *iswpunct*( ), *iswspace*( ), *iswupper*( ), *iswxdigit*( ), *setlocale*( ), *wctype*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<wctype.h>**, **<wchar.h>**

CHANGE HISTORY

First released as World-wide Portability Interfaces in Issue 4.

Issue 5

The following change has been made in this issue for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E):

- The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 6

The behavior of $n=0$ is now described.

An example is added.

A new function, *iswblank*( ), is added to the list in the APPLICATION USAGE.

NAME

iswdigit — test for a decimal digit wide-character code

SYNOPSIS

```
#include <wctype.h>

int iswdigit(wint_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *iswdigit*( ) function shall test whether *wc* is a wide-character code representing a character of class **digit** in the program's current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale.

The *wc* argument is a **wint_t**, the value of which the application shall ensure is a wide-character code corresponding to a valid character in the current locale, or equal to the value of the macro WEOF. If the argument has any other value, the behavior is undefined. |

RETURN VALUE

The *iswdigit*( ) function shall return non-zero if *wc* is a decimal digit wide-character code; otherwise, it shall return 0.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

To ensure applications portability, especially across natural languages, only this function and those listed in the SEE ALSO section should be used for classification of wide-character codes.

The following change has been made in this issue for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E):

- The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 6

The DESCRIPTION is updated to avoid use of the term "must" for application requirements.

NAME

iswgraph — test for a visible wide-character code

SYNOPSIS

```
#include <wctype.h>

int iswgraph(wint_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *iswgraph*( ) function shall test whether *wc* is a wide-character code representing a character of class **graph** in the program's current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale.

The *wc* argument is a **wint_t**, the value of which the application shall ensure is a wide-character code corresponding to a valid character in the current locale, or equal to the value of the macro WEOF. If the argument has any other value, the behavior is undefined. |

RETURN VALUE

The *iswgraph*( ) function shall return non-zero if *wc* is a wide-character code with a visible representation; otherwise, it shall return 0.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

To ensure applications portability, especially across natural languages, only this function and those listed in the SEE ALSO section should be used for classification of wide-character codes.

- The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 6

The DESCRIPTION is updated to avoid use of the term ''must'' for application requirements.

NAME

iswlower — test for a lowercase letter wide-character code

SYNOPSIS

```
#include <wctype.h>

int iswlower(wint_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *iswlower*( ) function shall test whether *wc* is a wide-character code representing a character of class **lower** in the program's current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale.

The *wc* argument is a **wint_t**, the value of which the application shall ensure is a wide-character code corresponding to a valid character in the current locale, or equal to the value of the macro WEOF. If the argument has any other value, the behavior is undefined. |

RETURN VALUE

The *iswlower*( ) function shall return non-zero if *wc* is a lowercase letter wide-character code; otherwise, it shall return 0.

ERRORS

No errors are defined.

NAME

iswxdigit — test for a hexadecimal digit wide-character code

SYNOPSIS

```
#include <wctype.h>

int iswxdigit(wint_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *iswxdigit*( ) function shall test whether *wc* is a wide-character code representing a character of class **xdigit** in the program's current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale.

The *wc* argument is a **wint_t**, the value of which the application shall ensure is a wide-character code corresponding to a valid character in the current locale, or equal to the value of the macro WEOF. If the argument has any other value, the behavior is undefined. |

RETURN VALUE

The *iswxdigit*( ) function shall return non-zero if *wc* is a hexadecimal digit wide-character code; otherwise, it shall return 0.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

To ensure applications portability, especially across natural languages, only this function and those listed in the SEE ALSO section should be used for classification of wide-character codes.

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 4.

Issue 5

The following change has been made in this issue for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E):

- The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 6

The DESCRIPTION is updated to avoid use of the term ''must'' for application requirements.

NAME

isxdigit — test for a hexadecimal digit

SYNOPSIS

```
#include <ctype.h>

int isxdigit(int c);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *isxdigit*( ) function shall test whether *c* is a character of class **xdigit** in the program's current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale.

The *c* argument is an **int**, the value of which the application shall ensure is a character representable as an **unsigned char** or equal to the value of the macro EOF. If the argument has any other value, the behavior is undefined. |

RETURN VALUE

The *isxdigit*( ) function shall return non-zero if *c* is a hexadecimal digit; otherwise, it shall return 0.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

To ensure applications portability, especially across natural languages, only this function and those listed in the SEE ALSO section should be used for character classification.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The DESCRIPTION is updated to avoid use of the term ''must'' for application requirements.

NAME

j0, j1, jn — Bessel functions of the first kind

SYNOPSIS

XSI
```
#include <math.h>

double j0(double x);
double j1(double x);
double jn(int n, double x);
```

DESCRIPTION

The *j0*( ), *j1*( ), and *jn*( ) functions shall compute Bessel functions of *x* of the first kind of orders 0, 1, and *n*, respectively.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the relevant Bessel value of *x* of the first kind.

If the *x* argument is too large in magnitude, or the correct result would cause underflow, 0 shall be returned and a range error may occur.

If *x* is NaN, a NaN shall be returned.

ERRORS

These functions may fail if:

Range Error The value of *x* was too large in magnitude, or an underflow occurred.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised. |

No other errors shall occur.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6

The may fail [EDOM] error is removed for the case for NaN.

The RETURN VALUE and ERRORS sections are reworked for alignment of the error handling with the ISO / IEC 9899: 1999 standard. |

NAME

jrand48 — generate a uniformly distributed pseudo-random long signed integer

SYNOPSIS

XSI

```
#include <stdlib.h>

long jrand48(unsigned short xsubi[3]);
```

DESCRIPTION

Refer to *drand48*( ).

NAME

kill — send a signal to a process or a group of processes

SYNOPSIS

CX
```
#include <signal.h>

int kill(pid_t pid, int sig);
```

DESCRIPTION

The *kill*( ) function shall send a signal to a process or a group of processes specified by *pid*. The signal to be sent is specified by *sig* and is either one from the list given in **<signal.h>** or 0. If *sig* is 0 (the null signal), error checking is performed but no signal is actually sent. The null signal can be used to check the validity of *pid*.

For a process to have permission to send a signal to a process designated by *pid*, unless the sending process has appropriate privileges, the real or effective user ID of the sending process shall match the real or saved set-user-ID of the receiving process.

If *pid* is greater than 0, *sig* shall be sent to the process whose process ID is equal to *pid*.

If *pid* is 0, *sig* shall be sent to all processes (excluding an unspecified set of system processes) whose process group ID is equal to the process group ID of the sender, and for which the process has permission to send a signal.

If *pid* is −1, *sig* shall be sent to all processes (excluding an unspecified set of system processes) for which the process has permission to send that signal.

If *pid* is negative, but not −1, *sig* shall be sent to all processes (excluding an unspecified set of system processes) whose process group ID is equal to the absolute value of *pid*, and for which the process has permission to send a signal.

If the value of *pid* causes *sig* to be generated for the sending process, and if *sig* is not blocked for the calling thread and if no other thread has *sig* unblocked or is waiting in a *sigwait*( ) function for *sig*, either *sig* or at least one pending unblocked signal shall be delivered to the sending thread before *kill*( ) returns.

The user ID tests described above shall not be applied when sending SIGCONT to a process that is a member of the same session as the sending process.

An implementation that provides extended security controls may impose further implementation-defined restrictions on the sending of signals, including the null signal. In particular, the system may deny the existence of some or all of the processes specified by *pid*.

The *kill*( ) function is successful if the process has permission to send *sig* to any of the processes specified by *pid*. If *kill*( ) fails, no signal shall be sent.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *kill*( ) function shall fail if:

[EINVAL]	The value of the *sig* argument is an invalid or unsupported signal number.
[EPERM]	The process does not have permission to send the signal to any receiving process.
[ESRCH]	No process or process group can be found corresponding to that specified by *pid*.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The semantics for permission checking for *kill*( ) differed between System V and most other implementations, such as Version 7 or 4.3 BSD. The semantics chosen for this volume of IEEE Std 1003.1-200x agree with System V. Specifically, a set-user-ID process cannot protect itself against signals (or at least not against SIGKILL) unless it changes its real user ID. This choice allows the user who starts an application to send it signals even if it changes its effective user ID. The other semantics give more power to an application that wants to protect itself from the user who ran it.

Some implementations provide semantic extensions to the *kill*( ) function when the absolute value of *pid* is greater than some maximum, or otherwise special, value. Negative values are a flag to *kill*( ). Since most implementations return [ESRCH] in this case, this behavior is not included in this volume of IEEE Std 1003.1-200x, although a conforming implementation could provide such an extension.

The implementation-defined processes to which a signal cannot be sent may include the scheduler or *init*.

There was initially strong sentiment to specify that, if *pid* specifies that a signal be sent to the calling process and that signal is not blocked, that signal would be delivered before *kill*( ) returns. This would permit a process to call *kill*( ) and be guaranteed that the call never return. However, historical implementations that provide only the *signal*( ) function make only the weaker guarantee in this volume of IEEE Std 1003.1-200x, because they only deliver one signal each time a process enters the kernel. Modifications to such implementations to support the *sigaction*( ) function generally require entry to the kernel following return from a signal-catching function, in order to restore the signal mask. Such modifications have the effect of satisfying the stronger requirement, at least when *sigaction*( ) is used, but not necessarily when *signal*( ) is used. The developers of this volume of IEEE Std 1003.1-200x considered making the stronger requirement except when *signal*( ) is used, but felt this would be unnecessarily complex. Implementors are encouraged to meet the stronger requirement whenever possible. In practice, the weaker requirement is the same, except in the rare case when two signals arrive during a very short window. This reasoning also applies to a similar requirement for *sigprocmask*( ).

In 4.2 BSD, the SIGCONT signal can be sent to any descendant process regardless of user-ID security checks. This allows a job control shell to continue a job even if processes in the job have altered their user IDs (as in the *su* command). In keeping with the addition of the concept of sessions, similar functionality is provided by allowing the SIGCONT signal to be sent to any process in the same session regardless of user ID security checks. This is less restrictive than BSD in the sense that ancestor processes (in the same session) can now be the recipient. It is more restrictive than BSD in the sense that descendant processes that form new sessions are now subject to the user ID checks. A similar relaxation of security is not necessary for the other job control signals since those signals are typically sent by the terminal driver in recognition of special characters being typed; the terminal driver bypasses all security checks.

In secure implementations, a process may be restricted from sending a signal to a process having a different security label. In order to prevent the existence or nonexistence of a process from being used as a covert channel, such processes should appear nonexistent to the sender; that is, [ESRCH] should be returned, rather than [EPERM], if *pid* refers only to such processes.

Existing implementations vary on the result of a *kill*( ) with *pid* indicating an inactive process (a terminated process that has not been waited for by its parent). Some indicate success on such a call (subject to permission checking), while others give an error of [ESRCH]. Since the definition of process lifetime in this volume of IEEE Std 1003.1-200x covers inactive processes, the [ESRCH] error as described is inappropriate in this case. In particular, this means that an application cannot have a parent process check for termination of a particular child with *kill*( ). (Usually this is done with the null signal; this can be done reliably with *waitpid*( ).)

There is some belief that the name *kill*( ) is misleading, since the function is not always intended to cause process termination. However, the name is common to all historical implementations, and any change would be in conflict with the goal of minimal changes to existing application code.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with POSIX Threads Extension.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the second paragraph is reworded to indicate that the saved set-user-ID of the calling process is checked in place of its effective user ID. This is a FIPS requirement.
- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- The behavior when *pid* is −1 is now specified. It was previously explicitly unspecified in the POSIX.1-1988 standard.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

killpg — send a signal to a process group

SYNOPSIS

XSI

```
#include <signal.h>

int killpg(pid_t pgrp, int sig);
```

DESCRIPTION

The *killpg*( ) function shall send the signal specified by *sig* to the process group specified by *pgrp*.

If *pgrp* is greater than 1, *killpg*(*pgrp*, *sig*) shall be equivalent to *kill*(−*pgrp*, *sig*). If *pgrp* is less than or equal to 1, the behavior of *killpg*( ) is undefined.

RETURN VALUE

Refer to *kill*( ).

ERRORS

Refer to *kill*( ).

NAME

lchown — change the owner and group of a symbolic link

SYNOPSIS

XSI
```
#include <unistd.h>

int lchown(const char *path, uid_t owner, gid_t group);
```

DESCRIPTION

The *lchown*( ) function shall be equivalent to *chown*( ), except in the case where the named file is a symbolic link. In this case, *lchown*( ) shall change the ownership of the symbolic link file itself, while *chown*( ) changes the ownership of the file or directory to which the symbolic link refers. |

RETURN VALUE

Upon successful completion, *lchown*( ) shall return 0. Otherwise, it shall return −1 and set *errno* to indicate an error.

ERRORS

The *lchown*( ) function shall fail if:

[EACCES]	Search permission is denied on a component of the path prefix of *path*.
[EINVAL]	The owner or group ID is not a value supported by the implementation.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of a pathname exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}. |
[ENOENT]	A component of *path* does not name an existing file or *path* is an empty string.
[ENOTDIR]	A component of the path prefix of *path* is not a directory.
[EOPNOTSUPP]	The *path* argument names a symbolic link and the implementation does not support setting the owner or group of a symbolic link.
[EPERM]	The effective user ID does not match the owner of the file and the process does not have appropriate privileges.
[EROFS]	The file resides on a read-only file system.

The *lchown*( ) function may fail if:

[EIO]	An I/O error occurred while reading or writing to the file system.
[EINTR]	A signal was caught during execution of the function.
[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[ENAMETOOLONG]	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds {PATH_MAX}. |

EXAMPLES

Changing the Current Owner of a File

The following example shows how to change the ownership of the symbolic link named **/modules/pass1** to the user ID associated with ‘‘jones’’ and the group ID associated with ‘‘cnd’’.

The numeric value for the user ID is obtained by using the *getpwnam*( ) function. The numeric value for the group ID is obtained by using the *getgrnam*( ) function.

```
#include <sys/types.h>
#include <unistd.h>
#include <pwd.h>
#include <grp.h>

struct passwd *pwd;
struct group  *grp;
char          *path = "/modules/pass1";
...
pwd = getpwnam("jones");
grp = getgrnam("cnd");
lchown(path, pwd->pw_uid, grp->gr_gid);
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

chown( ), *symlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<unistd.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X / OPEN UNIX extension to BASE.

Issue 6

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.

NAME

lcong48 — seed a uniformly distributed pseudo-random signed long integer generator

SYNOPSIS

XSI
```
#include <stdlib.h>

void lcong48(unsigned short param[7]);
```

DESCRIPTION

Refer to *drand48*( ).

NAME

ldexp, ldexpf, ldexpl — load exponent of a floating-point number

SYNOPSIS

```
#include <math.h>

double ldexp(double x, int exp);
float ldexpf(float x, int exp);
long double ldexpl(long double x, int exp);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the quantity $x * 2^{exp}$.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return *x* multiplied by 2, raised to the power *exp*.

If these functions would cause overflow, a range error shall occur and *ldexp*( ), *ldexpf*( ), and *ldexpl*( ) shall return ±HUGE_VAL, ±HUGE_VALF, and ±HUGE_VALL (according to the sign of *x*), respectively.

MX If the correct value would cause underflow, and is not representable, a range error may occur, and either 0.0 (if supported), or an implementation-defined value shall be returned.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0 or ±Inf, *x* shall be returned.

If *exp* is 0, *x* shall be returned.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value shall be returned.

ERRORS

These functions shall fail if:

Range Error	The result overflows. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

These functions may fail if:

Range Error	The result underflows. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6

The *ldexpf*( ) and *ldexpl*( ) functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

IEC 60559:1989 standard floating-point extensions over the ISO/IEC 9899:1999 standard are marked.

NAME

ldiv, lldiv — compute quotient and remainder of a long division

SYNOPSIS

```
#include <stdlib.h>

ldiv_t ldiv(long numer, long denom);
lldiv_t lldiv(long long numer, long long denom);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the quotient and remainder of the division of the numerator *numer* by the denominator *denom*. If the division is inexact, the resulting quotient is the **long** integer (for the *ldiv*( ) function) or **long long** integer (for the *lldiv*( ) function) of lesser magnitude that is the nearest to the algebraic quotient. If the result cannot be represented, the behavior is undefined; otherwise, *quot* * *denom*+*rem* shall equal *numer*.

RETURN VALUE

The *ldiv*( ) function shall return a structure of type **ldiv_t**, comprising both the quotient and the remainder. The structure shall include the following members, in any order: |

```
long   quot;    /* Quotient */
long   rem;     /* Remainder */
```

The *lldiv*( ) function shall return a structure of type **lldiv_t**, comprising both the quotient and the remainder. The structure shall include the following members, in any order: |

```
long long   quot;    /* Quotient */
long long   rem;     /* Remainder */
```

ERRORS

No errors are defined.

NAME

lfind — find entry in a linear search table

SYNOPSIS

XSI

```
#include <search.h>

void *lfind(const void *key, const void *base, size_t *nelp,
    size_t width, int (*compar)(const void *, const void *));

```

DESCRIPTION

Refer to *lsearch*( ).

NAME

lgamma, lgammaf, lgammal — log gamma function

SYNOPSIS

```
#include <math.h>

double lgamma(double x);
float lgammaf(float x);
long double lgammal(long double x);
extern int signgam;
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute $\log_e|\Gamma(x)|$ where $\Gamma(x)$ is defined as $\int_0^\infty e^{-t}t^{x-1}dt$. The argument x need not be a non-positive integer ($\Gamma(x)$ is defined over the reals, except the non-positive integers).

XSI The sign of $\Gamma(x)$ is returned in the external integer *signgam*.

CX These functions need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the logarithmic gamma of x.

If x is a non-positive integer, a pole error shall occur and *lgamma*( ), *lgammaf*( ), and *lgammal*( ) shall return +HUGE_VAL, +HUGE_VALF, and +HUGE_VALL, respectively.

If the correct value would cause overflow, a range error shall occur and *lgamma*( ), *lgammaf*( ), and *lgammal*( ) shall return ±HUGE_VAL, ±HUGE_VALF, and ±HUGE_VALL (having the same sign as the correct value), respectively.

MX If x is NaN, a NaN shall be returned.

If x is 1 or 2, +0 shall be returned.

If x is ±Inf, +Inf shall be returned

ERRORS

These functions shall fail if:

Pole Error	The x argument is a negative integer or zero. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.
Range Error	The result overflows

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

Issue 5

The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

A note indicating that this function need not be reentrant is added to the DESCRIPTION.

Issue 6

The *lgamma*( ) function is no longer marked as an extension.

The *lgammaf*( ) and *lgammal*( ) functions are added for alignment with the ISO / IEC 9899: 1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO / IEC 9899: 1999 standard.

IEC 60559: 1989 standard floating-point extensions over the ISO / IEC 9899: 1999 standard are marked.

XSI extensions are marked.

NAME

link — link to a file

SYNOPSIS

```
#include <unistd.h>

int link(const char *path1, const char *path2);
```

DESCRIPTION

The *link*( ) function shall create a new link (directory entry) for the existing file, *path1*.

The *path1* argument points to a pathname naming an existing file. The *path2* argument points to a pathname naming the new directory entry to be created. The *link*( ) function shall atomically create a new link for the existing file and the link count of the file shall be incremented by one.

If *path1* names a directory, *link*( ) shall fail unless the process has appropriate privileges and the implementation supports using *link*( ) on directories.

Upon successful completion, *link*( ) shall mark for update the *st_ctime* field of the file. Also, the *st_ctime* and *st_mtime* fields of the directory that contains the new entry shall be marked for update.

If *link*( ) fails, no link shall be created and the link count of the file shall remain unchanged.

The implementation may require that the calling process has permission to access the existing file.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *link*( ) function shall fail if:

[EACCES]	A component of either path prefix denies search permission, or the requested link requires writing in a directory that denies write permission, or the calling process does not have permission to access the existing file and this is required by the implementation.
[EEXIST]	The *path2* argument resolves to an existing file or refers to a symbolic link.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path1* or *path2* argument.
[EMLINK]	The number of links to the file named by *path1* would exceed {LINK_MAX}.
[ENAMETOOLONG]	The length of the *path1* or *path2* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of either path prefix does not exist; the file named by *path1* does not exist; or *path1* or *path2* points to an empty string.
[ENOSPC]	The directory to contain the link cannot be extended.
[ENOTDIR]	A component of either path prefix is not a directory.
[EPERM]	The file named by *path1* is a directory and either the calling process does not have appropriate privileges or the implementation prohibits using *link*( ) on directories.

[EROFS] The requested link requires writing in a directory on a read-only file system.

[EXDEV] The link named by *path2* and the file named by *path1* are on different file systems and the implementation does not support links between file systems, XSR or *path1* refers to a named STREAM.

The *link*( ) function may fail if:

[ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path1* or *path2* argument.

[ENAMETOOLONG] As a result of encountering a symbolic link in resolution of the *path1* or *path2* argument, the length of the substituted pathname string exceeded {PATH_MAX}. |

EXAMPLES

Creating a Link to a File

The following example shows how to create a link to a file named **/home/cnd/mod1** by creating a new directory entry named **/modules/pass1**.

```
#include <unistd.h>

char *path1 = "/home/cnd/mod1";
char *path2 = "/modules/pass1";
int   status;
...
status = link (path1, path2);
```

Creating a Link to a File Within a Program

In the following program example, the *link*( ) function links the **/etc/passwd** file (defined as **PASSWDFILE**) to a file named **/etc/opasswd** (defined as **SAVEFILE**), which is used to save the current password file. Then, after removing the current password file (defined as **PASSWDFILE**), the new password file is saved as the current password file using the *link*( ) function again. |

```
#include <unistd.h>

#define LOCKFILE "/etc/ptmp"
#define PASSWDFILE "/etc/passwd"
#define SAVEFILE "/etc/opasswd"
...
/* Save current password file */
link (PASSWDFILE, SAVEFILE);

/* Remove current password file. */
unlink (PASSWDFILE);

/* Save new password file as current password file. */
link (LOCKFILE,PASSWDFILE);
```

APPLICATION USAGE

Some implementations do allow links between file systems.

RATIONALE

Linking to a directory is restricted to the superuser in most historical implementations because this capability may produce loops in the file hierarchy or otherwise corrupt the file system. This volume of IEEE Std 1003.1-200x continues that philosophy by prohibiting *link*( ) and *unlink*( ) from doing this. Other functions could do it if the implementor designed such an extension.

Some historical implementations allow linking of files on different file systems. Wording was added to explicitly allow this optional behavior. |

The exception for cross-file system links is intended to apply only to links that are programmatically indistinguishable from ‘‘hard’’ links.

FUTURE DIRECTIONS

None.

SEE ALSO

symlink( ), *unlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<unistd.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification: |

- The [ELOOP] mandatory error condition is added.
- A second [ENAMETOOLONG] is added as an optional error condition.

The following changes were made to align with the IEEE P1003.1a draft standard:

- An explanation is added of action when *path2* refers to a symbolic link.
- The [ELOOP] optional error condition is added.

NAME

lio_listio — list directed I/O (**REALTIME**)

SYNOPSIS

AIO

```
#include <aio.h>

int lio_listio(int mode, struct aiocb *restrict const list[restrict],
    int nent, struct sigevent *restrict sig);

```

DESCRIPTION

The *lio_listio*( ) function shall initiate a list of I/O requests with a single function call.

The *mode* argument takes one of the values LIO_WAIT or LIO_NOWAIT declared in **<aio.h>** and determines whether the function returns when the I/O operations have been completed, or as soon as the operations have been queued. If the *mode* argument is LIO_WAIT, the function shall wait until all I/O is complete and the *sig* argument shall be ignored.

If the *mode* argument is LIO_NOWAIT, the function shall return immediately, and asynchronous notification shall occur, according to the *sig* argument, when all the I/O operations complete. If *sig* is NULL, then no asynchronous notification shall occur. If *sig* is not NULL, asynchronous notification occurs as specified in Section 2.4.1 (on page 478) when all the requests in *list* have completed.

The I/O requests enumerated by *list* are submitted in an unspecified order.

The *list* argument is an array of pointers to **aiocb** structures. The array contains *nent* elements. The array may contain NULL elements, which shall be ignored.

The *aio_lio_opcode* field of each **aiocb** structure specifies the operation to be performed. The supported operations are LIO_READ, LIO_WRITE, and LIO_NOP; these symbols are defined in **<aio.h>**. The LIO_NOP operation causes the list entry to be ignored. If the *aio_lio_opcode* element is equal to LIO_READ, then an I/O operation is submitted as if by a call to *aio_read*( ) with the *aiocbp* equal to the address of the **aiocb** structure. If the *aio_lio_opcode* element is equal to LIO_WRITE, then an I/O operation is submitted as if by a call to *aio_write*( ) with the *aiocbp* equal to the address of the **aiocb** structure.

The *aio_fildes* member specifies the file descriptor on which the operation is to be performed.

The *aio_buf* member specifies the address of the buffer to or from which the data is transferred.

The *aio_nbytes* member specifies the number of bytes of data to be transferred.

The members of the **aiocb** structure further describe the I/O operation to be performed, in a manner identical to that of the corresponding **aiocb** structure when used by the *aio_read*( ) and *aio_write*( ) functions.

The *nent* argument specifies how many elements are members of the list; that is, the length of the array.

The behavior of this function is altered according to the definitions of synchronized I/O data integrity completion and synchronized I/O file integrity completion if synchronized I/O is enabled on the file associated with *aio_fildes*.

For regular files, no data transfer shall occur past the offset maximum established in the open file description associated with *aiocbp*->*aio_fildes*.

RETURN VALUE

If the *mode* argument has the value LIO_NOWAIT, the *lio_listio*( ) function shall return the value zero if the I/O operations are successfully queued; otherwise, the function shall return the value −1 and set *errno* to indicate the error.

If the *mode* argument has the value LIO_WAIT, the *lio_listio*( ) function shall return the value zero when all the indicated I/O has completed successfully. Otherwise, *lio_listio*( ) shall return a value of −1 and set *errno* to indicate the error.

In either case, the return value only indicates the success or failure of the *lio_listio*( ) call itself, not the status of the individual I/O requests. In some cases one or more of the I/O requests contained in the list may fail. Failure of an individual request does not prevent completion of any other individual request. To determine the outcome of each I/O request, the application shall examine the error status associated with each **aiocb** control block. The error statuses so returned are identical to those returned as the result of an *aio_read*( ) or *aio_write*( ) function.

ERRORS

The *lio_listio*( ) function shall fail if:

[EAGAIN]	The resources necessary to queue all the I/O requests were not available. The application may check the error status for each **aiocb** to determine the individual request(s) that failed.
[EAGAIN]	The number of entries indicated by *nent* would cause the system-wide limit {AIO_MAX} to be exceeded.
[EINVAL]	The *mode* argument is not a proper value, or the value of *nent* was greater than {AIO_LISTIO_MAX}.
[EINTR]	A signal was delivered while waiting for all I/O requests to complete during an LIO_WAIT operation. Note that, since each I/O operation invoked by *lio_listio*( ) may possibly provoke a signal when it completes, this error return may be caused by the completion of one (or more) of the very I/O operations being awaited. Outstanding I/O requests are not canceled, and the application shall examine each list element to determine whether the request was initiated, canceled, or completed.
[EIO]	One or more of the individual I/O operations failed. The application may check the error status for each **aiocb** structure to determine the individual request(s) that failed.

In addition to the errors returned by the *lio_listio*( ) function, if the *lio_listio*( ) function succeeds or fails with errors of [EAGAIN], [EINTR], or [EIO], then some of the I/O specified by the list may have been initiated. If the *lio_listio*( ) function fails with an error code other than [EAGAIN], [EINTR], or [EIO], no operations from the list shall have been initiated. The I/O operation indicated by each list element can encounter errors specific to the individual read or write function being performed. In this event, the error status for each **aiocb** control block contains the associated error code. The error codes that can be set are the same as would be set by a *read*( ) or *write*( ) function, with the following additional error codes possible:

[EAGAIN]	The requested I/O operation was not queued due to resource limitations.
[ECANCELED]	The requested I/O was canceled before the I/O completed due to an explicit *aio_cancel*( ) request.
[EFBIG]	The *aiocbp*->*aio_lio_opcode* is LIO_WRITE, the file is a regular file, *aiocbp*->*aio_nbytes* is greater than 0, and the *aiocbp*->*aio_offset* is greater than or equal to the offset maximum in the open file description associated with *aiocbp*-

>aio_fildes.

[EINPROGRESS] The requested I/O is in progress.

[EOVERFLOW] The *aiocbp->aio_lio_opcode* is LIO_READ, the file is a regular file, *aiocbp->aio_nbytes* is greater than 0, and the *aiocbp->aio_offset* is before the end-of-file and is greater than or equal to the offset maximum in the open file description associated with *aiocbp->aio_fildes*.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Although it may appear that there are inconsistencies in the specified circumstances for error codes, the [EIO] error condition applies when any circumstance relating to an individual operation makes that operation fail. This might be due to a badly formulated request (for example, the *aio_lio_opcode* field is invalid, and *aio_error*( ) returns [EINVAL]) or might arise from application behavior (for example, the file descriptor is closed before the operation is initiated, and *aio_error*( ) returns [EBADF]).

The limitation on the set of error codes returned when operations from the list shall have been initiated enables applications to know when operations have been started and whether *aio_error*( ) is valid for a specific operation.

FUTURE DIRECTIONS

None.

SEE ALSO

aio_read( ), *aio_write*( ), *aio_error*( ), *aio_return*( ), *aio_cancel*( ), *close*( ), *exec*, *exit*( ), *fork*( ), *lseek*( ), *read*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<aio.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Large File Summit extensions are added.

Issue 6

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Asynchronous Input and Output option.

The *lio_listio*( ) function is marked as part of the Asynchronous Input and Output option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, text is added to indicate that for regular files no data transfer occurs past the offset maximum established in the open file description associated with *aiocbp->aio_fildes*. This change is to support large files.
- The [EBIG] and [EOVERFLOW] error conditions are defined. This change is to support large files.

The DESCRIPTION is updated to avoid use of the term “must” for application requirements.

The **restrict** keyword is added to the *lio_listio*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

listen — listen for socket connections and limit the queue of incoming connections

SYNOPSIS

```
#include <sys/socket.h>

int listen(int socket, int backlog);
```

DESCRIPTION

The *listen*( ) function shall mark a connection-mode socket, specified by the *socket* argument, as accepting connections.

The *backlog* argument provides a hint to the implementation which the implementation shall use to limit the number of outstanding connections in the socket's listen queue. Implementations may impose a limit on *backlog* and silently reduce the specified value. Normally, a larger *backlog* argument value shall result in a larger or equal length of the listen queue. Implementations shall support values of *backlog* up to SOMAXCONN, defined in **<sys/socket.h>**.

The implementation may include incomplete connections in its listen queue. The limits on the number of incomplete connections and completed connections queued may be different.

The implementation may have an upper limit on the length of the listen queue—either global or per accepting socket. If *backlog* exceeds this limit, the length of the listen queue is set to the limit.

If *listen*( ) is called with a *backlog* argument value that is less than 0, the function behaves as if it had been called with a *backlog* argument value of 0.

A *backlog* argument of 0 may allow the socket to accept connections, in which case the length of the listen queue may be set to an implementation-defined minimum value.

The socket in use may require the process to have appropriate privileges to use the *listen*( ) function.

RETURN VALUE

Upon successful completions, *listen*( ) shall return 0; otherwise, –1 shall be returned and *errno* set to indicate the error.

ERRORS

The *listen*( ) function shall fail if:

[EBADF]	The *socket* argument is not a valid file descriptor.
[EDESTADDRREQ]	The socket is not bound to a local address, and the protocol does not support listening on an unbound socket.
[EINVAL]	The *socket* is already connected.
[ENOTSOCK]	The *socket* argument does not refer to a socket.
[EOPNOTSUPP]	The socket protocol does not support *listen*( ).

The *listen*( ) function may fail if:

[EACCES]	The calling process does not have the appropriate privileges.
[EINVAL]	The *socket* has been shut down.
[ENOBUFS]	Insufficient resources are available in the system to complete the call.

CHANGE HISTORY

First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

The DESCRIPTION is updated to describe the relationship of SOMAXCONN and the *backlog* argument.

NAME

llabs — return a long integer absolute value

SYNOPSIS

```
#include <stdlib.h>

long long llabs(long long i);
```

DESCRIPTION

Refer to *labs*( ).

NAME

lldiv — compute quotient and remainder of a long division

SYNOPSIS

```
#include <stdlib.h>

lldiv_t lldiv(long long numer, long long denom);
```

DESCRIPTION

Refer to *ldiv*( ).

NAME

llrint, llrintf, llrintl, — round to nearest integer value using current rounding direction

SYNOPSIS

```
#include <math.h>

long long llrint(double x);
long long llrintf(float x);
long long llrintl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall round their argument to the nearest integer value, rounding according to the current rounding direction.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the rounded integer value.

MX If *x* is NaN, a domain error shall occur, and an unspecified value is returned.

If *x* is +Inf, a domain error shall occur and an unspecified value is returned.

If *x* is –Inf, a domain error shall occur and an unspecified value is returned.

If the correct value is positive and too large to represent as a **long long**, a domain error shall occur and an unspecified value is returned. |

If the correct value is negative and too large to represent as a **long long**, a domain error shall occur and an unspecified value is returned. |

ERRORS

These functions shall fail if:

MX Domain Error The *x* argument is NaN or ±Inf, or the correct value is not representable as an integer.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised. |

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

These functions provide floating-to-integer conversions. They round according to the current rounding direction. If the rounded value is outside the range of the return type, the numeric result is unspecified and the invalid floating-point exception is raised. When they raise no other floating-point exception and the result differs from the argument, they raise the inexact

floating-point exception.

FUTURE DIRECTIONS

None.

SEE ALSO

feclearexcept( ), *fetestexcept*( ), *lrint*( ), the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.18, Treatment of Error Conditions for Mathematical Functions, **<math.h>**

CHANGE HISTORY

First released in Issue 6. Derived from the ISO / IEC 9899: 1999 standard.

NAME

llround, llroundf, llroundl, — round to nearest integer value

SYNOPSIS

```
#include <math.h>

long long llround(double x);
long long llroundf(float x);
long long llroundl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall round their argument to the nearest integer value, rounding halfway cases away from zero, regardless of the current rounding direction.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the rounded integer value.

MX If *x* is NaN, a domain error shall occur, and an unspecified value is returned.

If *x* is +Inf, a domain error shall occur and an unspecified value is returned.

If *x* is –Inf, a domain error shall occur and an unspecified value is returned.

If the correct value is positive and too large to represent as a **long long**, a domain error shall occur and an unspecified value is returned.

If the correct value is negative and too large to represent as a **long long**, a domain error shall occur and an unspecified value is returned.

ERRORS

These functions shall fail if:

MX Domain Error The *x* argument is NaN or ±Inf, or the correct value is not representable as an integer.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

These functions provide floating-to-integer conversions. They round according to the current rounding direction. If the rounded value is outside the range of the return type, the numeric result is unspecified and the invalid floating-point exception is raised. When they raise no other floating-point exception and the result differs from the argument, they raise the inexact

floating-point exception.

These functions differ from the *llrint*( ) functions in that the default rounding direction for the *llround*( ) functions round halfway cases away from zero and need not raise the inexact floating-point exception for non-integer arguments that round to within the range of the return type.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 6. Derived from the ISO/IEC 9899:1999 standard.

NAME

localeconv — return locale-specific information

SYNOPSIS

```
#include <locale.h>

struct lconv *localeconv(void);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *localeconv*( ) function shall set the components of an object with the type **struct lconv** with the values appropriate for the formatting of numeric quantities (monetary and otherwise) according to the rules of the current locale.

The members of the structure with type **char *** are pointers to strings, any of which (except **decimal_point**) can point to `""`, to indicate that the value is not available in the current locale or is of zero length. The members with type **char** are non-negative numbers, any of which can be {CHAR_MAX} to indicate that the value is not available in the current locale.

The members include the following:

char *decimal_point
The radix character used to format non-monetary quantities.

char *thousands_sep
The character used to separate groups of digits before the decimal-point character in formatted non-monetary quantities.

char *grouping
A string whose elements taken as one-byte integer values indicate the size of each group of digits in formatted non-monetary quantities.

char *int_curr_symbol
The international currency symbol applicable to the current locale. The first three characters contain the alphabetic international currency symbol in accordance with those specified in the ISO 4217: 1995 standard. The fourth character (immediately preceding the null byte) is the character used to separate the international currency symbol from the monetary quantity.

char *currency_symbol
The local currency symbol applicable to the current locale.

char *mon_decimal_point
The radix character used to format monetary quantities.

char *mon_thousands_sep
The separator for groups of digits before the decimal-point in formatted monetary quantities.

char *mon_grouping
A string whose elements taken as one-byte integer values indicate the size of each group of digits in formatted monetary quantities.

char *positive_sign
The string used to indicate a non-negative valued formatted monetary quantity.

char *negative_sign
The string used to indicate a negative valued formatted monetary quantity.

char int_frac_digits
The number of fractional digits (those after the decimal-point) to be displayed in an internationally formatted monetary quantity.

char frac_digits
The number of fractional digits (those after the decimal-point) to be displayed in a formatted monetary quantity.

char p_cs_precedes
Set to 1 if the **currency_symbol** or **int_curr_symbol** precedes the value for a non-negative formatted monetary quantity. Set to 0 if the symbol succeeds the value.

char p_sep_by_space
Set to 0 if no space separates the **currency_symbol** or **int_curr_symbol** from the value for a non-negative formatted monetary quantity. Set to 1 if a space separates the symbol from the XSI value; and set to 2 if a space separates the symbol and the sign string, if adjacent.

char n_cs_precedes
Set to 1 if the **currency_symbol** or **int_curr_symbol** precedes the value for a negative formatted monetary quantity. Set to 0 if the symbol succeeds the value.

char n_sep_by_space
Set to 0 if no space separates the **currency_symbol** or **int_curr_symbol** from the value for a negative formatted monetary quantity. Set to 1 if a space separates the symbol from the XSI value; and set to 2 if a space separates the symbol and the sign string, if adjacent.

char p_sign_posn
Set to a value indicating the positioning of the **positive_sign** for a non-negative formatted monetary quantity.

char n_sign_posn
Set to a value indicating the positioning of the **negative_sign** for a negative formatted monetary quantity.

char int_p_cs_precedes
Set to 1 or 0 if the **int_curr_symbol** respectively precedes or succeeds the value for a non-negative internationally formatted monetary quantity. |

char int_n_cs_precedes
Set to 1 or 0 if the **int_curr_symbol** respectively precedes or succeeds the value for a negative internationally formatted monetary quantity. |

char int_p_sep_by_space
Set to a value indicating the separation of the **int_curr_symbol**, the sign string, and the value for a non-negative internationally formatted monetary quantity. |

char int_n_sep_by_space
Set to a value indicating the separation of the **int_curr_symbol**, the sign string, and the value for a negative internationally formatted monetary quantity. |

char int_p_sign_posn
Set to a value indicating the positioning of the **positive_sign** for a non-negative internationally formatted monetary quantity.

char int_n_sign_posn
Set to a value indicating the positioning of the **negative_sign** for a negative internationally

formatted monetary quantity.

The elements of **grouping** and **mon_grouping** are interpreted according to the following:

{CHAR_MAX}	No further grouping is to be performed.
0	The previous element is to be repeatedly used for the remainder of the digits.
other	The integer value is the number of digits that comprise the current group. The next element is examined to determine the size of the next group of digits before the current group.

The values of **p_sep_by_space**, **n_sep_by_space**, **int_p_sep_by_space**, and **int_n_sep_by_space** are interpreted according to the following:

0 No space separates the currency symbol and value.

1 If the currency symbol and sign string are adjacent, a space separates them from the value; otherwise, a space separates the currency symbol from the value.

2 If the currency symbol and sign string are adjacent, a space separates them; otherwise, a space separates the sign string from the value.

For **int_p_sep_by_space** and **int_n_sep_by_space**, the fourth character of **int_curr_symbol** is used instead of a space.

The values of **p_sign_posn**, **n_sign_posn**, **int_p_sign_posn**, and **int_n_sign_posn** are interpreted according to the following:

0 Parentheses surround the quantity and **currency_symbol** or **int_curr_symbol**.

1 The sign string precedes the quantity and **currency_symbol** or **int_curr_symbol**.

2 The sign string succeeds the quantity and **currency_symbol** or **int_curr_symbol**.

3 The sign string immediately precedes the **currency_symbol** or **int_curr_symbol**.

4 The sign string immediately succeeds the **currency_symbol** or **int_curr_symbol**.

The implementation shall behave as if no function in this volume of IEEE Std 1003.1-200x calls *localeconv*( ).

CX The *localeconv*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

The *localeconv*( ) function shall return a pointer to the filled-in object. The application shall not modify the structure pointed to by the return value which may be overwritten by a subsequent call to *localeconv*( ). In addition, calls to *setlocale*( ) with the categories *LC_ALL*, *LC_MONETARY*, or *LC_NUMERIC* may overwrite the contents of the structure.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The following table illustrates the rules which may be used by four countries to format monetary quantities.

Country	Positive Format	Negative Format	International Format
Italy	L.1.230	–L.1.230	ITL.1.230
Netherlands	F 1.234,56	F –1.234,56	NLG 1.234,56
Norway	kr1.234,56	kr1.234,56–	NOK 1.234,56
Switzerland	SFrs.1,234.56	SFrs.1,234.56C	CHF 1,234.56

For these four countries, the respective values for the monetary members of the structure returned by *localeconv*( ) are:

	Italy	Netherlands	Norway	Switzerland
int_curr_symbol	"ITL."	"NLG "	"NOK "	"CHF "

CHANGE HISTORY

First released in Issue 4. Derived from the ANSI C standard.

Issue 6

A note indicating that this function need not be reentrant is added to the DESCRIPTION.

The RETURN VALUE section is rewritten to avoid use of the term ‘‘must’’.

This reference page is updated for alignment with the ISO/IEC 9899:1999 standard. |

ISO/IEC 9899:1999 standard, Technical Corrigendum No. 1 is incorporated. |

NAME

localtime, localtime_r — convert a time value to a broken-down local time

SYNOPSIS

```
#include <time.h>

struct tm *localtime(const time_t *timer);
struct tm *localtime_r(const time_t *restrict timer,
    struct tm *restrict result);

```

DESCRIPTION

For *localtime*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *localtime*( ) function shall convert the time in seconds since the Epoch pointed to by *timer* into a broken-down time, expressed as a local time. The function corrects for the timezone and any seasonal time adjustments. Local timezone information is used as though *localtime*( ) calls *tzset*( ).

The relationship between a time in seconds since the Epoch used as an argument to *localtime*( ) and the **tm** structure (defined in the **<time.h>** header) is that the result shall be as specified in the expression given in the definition of seconds since the Epoch (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.14, Seconds Since the Epoch) corrected for timezone and any seasonal time adjustments, where the names in the structure and in the expression correspond.

The same relationship shall apply for *localtime_r*( ).

The *localtime*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

The *asctime*( ), *ctime*( ), *gmtime*( ), and *localtime*( ) functions shall return values in one of two static objects: a broken-down time structure and an array of type **char**. Execution of any of the functions may overwrite the information returned in either of these objects by any of the other functions.

The *localtime_r*( ) function shall convert the time in seconds since the Epoch pointed to by *timer* into a broken-down time stored in the structure to which *result* points. The *localtime_r*( ) function shall also return a pointer to that same structure.

Unlike *localtime*( ), the reentrant version is not required to set *tzname*.

RETURN VALUE

The *localtime*( ) function shall return a pointer to the broken-down time structure.

Upon successful completion, *localtime_r*( ) shall return a pointer to the structure pointed to by the argument *result*.

ERRORS

No errors are defined.

EXAMPLES

Getting the Local Date and Time

The following example uses the *time*( ) function to calculate the time elapsed, in seconds, since January 1, 1970 0:00 UTC (the Epoch), *localtime*( ) to convert that value to a broken-down time, and *asctime*( ) to convert the broken-down time values into a printable string.

```
#include <stdio.h>
#include <time.h>

main()
{
    time_t result;

    result = time(NULL);
    printf("%s%ld secs since the Epoch\n",
        asctime(localtime(&result)),
            (long)result);
    return(0);
}
```

This example writes the current time to *stdout* in a form like this:

```
Wed Jun 26 10:32:15 1996
835810335 secs since the Epoch
```

Getting the Modification Time for a File

The following example gets the modification time for a file. The *localtime*( ) function converts the **time_t** value of the last modification date, obtained by a previous call to *stat*( ), into a **tm** structure that contains the year, month, day, and so on.

```
#include <time.h>
...
struct stat statbuf;
...
tm = localtime(&statbuf.st_mtime);
...
```

Timing an Event

The following example gets the current time, converts it to a string using *localtime*( ) and *asctime*( ), and prints it to standard output using *fputs*( ). It then prints the number of minutes to an event being timed.

```
#include <time.h>
#include <stdio.h>
...
time_t now;
int minutes_to_event;
...
time(&now);
printf("The time is ");
fputs(asctime(localtime(&now)), stdout);
printf("There are still %d minutes to the event.\n",
```

```
        minutes_to_event);
    ...
```

APPLICATION USAGE

The *localtime_r*( ) function is thread-safe and returns values in a user-supplied buffer instead of possibly using a static data area that may be overwritten by each call.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

asctime( ), *clock*( ), *ctime*( ), *difftime*( ), *getdate*( ), *gmtime*( ), *mktime*( ), *strftime*( ), *strptime*( ), *time*( ), *utime*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<time.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

A note indicating that the *localtime*( ) function need not be reentrant is added to the DESCRIPTION.

The *localtime_r*( ) function is included for alignment with the POSIX Threads Extension.

Issue 6

The *localtime_r*( ) function is marked as part of the Thread-Safe Functions option.

Extensions beyond the ISO C standard are now marked.

The APPLICATION USAGE section is updated to include a note on the thread-safe function and its avoidance of possibly using a static data area.

The **restrict** keyword is added to the *localtime_r*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

Examples are added.

NAME

lockf — record locking on files

SYNOPSIS

XSI

```
#include <unistd.h>

int lockf(int fildes, int function, off_t size);
```

DESCRIPTION

The *lockf*( ) function shall lock sections of a file with advisory-mode locks. Calls to *lockf*( ) from other threads which attempt to lock the locked file section shall either return an error value or block until the section becomes unlocked. All the locks for a process are removed when the process terminates. Record locking with *lockf*( ) shall be supported for regular files and may be supported for other files.

The *fildes* argument is an open file descriptor. To establish a lock with this function, the file descriptor shall be opened with write-only permission (O_WRONLY) or with read/write permission (O_RDWR).

The *function* argument is a control value which specifies the action to be taken. The permissible values for *function* are defined in **<unistd.h>** as follows:

Function	Description
F_ULOCK	Unlock locked sections.
F_LOCK	Lock a section for exclusive use.
F_TLOCK	Test and lock a section for exclusive use.
F_TEST	Test a section for locks by other processes.

F_TEST shall detect if a lock by another process is present on the specified section.

F_LOCK and F_TLOCK shall both lock a section of a file if the section is available.

F_ULOCK shall remove locks from a section of the file.

The *size* argument is the number of contiguous bytes to be locked or unlocked. The section to be locked or unlocked starts at the current offset in the file and extends forward for a positive size or backward for a negative size (the preceding bytes up to but not including the current offset). If *size* is 0, the section from the current offset through the largest possible file offset shall be locked (that is, from the current offset through the present or any future end-of-file). An area need not be allocated to the file to be locked because locks may exist past the end-of-file.

The sections locked with F_LOCK or F_TLOCK may, in whole or in part, contain or be contained by a previously locked section for the same process. When this occurs, or if adjacent locked sections would occur, the sections shall be combined into a single locked section. If the request would cause the number of locks to exceed a system-imposed limit, the request shall fail.

F_LOCK and F_TLOCK requests differ only by the action taken if the section is not available. F_LOCK shall block the calling thread until the section is available. F_TLOCK shall cause the function to fail if the section is already locked by another process.

File locks shall be released on first close by the locking process of any file descriptor for the file.

F_ULOCK requests may release (wholly or in part) one or more locked sections controlled by the process. Locked sections shall be unlocked starting at the current file offset through *size* bytes or to the end-of-file if *size* is (**off_t**)0. When all of a locked section is not released (that is, when the beginning or end of the area to be unlocked falls within a locked section), the remaining portions of that section shall remain locked by the process. Releasing the center portion of a locked section shall cause the remaining locked beginning and end portions to become two separate locked sections. If the request would cause the number of locks in the system to exceed a system-imposed limit, the request shall fail.

A potential for deadlock occurs if the threads of a process controlling a locked section are blocked by accessing another process' locked section. If the system detects that deadlock would occur, *lockf*( ) shall fail with an [EDEADLK] error.

The interaction between *fcntl*( ) and *lockf*( ) locks is unspecified.

Blocking on a section shall be interrupted by any signal.

An F_ULOCK request in which *size* is non-zero and the offset of the last byte of the requested section is the maximum value for an object of type **off_t**, when the process has an existing lock in which *size* is 0 and which includes the last byte of the requested section, shall be treated as a request to unlock from the start of the requested section with a size equal to 0. Otherwise, an F_ULOCK request shall attempt to unlock only the requested section.

Attempting to lock a section of a file that is associated with a buffered stream produces unspecified results.

RETURN VALUE

Upon successful completion, *lockf*( ) shall return 0. Otherwise, it shall return −1, set *errno* to indicate an error, and existing locks shall not be changed.

ERRORS

The *lockf*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid open file descriptor; or *function* is F_LOCK or F_TLOCK and *fildes* is not a valid file descriptor open for writing.
[EACCES] or [EAGAIN]	The *function* argument is F_TLOCK or F_TEST and the section is already locked by another process.
[EDEADLK]	The *function* argument is F_LOCK and a deadlock is detected.
[EINTR]	A signal was caught during execution of the function.
[EINVAL]	The *function* argument is not one of F_LOCK, F_TLOCK, F_TEST, or F_ULOCK; or *size* plus the current file offset is less than 0.
[EOVERFLOW]	The offset of the first, or if *size* is not 0 then the last, byte in the requested section cannot be represented correctly in an object of type **off_t**.

The *lockf*( ) function may fail if:

[EAGAIN]	The *function* argument is F_LOCK or F_TLOCK and the file is mapped with *mmap*( ).
[EDEADLK] or [ENOLCK]	The *function* argument is F_LOCK, F_TLOCK, or F_ULOCK, and the request would cause the number of locks to exceed a system-imposed limit.
[EOPNOTSUPP] or [EINVAL]	The implementation does not support the locking of files of the type indicated by the *fildes* argument.

EXAMPLES

Locking a Portion of a File

In the following example, a file named **/home/cnd/mod1** is being modified. Other processes that use locking are prevented from changing it during this process. Only the first 10,000 bytes are locked, and the lock call fails if another process has any part of this area locked already.

```
#include <fcntl.h>
#include <unistd.h>

int fildes;
int status;
...
fildes = open("/home/cnd/mod1", O_RDWR);
status = lockf(fildes, F_TLOCK, (off_t)10000);
```

APPLICATION USAGE

Record-locking should not be used in combination with the *fopen*( ), *fread*( ), *fwrite*( ), and other *stdio* functions. Instead, the more primitive, non-buffered functions (such as *open*( )) should be used. Unexpected results may occur in processes that do buffering in the user address space. The process may later read/write data which is/was locked. The *stdio* functions are the most common source of unexpected buffering.

The *alarm*( ) function may be used to provide a timeout facility in applications requiring it.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Large File Summit extensions are added. In particular, the description of [EINVAL] is clarified and moved from optional to mandatory status.

A note is added to the DESCRIPTION indicating the effects of attempting to lock a section of a file that is associated with a buffered stream.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

log, logf, logl — natural logarithm function

SYNOPSIS

```
#include <math.h>

double log(double x);
float logf(float x);
long double logl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the natural logarithm of their argument x, $\log_e(x)$.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the natural logarithm of x.

If x is ±0, a pole error shall occur and *log*( ), *logf*( ), and *logl*( ) shall return −HUGE_VAL, −HUGE_VALF, and −HUGE_VALL, respectively.

MX For finite values of x that are less than 0, or if x is −Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

MX If x is NaN, a NaN shall be returned.

If x is 1, +0 shall be returned.

If x is +Inf, x shall be returned.

ERRORS

These functions shall fail if:

Domain Error	MX The finite value of x is negative, or x is −Inf. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.
Pole Error	The value of x is zero. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

log1p, log1pf, log1pl — compute a natural logarithm

SYNOPSIS

```
#include <math.h>

double log1p(double x);
float log1pf(float x);
long double log1pl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute $\log_e(1.0 + x)$.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the natural logarithm of 1.0 + *x*.

If *x* is –1, a pole error shall occur and *log1p*( ), *log1pf*( ), and *log1pl*( ) shall return –HUGE_VAL, –HUGE_VALF, and –HUGE_VALL, respectively.

MX For finite values of *x* that are less than –1, or if *x* is –Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0, or +Inf, *x* shall be returned.

If *x* is subnormal, a range error may occur and *x* should be returned.

ERRORS

These functions shall fail if:

MX Domain Error — The finite value of *x* is less than –1, or *x* is –Inf.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

Pole Error — The value of *x* is –1.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.

These functions may fail if:

MX Range Error — The value of *x* is subnormal.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

log2()

NAME

log2, log2f, log2l — compute base 2 logarithm functions

SYNOPSIS

```
#include <math.h>

double log2(double x);
float log2f(float x);
long double log2l(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the base 2 logarithm of their argument x, $\log_2(x)$.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the base 2 logarithm of x.

If x is ±0, a pole error shall occur and *log2*( ), *log2f*( ), and *log2l*( ) shall return –HUGE_VAL, –HUGE_VALF, and –HUGE_VALL, respectively.

MX For finite values of x that are less than 0, or if x is –Inf a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

MX If x is NaN, a NaN shall be returned.

If x is 1, +0 shall be returned.

If x is +Inf, x shall be returned.

ERRORS

These functions shall fail if:

MX Domain Error	The finite value of x is less than zero, or x is –Inf. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.
Pole Error	The value of x is zero. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.

EXAMPLES

CHANGE HISTORY

First released in Issue 6. Derived from the ISO / IEC 9899: 1999 standard.

NAME

logb, logbf, logbl — radix-independent exponent

SYNOPSIS

```
#include <math.h>

double logb(double x);
float logbf(float x);
long double logbl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the exponent of *x*, which is the integral part of $\log_r |x|$, as a signed floating-point value, for non-zero *x*, where *r* is the radix of the machine's floating-point arithmetic, which is the value of FLT_RADIX defined in the **<float.h>** header.

If *x* is subnormal it is treated a though it were normalized; thus for finite positive *x*:

$$1 <= x * \texttt{FLT\_RADIX}^{-\texttt{logb}(x)} < \texttt{FLT\_RADIX}$$

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the exponent of *x*.

If *x* is ±0, a pole error shall occur and *logb*( ), *logbf*( ), and *logbl*( ) shall return −HUGE_VAL, −HUGE_VALF, and −HUGE_VALL, respectively.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±Inf, +Inf shall be returned.

ERRORS

These functions shall fail if:

Pole Error The value of *x* is ±0.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

The *logb*( ) function is no longer marked as an extension.

The *logbf*( ) and *logbl*( ) functions are added for alignment with the ISO/IEC 9899: 1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899: 1999 standard.

IEC 60559: 1989 standard floating-point extensions over the ISO/IEC 9899: 1999 standard are marked.

NAME

logf — natural logarithm function

SYNOPSIS

```
#include <math.h>

float logf(float x);
```

DESCRIPTION

Refer to *log*( ).

NAME

logl — natural logarithm function

SYNOPSIS

```
#include <math.h>

long double logl(long double x);
```

DESCRIPTION

Refer to *log*( ).

NAME

longjmp — non-local goto

SYNOPSIS

```
#include <setjmp.h>

void longjmp(jmp_buf env, int val);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *longjmp*( ) function shall restore the environment saved by the most recent invocation of *setjmp*( ) in the same thread, with the corresponding **jmp_buf** argument. If there is no such invocation, or if the function containing the invocation of *setjmp*( ) has terminated execution in the interim, or if the invocation of *setjmp*( ) was within the scope of an identifier with variably modified type and execution has left that scope in the interim, the behavior is undefined. CX It is unspecified whether *longjmp*( ) restores the signal mask, leaves the signal mask unchanged, or restores it to its value at the time *setjmp*( ) was called.

All accessible objects have values, and all other components of the abstract machine have state (for example, floating-point status flags and open files), as of the time *longjmp*( ) was called, except that the values of objects of automatic storage duration are unspecified if they meet all the following conditions:

- They are local to the function containing the corresponding *setjmp*( ) invocation.
- They do not have volatile-qualified type.
- They are changed between the *setjmp*( ) invocation and *longjmp*( ) call.

CX As it bypasses the usual function call and return mechanisms, *longjmp*( ) shall execute correctly in contexts of interrupts, signals, and any of their associated functions. However, if *longjmp*( ) is invoked from a nested signal handler (that is, from a function invoked as a result of a signal raised during the handling of another signal), the behavior is undefined.

The effect of a call to *longjmp*( ) where initialization of the **jmp_buf** structure was not performed in the calling thread is undefined.

RETURN VALUE

After *longjmp*( ) is completed, program execution continues as if the corresponding invocation of *setjmp*( ) had just returned the value specified by *val*. The *longjmp*( ) function shall not cause *setjmp*( ) to return 0; if *val* is 0, *setjmp*( ) shall return 1.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

Applications whose behavior depends on the value of the signal mask should not use *longjmp*( ) and *setjmp*( ), since their effect on the signal mask is unspecified, but should instead use the *siglongjmp*( ) and *sigsetjmp*( ) functions (which can save and restore the signal mask under application control).

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION now explicitly makes *longjmp*( )'s effect on the signal mask unspecified.

The DESCRIPTION is updated for alignment with the ISO/IEC 9899: 1999 standard.

NAME

lrand48 — generate uniformly distributed pseudo-random non-negative long integers

SYNOPSIS

XSI

```
#include <stdlib.h>

long lrand48(void);
```

DESCRIPTION

Refer to *drand48*( ).

NAME

lrint, lrintf, lrintl — round to nearest integer value using current rounding direction

SYNOPSIS

```
#include <math.h>

long lrint(double x);
long lrintf(float x);
long lrintl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall round their argument to the nearest integer value, rounding according to the current rounding direction.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the rounded integer value.

MX If *x* is NaN, a domain error shall occur, and an unspecified value is returned.

If *x* is +Inf, a domain error shall occur and an unspecified value is returned.

If *x* is –Inf, a domain error shall occur and an unspecified value is returned.

If the correct value is positive and too large to represent as a **long**, a domain error shall occur and an unspecified value is returned. |

If the correct value is negative and too large to represent as a **long**, a domain error shall occur and an unspecified value is returned. |

ERRORS

These functions shall fail if:

MX Domain Error The *x* argument is NaN or ±Inf, or the correct value is not representable as an integer.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised. |

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

These functions provide floating-to-integer conversions. They round according to the current rounding direction. If the rounded value is outside the range of the return type, the numeric result is unspecified and the invalid floating-point exception is raised. When they raise no other floating-point exception and the result differs from the argument, they raise the inexact

floating-point exception.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 6. Derived from the ISO / IEC 9899: 1999 standard.

NAME

lround, lroundf, lroundl — round to nearest integer value

SYNOPSIS

```
#include <math.h>

long lround(double x);
long lroundf(float x);
long lroundl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall round their argument to the nearest integer value, rounding halfway cases away from zero, regardless of the current rounding direction.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the rounded integer value.

MX If *x* is NaN, a domain error shall occur, and an unspecified value is returned.

If *x* is +Inf, a domain error shall occur and an unspecified value is returned.

If *x* is –Inf, a domain error shall occur and an unspecified value is returned.

If the correct value is positive and too large to represent as a **long**, a domain error shall occur and an unspecified value is returned. |

If the correct value is negative and too large to represent as a **long**, a domain error shall occur and an unspecified value is returned. |

ERRORS

These functions shall fail if:

MX Domain Error The *x* argument is NaN or ±Inf, or the correct value is not representable as an integer.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised. |

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

These functions provide floating-to-integer conversions. They round according to the current rounding direction. If the rounded value is outside the range of the return type, the numeric result is unspecified and the invalid floating-point exception is raised. When they raise no other floating-point exception and the result differs from the argument, they raise the inexact

floating-point exception.

These functions differ from the *lrint*( ) functions in the default rounding direction, with the *lround*( ) functions rounding halfway cases away from zero and needing not to raise the inexact floating-point exception for non-integer arguments that round to within the range of the return type.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 6. Derived from the ISO/IEC 9899:1999 standard.

NAME

lsearch, lfind — linear search and update

SYNOPSIS

XSI
```
#include <search.h>

void *lsearch(const void *key, void *base, size_t *nelp, size_t width,
    int (*compar)(const void *, const void *));
void *lfind(const void *key, const void *base, size_t *nelp,
    size_t width, int (*compar)(const void *, const void *));

```

DESCRIPTION

The *lsearch*( ) function shall linearly search the table and return a pointer into the table for the matching entry. If the entry does not occur, it shall be added at the end of the table. The *key* argument points to the entry to be sought in the table. The *base* argument points to the first element in the table. The *width* argument is the size of an element in bytes. The *nelp* argument points to an integer containing the current number of elements in the table. The integer to which *nelp* points shall be incremented if the entry is added to the table. The *compar* argument points to a comparison function which the application shall supply (for example, *strcmp*( )). It is called with two arguments that point to the elements being compared. The application shall ensure that the function returns 0 if the elements are equal, and non-zero otherwise. |

The *lfind*( ) function shall be equivalent to *lsearch*( ), except that if the entry is not found, it is not added to the table. Instead, a null pointer is returned. |

RETURN VALUE

If the searched for entry is found, both *lsearch*( ) and *lfind*( ) shall return a pointer to it. Otherwise, *lfind*( ) shall return a null pointer and *lsearch*( ) shall return a pointer to the newly added element.

Both functions shall return a null pointer in case of error.

ERRORS

No errors are defined.

EXAMPLES

Storing Strings in a Table

This fragment reads in less than or equal to TABSIZE strings of length less than or equal to ELSIZE and stores them in a table, eliminating duplicates.

```
#include <stdio.h>
#include <string.h>
#include <search.h>

#define TABSIZE 50
#define ELSIZE 120

...
    char line[ELSIZE], tab[TABSIZE][ELSIZE];
    size_t nel = 0;
    ...
    while (fgets(line, ELSIZE, stdin) != NULL && nel < TABSIZE)
        (void) lsearch(line, tab, &nel,
            ELSIZE, (int (*)(const void *, const void *)) strcmp);
    ...
```

Finding a Matching Entry

The following example finds any line that reads `"This is a test."`.

```
#include <search.h>
#include <string.h>
...
char line[ELSIZE], tab[TABSIZE][ELSIZE];
size_t nel = 0;
char *findline;
void *entry;

findline = "This is a test.\n";

entry = lfind(findline, tab, &nel, ELSIZE, (
    int (*)(const void *, const void *)) strcmp);
```

APPLICATION USAGE

The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

Undefined results can occur if there is not enough room in the table to add a new item.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

hcreate( ), *tsearch*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<search.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

lseek — move the read/write file offset

SYNOPSIS

```
#include <unistd.h>

off_t lseek(int fildes, off_t offset, int whence);
```

DESCRIPTION

The *lseek*( ) function shall set the file offset for the open file description associated with the file descriptor *fildes*, as follows:

- If *whence* is SEEK_SET, the file offset shall be set to *offset* bytes.
- If *whence* is SEEK_CUR, the file offset shall be set to its current location plus *offset*.
- If *whence* is SEEK_END, the file offset shall be set to the size of the file plus *offset*.

The symbolic constants SEEK_SET, SEEK_CUR, and SEEK_END are defined in **<unistd.h>**.

The behavior of *lseek*( ) on devices which are incapable of seeking is implementation-defined. The value of the file offset associated with such a device is undefined.

The *lseek*( ) function shall allow the file offset to be set beyond the end of the existing data in the file. If data is later written at this point, subsequent reads of data in the gap shall return bytes with the value 0 until data is actually written into the gap.

The *lseek*( ) function shall not, by itself, extend the size of a file.

SHM If *fildes* refers to a shared memory object, the result of the *lseek*( ) function is unspecified.

TYM If *fildes* refers to a typed memory object, the result of the *lseek*( ) function is unspecified.

RETURN VALUE

Upon successful completion, the resulting offset, as measured in bytes from the beginning of the file, shall be returned. Otherwise, (**off_t**)−1 shall be returned, *errno* shall be set to indicate the error, and the file offset shall remain unchanged.

ERRORS

The *lseek*( ) function shall fail if:

[EBADF]	The *fildes* argument is not an open file descriptor.
[EINVAL]	The *whence* argument is not a proper value, or the resulting file offset would be negative for a regular file, block special file, or directory.
[EOVERFLOW]	The resulting file offset would be a value which cannot be represented correctly in an object of type **off_t**.
[ESPIPE]	The *fildes* argument is associated with a pipe, FIFO, or socket.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The ISO C standard includes the functions *fgetpos*( ) and *fsetpos*( ), which work on very large files by use of a special positioning type.

Although *lseek*( ) may position the file offset beyond the end of the file, this function does not itself extend the size of the file. While the only function in IEEE Std 1003.1-200x that may directly extend the size of the file is *write*( ), *truncate*( ), and *ftruncate*( ), several functions originally derived from the ISO C standard, such as *fwrite*( ), *fprintf*( ), and so on, may do so (by causing calls on *write*( )).

An invalid file offset that would cause [EINVAL] to be returned may be both implementation-defined and device-dependent (for example, memory may have few invalid values). A negative file offset may be valid for some devices in some implementations.

The POSIX.1-1990 standard did not specifically prohibit *lseek*( ) from returning a negative offset. Therefore, an application was required to clear *errno* prior to the call and check *errno* upon return to determine whether a return value of (**off_t**)−1 is a negative offset or an indication of an error condition. The standard developers did not wish to require this action on the part of a conforming application, and chose to require that *errno* be set to [EINVAL] when the resulting file offset would be negative for a regular file, block special file, or directory.

FUTURE DIRECTIONS

None.

SEE ALSO

open( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/types.h>**, **<unistd.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension.

Large File Summit extensions are added.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- The [EOVERFLOW] error condition is added. This change is to support large files.

An additional [ESPIPE] error condition is added for sockets.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that *lseek*( ) results are unspecified for typed memory objects.

NAME

lstat — get symbolic link status

SYNOPSIS

```
#include <sys/stat.h>

int lstat(const char *restrict path, struct stat *restrict buf);
```

DESCRIPTION

The *lstat*( ) function shall be equivalent to *stat*( ), except when *path* refers to a symbolic link. In that case *lstat*( ) shall return information about the link, while *stat*( ) shall return information about the file the link references.

For symbolic links, the *st_mode* member shall contain meaningful information when used with the file type macros, and the *st_size* member shall contain the length of the pathname contained in the symbolic link. File mode bits and the contents of the remaining members of the **stat** structure are unspecified. The value returned in the *st_size* member is the length of the contents of the symbolic link, and does not count any trailing null.

RETURN VALUE

Upon successful completion, *lstat*( ) shall return 0. Otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *lstat*( ) function shall fail if:

[EACCES]	A component of the path prefix denies search permission.
[EIO]	An error occurred while reading from the file system.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of a pathname exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOTDIR]	A component of the path prefix is not a directory.
[ENOENT]	A component of *path* does not name an existing file or *path* is an empty string.
[EOVERFLOW]	The file size in bytes or the number of blocks allocated to the file or the file serial number cannot be represented correctly in the structure pointed to by *buf*.

The *lstat*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[ENAMETOOLONG]	As a result of encountering a symbolic link in resolution of the *path* argument, the length of the substituted pathname string exceeded {PATH_MAX}.
[EOVERFLOW]	One of the members is too large to store into the structure pointed to by the *buf* argument.

EXAMPLES

Obtaining Symbolic Link Status Information

The following example shows how to obtain status information for a symbolic link named **/modules/pass1**. The structure variable *buffer* is defined for the **stat** structure. If the *path* argument specified the filename for the file pointed to by the symbolic link (**/home/cnd/mod1**), the results of calling the function would be the same as those returned by a call to the *stat*( ) function.

```
#include <sys/stat.h>

struct stat buffer;
int status;
...
status = lstat("/modules/pass1", &buffer);
```

APPLICATION USAGE

None.

RATIONALE

The *lstat*( ) function is not required to update the time-related fields if the named file is not a symbolic link. While the *st_uid*, *st_gid*, *st_atime*, *st_mtime*, and *st_ctime* members of the **stat** structure may apply to a symbolic link, they are not required to do so. No functions in IEEE Std 1003.1-200x are required to maintain any of these time fields.

FUTURE DIRECTIONS

None.

SEE ALSO

fstat( ), *readlink*( ), *stat*( ), *symlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/stat.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Large File Summit extensions are added.

Issue 6

The following changes were made to align with the IEEE P1003.1a draft standard:

- This function is now mandatory.
- The [ELOOP] optional error condition is added.

The **restrict** keyword is added to the *lstat*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

makecontext, swapcontext — manipulate user contexts

SYNOPSIS

XSI
```
#include <ucontext.h>

void makecontext(ucontext_t *ucp, void (*func)(void),
    int argc, ...);
int swapcontext(ucontext_t *restrict oucp,
    const ucontext_t *restrict ucp);
```

DESCRIPTION

The *makecontext*( ) function shall modify the context specified by *ucp*, which has been initialized using *getcontext*( ). When this context is resumed using *swapcontext*( ) or *setcontext*( ), program execution shall continue by calling *func*, passing it the arguments that follow *argc* in the *makecontext*( ) call.

Before a call is made to *makecontext*( ), the application shall ensure that the context being modified has a stack allocated for it. The application shall ensure that the value of *argc* matches the number of integer arguments passed to *func*; otherwise, the behavior is undefined.

The *uc_link* member is used to determine the context that shall be resumed when the context being modified by *makecontext*( ) returns. The application shall ensure that the *uc_link* member is initialized prior to the call to *makecontext*( ).

The *swapcontext*( ) function shall save the current context in the context structure pointed to by *oucp* and shall set the context to the context structure pointed to by *ucp*.

RETURN VALUE

Upon successful completion, *swapcontext*( ) shall return 0. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *swapcontext*( ) function shall fail if:

[ENOMEM] The *ucp* argument does not have enough stack left to complete the operation.

EXAMPLES

The following example illustrates the use of *makecontext*( ):

```
#include <stdio.h>
#include <ucontext.h>

static ucontext_t ctx[3];

static void
f1 (void)
{
    puts("start f1");
    swapcontext(&ctx[1], &ctx[2]);
    puts("finish f1");
}

static void
f2 (void)
{
    puts("start f2");
    swapcontext(&ctx[2], &ctx[1]);
```

```
    puts("finish f2");
}

int
main (void)
{
    char st1[8192];
    char st2[8192];

    getcontext(&ctx[1]);
    ctx[1].uc_stack.ss_sp = st1;
    ctx[1].uc_stack.ss_size = sizeof st1;
    ctx[1].uc_link = &ctx[0];
    makecontext(&ctx[1], f1, 0);

    getcontext(&ctx[2]);
    ctx[2].uc_stack.ss_sp = st2;
    ctx[2].uc_stack.ss_size = sizeof st2;
    ctx[2].uc_link = &ctx[1];
    makecontext(&ctx[2], f2, 0);

    swapcontext(&ctx[0], &ctx[2]);
    return 0;
}
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

In the ERRORS section, the description of [ENOMEM] is changed to apply to *swapcontext*( ) only.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The **restrict** keyword is added to the *swapcontext*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

malloc — a memory allocator

SYNOPSIS

```
#include <stdlib.h>

void *malloc(size_t size);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *malloc*( ) function shall allocate unused space for an object whose size in bytes is specified by *size* and whose value is unspecified.

The order and contiguity of storage allocated by successive calls to *malloc*( ) is unspecified. The pointer returned if the allocation succeeds shall be suitably aligned so that it may be assigned to a pointer to any type of object and then used to access such an object in the space allocated (until the space is explicitly freed or reallocated). Each such allocation shall yield a pointer to an object disjoint from any other object. The pointer returned points to the start (lowest byte address) of the allocated space. If the space cannot be allocated, a null pointer shall be returned. If the size of the space requested is 0, the behavior is implementation-defined: the value returned shall be either a null pointer or a unique pointer.

RETURN VALUE

Upon successful completion with *size* not equal to 0, *malloc*( ) shall return a pointer to the allocated space. If *size* is 0, either a null pointer or a unique pointer that can be successfully passed to *free*( ) shall be returned. Otherwise, it shall return a null pointer CX and set *errno* to indicate the error.

ERRORS

The *malloc*( ) function shall fail if:

CX [ENOMEM] Insufficient storage space is available.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE section, the requirement to set *errno* to indicate an error is added.
- The [ENOMEM] error condition is added.

NAME

mblen — get number of bytes in a character

SYNOPSIS

```
#include <stdlib.h>

int mblen(const char *s, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

If *s* is not a null pointer, *mblen*( ) shall determine the number of bytes constituting the character pointed to by *s*. Except that the shift state of *mbtowc*( ) is not affected, it shall be equivalent to:

```
mbtowc((wchar_t *)0, s, n);
```

The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *mblen*( ).

The behavior of this function is affected by the *LC_CTYPE* category of the current locale. For a state-dependent encoding, this function shall be placed into its initial state by a call for which its character pointer argument, *s*, is a null pointer. Subsequent calls with *s* as other than a null pointer shall cause the internal state of the function to be altered as necessary. A call with *s* as a null pointer shall cause this function to return a non-zero value if encodings have state dependency, and 0 otherwise. If the implementation employs special bytes to change the shift state, these bytes shall not produce separate wide-character codes, but shall be grouped with an adjacent character. Changing the *LC_CTYPE* category causes the shift state of this function to be unspecified.

RETURN VALUE

If *s* is a null pointer, *mblen*( ) shall return a non-zero or 0 value, if character encodings, respectively, do or do not have state-dependent encodings. If *s* is not a null pointer, *mblen*( ) shall either return 0 (if *s* points to the null byte), or return the number of bytes that constitute the character (if the next *n* or fewer bytes form a valid character), or return −1 (if they do not form a valid character) CX and may set *errno* to indicate the error. In no case shall the value returned be greater than *n* or the value of the {MB_CUR_MAX} macro.

ERRORS

The *mblen*( ) function may fail if:

XSI [EILSEQ] Invalid character sequence is detected.

CHANGE HISTORY

First released in Issue 4. Aligned with the ISO C standard.

NAME

mbrlen — get number of bytes in a character (restartable)

SYNOPSIS

```
#include <wchar.h>

size_t mbrlen(const char *restrict s, size_t n,
    mbstate_t *restrict ps);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

If *s* is not a null pointer, *mbrlen*( ) shall determine the number of bytes constituting the character pointed to by *s*. It shall be equivalent to:

```
mbstate_t internal;
mbrtowc(NULL, s, n, ps != NULL ? ps : &internal);
```

If *ps* is a null pointer, the *mbrlen*( ) function shall use its own internal **mbstate_t** object, which is initialized at program start-up to the initial conversion state. Otherwise, the **mbstate_t** object pointed to by *ps* shall be used to completely describe the current conversion state of the associated character sequence. The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *mbrlen*( ).

The behavior of this function is affected by the *LC_CTYPE* category of the current locale.

RETURN VALUE

The *mbrlen*( ) function shall return the first of the following that applies:

0	If the next *n* or fewer bytes complete the character that corresponds to the null wide character.
positive	If the next *n* or fewer bytes complete a valid character; the value returned shall be the number of bytes that complete the character.
(**size_t**)–2	If the next *n* bytes contribute to an incomplete but potentially valid character, and all *n* bytes have been processed. When *n* has at least the value of the {MB_CUR_MAX} macro, this case can only occur if *s* points at a sequence of redundant shift sequences (for implementations with state-dependent encodings).
(**size_t**)–1	If an encoding error occurs, in which case the next *n* or fewer bytes do not contribute to a complete and valid character. In this case, [EILSEQ] shall be stored in *errno* and the conversion state is undefined.

ERRORS

The *mbrlen*( ) function may fail if:

[EINVAL]	*ps* points to an object that contains an invalid conversion state.
[EILSEQ]	Invalid character sequence is detected.

First released in Issue 5. Included for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E).

Issue 6

The *mbrlen*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

mbrtowc — convert a character to a wide-character code (restartable)

SYNOPSIS

```
#include <wchar.h>

size_t mbrtowc(wchar_t *restrict pwc, const char *restrict s,
    size_t n, mbstate_t *restrict ps);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

If *s* is a null pointer, the *mbrtowc*( ) function shall be equivalent to the call:

```
mbrtowc(NULL, "", 1, ps)
```

In this case, the values of the arguments *pwc* and *n* are ignored.

If *s* is not a null pointer, the *mbrtowc*( ) function shall inspect at most *n* bytes beginning at the byte pointed to by *s* to determine the number of bytes needed to complete the next character (including any shift sequences). If the function determines that the next character is completed, it shall determine the value of the corresponding wide character and then, if *pwc* is not a null pointer, shall store that value in the object pointed to by *pwc*. If the corresponding wide character is the null wide character, the resulting state described shall be the initial conversion state.

If *ps* is a null pointer, the *mbrtowc*( ) function shall use its own internal **mbstate_t** object, which shall be initialized at program start-up to the initial conversion state. Otherwise, the **mbstate_t** object pointed to by *ps* shall be used to completely describe the current conversion state of the associated character sequence. The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *mbrtowc*( ).

The behavior of this function is affected by the *LC_CTYPE* category of the current locale.

RETURN VALUE

The *mbrtowc*( ) function shall return the first of the following that applies:

0	If the next *n* or fewer bytes complete the character that corresponds to the null wide character (which is the value stored).
between 1 and *n* inclusive	If the next *n* or fewer bytes complete a valid character (which is the value stored); the value returned shall be the number of bytes that complete the character.
(**size_t**)–2	If the next *n* bytes contribute to an incomplete but potentially valid character, and all *n* bytes have been processed (no value is stored). When *n* has at least the value of the {MB_CUR_MAX} macro, this case can only occur if *s* points at a sequence of redundant shift sequences (for implementations with state-dependent encodings).
(**size_t**)–1	If an encoding error occurs, in which case the next *n* or fewer bytes do not contribute to a complete and valid character (no value is stored). In this case, [EILSEQ] shall be stored in *errno* and the conversion state is undefined.

ERRORS

The *mbrtowc*( ) function may fail if:

CX	[EINVAL]	*ps* points to an object that contains an invalid conversion state.
	[EILSEQ]	Invalid character sequence is detected.

CHANGE HISTORY

First released in Issue 5. Included for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E).

Issue 6

The *mbrtowc*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The [EINVAL] error condition is added.

ISO/IEC 9899:1999 standard, Technical Corrigendum No. 1 is incorporated.

NAME

mbsinit — determine conversion object status

SYNOPSIS

```
#include <wchar.h>

int mbsinit(const mbstate_t *ps);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

If *ps* is not a null pointer, the *mbsinit*( ) function shall determine whether the object pointed to by *ps* describes an initial conversion state.

RETURN VALUE

The *mbsinit*( ) function shall return non-zero if *ps* is a null pointer, or if the pointed-to object describes an initial conversion state; otherwise, it shall return zero.

If an **mbstate_t** object is altered by any of the functions described as ‘‘restartable’’, and is then used with a different character sequence, or in the other conversion direction, or with a different *LC_CTYPE* category setting than on earlier function calls, the behavior is undefined.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The **mbstate_t** object is used to describe the current conversion state from a particular character sequence to a wide-character sequence (or *vice versa*) under the rules of a particular setting of the *LC_CTYPE* category of the current locale.

The initial conversion state corresponds, for a conversion in either direction, to the beginning of a new character sequence in the initial shift state. A zero valued **mbstate_t** object is at least one way to describe an initial conversion state. A zero valued **mbstate_t** object can be used to initiate conversion involving any character sequence, in any *LC_CTYPE* category setting.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

mbsrtowcs — convert a character string to a wide-character string (restartable)

SYNOPSIS

```
#include <wchar.h>

size_t mbsrtowcs(wchar_t *restrict dst, const char **restrict src,
    size_t len, mbstate_t *restrict ps);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *mbsrtowcs*( ) function shall convert a sequence of characters, beginning in the conversion state described by the object pointed to by *ps*, from the array indirectly pointed to by *src* into a sequence of corresponding wide characters. If *dst* is not a null pointer, the converted characters shall be stored into the array pointed to by *dst*. Conversion continues up to and including a terminating null character, which shall also be stored. Conversion shall stop early in either of the following cases:

- A sequence of bytes is encountered that does not form a valid character.
- *len* codes have been stored into the array pointed to by *dst* (and *dst* is not a null pointer).

Each conversion shall take place as if by a call to the *mbrtowc*( ) function.

If *dst* is not a null pointer, the pointer object pointed to by *src* shall be assigned either a null pointer (if conversion stopped due to reaching a terminating null character) or the address just past the last character converted (if any). If conversion stopped due to reaching a terminating null character, and if *dst* is not a null pointer, the resulting state described shall be the initial conversion state.

If *ps* is a null pointer, the *mbsrtowcs*( ) function shall use its own internal **mbstate_t** object, which is initialized at program start-up to the initial conversion state. Otherwise, the **mbstate_t** object pointed to by *ps* shall be used to completely describe the current conversion state of the associated character sequence. The implementation behaves as if no function defined in this volume of IEEE Std 1003.1-200x calls *mbsrtowcs*( ).

The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale.

RETURN VALUE

If the input conversion encounters a sequence of bytes that do not form a valid character, an encoding error occurs. In this case, the *mbsrtowcs*( ) function stores the value of the macro [EILSEQ] in *errno* and shall return (**size_t**)−1; the conversion state is undefined. Otherwise, it shall return the number of characters successfully converted, not including the terminating null (if any).

ERRORS

The *mbsrtowcs*( ) function may fail if:

CX [EINVAL]	*ps* points to an object that contains an invalid conversion state.
[EILSEQ]	Invalid character sequence is detected.

NAME

mbstowcs — convert a character string to a wide-character string

SYNOPSIS

```
#include <stdlib.h>

size_t mbstowcs(wchar_t *restrict pwcs, const char *restrict s,
    size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *mbstowcs*( ) function shall convert a sequence of characters that begins in the initial shift state from the array pointed to by *s* into a sequence of corresponding wide-character codes and shall store not more than *n* wide-character codes into the array pointed to by *pwcs*. No characters that follow a null byte (which is converted into a wide-character code with value 0) shall be examined or converted. Each character shall be converted as if by a call to *mbtowc*( ), except that the shift state of *mbtowc*( ) is not affected.

No more than *n* elements shall be modified in the array pointed to by *pwcs*. If copying takes place between objects that overlap, the behavior is undefined.

XSI The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale. If *pwcs* is a null pointer, *mbstowcs*( ) shall return the length required to convert the entire array regardless of the value of *n*, but no values are stored.

RETURN VALUE

CX XSI If an invalid character is encountered, *mbstowcs*( ) shall return (**size_t**)–1 and may set *errno* to indicate the error. Otherwise, *mbstowcs*( ) shall return the number of the array elements modified (or required if *pwcs* is null), not including a terminating 0 code, if any. The array shall not be zero-terminated if the value returned is *n*.

ERRORS

The *mbstowcs*( ) function may fail if:

XSI [EILSEQ] Invalid byte sequence is detected.

NAME

mbtowc — convert a character to a wide-character code

SYNOPSIS

```
#include <stdlib.h>

int mbtowc(wchar_t *restrict pwc, const char *restrict s, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

If *s* is not a null pointer, *mbtowc*( ) shall determine the number of the bytes that constitute the character pointed to by *s*. It shall then determine the wide-character code for the value of type **wchar_t** that corresponds to that character. (The value of the wide-character code corresponding to the null byte is 0.) If the character is valid and *pwc* is not a null pointer, *mbtowc*( ) shall store the wide-character code in the object pointed to by *pwc*.

The behavior of this function is affected by the *LC_CTYPE* category of the current locale. For a state-dependent encoding, this function is placed into its initial state by a call for which its character pointer argument, *s*, is a null pointer. Subsequent calls with *s* as other than a null pointer shall cause the internal state of the function to be altered as necessary. A call with *s* as a null pointer shall cause this function to return a non-zero value if encodings have state dependency, and 0 otherwise. If the implementation employs special bytes to change the shift state, these bytes shall not produce separate wide-character codes, but shall be grouped with an adjacent character. Changing the *LC_CTYPE* category causes the shift state of this function to be unspecified. At most *n* bytes of the array pointed to by *s* shall be examined.

The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *mbtowc*( ).

RETURN VALUE

If *s* is a null pointer, *mbtowc*( ) shall return a non-zero or 0 value, if character encodings, respectively, do or do not have state-dependent encodings. If *s* is not a null pointer, *mbtowc*( ) shall either return 0 (if *s* points to the null byte), or return the number of bytes that constitute the converted character (if the next *n* or fewer bytes form a valid character), or return −1 CX and may set *errno* to indicate the error (if they do not form a valid character).

In no case shall the value returned be greater than *n* or the value of the {MB_CUR_MAX} macro.

ERRORS

The *mbtowc*( ) function may fail if:

XSI [EILSEQ] Invalid character sequence is detected.

NAME

memccpy — copy bytes in memory

SYNOPSIS

XSI

```
#include <string.h>

void *memccpy(void *restrict s1, const void *restrict s2,
    int c, size_t n);
```

DESCRIPTION

The *memccpy*( ) function shall copy bytes from memory area *s2* into *s1*, stopping after the first occurrence of byte *c* (converted to an **unsigned char**) is copied, or after *n* bytes are copied, whichever comes first. If copying takes place between objects that overlap, the behavior is undefined.

RETURN VALUE

The *memccpy*( ) function shall return a pointer to the byte after the copy of *c* in *s1*, or a null pointer if *c* was not found in the first *n* bytes of *s2*.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The *memccpy*( ) function does not check for the overflow of the receiving memory area.

RATIONALE

None.

FUTURE DIRECTIONS

None.

The **restrict** keyword is added to the *memccpy*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

memchr — find byte in memory

SYNOPSIS

```
#include <string.h>

void *memchr(const void *s, int c, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *memchr*( ) function shall locate the first occurrence of *c* (converted to an **unsigned char**) in the initial *n* bytes (each interpreted as **unsigned char**) of the object pointed to by *s*.

RETURN VALUE

The *memchr*( ) function shall return a pointer to the located byte, or a null pointer if the byte does not occur in the object.

ERRORS

No errors are defined.

NAME

memcmp — compare bytes in memory

SYNOPSIS

```
#include <string.h>

int memcmp(const void *s1, const void *s2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *memcmp*( ) function shall compare the first *n* bytes (each interpreted as **unsigned char**) of the object pointed to by *s1* to the first *n* bytes of the object pointed to by *s2*.

The sign of a non-zero return value shall be determined by the sign of the difference between the values of the first pair of bytes (both interpreted as type **unsigned char**) that differ in the objects being compared.

RETURN VALUE

The *memcmp*( ) function shall return an integer greater than, equal to, or less than 0, if the object pointed to by *s1* is greater than, equal to, or less than the object pointed to by *s2*, respectively.

ERRORS

No errors are defined.

NAME

mkdir — make a directory

SYNOPSIS

```
#include <sys/stat.h>

int mkdir(const char *path, mode_t mode);
```

DESCRIPTION

The *mkdir*( ) function shall create a new directory with name *path*. The file permission bits of the new directory shall be initialized from *mode*. These file permission bits of the *mode* argument shall be modified by the process' file creation mask.

When bits in *mode* other than the file permission bits are set, the meaning of these additional bits is implementation-defined.

The directory's user ID shall be set to the process' effective user ID. The directory's group ID shall be set to the group ID of the parent directory or to the effective group ID of the process. Implementations shall provide a way to initialize the directory's group ID to the group ID of the parent directory. Implementations may, but need not, provide an implementation-defined way to initialize the directory's group ID to the effective group ID of the calling process.

The newly created directory shall be an empty directory.

If *path* names a symbolic link, *mkdir*( ) shall fail and set *errno* to [EEXIST].

Upon successful completion, *mkdir*( ) shall mark for update the *st_atime*, *st_ctime*, and *st_mtime* fields of the directory. Also, the *st_ctime* and *st_mtime* fields of the directory that contains the new entry shall be marked for update.

RETURN VALUE

Upon successful completion, *mkdir*( ) shall return 0. Otherwise, −1 shall be returned, no directory shall be created, and *errno* shall be set to indicate the error.

ERRORS

The *mkdir*( ) function shall fail if:

[EACCES]	Search permission is denied on a component of the path prefix, or write permission is denied on the parent directory of the directory to be created.
[EEXIST]	The named file exists.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[EMLINK]	The link count of the parent directory would exceed {LINK_MAX}.
[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of the path prefix specified by *path* does not name an existing directory or *path* is an empty string.
[ENOSPC]	The file system does not contain enough space to hold the contents of the new directory or to extend the parent directory of the new directory.
[ENOTDIR]	A component of the path prefix is not a directory.
[EROFS]	The parent directory resides on a read-only file system.

The *mkdir*( ) function may fail if:

[ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.

[ENAMETOOLONG]
As a result of encountering a symbolic link in resolution of the *path* argument, the length of the substituted pathname string exceeded {PATH_MAX}.

EXAMPLES

Creating a Directory

The following example shows how to create a directory named **/home/cnd/mod1**, with read/write/search permissions for owner and group, and with read/search permissions for others.

```
#include <sys/types.h>
#include <sys/stat.h>

int status;
...
status = mkdir("/home/cnd/mod1", S_IRWXU | S_IRWXG | S_IROTH | S_IXOTH);
```

APPLICATION USAGE

None.

RATIONALE

The *mkdir*( ) function originated in 4.2 BSD and was added to System V in Release 3.0.

4.3 BSD detects [ENAMETOOLONG].

The POSIX.1-1990 standard required that the group ID of a newly created directory be set to the group ID of its parent directory or to the effective group ID of the creating process. FIPS 151-2 required that implementations provide a way to have the group ID be set to the group ID of the containing directory, but did not prohibit implementations also supporting a way to set the group ID to the effective group ID of the creating process. Conforming applications should not assume which group ID will be used. If it matters, an application can use *chown*( ) to set the group ID after the directory is created, or determine under what conditions the implementation will set the desired group ID.

FUTURE DIRECTIONS

None.

SEE ALSO

umask( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/stat.h>**, **<sys/types.h>**

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

- The [ELOOP] mandatory error condition is added.
- A second [ENAMETOOLONG] is added as an optional error condition.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The [ELOOP] optional error condition is added.

NAME

mkfifo — make a FIFO special file

SYNOPSIS

```
#include <sys/stat.h>

int mkfifo(const char *path, mode_t mode);
```

DESCRIPTION

The *mkfifo*( ) function shall create a new FIFO special file named by the pathname pointed to by *path*. The file permission bits of the new FIFO shall be initialized from *mode*. The file permission bits of the *mode* argument shall be modified by the process' file creation mask.

When bits in *mode* other than the file permission bits are set, the effect is implementation-defined.

If *path* names a symbolic link, *mkfifo*( ) shall fail and set *errno* to [EEXIST].

The FIFO's user ID shall be set to the process' effective user ID. The FIFO's group ID shall be set to the group ID of the parent directory or to the effective group ID of the process. Implementation shall provide a way to initialize the FIFO's group ID to the group ID of the parent directory. Implementations may, but need not, provide an implementation-defined way to initialize the FIFO's group ID to the effective group ID of the calling process.

Upon successful completion, *mkfifo*( ) shall mark for update the *st_atime*, *st_ctime*, and *st_mtime* fields of the file. Also, the *st_ctime* and *st_mtime* fields of the directory that contains the new entry shall be marked for update.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned, no FIFO shall be created, and *errno* shall be set to indicate the error.

ERRORS

The *mkfifo*( ) function shall fail if:

[EACCES]	A component of the path prefix denies search permission, or write permission is denied on the parent directory of the FIFO to be created.
[EEXIST]	The named file already exists.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of the path prefix specified by *path* does not name an existing directory or *path* is an empty string.
[ENOSPC]	The directory that would contain the new file cannot be extended or the file system is out of file-allocation resources.
[ENOTDIR]	A component of the path prefix is not a directory.
[EROFS]	The named file resides on a read-only file system.

The *mkfifo*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.

[ENAMETOOLONG]
As a result of encountering a symbolic link in resolution of the *path* argument, the length of the substituted pathname string exceeded {PATH_MAX}. |

EXAMPLES

Creating a FIFO File

The following example shows how to create a FIFO file named **/home/cnd/mod_done**, with read/write permissions for owner, and with read permissions for group and others.

```
#include <sys/types.h>
#include <sys/stat.h>

int status;
...
status = mkfifo("/home/cnd/mod_done", S_IWUSR | S_IRUSR |
    S_IRGRP | S_IROTH);
```

APPLICATION USAGE

None.

RATIONALE

The syntax of this function is intended to maintain compatibility with historical implementations of *mknod*( ). The latter function was included in the 1984 /usr/group standard but only for use in creating FIFO special files. The *mknod*( ) function was originally excluded from the POSIX.1-1988 standard as implementation-defined and replaced by *mkdir*( ) and *mkfifo*( ). The *mknod*( ) function is now included for alignment with the Single UNIX Specification.

The POSIX.1-1990 standard required that the group ID of a newly created FIFO be set to the group ID of its parent directory or to the effective group ID of the creating process. FIPS 151-2 required that implementations provide a way to have the group ID be set to the group ID of the containing directory, but did not prohibit implementations also supporting a way to set the group ID to the effective group ID of the creating process. Conforming applications should not assume which group ID will be used. If it matters, an application can use *chown*( ) to set the group ID after the FIFO is created, or determine under what conditions the implementation will set the desired group ID. |

FUTURE DIRECTIONS

None.

NAME

mknod — make a directory, a special or regular file

SYNOPSIS

XSI
```
#include <sys/stat.h>

int mknod(const char *path, mode_t mode, dev_t dev);
```

DESCRIPTION

The *mknod*( ) function shall create a new file named by the pathname to which the argument *path* points. |

The file type for *path* is OR'ed into the *mode* argument, and the application shall select one of the following symbolic constants:

Name	Description
S_IFIFO	FIFO-special
S_IFCHR	Character-special (non-portable)
S_IFDIR	Directory (non-portable)
S_IFBLK	Block-special (non-portable)
S_IFREG	Regular (non-portable)

The only portable use of *mknod*( ) is to create a FIFO-special file. If *mode* is not S_IFIFO or *dev* is not 0, the behavior of *mknod*( ) is unspecified.

The permissions for the new file are OR'ed into the *mode* argument, and may be selected from any combination of the following symbolic constants:

Name	Description
S_ISUID	Set user ID on execution.
S_ISGID	Set group ID on execution.
S_IRWXU	Read, write, or execute (search) by owner.
S_IRUSR	Read by owner.
S_IWUSR	Write by owner.
S_IXUSR	Execute (search) by owner.
S_IRWXG	Read, write, or execute (search) by group.
S_IRGRP	Read by group.
S_IWGRP	Write by group.
S_IXGRP	Execute (search) by group.
S_IRWXO	Read, write, or execute (search) by others.
S_IROTH	Read by others.
S_IWOTH	Write by others.
S_IXOTH	Execute (search) by others.
S_ISVTX	On directories, restricted deletion flag.

The user ID of the file shall be initialized to the effective user ID of the process. The group ID of the file shall be initialized to either the effective group ID of the process or the group ID of the parent directory. Implementations shall provide a way to initialize the file's group ID to the group ID of the parent directory. Implementations may, but need not, provide an implementation-defined way to initialize the file's gorup ID to the effective group ID of the calling proces. |

The owner, group, and other permission bits of *mode* shall be modified by the file mode creation mask of the process. The *mknod*( ) function shall clear each bit whose corresponding bit in the file mode creation mask of the process is set.

If *path* names a symbolic link, *mknod*( ) shall fail and set *errno* to [EEXIST].

Upon successful completion, *mknod*( ) shall mark for update the *st_atime*, *st_ctime*, and *st_mtime* fields of the file. Also, the *st_ctime* and *st_mtime* fields of the directory that contains the new entry shall be marked for update.

Only a process with appropriate privileges may invoke *mknod*( ) for file types other than FIFO-special.

RETURN VALUE

Upon successful completion, *mknod*( ) shall return 0. Otherwise, it shall return −1, the new file shall not be created, and *errno* shall be set to indicate the error.

ERRORS

The *mknod*( ) function shall fail if:

[EACCES]	A component of the path prefix denies search permission, or write permission is denied on the parent directory.
[EEXIST]	The named file exists.
[EINVAL]	An invalid argument exists.
[EIO]	An I/O error occurred while accessing the file system.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of a pathname exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of the path prefix specified by *path* does not name an existing directory or *path* is an empty string.
[ENOSPC]	The directory that would contain the new file cannot be extended or the file system is out of file allocation resources.
[ENOTDIR]	A component of the path prefix is not a directory.
[EPERM]	The invoking process does not have appropriate privileges and the file type is not FIFO-special.
[EROFS]	The directory in which the file is to be created is located on a read-only file system.

The *mknod*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[ENAMETOOLONG]	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds {PATH_MAX}.

EXAMPLES

Creating a FIFO Special File

The following example shows how to create a FIFO special file named **/home/cnd/mod_done**, with read/write permissions for owner, and with read permissions for group and others.

```
#include <sys/types.h>
#include <sys/stat.h>

dev_t dev;
int   status;
...
status  = mknod("/home/cnd/mod_done", S_IFIFO | S_IWUSR |
    S_IRUSR | S_IRGRP | S_IROTH, dev);
```

APPLICATION USAGE

mkfifo( ) is preferred over this function for making FIFO special files.

RATIONALE

The POSIX.1-1990 standard required that the group ID of a newly created file be set to the group ID of its parent directory or to the effective group ID of the creating process. FIPS 151-2 required that implementations provide a way to have the group ID be set to the group ID of the containing directory, but did not prohibit implementations also supporting a way to set the group ID to the effective group ID of the creating process. Conforming applications should not assume which group ID will be used. If it matters, an application can use *chown*( ) to set the group ID after the file is created, or determine under what conditions the implementation will set the desired group ID.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.

NAME

mkstemp — make a unique filename

SYNOPSIS

XSI
```
#include <stdlib.h>

int mkstemp(char *template);
```

DESCRIPTION

The *mkstemp*( ) function shall replace the contents of the string pointed to by *template* by a unique filename, and return a file descriptor for the file open for reading and writing. The function thus prevents any possible race condition between testing whether the file exists and opening it for use. The string in *template* should look like a filename with six trailing *X*s; *mkstemp*( ) replaces each *X* with a character from the portable filename character set. The characters are chosen such that the resulting name does not duplicate the name of an existing file at the time of a call to *mkstemp*( ).

RETURN VALUE

Upon successful completion, *mkstemp*( ) shall return an open file descriptor. Otherwise, –1 shall be returned if no suitable file could be created.

ERRORS

No errors are defined.

EXAMPLES

Generating a Filename

The following example creates a file with a 10-character name beginning with the characters `"file"` and opens the file for reading and writing. The value returned as the value of *fd* is a file descriptor that identifies the file.

```
#include <stdlib.h>
...
char template[] = "/tmp/fileXXXXXX";
int fd;

fd = mkstemp(template);
```

APPLICATION USAGE

It is possible to run out of letters.

The *mkstemp*( ) function need not check to determine whether the filename part of *template* exceeds the maximum allowable filename length.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

NAME

mktemp — make a unique filename (**LEGACY**)

SYNOPSIS

XSI

```
#include <stdlib.h>

char *mktemp(char *template);
```

DESCRIPTION

The *mktemp*( ) function shall replace the contents of the string pointed to by *template* by a unique filename and return *template*. The application shall initialize *template* to be a filename with six trailing *X*s; *mktemp*( ) shall replace each *X* with a single byte character from the portable filename character set.

RETURN VALUE

The *mktemp*( ) function shall return the pointer *template*. If a unique name cannot be created, *template* shall point to a null string.

ERRORS

No errors are defined.

EXAMPLES

Generating a Filename

The following example replaces the contents of the `"template"` string with a 10-character filename beginning with the characters `"file"` and returns a pointer to the `"template"` string that contains the new filename.

```
#include <stdlib.h>
...
char *template = "/tmp/fileXXXXXX";
char *ptr;

ptr = mktemp(template);
```

APPLICATION USAGE

Between the time a pathname is created and the file opened, it is possible for some other process | to create a file with the same name. The *mkstemp*( ) function avoids this problem and is preferred over this function.

RATIONALE

None.

FUTURE DIRECTIONS

This function may be withdrawn in a future version.

SEE ALSO

mkstemp( ), *tmpfile*( ), *tmpnam*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdlib.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

This function is marked LEGACY.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

mktime — convert broken-down time into time since the Epoch

SYNOPSIS

```
#include <time.h>

time_t mktime(struct tm *timeptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *mktime*( ) function shall convert the broken-down time, expressed as local time, in the structure pointed to by *timeptr*, into a time since the Epoch value with the same encoding as that of the values returned by *time*( ). The original values of the *tm_wday* and *tm_yday* components of the structure are ignored, and the original values of the other components are not restricted to the ranges described in **<time.h>**.

CX A positive or 0 value for *tm_isdst* shall cause *mktime*( ) to presume initially that Daylight Savings Time, respectively, is or is not in effect for the specified time. A negative value for *tm_isdst* shall cause *mktime*( ) to attempt to determine whether Daylight Saving Time is in effect for the specified time.

Local timezone information shall be set as though *mktime*( ) called *tzset*( ).

The relationship between the **tm** structure (defined in the **<time.h>** header) and the time in seconds since the Epoch is that the result shall be as specified in the expression given in the definition of seconds since the Epoch (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.14, Seconds Since the Epoch) corrected for timezone and any seasonal time adjustments, where the names in the structure and in the expression correspond.

Upon successful completion, the values of the *tm_wday* and *tm_yday* components of the structure shall be set appropriately, and the other components are set to represent the specified time since the Epoch, but with their values forced to the ranges indicated in the **<time.h>** entry; the final value of *tm_mday* shall not be set until *tm_mon* and *tm_year* are determined.

RETURN VALUE

The *mktime*( ) function shall return the specified time since the Epoch encoded as a value of type **time_t**. If the time since the Epoch cannot be represented, the function shall return the value (**time_t**)–1.

ERRORS

No errors are defined.

EXAMPLES

What day of the week is July 4, 2001?

```
#include <stdio.h>
#include <time.h>

struct tm time_str;

char daybuf[20];

int main(void)
{
    time_str.tm_year = 2001 – 1900;
    time_str.tm_mon = 7 – 1;
    time_str.tm_mday = 4;
```

```
        time_str.tm_hour = 0;
        time_str.tm_min = 0;
        time_str.tm_sec = 1;
        time_str.tm_isdst = −1;
        if (mktime(&time_str) == -1)
            (void)puts("-unknown-");
        else {
            (void)strftime(daybuf, sizeof(daybuf), "%A", &time_str);
            (void)puts(daybuf);
        }
        return 0;
    }
```

APPLICATION USAGE

None.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard and the ANSI C standard.

Issue 6

Extensions beyond the ISO C standard are now marked.

NAME

mlock, munlock — lock or unlock a range of process address space (**REALTIME**)

SYNOPSIS

MLR
```
#include <sys/mman.h>

int mlock(const void *addr, size_t len);
int munlock(const void *addr, size_t len);
```

DESCRIPTION

The *mlock*( ) function shall cause those whole pages containing any part of the address space of the process starting at address *addr* and continuing for *len* bytes to be memory-resident until unlocked or until the process exits or *exec*s another process image. The implementation may require that *addr* be a multiple of {PAGESIZE}.

The *munlock*( ) function shall unlock those whole pages containing any part of the address space of the process starting at address *addr* and continuing for *len* bytes, regardless of how many times *mlock*( ) has been called by the process for any of the pages in the specified range. The implementation may require that *addr* be a multiple of {PAGESIZE}. |

If any of the pages in the range specified to a call to *munlock*( ) are also mapped into the address spaces of other processes, any locks established on those pages by another process are unaffected by the call of this process to *munlock*( ). If any of the pages in the range specified by a call to *munlock*( ) are also mapped into other portions of the address space of the calling process outside the range specified, any locks established on those pages via the other mappings are also unaffected by this call.

Upon successful return from *mlock*( ), pages in the specified range shall be locked and memory-resident. Upon successful return from *munlock*( ), pages in the specified range shall be unlocked with respect to the address space of the process. Memory residency of unlocked pages is unspecified.

The appropriate privilege is required to lock process memory with *mlock*( ).

RETURN VALUE

Upon successful completion, the *mlock*( ) and *munlock*( ) functions shall return a value of zero. Otherwise, no change is made to any locks in the address space of the process, and the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *mlock*( ) and *munlock*( ) functions shall fail if:

[ENOMEM] Some or all of the address range specified by the *addr* and *len* arguments does not correspond to valid mapped pages in the address space of the process.

The *mlock*( ) function shall fail if:

[EAGAIN] Some or all of the memory identified by the operation could not be locked when the call was made.

The *mlock*( ) and *munlock*( ) functions may fail if:

[EINVAL] The *addr* argument is not a multiple of {PAGESIZE}.

The *mlock*( ) function may fail if:

[ENOMEM] Locking the pages mapped by the specified range would exceed an implementation-defined limit on the amount of memory that the process may lock.

[EPERM] The calling process does not have the appropriate privilege to perform the requested operation.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

exec, *exit*( ), *fork*( ), *mlockall*( ), *munmap*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/mman.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *mlock*( ) and *munlock*( ) functions are marked as part of the Range Memory Locking option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Range Memory Locking option.

NAME

mlockall, munlockall — lock/unlock the address space of a process (**REALTIME**)

SYNOPSIS

ML
```
#include <sys/mman.h>

int mlockall(int flags);
int munlockall(void);
```

DESCRIPTION

The *mlockall*( ) function shall cause all of the pages mapped by the address space of a process to be memory-resident until unlocked or until the process exits or *exec*s another process image. The *flags* argument determines whether the pages to be locked are those currently mapped by the address space of the process, those that are mapped in the future, or both. The *flags* argument is constructed from the bitwise-inclusive OR of one or more of the following symbolic constants, defined in **<sys/mman.h>**:

MCL_CURRENT	Lock all of the pages currently mapped into the address space of the process.
MCL_FUTURE	Lock all of the pages that become mapped into the address space of the process in the future, when those mappings are established.

If MCL_FUTURE is specified, and the automatic locking of future mappings eventually causes the amount of locked memory to exceed the amount of available physical memory or any other implementation-defined limit, the behavior is implementation-defined. The manner in which the implementation informs the application of these situations is also implementation-defined.

The *munlockall*( ) function shall unlock all currently mapped pages of the address space of the process. Any pages that become mapped into the address space of the process after a call to *munlockall*( ) shall not be locked, unless there is an intervening call to *mlockall*( ) specifying MCL_FUTURE or a subsequent call to *mlockall*( ) specifying MCL_CURRENT. If pages mapped into the address space of the process are also mapped into the address spaces of other processes and are locked by those processes, the locks established by the other processes shall be unaffected by a call by this process to *munlockall*( ). |

Upon successful return from the *mlockall*( ) function that specifies MCL_CURRENT, all currently mapped pages of the process' address space shall be memory-resident and locked. Upon return from the *munlockall*( ) function, all currently mapped pages of the process' address space shall be unlocked with respect to the process' address space. The memory residency of unlocked pages is unspecified.

The appropriate privilege is required to lock process memory with *mlockall*( ).

RETURN VALUE

Upon successful completion, the *mlockall*( ) function shall return a value of zero. Otherwise, no additional memory shall be locked, and the function shall return a value of −1 and set *errno* to indicate the error. The effect of failure of *mlockall*( ) on previously existing locks in the address space is unspecified.

If it is supported by the implementation, the *munlockall*( ) function shall always return a value of zero. Otherwise, the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *mlockall*( ) function shall fail if:

[EAGAIN]	Some or all of the memory identified by the operation could not be locked when the call was made.

[EINVAL]	The *flags* argument is zero, or includes unimplemented flags.

The *mlockall*( ) function may fail if:

[ENOMEM]	Locking all of the pages currently mapped into the address space of the process would exceed an implementation-defined limit on the amount of memory that the process may lock.
[EPERM]	The calling process does not have the appropriate privilege to perform the requested operation.

EXAMPLES

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *mlockall*( ) and *munlockall*( ) functions are marked as part of the Process Memory Locking option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Process Memory Locking option.

NAME

mmap — map pages of memory

SYNOPSIS

MF|SHM

```
#include <sys/mman.h>

void *mmap(void *addr, size_t len, int prot, int flags,
    int fildes, off_t off);
```

DESCRIPTION

TYM The *mmap*( ) function shall establish a mapping between a process' address space and a file, shared memory object, or typed memory object. The format of the call is as follows:

```
pa=mmap(addr, len, prot, flags, fildes, off);
```

The *mmap*( ) function shall establish a mapping between the address space of the process at an address *pa* for *len* bytes to the memory object represented by the file descriptor *fildes* at offset *off* for *len* bytes. The value of *pa* is an implementation-defined function of the parameter *addr* and the values of *flags*, further described below. A successful *mmap*( ) call shall return *pa* as its result. The address range starting at *pa* and continuing for *len* bytes shall be legitimate for the possible (not necessarily current) address space of the process. The range of bytes starting at *off* and continuing for *len* bytes shall be legitimate for the possible (not necessarily current) offsets in the TYM file, shared memory object, or typed memory object represented by *fildes*.

TYM If *fildes* represents a typed memory object opened with either the POSIX_TYPED_MEM_ALLOCATE flag or the POSIX_TYPED_MEM_ALLOCATE_CONTIG flag, the memory object to be mapped shall be that portion of the typed memory object allocated by the implementation as specified below. In this case, if *off* is non-zero, the behavior of *mmap*( ) is undefined. If *fildes* refers to a valid typed memory object that is not accessible from the calling process, *mmap*( ) shall fail.

The mapping established by *mmap*( ) shall replace any previous mappings for those whole pages containing any part of the address space of the process starting at *pa* and continuing for *len* bytes.

If the size of the mapped file changes after the call to *mmap*( ) as a result of some other operation on the mapped file, the effect of references to portions of the mapped region that correspond to added or removed portions of the file is unspecified.

TYM The *mmap*( ) function shall be supported for regular files, shared memory objects, and typed memory objects. Support for any other type of file is unspecified.

The parameter *prot* determines whether read, write, execute, or some combination of accesses are permitted to the data being mapped. The *prot* shall be either PROT_NONE or the bitwise-inclusive OR of one or more of the other flags in the following table, defined in the **<sys/mman.h>** header.

Symbolic Constant	Description
PROT_READ	Data can be read.
PROT_WRITE	Data can be written.
PROT_EXEC	Data can be executed.
PROT_NONE	Data cannot be accessed.

If an implementation cannot support the combination of access types specified by *prot*, the call MPR to *mmap*( ) shall fail. An implementation may permit accesses other than those specified by *prot*; however, if the Memory Protection option is supported, the implementation shall not permit a write to succeed where PROT_WRITE has not been set or shall not permit any access where PROT_NONE alone has been set. The implementation shall support at least the following values of *prot*: PROT_NONE, PROT_READ, PROT_WRITE, and the bitwise-inclusive OR of PROT_READ and PROT_WRITE. If the Memory Protection option is not supported, the result of any access that conflicts with the specified protection is undefined. The file descriptor *fildes* shall have been opened with read permission, regardless of the protection options specified. If PROT_WRITE is specified, the application shall ensure that it has opened the file descriptor *fildes* with write permission unless MAP_PRIVATE is specified in the *flags* parameter as described below.

The parameter *flags* provides other information about the handling of the mapped data. The value of *flags* is the bitwise-inclusive OR of these options, defined in **<sys/mman.h>**:

Symbolic Constant	Description
MAP_SHARED	Changes are shared.
MAP_PRIVATE	Changes are private.
MAP_FIXED	Interpret *addr* exactly.

Implementations that do not support the Memory Mapped Files option are not required to support MAP_PRIVATE.

XSI It is implementation-defined whether MAP_FIXED shall be supported. MAP_FIXED shall be supported on XSI-conformant systems.

MAP_SHARED and MAP_PRIVATE describe the disposition of write references to the memory object. If MAP_SHARED is specified, write references shall change the underlying object. If MAP_PRIVATE is specified, modifications to the mapped data by the calling process shall be visible only to the calling process and shall not change the underlying object. It is unspecified whether modifications to the underlying object done after the MAP_PRIVATE mapping is established are visible through the MAP_PRIVATE mapping. Either MAP_SHARED or MAP_PRIVATE can be specified, but not both. The mapping type is retained across *fork*( ). |

TYM When *fildes* represents a typed memory object opened with either the POSIX_TYPED_MEM_ALLOCATE flag or the POSIX_TYPED_MEM_ALLOCATE_CONTIG flag, *mmap*( ) shall, if there are enough resources available, map *len* bytes allocated from the corresponding typed memory object which were not previously allocated to any process in any processor that may access that typed memory object. If there are not enough resources available, the function shall fail. If *fildes* represents a typed memory object opened with the POSIX_TYPED_MEM_ALLOCATE_CONTIG flag, these allocated bytes shall be contiguous within the typed memory object. If *fildes* represents a typed memory object opened with the POSIX_TYPED_MEM_ALLOCATE flag, these allocated bytes may be composed of non-contiguous fragments within the typed memory object. If *fildes* represents a typed memory object opened with neither the POSIX_TYPED_MEM_ALLOCATE_CONTIG flag nor the POSIX_TYPED_MEM_ALLOCATE flag, *len* bytes starting at offset *off* within the typed memory object are mapped, exactly as when mapping a file or shared memory object. In this case, if two processes map an area of typed memory using the same *off* and *len* values and using file descriptors that refer to the same memory pool (either from the same port or from a different port), both processes shall map the same region of storage.

When MAP_FIXED is set in the *flags* argument, the implementation is informed that the value of *pa* shall be *addr*, exactly. If MAP_FIXED is set, *mmap*( ) may return MAP_FAILED and set *errno* to [EINVAL]. If a MAP_FIXED request is successful, the mapping established by *mmap*( ) replaces any previous mappings for the process' pages in the range [*pa*,*pa*+*len*).

When MAP_FIXED is not set, the implementation uses *addr* in an implementation-defined manner to arrive at *pa*. The *pa* so chosen shall be an area of the address space that the implementation deems suitable for a mapping of *len* bytes to the file. All implementations interpret an *addr* value of 0 as granting the implementation complete freedom in selecting *pa*, subject to constraints described below. A non-zero value of *addr* is taken to be a suggestion of a process address near which the mapping should be placed. When the implementation selects a value for *pa*, it never places a mapping at address 0, nor does it replace any extant mapping.

The *off* argument is constrained to be aligned and sized according to the value returned by *sysconf*( ) when passed _SC_PAGESIZE or _SC_PAGE_SIZE. When MAP_FIXED is specified, the application shall ensure that the argument *addr* also meets these constraints. The implementation performs mapping operations over whole pages. Thus, while the argument *len* need not meet a size or alignment constraint, the implementation shall include, in any mapping operation, any partial page specified by the range [*pa*,*pa*+*len*).

MPR The system shall always zero-fill any partial page at the end of an object. Further, the system shall never write out any modified portions of the last page of an object which are beyond its end. References within the address range starting at *pa* and continuing for *len* bytes to whole pages following the end of an object shall result in delivery of a SIGBUS signal.

An implementation may generate SIGBUS signals when a reference would cause an error in the mapped object, such as out-of-space condition.

The *mmap*( ) function shall add an extra reference to the file associated with the file descriptor *fildes* which is not removed by a subsequent *close*( ) on that file descriptor. This reference shall be removed when there are no more mappings to the file.

The *st_atime* field of the mapped file may be marked for update at any time between the *mmap*( ) call and the corresponding *munmap*( ) call. The initial read or write reference to a mapped region shall cause the file's *st_atime* field to be marked for update if it has not already been marked for update.

The *st_ctime* and *st_mtime* fields of a file that is mapped with MAP_SHARED and PROT_WRITE shall be marked for update at some point in the interval between a write reference to the mapped region and the next call to *msync*( ) with MS_ASYNC or MS_SYNC for that portion of the file by any process. If there is no such call and if the underlying file is modified as a result of a write reference, then these fields shall be marked for update at some time after the write reference.

There may be implementation-defined limits on the number of memory regions that can be mapped (per process or per system).

XSI If such a limit is imposed, whether the number of memory regions that can be mapped by a process is decreased by the use of *shmat*( ) is implementation-defined.

If *mmap*( ) fails for reasons other than [EBADF], [EINVAL], or [ENOTSUP], some of the mappings in the address range starting at *addr* and continuing for *len* bytes may have been unmapped.

RETURN VALUE

Upon successful completion, the *mmap*( ) function shall return the address at which the mapping was placed (*pa*); otherwise, it shall return a value of MAP_FAILED and set *errno* to indicate the error. The symbol MAP_FAILED is defined in the **<sys/mman.h>** header. No successful return from *mmap*( ) shall return the value MAP_FAILED.

ERRORS

The *mmap*( ) function shall fail if:

	[EACCES]	The *fildes* argument is not open for read, regardless of the protection specified, or *fildes* is not open for write and PROT_WRITE was specified for a MAP_SHARED type mapping.
ML	[EAGAIN]	The mapping could not be locked in memory, if required by *mlockall*( ), due to a lack of resources.
	[EBADF]	The *fildes* argument is not a valid open file descriptor.
	[EINVAL]	The *addr* argument (if MAP_FIXED was specified) or *off* is not a multiple of the page size as returned by *sysconf*( ), or are considered invalid by the implementation.
	[EINVAL]	The value of *flags* is invalid (neither MAP_PRIVATE nor MAP_SHARED is set).
	[EMFILE]	The number of mapped regions would exceed an implementation-defined limit (per process or per system).
	[ENODEV]	The *fildes* argument refers to a file whose type is not supported by *mmap*( ).
	[ENOMEM]	MAP_FIXED was specified, and the range [*addr*,*addr*+*len*) exceeds that allowed for the address space of a process; or, if MAP_FIXED was not specified and there is insufficient room in the address space to effect the mapping.
ML	[ENOMEM]	The mapping could not be locked in memory, if required by *mlockall*( ), because it would require more space than the system is able to supply.
		MAP_FIXED or MAP_PRIVATE was specified in the *flags* argument and the implementation does not support this functionality.
TYM	[ENOMEM]	Not enough unallocated memory resources remain in the typed memory object designated by *fildes* to allocate *len* bytes.
	[ENOTSUP]	The implementation does not support the combination of accesses requested in the *prot* argument.
	[ENXIO]	Addresses in the range [*off*,*off*+*len*) are invalid for the object specified by *fildes*.
	[ENXIO]	MAP_FIXED was specified in *flags* and the combination of *addr*, *len*, and *off* is invalid for the object specified by *fildes*.
TYM	[ENXIO]	The *fildes* argument refers to a typed memory object that is not accessible from the calling process.
	[EOVERFLOW]	The file is a regular file and the value of *off* plus *len* exceeds the offset maximum established in the open file description associated with *fildes*.

EXAMPLES

None.

APPLICATION USAGE

Use of *mmap*( ) may reduce the amount of memory available to other memory allocation functions.

Use of MAP_FIXED may result in unspecified behavior in further use of *malloc*( ) and *shmat*( ). The use of MAP_FIXED is discouraged, as it may prevent an implementation from making the most effective use of resources.

The application must ensure correct synchronization when using *mmap*( ) in conjunction with any other file access method, such as *read*( ) and *write*( ), standard input/output, and *shmat*( ).

The *mmap*( ) function allows access to resources via address space manipulations, instead of *read*( )/*write*( ). Once a file is mapped, all a process has to do to access it is use the data at the address to which the file was mapped. So, using pseudo-code to illustrate the way in which an existing program might be changed to use *mmap*( ), the following:

```
fildes = open(...)
lseek(fildes, some_offset)
read(fildes, buf, len)
/* Use data in buf. */
```

becomes:

```
fildes = open(...)
address = mmap(0, len, PROT_READ, MAP_PRIVATE, fildes, some_offset)
/* Use data at address. */
```

The [EINVAL] error above is marked EX because it is defined as an optional error in the POSIX Realtime Extension.

RATIONALE

After considering several other alternatives, it was decided to adopt the *mmap*( ) definition found in SVR4 for mapping memory objects into process address spaces. The SVR4 definition is minimal, in that it describes only what has been built, and what appears to be necessary for a general and portable mapping facility.

Note that while *mmap*( ) was first designed for mapping files, it is actually a general-purpose mapping facility. It can be used to map any appropriate object, such as memory, files, devices, and so on, into the address space of a process.

When a mapping is established, it is possible that the implementation may need to map more than is requested into the address space of the process because of hardware requirements. An application, however, cannot count on this behavior. Implementations that do not use a paged architecture may simply allocate a common memory region and return the address of it; such implementations probably do not allocate any more than is necessary. References past the end of the requested area are unspecified.

If an application requests a mapping that would overlay existing mappings in the process, it might be desirable that an implementation detect this and inform the application. However, the default, portable (not MAP_FIXED) operation does not overlay existing mappings. On the other hand, if the program specifies a fixed address mapping (which requires some implementation knowledge to determine a suitable address, if the function is supported at all), then the program is presumed to be successfully managing its own address space and should be trusted when it asks to map over existing data structures. Furthermore, it is also desirable to make as few system calls as possible, and it might be considered onerous to require an *munmap*( ) before an *mmap*( ) to the same address range. This volume of IEEE Std 1003.1-200x specifies that the new mappings replace any existing mappings, following existing practice in this regard.

It is not expected, when the Memory Protection option is supported, that all hardware implementations are able to support all combinations of permissions at all addresses. When this option is supported, implementations are required to disallow write access to mappings without write permission and to disallow access to mappings without any access permission. Other than these restrictions, implementations may allow access types other than those requested by the application. For example, if the application requests only PROT_WRITE, the implementation may also allow read access. A call to *mmap*( ) fails if the implementation cannot support allowing all the access requested by the application. For example, some implementations cannot support a request for both write access and execute access simultaneously. All implementations supporting the Memory Protection option must support requests for no access, read access, write access, and both read and write access. Strictly conforming code must only rely on the required checks. These restrictions allow for portability across a wide range of hardware.

The MAP_FIXED address treatment is likely to fail for non-page-aligned values and for certain architecture-dependent address ranges. Conforming implementations cannot count on being able to choose address values for MAP_FIXED without utilizing non-portable, implementation-defined knowledge. Nonetheless, MAP_FIXED is provided as a standard interface conforming to existing practice for utilizing such knowledge when it is available.

Similarly, in order to allow implementations that do not support virtual addresses, support for directly specifying any mapping addresses via MAP_FIXED is not required and thus a conforming application may not count on it.

The MAP_PRIVATE function can be implemented efficiently when memory protection hardware is available. When such hardware is not available, implementations can implement such ‘‘mappings’’ by simply making a real copy of the relevant data into process private memory, though this tends to behave similarly to *read*( ).

The function has been defined to allow for many different models of using shared memory. However, all uses are not equally portable across all machine architectures. In particular, the *mmap*( ) function allows the system as well as the application to specify the address at which to map a specific region of a memory object. The most portable way to use the function is always to let the system choose the address, specifying NULL as the value for the argument *addr* and not to specify MAP_FIXED.

If it is intended that a particular region of a memory object be mapped at the same address in a group of processes (on machines where this is even possible), then MAP_FIXED can be used to pass in the desired mapping address. The system can still be used to choose the desired address if the first such mapping is made without specifying MAP_FIXED, and then the resulting mapping address can be passed to subsequent processes for them to pass in via MAP_FIXED. The availability of a specific address range cannot be guaranteed, in general.

The *mmap*( ) function can be used to map a region of memory that is larger than the current size of the object. Memory access within the mapping but beyond the current end of the underlying objects may result in SIGBUS signals being sent to the process. The reason for this is that the size of the object can be manipulated by other processes and can change at any moment. The implementation should tell the application that a memory reference is outside the object where this can be detected; otherwise, written data may be lost and read data may not reflect actual data in the object.

Note that references beyond the end of the object do not extend the object as the new end cannot be determined precisely by most virtual memory hardware. Instead, the size can be directly manipulated by *ftruncate*( ).

Process memory locking does apply to shared memory regions, and the MEMLOCK_FUTURE argument to *memlockall*( ) can be relied upon to cause new shared memory regions to be automatically locked.

Existing implementations of *mmap*( ) return the value −1 when unsuccessful. Since the casting of this value to type **void *** cannot be guaranteed by the ISO C standard to be distinct from a successful value, this volume of IEEE Std 1003.1-200x defines the symbol MAP_FAILED, which a conforming implementation does not return as the result of a successful call.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Aligned with *mmap*( ) in the POSIX Realtime Extension as follows:

- The DESCRIPTION is extensively reworded.
- The [EAGAIN] and [ENOTSUP] mandatory error conditions are added.
- New cases of [ENOMEM] and [ENXIO] are added as mandatory error conditions.
- The value returned on failure is the value of the constant MAP_FAILED; this was previously defined as –1.

Large File Summit extensions are added.

Issue 6

The *mmap*( ) function is marked as part of the Memory Mapped Files option.

The Open Group Corrigendum U028/6 is applied, changing (**void** *)–1 to MAP_FAILED.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION is updated to described the use of MAP_FIXED.
- The DESCRIPTION is updated to describe the addition of an extra reference to the file associated with the file descriptor passed to *mmap*( ).
- The DESCRIPTION is updated to state that there may be implementation-defined limits on the number of memory regions that can be mapped.
- The DESCRIPTION is updated to describe constraints on the alignment and size of the *off* argument.
- The [EINVAL] and [EMFILE] error conditions are added.
- The [EOVERFLOW] error condition is added. This change is to support large files.

The following changes are made for alignment with the ISO POSIX-1: 1996 standard:

- The DESCRIPTION is updated to describe the cases when MAP_PRIVATE and MAP_FIXED need not be supported.

The following changes are made for alignment with IEEE Std 1003.1j-2000:

- Semantics for typed memory objects are added to the DESCRIPTION.
- New [ENOMEM] and [ENXIO] errors are added to the ERRORS section.
- The *posix_typed_mem_open*( ) function is added to the SEE ALSO section.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

modf, modff, modfl — decompose a floating-point number

SYNOPSIS

```
#include <math.h>

double modf(double x, double *iptr);
float modff(float value, float *iptr);
long double modfl(long double value, long double *iptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall break the argument *x* into integral and fractional parts, each of which has the same sign as the argument. It stores the integral part as a **double** (for the *modf*( ) function), a **float** (for the *modff*( ) function), or a **long double** (for the *modfl*( ) function), in the object pointed to by *iptr*.

RETURN VALUE

Upon successful completion, these functions shall return the signed fractional part of *x*.

MX If *x* is NaN, a NaN shall be returned, and **iptr* shall be set to a NaN.

If *x* is ±Inf, ±0 shall be returned, and **iptr* shall be set to ±Inf.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The *modf*( ) function computes the function result and **iptr* such that:

```
a = modf(x, &iptr) ;
x == a+*iptr ;
```

allowing for the usual floating-point inaccuracies.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6

The *modff*( ) and *modfl*( ) functions are added for alignment with the ISO/IEC 9899: 1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

IEC 60559:1989 standard floating-point extensions over the ISO/IEC 9899:1999 standard are marked.

NAME

mprotect — set protection of memory mapping

SYNOPSIS

MPR

```
#include <sys/mman.h>

int mprotect(void *addr, size_t len, int prot);
```

DESCRIPTION

The *mprotect*( ) function shall change the access protections to be that specified by *prot* for those whole pages containing any part of the address space of the process starting at address *addr* and continuing for *len* bytes. The parameter *prot* determines whether read, write, execute, or some combination of accesses are permitted to the data being mapped. The *prot* argument should be either PROT_NONE or the bitwise-inclusive OR of one or more of PROT_READ, PROT_WRITE, and PROT_EXEC.

If an implementation cannot support the combination of access types specified by *prot*, the call to *mprotect*( ) shall fail.

An implementation may permit accesses other than those specified by *prot*; however, no implementation shall permit a write to succeed where PROT_WRITE has not been set or shall permit any access where PROT_NONE alone has been set. Implementations shall support at least the following values of *prot*: PROT_NONE, PROT_READ, PROT_WRITE, and the bitwise-inclusive OR of PROT_READ and PROT_WRITE. If PROT_WRITE is specified, the application shall ensure that it has opened the mapped objects in the specified address range with write permission, unless MAP_PRIVATE was specified in the original mapping, regardless of whether the file descriptors used to map the objects have since been closed.

The implementation shall require that *addr* be a multiple of the page size as returned by *sysconf*( ).

The behavior of this function is unspecified if the mapping was not established by a call to *mmap*( ).

When *mprotect*( ) fails for reasons other than [EINVAL], the protections on some of the pages in the range [*addr*,*addr*+*len*) may have been changed.

RETURN VALUE

Upon successful completion, *mprotect*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *mprotect*( ) function shall fail if:

[EACCES]	The *prot* argument specifies a protection that violates the access permission the process has to the underlying memory object.
[EAGAIN]	The *prot* argument specifies PROT_WRITE over a MAP_PRIVATE mapping and there are insufficient memory resources to reserve for locking the private page.
[EINVAL]	The *addr* argument is not a multiple of the page size as returned by *sysconf*( ).
[ENOMEM]	Addresses in the range [*addr*,*addr*+*len*) are invalid for the address space of a process, or specify one or more pages which are not mapped.
[ENOMEM]	The *prot* argument specifies PROT_WRITE on a MAP_PRIVATE mapping, and it would require more space than the system is able to supply for locking the private pages, if required.

[ENOTSUP] The implementation does not support the combination of accesses requested in the *prot* argument.

EXAMPLES

None.

APPLICATION USAGE

The [EINVAL] error above is marked EX because it is defined as an optional error in the POSIX Realtime Extension.

RATIONALE

None.

FUTURE DIRECTIONS

None.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Aligned with *mprotect*( ) in the POSIX Realtime Extension as follows:

- The DESCRIPTION is largely reworded.
- [ENOTSUP] and a second form of [ENOMEM] are added as mandatory error conditions.
- [EAGAIN] is moved from the optional to the mandatory error conditions.

Issue 6

The *mprotect*( ) function is marked as part of the Memory Protection option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION is updated to state that implementations require *addr* to be a multiple of the page size as returned by *sysconf*( ).
- The [EINVAL] error condition is added.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

mq_close — close a message queue (**REALTIME**)

SYNOPSIS

MSG

```
#include <mqueue.h>

int mq_close(mqd_t mqdes);

```

DESCRIPTION

The *mq_close*( ) function shall remove the association between the message queue descriptor, *mqdes*, and its message queue. The results of using this message queue descriptor after successful return from this *mq_close*( ), and until the return of this message queue descriptor from a subsequent *mq_open*( ), are undefined.

If the process has successfully attached a notification request to the message queue via this *mqdes*, this attachment shall be removed, and the message queue is available for another process to attach for notification.

RETURN VALUE

Upon successful completion, the *mq_close*( ) function shall return a value of zero; otherwise, the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *mq_close*( ) function shall fail if:

[EBADF] The *mqdes* argument is not a valid message queue descriptor.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *mq_close*( ) function is marked as part of the Message Passing option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Message Passing option.

NAME

mq_getattr — get message queue attributes (**REALTIME**)

SYNOPSIS

MSG
```
#include <mqueue.h>

int mq_getattr(mqd_t mqdes, struct mq_attr *mqstat);

```

DESCRIPTION

The *mqdes* argument specifies a message queue descriptor.

The *mq_getattr*( ) function shall obtain status information and attributes of the message queue and the open message queue description associated with the message queue descriptor.

The results shall be returned in the **mq_attr** structure referenced by the *mqstat* argument.

Upon return, the following members shall have the values associated with the open message queue description as set when the message queue was opened and as modified by subsequent *mq_setattr*( ) calls: *mq_flags*.

The following attributes of the message queue shall be returned as set at message queue creation: *mq_maxmsg*, *mq_msgsize*.

Upon return, the following members within the **mq_attr** structure referenced by the *mqstat* argument shall be set to the current state of the message queue:

mq_curmsgs The number of messages currently on the queue.

RETURN VALUE

Upon successful completion, the *mq_getattr*( ) function shall return zero. Otherwise, the function shall return −1 and set *errno* to indicate the error.

ERRORS

The *mq_getattr*( ) function shall fail if:

[EBADF] The *mqdes* argument is not a valid message queue descriptor.

EXAMPLES

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *mq_getattr*( ) function is marked as part of the Message Passing option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Message Passing option.

The *mq_timedsend*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

NAME

mq_notify — notify process that a message is available (**REALTIME**)

SYNOPSIS

MSG

```
#include <mqueue.h>

int mq_notify(mqd_t mqdes, const struct sigevent *notification);
```

DESCRIPTION

If the argument *notification* is not NULL, this function shall register the calling process to be notified of message arrival at an empty message queue associated with the specified message queue descriptor, *mqdes*. The notification specified by the *notification* argument shall be sent to the process when the message queue transitions from empty to non-empty. At any time, only one process may be registered for notification by a message queue. If the calling process or any other process has already registered for notification of message arrival at the specified message queue, subsequent attempts to register for that message queue shall fail.

If *notification* is NULL and the process is currently registered for notification by the specified message queue, the existing registration shall be removed.

When the notification is sent to the registered process, its registration shall be removed. The message queue shall then be available for registration.

If a process has registered for notification of message arrival at a message queue and some thread is blocked in *mq_receive*( ) waiting to receive a message when a message arrives at the queue, the arriving message shall satisfy the appropriate *mq_receive*( ). The resulting behavior is as if the message queue remains empty, and no notification shall be sent.

RETURN VALUE

Upon successful completion, the *mq_notify*( ) function shall return a value of zero; otherwise, the function shall return a value of –1 and set *errno* to indicate the error.

ERRORS

The *mq_notify*( ) function shall fail if:

[EBADF]	The *mqdes* argument is not a valid message queue descriptor.
[EBUSY]	A process is already registered for notification by the message queue.

EXAMPLES

None.

APPLICATION USAGE

None.

The *mq_notify*( ) function is marked as part of the Message Passing option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Message Passing option.

The *mq_timedsend*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

NAME

mq_open — open a message queue (**REALTIME**)

SYNOPSIS

MSG
```
#include <mqueue.h>

mqd_t mq_open(const char *name, int oflag, ...);
```

DESCRIPTION

The *mq_open*( ) function shall establish the connection between a process and a message queue with a message queue descriptor. It shall create an open message queue description that refers to the message queue, and a message queue descriptor that refers to that open message queue description. The message queue descriptor is used by other functions to refer to that message queue. The *name* argument points to a string naming a message queue. It is unspecified whether the name appears in the file system and is visible to other functions that take pathnames as arguments. The *name* argument shall conform to the construction rules for a pathname. If *name* begins with the slash character, then processes calling *mq_open*( ) with the same value of *name* shall refer to the same message queue object, as long as that name has not been removed. If *name* does not begin with the slash character, the effect is implementation-defined. The interpretation of slash characters other than the leading slash character in *name* is implementation-defined. If the *name* argument is not the name of an existing message queue and creation is not requested, *mq_open*( ) shall fail and return an error.

A message queue descriptor may be implemented using a file descriptor, in which case applications can open up to at least {OPEN_MAX} file and message queues.

The *oflag* argument requests the desired receive and/or send access to the message queue. The requested access permission to receive messages or send messages shall be granted if the calling process would be granted read or write access, respectively, to an equivalently protected file.

The value of *oflag* is the bitwise-inclusive OR of values from the following list. Applications shall specify exactly one of the first three values (access modes) below in the value of *oflag*:

O_RDONLY	Open the message queue for receiving messages. The process can use the returned message queue descriptor with *mq_receive*( ), but not *mq_send*( ). A message queue may be open multiple times in the same or different processes for receiving messages.
O_WRONLY	Open the queue for sending messages. The process can use the returned message queue descriptor with *mq_send*( ) but not *mq_receive*( ). A message queue may be open multiple times in the same or different processes for sending messages.
O_RDWR	Open the queue for both receiving and sending messages. The process can use any of the functions allowed for O_RDONLY and O_WRONLY. A message queue may be open multiple times in the same or different processes for sending messages.

Any combination of the remaining flags may be specified in the value of *oflag*:

O_CREAT	Create a message queue. It requires two additional arguments: *mode*, which shall be of type **mode_t**, and *attr*, which shall be a pointer to a **mq_attr** structure. If the pathname *name* has already been used to create a message queue that still exists, then this flag shall have no effect, except as noted under O_EXCL. Otherwise, a message queue shall be created without any messages in it. The user ID of the message queue shall be set to the effective user ID of the process, and the group ID of the message queue shall be set to the effective

group ID of the process. The file permission bits shall be set to the value of *mode*. When bits in *mode* other than file permission bits are set, the effect is implementation-defined. If *attr* is NULL, the message queue shall be created with implementation-defined default message queue attributes. If *attr* is non-NULL and the calling process has the appropriate privilege on *name*, the message queue *mq_maxmsg* and *mq_msgsize* attributes shall be set to the values of the corresponding members in the **mq_attr** structure referred to by *attr*. If *attr* is non-NULL, but the calling process does not have the appropriate privilege on *name*, the *mq_open*() function shall fail and return an error without creating the message queue.

O_EXCL If O_EXCL and O_CREAT are set, *mq_open*( ) shall fail if the message queue *name* exists. The check for the existence of the message queue and the creation of the message queue if it does not exist shall be atomic with respect to other threads executing *mq_open*() naming the same *name* with O_EXCL and O_CREAT set. If O_EXCL is set and O_CREAT is not set, the result is undefined.

O_NONBLOCK Determines whether a *mq_send*() or *mq_receive*() waits for resources or messages that are not currently available, or fails with *errno* set to [EAGAIN]; see *mq_send*( ) and *mq_receive*( ) for details.

The *mq_open*( ) function does not add or remove messages from the queue.

RETURN VALUE

Upon successful completion, the function shall return a message queue descriptor; otherwise, the function shall return (**mqd_t**)−1 and set *errno* to indicate the error.

ERRORS

The *mq_open*( ) function shall fail if:

[EACCES] The message queue exists and the permissions specified by *oflag* are denied, or the message queue does not exist and permission to create the message queue is denied.

[EEXIST] O_CREAT and O_EXCL are set and the named message queue already exists.

[EINTR] The *mq_open*( ) function was interrupted by a signal.

[EINVAL] The *mq_open*( ) function is not supported for the given name.

[EINVAL] O_CREAT was specified in *oflag*, the value of *attr* is not NULL, and either *mq_maxmsg* or *mq_msgsize* was less than or equal to zero.

[EMFILE] Too many message queue descriptors or file descriptors are currently in use by this process.

[ENAMETOOLONG]
The length of the *name* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.

[ENFILE] Too many message queues are currently open in the system.

[ENOENT] O_CREAT is not set and the named message queue does not exist.

[ENOSPC] There is insufficient space for the creation of the new message queue.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *mq_open*( ) function is marked as part of the Message Passing option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Message Passing option.

The *mq_timedreceive*( ) and *mq_timedsend*( ) functions are added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

The DESCRIPTION of O_EXCL is updated in response to IEEE PASC Interpretation 1003.1c #48.

NAME

mq_receive, mq_timedreceive — receive a message from a message queue (**REALTIME**)

SYNOPSIS

MSG

```
#include <mqueue.h>

ssize_t mq_receive(mqd_t mqdes, char *msg_ptr, size_t msg_len,
    unsigned *msg_prio);
```

MSG TMO

```
#include <mqueue.h>
#include <time.h>

ssize_t mq_timedreceive(mqd_t mqdes, char *restrict msg_ptr,
    size_t msg_len, unsigned *restrict msg_prio,
    const struct timespec *restrict abs_timeout);
```

DESCRIPTION

The *mq_receive*( ) function shall receive the oldest of the highest priority message(s) from the message queue specified by *mqdes*. If the size of the buffer in bytes, specified by the *msg_len* argument, is less than the *mq_msgsize* attribute of the message queue, the function shall fail and return an error. Otherwise, the selected message shall be removed from the queue and copied to the buffer pointed to by the *msg_ptr* argument.

If the value of *msg_len* is greater than {SSIZE_MAX}, the result is implementation-defined.

If the argument *msg_prio* is not NULL, the priority of the selected message shall be stored in the location referenced by *msg_prio*.

If the specified message queue is empty and O_NONBLOCK is not set in the message queue description associated with *mqdes*, *mq_receive*( ) shall block until a message is enqueued on the message queue or until *mq_receive*( ) is interrupted by a signal. If more than one thread is waiting to receive a message when a message arrives at an empty queue and the Priority Scheduling option is supported, then the thread of highest priority that has been waiting the longest shall be selected to receive the message. Otherwise, it is unspecified which waiting thread receives the message. If the specified message queue is empty and O_NONBLOCK is set in the message queue description associated with *mqdes*, no message shall be removed from the queue, and *mq_receive*( ) shall return an error.

TMO The *mq_timedreceive*( ) function shall receive the oldest of the highest priority messages from the message queue specified by *mqdes* as described for the *mq_receive*( ) function. However, if O_NONBLOCK was not specified when the message queue was opened via the *mq_open*( ) function, and no message exists on the queue to satisfy the receive, the wait for such a message shall be terminated when the specified timeout expires. If O_NONBLOCK is set, this function is equivalent to *mq_receive*( ).

The timeout expires when the absolute time specified by *abs_timeout* passes, as measured by the clock on which timeouts are based (that is, when the value of that clock equals or exceeds *abs_timeout*), or if the absolute time specified by *abs_timeout* has already been passed at the time of the call.

TMO TMR If the Timers option is supported, the timeout shall be based on the CLOCK_REALTIME clock; if the Timers option is not supported, the timeout shall be based on the system clock as returned by the *time*( ) function.

TMO The resolution of the timeout shall be the resolution of the clock on which it is based. The *timespec* argument is defined in the **<time.h>** header.

Under no circumstance shall the operation fail with a timeout if a message can be removed from the message queue immediately. The validity of the *abs_timeout* parameter need not be checked if a message can be removed from the message queue immediately.

RETURN VALUE

TMO Upon successful completion, the *mq_receive*( ) and *mq_timedreceive*( ) functions shall return the length of the selected message in bytes and the message shall be removed from the queue. Otherwise, no message shall be removed from the queue, the functions shall return a value of −1, and set *errno* to indicate the error.

ERRORS

TMO The *mq_receive*( ) and *mq_timedreceive*( ) functions shall fail if:

	[EAGAIN]	O_NONBLOCK was set in the message description associated with *mqdes*, and the specified message queue is empty.
	[EBADF]	The *mqdes* argument is not a valid message queue descriptor open for reading.
	[EMSGSIZE]	The specified message buffer size, *msg_len*, is less than the message size attribute of the message queue.
TMO	[EINTR]	The *mq_receive*( ) or *mq_timedreceive*( ) operation was interrupted by a signal.
TMO	[EINVAL]	The process or thread would have blocked, and the *abs_timeout* parameter specified a nanoseconds field value less than zero or greater than or equal to 1 000 million.
TMO	[ETIMEDOUT]	The O_NONBLOCK flag was not set when the message queue was opened, but no message arrived on the queue before the specified timeout expired.

TMO The *mq_receive*( ) and *mq_timedreceive*( ) functions may fail if:

[EBADMSG]	The implementation has detected a data corruption problem with the message.

EXAMPLES

SEE ALSO

mq_open( ), *mq_send*( ), *mq_timedsend*( ), *msgctl*( ), *msgget*( ), *msgrcv*( ), *msgsnd*( ), *time*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<mqueue.h>**, **<time.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *mq_receive*( ) function is marked as part of the Message Passing option.

The Open Group Corrigendum U021/4 is applied. The DESCRIPTION is changed to refer to *msg_len* rather than *maxsize*.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Message Passing option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In this function it is possible for the return value to exceed the range of the type **ssize_t** (since **size_t** has a larger range of positive values than **ssize_t**). A sentence restricting the size of the **size_t** object is added to the description to resolve this conflict.

The *mq_timedreceive*( ) function is added for alignment with IEEE Std 1003.1d-1999.

The **restrict** keyword is added to the *mq_timedreceive*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

IEEE PASC Interpretation 1003.1 #109 is applied, correcting the return type for *mq_timedreceive*( ) from **int** to **ssize_t**.

NAME

mq_send, mq_timedsend — send a message to a message queue (**REALTIME**)

SYNOPSIS

MSG
```
#include <mqueue.h>

int mq_send(mqd_t mqdes, const char *msg_ptr, size_t msg_len,
    unsigned msg_prio);

```

MSG TMO
```
#include <mqueue.h>
#include <time.h>

int mq_timedsend(mqd_t mqdes, const char *msg_ptr, size_t msg_len,
    unsigned msg_prio, const struct timespec *abs_timeout);

```

DESCRIPTION

The *mq_send*( ) function shall add the message pointed to by the argument *msg_ptr* to the message queue specified by *mqdes*. The *msg_len* argument specifies the length of the message, in bytes, pointed to by *msg_ptr*. The value of *msg_len* shall be less than or equal to the *mq_msgsize* attribute of the message queue, or *mq_send*( ) shall fail.

If the specified message queue is not full, *mq_send*( ) shall behave as if the message is inserted into the message queue at the position indicated by the *msg_prio* argument. A message with a larger numeric value of *msg_prio* shall be inserted before messages with lower values of *msg_prio*. A message shall be inserted after other messages in the queue, if any, with equal *msg_prio*. The value of *msg_prio* shall be less than {MQ_PRIO_MAX}.

If the specified message queue is full and O_NONBLOCK is not set in the message queue description associated with *mqdes*, *mq_send*( ) shall block until space becomes available to enqueue the message, or until *mq_send*( ) is interrupted by a signal. If more than one thread is waiting to send when space becomes available in the message queue and the Priority Scheduling option is supported, then the thread of the highest priority that has been waiting the longest shall be unblocked to send its message. Otherwise, it is unspecified which waiting thread is unblocked. If the specified message queue is full and O_NONBLOCK is set in the message queue description associated with *mqdes*, the message shall not be queued and *mq_send*( ) shall return an error.

TMO The *mq_timedsend*( ) function shall add a message to the message queue specified by *mqdes* in the manner defined for the *mq_send*( ) function. However, if the specified message queue is full and O_NONBLOCK is not set in the message queue description associated with *mqdes*, the wait for sufficient room in the queue shall be terminated when the specified timeout expires. If O_NONBLOCK is set in the message queue description, this function shall be equivalent to *mq_send*( ).

The timeout shall expire when the absolute time specified by *abs_timeout* passes, as measured by the clock on which timeouts are based (that is, when the value of that clock equals or exceeds *abs_timeout*), or if the absolute time specified by *abs_timeout* has already been passed at the time of the call.

TMO TMR If the Timers option is supported, the timeout shall be based on the CLOCK_REALTIME clock; if the Timers option is not supported, the timeout shall be based on the system clock as returned by the *time*( ) function.

TMO The resolution of the timeout shall be the resolution of the clock on which it is based. The *timespec* argument is defined in the **<time.h>** header.

Under no circumstance shall the operation fail with a timeout if there is sufficient room in the queue to add the message immediately. The validity of the *abs_timeout* parameter need not be checked when there is sufficient room in the queue.

RETURN VALUE

TMO Upon successful completion, the *mq_send*( ) and *mq_timedsend*( ) functions shall return a value of zero. Otherwise, no message shall be enqueued, the functions shall return −1, and *errno* shall be set to indicate the error.

ERRORS

TMO The *mq_send*( ) and *mq_timedsend*( ) functions shall fail if:

	[EAGAIN]	The O_NONBLOCK flag is set in the message queue description associated with *mqdes*, and the specified message queue is full.
	[EBADF]	The *mqdes* argument is not a valid message queue descriptor open for writing.
TMO	[EINTR]	A signal interrupted the call to *mq_send*( ) or *mq_timedsend*( ).
	[EINVAL]	The value of *msg_prio* was outside the valid range.
TMO	[EINVAL]	The process or thread would have blocked, and the *abs_timeout* parameter specified a nanoseconds field value less than zero or greater than or equal to 1 000 million.
	[EMSGSIZE]	The specified message length, *msg_len*, exceeds the message size attribute of the message queue.
TMO	[ETIMEDOUT]	The O_NONBLOCK flag was not set when the message queue was opened, but the timeout expired before the message could be added to the queue.

EXAMPLES

None.

APPLICATION USAGE

The value of the symbol {MQ_PRIO_MAX} limits the number of priority levels supported by the application. Message priorities range from 0 to {MQ_PRIO_MAX}−1.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *mq_send*( ) function is marked as part of the Message Passing option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Message Passing option.

The *mq_timedsend*( ) function is added for alignment with IEEE Std 1003.1d-1999.

NAME

mq_setattr — set message queue attributes (**REALTIME**)

SYNOPSIS

MSG

```
#include <mqueue.h>

int mq_setattr(mqd_t mqdes, const struct mq_attr *restrict mqstat,
    struct mq_attr *restrict omqstat);
```

DESCRIPTION

The *mq_setattr*( ) function shall set attributes associated with the open message queue description referenced by the message queue descriptor specified by *mqdes*.

The message queue attributes corresponding to the following members defined in the **mq_attr** structure shall be set to the specified values upon successful completion of *mq_setattr*( ):

mq_flags	The value of this member is the bitwise-logical OR of zero or more of O_NONBLOCK and any implementation-defined flags.

The values of the *mq_maxmsg*, *mq_msgsize*, and *mq_curmsgs* members of the **mq_attr** structure shall be ignored by *mq_setattr*( ).

If *omqstat* is non-NULL, the *mq_setattr*( ) function shall store, in the location referenced by *omqstat*, the previous message queue attributes and the current queue status. These values shall be the same as would be returned by a call to *mq_getattr*( ) at that point.

RETURN VALUE

Upon successful completion, the function shall return a value of zero and the attributes of the message queue shall have been changed as specified.

Otherwise, the message queue attributes shall be unchanged, and the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *mq_setattr*( ) function shall fail if:

[EBADF]	The *mqdes* argument is not a valid message queue descriptor.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *mq_setattr*( ) function is marked as part of the Message Passing option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Message Passing option.

The *mq_timedsend*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

The **restrict** keyword is added to the *mq_setattr*( ) prototype for alignment with the ISO/IEC 9899: 1999 standard.

NAME

mq_timedreceive — receive a message from a message queue (**ADVANCED REALTIME**)

SYNOPSIS

MSG TMO
```
#include <mqueue.h>
#include <time.h>

ssize_t mq_timedreceive(mqd_t mqdes, char *restrict msg_ptr,
    size_t msg_len, unsigned *restrict msg_prio,
    const struct timespec *restrict abs_timeout);
```

DESCRIPTION

Refer to *mq_receive*( ).

NAME

mq_timedsend — send a message to a message queue (**ADVANCED REALTIME**)

SYNOPSIS

MSG TMO

```
#include <mqueue.h>
#include <time.h>

int mq_timedsend(mqd_t mqdes, const char *msg_ptr, size_t msg_len,
    unsigned msg_prio, const struct timespec *abs_timeout);
```

DESCRIPTION

Refer to *mq_send*( ).

NAME

mq_unlink — remove a message queue (**REALTIME**)

SYNOPSIS

MSG

```
#include <mqueue.h>

int mq_unlink(const char *name);
```

DESCRIPTION

The *mq_unlink*( ) function shall remove the message queue named by the pathname *name*. After a successful call to *mq_unlink*( ) with *name*, a call to *mq_open*( ) with *name* shall fail if the flag O_CREAT is not set in *flags*. If one or more processes have the message queue open when *mq_unlink*( ) is called, destruction of the message queue shall be postponed until all references to the message queue have been closed.

Calls to *mq_open*( ) to recreate the message queue may fail until the message queue is actually removed. However, the *mq_unlink*( ) call need not block until all references have been closed; it may return immediately.

RETURN VALUE

Upon successful completion, the function shall return a value of zero. Otherwise, the named message queue shall be unchanged by this function call, and the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *mq_unlink*( ) function shall fail if:

[EACCES]	Permission is denied to unlink the named message queue.
[ENAMETOOLONG]	The length of the *name* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	The named message queue does not exist.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *mq_unlink*( ) function is marked as part of the Message Passing option.

The Open Group Corrigendum U021/5 is applied, clarifying that upon unsuccessful completion, the named message queue is unchanged by this function.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Message Passing option.

NAME

mrand48 — generate uniformly distributed pseudo-random signed long integers

SYNOPSIS

XSI

```
#include <stdlib.h>

long mrand48(void);
```

DESCRIPTION

Refer to *drand48*( ).

NAME

msgctl — XSI message control operations

SYNOPSIS

XSI
```
#include <sys/msg.h>

int msgctl(int msqid, int cmd, struct msqid_ds *buf);
```

DESCRIPTION

The *msgctl*( ) function operates on XSI message queues (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.224, Message Queue). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *msgctl*( ) function shall provide message control operations as specified by *cmd*. The following values for *cmd*, and the message control operations they specify, are:

IPC_STAT	Place the current value of each member of the **msqid_ds** data structure associated with *msqid* into the structure pointed to by *buf*. The contents of this structure are defined in **<sys/msg.h>**.

IPC_SET	Set the value of the following members of the **msqid_ds** data structure associated with *msqid* to the corresponding value found in the structure pointed to by *buf*:
	`msg_perm.uid`
	`msg_perm.gid`
	`msg_perm.mode`
	`msg_qbytes`
	IPC_SET can only be executed by a process with appropriate privileges or that has an effective user ID equal to the value of **msg_perm.cuid** or **msg_perm.uid** in the **msqid_ds** data structure associated with *msqid*. Only a process with appropriate privileges can raise the value of **msg_qbytes**.

IPC_RMID	Remove the message queue identifier specified by *msqid* from the system and destroy the message queue and **msqid_ds** data structure associated with it. IPC_RMD can only be executed by a process with appropriate privileges or one that has an effective user ID equal to the value of **msg_perm.cuid** or **msg_perm.uid** in the **msqid_ds** data structure associated with *msqid*.

RETURN VALUE

Upon successful completion, *msgctl*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *msgctl*( ) function shall fail if:

[EACCES]	The argument *cmd* is IPC_STAT and the calling process does not have read permission; see Section 2.7 (on page 489).
[EINVAL]	The value of *msqid* is not a valid message queue identifier; or the value of *cmd* is not a valid command.
[EPERM]	The argument *cmd* is IPC_RMID or IPC_SET and the effective user ID of the calling process is not equal to that of a process with appropriate privileges and it is not equal to the value of **msg_perm.cuid** or **msg_perm.uid** in the data structure associated with *msqid*.

[EPERM]	The argument *cmd* is IPC_SET, an attempt is being made to increase to the value of **msg_qbytes**, and the effective user ID of the calling process does not have appropriate privileges.

EXAMPLES

None.

APPLICATION USAGE

The POSIX Realtime Extension defines alternative interfaces for interprocess communication (IPC). Application developers who need to use IPC should design their applications so that modules using the IPC routines described in Section 2.7 (on page 489) can be easily modified to use the alternative interfaces.

RATIONALE

Issue 5

The note about use of POSIX Realtime Extension IPC routines has been moved from FUTURE DIRECTIONS to a new APPLICATION USAGE section.

NAME

msgget — get the XSI message queue identifier

SYNOPSIS

XSI
```
#include <sys/msg.h>

int msgget(key_t key, int msgflg);
```

DESCRIPTION

The *msgget*( ) function operates on XSI message queues (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.224, Message Queue). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *msgget*( ) function shall return the message queue identifier associated with the argument *key*.

A message queue identifier, associated message queue, and data structure (see **<sys/msg.h>**), shall be created for the argument *key* if one of the following is true:

- The argument *key* is equal to IPC_PRIVATE.
- The argument *key* does not already have a message queue identifier associated with it, and (*msgflg* & IPC_CREAT) is non-zero.

Upon creation, the data structure associated with the new message queue identifier shall be initialized as follows:

- **msg_perm.cuid**, **msg_perm.uid**, **msg_perm.cgid**, and **msg_perm.gid** shall be set equal to the effective user ID and effective group ID, respectively, of the calling process.
- The low-order 9 bits of **msg_perm.mode** shall be set equal to the low-order 9 bits of *msgflg*.
- **msg_qnum**, **msg_lspid**, **msg_lrpid**, **msg_stime**, and **msg_rtime** shall be set equal to 0.
- **msg_ctime** shall be set equal to the current time.
- **msg_qbytes** shall be set equal to the system limit.

RETURN VALUE

Upon successful completion, *msgget*( ) shall return a non-negative integer, namely a message queue identifier. Otherwise, it shall return –1 and set *errno* to indicate the error.

ERRORS

The *msgget*( ) function shall fail if:

[EACCES]	A message queue identifier exists for the argument *key*, but operation permission as specified by the low-order 9 bits of *msgflg* would not be granted; see Section 2.7 (on page 489).
[EEXIST]	A message queue identifier exists for the argument *key* but ((*msgflg* & IPC_CREAT) && (*msgflg* & IPC_EXCL)) is non-zero.
[ENOENT]	A message queue identifier does not exist for the argument *key* and (*msgflg* & IPC_CREAT) is 0.
[ENOSPC]	A message queue identifier is to be created but the system-imposed limit on the maximum number of allowed message queue identifiers system-wide would be exceeded.

EXAMPLES

None.

APPLICATION USAGE

The POSIX Realtime Extension defines alternative interfaces for interprocess communication (IPC). Application developers who need to use IPC should design their applications so that modules using the IPC routines described in Section 2.7 (on page 489) can be easily modified to use the alternative interfaces.

NAME

msgrcv — XSI message receive operation

SYNOPSIS

XSI

```
#include <sys/msg.h>

ssize_t msgrcv(int msqid, void *msgp, size_t msgsz, long msgtyp,
    int msgflg);
```

DESCRIPTION

The *msgrcv*( ) function operates on XSI message queues (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.224, Message Queue). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *msgrcv*( ) function shall read a message from the queue associated with the message queue identifier specified by *msqid* and place it in the user-defined buffer pointed to by *msgp*.

The application shall ensure that the argument *msgp* points to a user-defined buffer that contains first a field of type **long** specifying the type of the message, and then a data portion that holds the data bytes of the message. The structure below is an example of what this user-defined buffer might look like:

```
struct mymsg {
    long    mtype;     /* Message type. */
    char    mtext[1];  /* Message text. */
}
```

The structure member *mtype* is the received message's type as specified by the sending process.

The structure member *mtext* is the text of the message.

The argument *msgsz* specifies the size in bytes of *mtext*. The received message shall be truncated to *msgsz* bytes if it is larger than *msgsz* and (*msgflg* & MSG_NOERROR) is non-zero. The truncated part of the message shall be lost and no indication of the truncation shall be given to the calling process.

If the value of *msgsz* is greater than {SSIZE_MAX}, the result is implementation-defined.

The argument *msgtyp* specifies the type of message requested as follows:

- If *msgtyp* is 0, the first message on the queue shall be received.
- If *msgtyp* is greater than 0, the first message of type *msgtyp* shall be received.
- If *msgtyp* is less than 0, the first message of the lowest type that is less than or equal to the absolute value of *msgtyp* shall be received.

The argument *msgflg* specifies the action to be taken if a message of the desired type is not on the queue. These are as follows:

- If (*msgflg* & IPC_NOWAIT) is non-zero, the calling thread shall return immediately with a return value of –1 and *errno* set to [ENOMSG].
- If (*msgflg* & IPC_NOWAIT) is 0, the calling thread shall suspend execution until one of the following occurs:
  - — A message of the desired type is placed on the queue.
  - — The message queue identifier *msqid* is removed from the system; when this occurs, *errno* shall be set equal to [EIDRM] and –1 shall be returned.

  - The calling thread receives a signal that is to be caught; in this case a message is not received and the calling thread resumes execution in the manner prescribed in *sigaction*( ).

Upon successful completion, the following actions are taken with respect to the data structure associated with *msqid*:

- **msg_qnum** shall be decremented by 1. |
- **msg_lrpid** shall be set equal to the process ID of the calling process. |
- **msg_rtime** shall be set equal to the current time. |

RETURN VALUE

Upon successful completion, *msgrcv*( ) shall return a value equal to the number of bytes actually placed into the buffer *mtext*. Otherwise, no message shall be received, *msgrcv*( ) shall return (**ssize_t**)−1, and *errno* shall be set to indicate the error.

ERRORS

The *msgrcv*( ) function shall fail if:

[E2BIG]	The value of *mtext* is greater than *msgsz* and (*msgflg* & MSG_NOERROR) is 0.
[EACCES]	Operation permission is denied to the calling process; see Section 2.7 (on page 489).
[EIDRM]	The message queue identifier *msqid* is removed from the system.
[EINTR]	The *msgrcv*( ) function was interrupted by a signal.
[EINVAL]	*msqid* is not a valid message queue identifier.
[ENOMSG]	The queue does not contain a message of the desired type and (*msgflg* & IPC_NOWAIT) is non-zero.

EXAMPLES

Receiving a Message

The following example receives the first message on the queue (based on the value of the *msgtyp* argument, 0). The queue is identified by the *msqid* argument (assuming that the value has previously been set). This call specifies that an error should be reported if no message is available, but not if the message is too large. The message size is calculated directly using the *sizeof* operator.

```
#include <sys/msg.h>
...
int result;
int msqid;
struct message {
    long type;
    char text[20];
} msg;
long msgtyp = 0;
...
result = msgrcv(msqid, (void *) &msg, sizeof(msg.text),
         msgtyp, MSG_NOERROR | IPC_NOWAIT);
```

APPLICATION USAGE

The POSIX Realtime Extension defines alternative interfaces for interprocess communication (IPC). Application developers who need to use IPC should design their applications so that modules using the IPC routines described in Section 2.7 (on page 489) can be easily modified to use the alternative interfaces.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2. Derived from Issue 2 of the SVID.

Issue 5

The type of the return value is changed from **int** to **ssize_t**, and a warning is added to the DESCRIPTION about values of *msgsz* larger the {SSIZE_MAX}.

The note about use of POSIX Realtime Extension IPC routines has been moved from FUTURE DIRECTIONS to the APPLICATION USAGE section.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

msgsnd — XSI message send operation

SYNOPSIS

XSI

```
#include <sys/msg.h>

int msgsnd(int msqid, const void *msgp, size_t msgsz, int msgflg);
```

DESCRIPTION

The *msgsnd*( ) function operates on XSI message queues (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.224, Message Queue). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *msgsnd*( ) function shall send a message to the queue associated with the message queue identifier specified by *msqid*.

The application shall ensure that the argument *msgp* points to a user-defined buffer that contains first a field of type **long** specifying the type of the message, and then a data portion that holds the data bytes of the message. The structure below is an example of what this user-defined buffer might look like:

```
struct mymsg {
    long   mtype;       /* Message type. */
    char   mtext[1];    /* Message text. */
}
```

The structure member *mtype* is a non-zero positive type **long** that can be used by the receiving process for message selection.

The structure member *mtext* is any text of length *msgsz* bytes. The argument *msgsz* can range from 0 to a system-imposed maximum.

The argument *msgflg* specifies the action to be taken if one or more of the following are true:

- The number of bytes already on the queue is equal to **msg_qbytes**; see **<sys/msg.h>**.
- The total number of messages on all queues system-wide is equal to the system-imposed limit.

These actions are as follows:

- If (*msgflg* & IPC_NOWAIT) is non-zero, the message shall not be sent and the calling thread shall return immediately.
- If (*msgflg* & IPC_NOWAIT) is 0, the calling thread shall suspend execution until one of the following occurs:
  - — The condition responsible for the suspension no longer exists, in which case the message is sent.
  - — The message queue identifier *msqid* is removed from the system; when this occurs, *errno* shall be set equal to [EIDRM] and −1 shall be returned.
  - — The calling thread receives a signal that is to be caught; in this case the message is not sent and the calling thread resumes execution in the manner prescribed in *sigaction*( ).

Upon successful completion, the following actions are taken with respect to the data structure associated with *msqid*; see **<sys/msg.h>**:

- **msg_qnum** shall be incremented by 1.
- **msg_lspid** shall be set equal to the process ID of the calling process.
- **msg_stime** shall be set equal to the current time.

RETURN VALUE

Upon successful completion, *msgsnd*( ) shall return 0; otherwise, no message shall be sent, *msgsnd*( ) shall return −1, and *errno* shall be set to indicate the error.

ERRORS

The *msgsnd*( ) function shall fail if:

[EACCES]	Operation permission is denied to the calling process; see Section 2.7 (on page 489).
[EAGAIN]	The message cannot be sent for one of the reasons cited above and (*msgflg* & IPC_NOWAIT) is non-zero.
[EIDRM]	The message queue identifier *msgid* is removed from the system.
[EINTR]	The *msgsnd*( ) function was interrupted by a signal.
[EINVAL]	The value of *msqid* is not a valid message queue identifier, or the value of *mtype* is less than 1; or the value of *msgsz* is less than 0 or greater than the system-imposed limit.

EXAMPLES

Sending a Message

The following example sends a message to the queue identified by the *msqid* argument (assuming that value has previously been set). This call specifies that an error should be reported if no message is available. The message size is calculated directly using the *sizeof* operator.

```
#include <sys/msg.h>
...
int result;
int msqid;
struct message {
    long type;
    char text[20];
} msg;

msg.type = 1;
strcpy(msg.text, "This is message 1");
...
result = msgsnd(msqid, (void *) &msg, sizeof(msg.text), IPC_NOWAIT);
```

APPLICATION USAGE

The POSIX Realtime Extension defines alternative interfaces for interprocess communication (IPC). Application developers who need to use IPC should design their applications so that modules using the IPC routines described in Section 2.7 (on page 489) can be easily modified to use the alternative interfaces.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2. Derived from Issue 2 of the SVID.

Issue 5

The note about use of POSIX Realtime Extension IPC routines has been moved from FUTURE DIRECTIONS to a new APPLICATION USAGE section.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

msync — synchronize memory with physical storage

SYNOPSIS

MF SIO

```
#include <sys/mman.h>

int msync(void *addr, size_t len, int flags);
```

DESCRIPTION

The *msync*( ) function shall write all modified data to permanent storage locations, if any, in those whole pages containing any part of the address space of the process starting at address *addr* and continuing for *len* bytes. If no such storage exists, *msync*( ) need not have any effect. If requested, the *msync*( ) function shall then invalidate cached copies of data. |

The implementation shall require that *addr* be a multiple of the page size as returned by *sysconf*( ).

For mappings to files, the *msync*( ) function shall ensure that all write operations are completed as defined for synchronized I/O data integrity completion. It is unspecified whether the implementation also writes out other file attributes. When the *msync*( ) function is called on MAP_PRIVATE mappings, any modified data shall not be written to the underlying object and shall not cause such data to be made visible to other processes. It is unspecified whether data in MAP_PRIVATE mappings has any permanent storage locations. SHM|TYM The effect of *msync*( ) on a shared memory object or a typed memory object is unspecified. The behavior of this function is unspecified if the mapping was not established by a call to *mmap*( ). |

The *flags* argument is constructed from the bitwise-inclusive OR of one or more of the following flags defined in the **<sys/mman.h>** header:

Symbolic Constant	Description
MS_ASYNC	Perform asynchronous writes.
MS_SYNC	Perform synchronous writes.
MS_INVALIDATE	Invalidate cached data.

When MS_ASYNC is specified, *msync*( ) shall return immediately once all the write operations are initiated or queued for servicing; when MS_SYNC is specified, *msync*( ) shall not return until all write operations are completed as defined for synchronized I/O data integrity completion. Either MS_ASYNC or MS_SYNC is specified, but not both.

When MS_INVALIDATE is specified, *msync*( ) shall invalidate all cached copies of mapped data that are inconsistent with the permanent storage locations such that subsequent references shall obtain data that was consistent with the permanent storage locations sometime between the call to *msync*( ) and the first subsequent memory reference to the data. |

If *msync*( ) causes any write to a file, the file's *st_ctime* and *st_mtime* fields shall be marked for update.

RETURN VALUE

Upon successful completion, *msync*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *msync*( ) function shall fail if:

[EBUSY]	Some or all of the addresses in the range starting at *addr* and continuing for *len* bytes are locked, and MS_INVALIDATE is specified.

[EINVAL]	The value of *flags* is invalid.
[EINVAL]	The value of *addr* is not a multiple of the page size, {PAGESIZE}.
[ENOMEM]	The addresses in the range starting at *addr* and continuing for *len* bytes are outside the range allowed for the address space of a process or specify one or more pages that are not mapped.

EXAMPLES

None.

APPLICATION USAGE

The *msync*( ) function is only supported if the Memory Mapped Files option and the Synchronized Input and Output option are supported, and thus need not be available on all implementations.

The *msync*( ) function should be used by programs that require a memory object to be in a known state; for example, in building transaction facilities.

Normal system activity can cause pages to be written to disk. Therefore, there are no guarantees that *msync*( ) is the only control over when pages are or are not written to disk.

RATIONALE

The *msync*( ) function writes out data in a mapped region to the permanent storage for the underlying object. The call to *msync*( ) ensures data integrity of the file.

After the data is written out, any cached data may be invalidated if the MS_INVALIDATE flag was specified. This is useful on systems that do not support read/write consistency.

FUTURE DIRECTIONS

None.

SEE ALSO

mmap( ), *sysconf*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/mman.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Aligned with *msync*( ) in the POSIX Realtime Extension as follows:

- The DESCRIPTION is extensively reworded.
- [EBUSY] and a new form of [EINVAL] are added as mandatory error conditions.

Issue 6

The *msync*( ) function is marked as part of the Memory Mapped Files and Synchronized Input and Output options.

The following changes are made for alignment with the ISO POSIX-1:1996 standard:

- The [EBUSY] mandatory error condition is added.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION is updated to state that implementations require *addr* to be a multiple of the page size.
- The second [EINVAL] error condition is made mandatory.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by adding reference to typed memory objects.

NAME

munlock — unlock a range of process address space

SYNOPSIS

MLR

```
#include <sys/mman.h>

int munlock(const void *addr, size_t len);
```

DESCRIPTION

Refer to *mlock*( ).

NAME

munlockall — unlock the address space of a process

SYNOPSIS

ML
```
#include <sys/mman.h>

int munlockall(void);
```

DESCRIPTION

Refer to *mlockall*( ).

NAME

munmap — unmap pages of memory

SYNOPSIS

MF|SHM

```
#include <sys/mman.h>

int munmap(void *addr, size_t len);
```

DESCRIPTION

The *munmap*( ) function shall remove any mappings for those entire pages containing any part of the address space of the process starting at *addr* and continuing for *len* bytes. Further references to these pages shall result in the generation of a SIGSEGV signal to the process. If there are no mappings in the specified address range, then *munmap*( ) has no effect. |

The implementation shall require that *addr* be a multiple of the page size {PAGESIZE}.

If a mapping to be removed was private, any modifications made in this address range shall be discarded.

ML|MLR Any memory locks (see *mlock*( ) and *mlockall*( )) associated with this address range shall be removed, as if by an appropriate call to *munlock*( ).

TYM If a mapping removed from a typed memory object causes the corresponding address range of the memory pool to be inaccessible by any process in the system except through allocatable mappings (that is, mappings of typed memory objects opened with the POSIX_TYPED_MEM_MAP_ALLOCATABLE flag), then that range of the memory pool shall become deallocated and may become available to satisfy future typed memory allocation requests.

A mapping removed from a typed memory object opened with the POSIX_TYPED_MEM_MAP_ALLOCATABLE flag shall not affect in any way the availability of that typed memory for allocation.

The behavior of this function is unspecified if the mapping was not established by a call to *mmap*( ).

RETURN VALUE

Upon successful completion, *munmap*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *munmap*( ) function shall fail if:

[EINVAL]	Addresses in the range [*addr*,*addr*+*len*) are outside the valid range for the address space of a process.
[EINVAL]	The *len* argument is 0.
[EINVAL]	The *addr* argument is not a multiple of the page size as returned by *sysconf*( ).

EXAMPLES

None.

APPLICATION USAGE

The *munmap*( ) function is only supported if the Memory Mapped Files option or the Shared Memory Objects option is supported.

RATIONALE

The *munmap*( ) function corresponds to SVR4, just as the *mmap*( ) function does.

It is possible that an application has applied process memory locking to a region that contains shared memory. If this has occurred, the *munmap*( ) call ignores those locks and, if necessary, causes those locks to be removed.

FUTURE DIRECTIONS

None.

SEE ALSO

mlock( ), *mlockall*( ), *mmap*( ), *posix_typed_mem_open*( ), *sysconf*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<signal.h>**, **<sys/mman.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Aligned with *munmap*( ) in the POSIX Realtime Extension as follows:

- The DESCRIPTION is extensively reworded.
- The SIGBUS error is no longer permitted to be generated.

Issue 6

The *munmap*( ) function is marked as part of the Memory Mapped Files and Shared Memory Objects option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION is updated to state that implementations require *addr* to be a multiple of the page size.
- The [EINVAL] error conditions are added.

The following changes are made for alignment with IEEE Std 1003.1j-2000:

- Semantics for typed memory objects are added to the DESCRIPTION.
- The *posix_typed_mem_open*( ) function is added to the SEE ALSO section.

NAME

nan, nanf, nanl — return quiet NaN

SYNOPSIS

```
#include <math.h>

double nan(const char *tagp);
float nanf(const char *tagp);
long double nanl(const char *tagp);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The function call *nan*("*n-char-sequence*") shall be equivalent to:

```
strtod("NAN(n-char-sequence)", (char **) NULL);
```

The function call *nan*(" ") shall be equivalent to:

```
strtod("NAN()", (char **) NULL)
```

If *tagp* does not point to an *n*-**char** sequence or an empty string, the function call shall be equivalent to:

```
strtod("NAN", (char **) NULL)
```

Function calls to *nanf*( ) and *nanl*( ) are equivalent to the corresponding function calls to *strtof*( ) and *strtold*( ).

RETURN VALUE

These functions shall return a quiet NaN, if available, with content indicated through *tagp*.

If the implementation does not support quiet NaNs, these functions shall return zero.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

NAME

nanosleep — high resolution sleep (**REALTIME**)

SYNOPSIS

TMR
```
#include <time.h>

int nanosleep(const struct timespec *rqtp, struct timespec *rmtp);
```

DESCRIPTION

The *nanosleep*( ) function shall cause the current thread to be suspended from execution until either the time interval specified by the *rqtp* argument has elapsed or a signal is delivered to the calling thread, and its action is to invoke a signal-catching function or to terminate the process. The suspension time may be longer than requested because the argument value is rounded up to an integer multiple of the sleep resolution or because of the scheduling of other activity by the system. But, except for the case of being interrupted by a signal, the suspension time shall not be less than the time specified by *rqtp*, as measured by the system clock, CLOCK_REALTIME.

The use of the *nanosleep*( ) function has no effect on the action or blockage of any signal.

RETURN VALUE

If the *nanosleep*( ) function returns because the requested time has elapsed, its return value shall be zero.

If the *nanosleep*( ) function returns because it has been interrupted by a signal, it shall return a value of −1 and set *errno* to indicate the interruption. If the *rmtp* argument is non-NULL, the **timespec** structure referenced by it is updated to contain the amount of time remaining in the interval (the requested time minus the time actually slept). If the *rmtp* argument is NULL, the remaining time is not returned.

If *nanosleep*( ) fails, it shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *nanosleep*( ) function shall fail if:

[EINTR]	The *nanosleep*( ) function was interrupted by a signal.
[EINVAL]	The *rqtp* argument specified a nanosecond value less than zero or greater than or equal to 1000 million.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

It is common to suspend execution of a process for an interval in order to poll the status of a non-interrupting function. A large number of actual needs can be met with a simple extension to *sleep*( ) that provides finer resolution.

In the POSIX.1-1990 standard and SVR4, it is possible to implement such a routine, but the frequency of wakeup is limited by the resolution of the *alarm*( ) and *sleep*( ) functions. In 4.3 BSD, it is possible to write such a routine using no static storage and reserving no system facilities. Although it is possible to write a function with similar functionality to *sleep*( ) using the remainder of the timers function, such a function requires the use of signals and the reservation of some signal number. This volume of IEEE Std 1003.1-200x requires that *nanosleep*( ) be non-intrusive of the signals function.

The *nanosleep*( ) function shall return a value of 0 on success and −1 on failure or if interrupted. This latter case is different from *sleep*( ). This was done because the remaining time is returned via an argument structure pointer, *rmtp*, instead of as the return value.

FUTURE DIRECTIONS

None.

SEE ALSO

sleep( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<time.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *nanosleep*( ) function is marked as part of the Timers option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Timers option.

NAME

nearbyint, nearbyintf, nearbyintl — floating-point rounding functions

SYNOPSIS

```
#include <math.h>

double nearbyint(double x);
float nearbyintf(float x);
long double nearbyintl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall round their argument to an integer value in floating-point format, using the current rounding direction and without raising the inexact floating-point exception.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the rounded integer value.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0, ±0 shall be returned.

If *x* is ±Inf, *x* shall be returned.

XSI If the correct value would cause overflow, a range error shall occur and *nearbyint*( ), *nearbyintf*( ), and *nearbyintl*( ) shall return the value of the macro HUGE_VAL, HUGE_VALF, and HUGE_VALL, respectively.

ERRORS

These functions shall fail if:

XSI Range Error The result would cause an overflow.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised. |

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from the ISO / IEC 9899: 1999 standard.

NAME

nextafter, nextafterf, nextafterl, nexttoward, nexttowardf, nexttowardl — next representable floating-point number

SYNOPSIS

```
#include <math.h>

double nextafter(double x, double y);
float nextafterf(float x, float y);
long double nextafterl(long double x, long double y);
double nexttoward(double x, long double y);
float nexttowardf(float x, long double y);
long double nexttowardl(long double x, long double y);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *nextafter*( ), *nextafterf*( ), and *nextafterl*( ) functions shall compute the next representable floating-point value following *x* in the direction of *y*. Thus, if *y* is less than *x*, *nextafter*( ) shall return the largest representable floating-point number less than *x*. The *nextafter*( ), *nextafterf*( ), and *nextafterl*( ) functions shall return *y* if *x* equals *y*.

The *nexttoward*( ), *nexttowardf*( ), and *nexttowardl*( ) functions shall be equivalent to the corresponding *nextafter*( ) functions, except that the second parameter shall have type **long double** and the functions shall return *y* converted to the type of the function if *x* equals *y*. |

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the next representable floating-point value following *x* in the direction of *y*.

If *x*==*y*, *y* (of the type *x*) shall be returned.

If *x* is finite and the correct function value would overflow, a range error shall occur and ±HUGE_VAL, ±HUGE_VALF, and ±HUGE_VALL (with the same sign as *x*) shall be returned as appropriate for the return type of the function.

MX If *x* or *y* is NaN, a NaN shall be returned.

If *x*!=*y* and the correct function value is subnormal, zero, or underflows, a range error shall occur, and either the correct function value (if representable) or 0.0 shall be returned.

ERRORS

These functions shall fail if:

Range Error The correct value overflows

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised. |

MX Range Error The correct value is subnormal or underflows

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

The *nextafter*( ) function is no longer marked as an extension.

The *nextafterf*( ), *nextafterl*( ), *nexttoward*( ), *nexttowardf*( ), *nexttowardl*( ) functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

IEC 60559:1989 standard floating-point extensions over the ISO/IEC 9899:1999 standard are marked.

NAME

nexttoward, nexttowardf, nexttowardl — next representable floating-point number

SYNOPSIS

```
#include <math.h>

double nexttoward(double x, long double y);
float nexttowardf(float x, long double y);
long double nexttowardl(long double x, long double y);
```

DESCRIPTION

Refer to *nextafter*( ).

NAME

nftw — walk a file tree

SYNOPSIS

XSI

```
#include <ftw.h>

int nftw(const char *path, int (*fn)(const char *,
    const struct stat *, int, struct FTW *), int depth, int flags);
```

DESCRIPTION

The *nftw*( ) function shall recursively descend the directory hierarchy rooted in *path*. The *nftw*( ) function has a similar effect to *ftw*( ) except that it takes an additional argument *flags*, which is a bitwise-inclusive OR of zero or more of the following flags:

FTW_CHDIR	If set, *nftw*( ) shall change the current working directory to each directory as it reports files in that directory. If clear, *nftw*( ) shall not change the current working directory.
FTW_DEPTH	If set, *nftw*( ) shall report all files in a directory before reporting the directory itself. If clear, *nftw*( ) shall report any directory before reporting the files in that directory.
FTW_MOUNT	If set, *nftw*( ) shall only report files in the same file system as *path*. If clear, *nftw*( ) shall report all files encountered during the walk.
FTW_PHYS	If set, *nftw*( ) shall perform a physical walk and shall not follow symbolic links.

If FTW_PHYS is clear and FTW_DEPTH is set, *nftw*( ) shall follow links instead of reporting them, but shall not report any directory that would be a descendant of itself. If FTW_PHYS is clear and FTW_DEPTH is clear, *nftw*( ) shall follow links instead of reporting them, but shall not report the contents of any directory that would be a descendant of itself.

At each file it encounters, *nftw*( ) shall call the user-supplied function *fn* with four arguments:

- The first argument is the pathname of the object.
- The second argument is a pointer to the **stat** buffer containing information on the object.
- The third argument is an integer giving additional information. Its value is one of the following:

FTW_F	The object is a file.
FTW_D	The object is a directory.
FTW_DP	The object is a directory and subdirectories have been visited. (This condition shall only occur if the FTW_DEPTH flag is included in *flags*.)
FTW_SL	The object is a symbolic link. (This condition shall only occur if the FTW_PHYS flag is included in *flags*.)
FTW_SLN	The object is a symbolic link that does not name an existing file. (This condition shall only occur if the FTW_PHYS flag is not included in *flags*.)
FTW_DNR	The object is a directory that cannot be read. The *fn* function shall not be called for any of its descendants.
FTW_NS	The *stat*( ) function failed on the object because of lack of appropriate permission. The **stat** buffer passed to *fn* is undefined. Failure of *stat*( ) for any other reason is considered an error and *nftw*( ) shall return −1.

- The fourth argument is a pointer to an **FTW** structure. The value of **base** is the offset of the object's filename in the pathname passed as the first argument to *fn*. The value of **level** indicates depth relative to the root of the walk, where the root level is 0.

The results are unspecified if the application-supplied *fn* function does not preserve the current working directory.

The argument *depth* sets the maximum number of file descriptors that are shall be used by *nftw*( ) while traversing the file tree. At most one file descriptor shall be used for each directory level.

The *nftw*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

The *nftw*( ) function shall continue until the first of the following conditions occurs:

- An invocation of *fn* shall return a non-zero value, in which case *nftw*( ) shall return that value.
- The *nftw*( ) function detects an error other than [EACCES] (see FTW_DNR and FTW_NS above), in which case *nftw*( ) shall return −1 and set *errno* to indicate the error.
- The tree is exhausted, in which case *nftw*( ) shall return 0.

ERRORS

The *nftw*( ) function shall fail if:

[EACCES]	Search permission is denied for any component of *path* or read permission is denied for *path*, or *fn* returns −1 and does not reset *errno*.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of *path* does not name an existing file or *path* is an empty string.
[ENOTDIR]	A component of *path* is not a directory.
[EOVERFLOW]	A field in the **stat** structure cannot be represented correctly in the current programming environment for one or more files found in the file hierarchy.

The *nftw*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[EMFILE]	{OPEN_MAX} file descriptors are currently open in the calling process.
[ENAMETOOLONG]	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds {PATH_MAX}.
[ENFILE]	Too many files are currently open in the system.

In addition, *errno* may be set if the function pointed by *fn* causes *errno* to be set.

EXAMPLES

The following example walks the **/tmp** directory and its subdirectories, calling the *nftw*( ) function for every directory entry, to a maximum of 5 levels deep.

```
#include <ftw.h>
...
int nftwfunc(const char *, const struct stat *, int, struct FTW *);

int nftwfunc(const char *filename, const struct stat *statptr,
    int fileflags, struct FTW *pfwt)
{
    return 0;
}
...
char *startpath = "/tmp";
int depth = 5;
int flags = FTW_CHDIR | FTW_DEPTH | FTW_MOUNT;
int ret;

ret = nftw(startpath, nftwfunc, depth, flags);
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

In the DESCRIPTION, the definition of the *depth* argument is clarified.

Issue 6

The Open Group Base Resolution bwg97-003 is applied.

The ERRORS section is updated as follows: |

- The wording of the mandatory [ELOOP] error condition is updated. |
- A second optional [ELOOP] error condition is added. |
- The [EOVERFLOW] mandatory error condition is added. |

Text is added to the DESCRIPTION to say that the *nftw*( ) function need not be reentrant and that the results are unspecified if the application-supplied *fn* function does not preserve the current working directory. |

NAME

nice — change the nice value of a process

SYNOPSIS

XSI

```
#include <unistd.h>

int nice(int incr);
```

DESCRIPTION

The *nice*( ) function shall add the value of *incr* to the nice value of the calling process. A process' nice value is a non-negative number for which a more positive value shall result in less favorable scheduling.

A maximum nice value of 2*{NZERO}−1 and a minimum nice value of 0 shall be imposed by the system. Requests for values above or below these limits shall result in the nice value being set to the corresponding limit. Only a process with appropriate privileges can lower the nice value.

PS|TPS Calling the *nice*() function has no effect on the priority of processes or threads with policy SCHED_FIFO or SCHED_RR. The effect on processes or threads with other scheduling policies is implementation-defined.

The nice value set with *nice*( ) shall be applied to the process. If the process is multi-threaded, the nice value shall affect all system scope threads in the process.

As −1 is a permissible return value in a successful situation, an application wishing to check for error situations should set *errno* to 0, then call *nice*( ), and if it returns −1, check to see whether *errno* is non-zero.

RETURN VALUE

Upon successful completion, *nice*( ) shall return the new nice value −{NZERO}. Otherwise, −1 shall be returned, the process' nice value shall not be changed, and *errno* shall be set to indicate the error.

ERRORS

The *nice*( ) function shall fail if:

[EPERM] The *incr* argument is negative and the calling process does not have appropriate privileges.

EXAMPLES

Changing the Nice Value

The following example adds the value of the *incr* argument, −20, to the nice value of the calling process.

```
#include <unistd.h>
...
int incr = -20;
int ret;

ret = nice(incr);
```

APPLICATION USAGE

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

A statement is added to the description indicating the effects of this function on the different scheduling policies and multi-threaded processes.

NAME

nl_langinfo — language information

SYNOPSIS

XSI
```
#include <langinfo.h>

char *nl_langinfo(nl_item item);

```

DESCRIPTION

The *nl_langinfo*( ) function shall return a pointer to a string containing information relevant to the particular language or cultural area defined in the program's locale (see **<langinfo.h>**). The manifest constant names and values of *item* are defined in **<langinfo.h>**. For example:

```
nl_langinfo(ABDAY_1)
```

would return a pointer to the string `"Dom"` if the identified language was Portuguese, and `"Sun"` if the identified language was English.

Calls to *setlocale*( ) with a category corresponding to the category of *item* (see **<langinfo.h>**), or to the category *LC_ALL*, may overwrite the array pointed to by the return value.

The *nl_langinfo*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

In a locale where *langinfo* data is not defined, *nl_langinfo*( ) shall return a pointer to the corresponding string in the POSIX locale. In all locales, *nl_langinfo*( ) shall return a pointer to an empty string if *item* contains an invalid setting.

This pointer may point to static data that may be overwritten on the next call.

ERRORS

No errors are defined.

EXAMPLES

Getting Date and Time Formatting Information

The following example returns a pointer to a string containing date and time formatting information, as defined in the *LC_TIME* category of the current locale.

```
#include <time.h>
#include <langinfo.h>
...
strftime(datestring, sizeof(datestring), nl_langinfo(D_T_FMT), tm);
...
```

APPLICATION USAGE

The array pointed to by the return value should not be modified by the program, but may be modified by further calls to *nl_langinfo*( ).

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The last paragraph of the DESCRIPTION is moved from the APPLICATION USAGE section.

A note indicating that this function need not be reentrant is added to the DESCRIPTION.

NAME

nrand48 — generate uniformly distributed pseudo-random non-negative long integers

SYNOPSIS

XSI

```
#include <stdlib.h>

long nrand48(unsigned short xsubi[3]);
```

DESCRIPTION

Refer to *drand48*( ).

NAME

ntohl — convert values between host and network byte order

SYNOPSIS

```
#include <arpa/inet.h>

uint32_t ntohl(uint32_t netlong);
```

DESCRIPTION

Refer to *htonl*( ).

NAME

ntohs — convert values between host and network byte order

SYNOPSIS

```
#include <arpa/inet.h>

uint16_t ntohs(uint16_t netshort);
```

DESCRIPTION

Refer to *htonl*( ).

NAME

open — open a file

SYNOPSIS

OH

```
#include <sys/stat.h>
#include <fcntl.h>

int open(const char *path, int oflag, ... );
```

DESCRIPTION

The *open*( ) function shall establish the connection between a file and a file descriptor. It shall create an open file description that refers to a file and a file descriptor that refers to that open file description. The file descriptor is used by other I/O functions to refer to that file. The *path* argument points to a pathname naming the file.

The *open*( ) function shall return a file descriptor for the named file that is the lowest file descriptor not currently open for that process. The open file description is new, and therefore the file descriptor shall not share it with any other process in the system. The FD_CLOEXEC file descriptor flag associated with the new file descriptor shall be cleared.

The file offset used to mark the current position within the file shall be set to the beginning of the file.

The file status flags and file access modes of the open file description shall be set according to the value of *oflag*.

Values for *oflag* are constructed by a bitwise-inclusive OR of flags from the following list, defined in **<fcntl.h>**. Applications shall specify exactly one of the first three values (file access modes) below in the value of *oflag*:

O_RDONLY	Open for reading only.
O_WRONLY	Open for writing only.
O_RDWR	Open for reading and writing. The result is undefined if this flag is applied to a FIFO.

Any combination of the following may be used:

O_APPEND	If set, the file offset shall be set to the end of the file prior to each write.
O_CREAT	If the file exists, this flag has no effect except as noted under O_EXCL below. Otherwise, the file shall be created; the user ID of the file shall be set to the effective user ID of the process; the group ID of the file shall be set to the group ID of the file's parent directory or to the effective group ID of the process; and the access permission bits (see **<sys/stat.h>**) of the file mode shall be set to the value of the third argument taken as type **mode_t** modified as follows: a bitwise AND is performed on the file-mode bits and the corresponding bits in the complement of the process' file mode creation mask. Thus, all bits in the file mode whose corresponding bit in the file mode creation mask is set are cleared. When bits other than the file permission bits are set, the effect is unspecified. The third argument does not affect whether the file is open for reading, writing, or for both. Implementations shall provide a way to initialize the file's group ID to the group ID of the parent directory. Implementations may, but need not, provide an implementation-defined way to initialize the file's group ID to the effective group ID of the calling process.
SIO O_DSYNC	Write I/O operations on the file descriptor shall complete as defined by synchronized I/O data integrity completion.

O_EXCL If O_CREAT and O_EXCL are set, *open*( ) shall fail if the file exists. The check for the existence of the file and the creation of the file if it does not exist shall be atomic with respect to other threads executing *open*( ) naming the same filename in the same directory with O_EXCL and O_CREAT set. If O_EXCL and O_CREAT are set, and *path* names a symbolic link, *open*( ) shall fail and set *errno* to [EEXIST], regardless of the contents of the symbolic link. If O_EXCL is set and O_CREAT is not set, the result is undefined.

O_NOCTTY If set and *path* identifies a terminal device, *open*( ) shall not cause the terminal device to become the controlling terminal for the process.

O_NONBLOCK When opening a FIFO with O_RDONLY or O_WRONLY set:

- If O_NONBLOCK is set, an *open*( ) for reading-only shall return without delay. An *open*( ) for writing-only shall return an error if no process currently has the file open for reading.
- If O_NONBLOCK is clear, an *open*( ) for reading-only shall block the calling thread until a thread opens the file for writing. An *open*( ) for writing-only shall block the calling thread until a thread opens the file for reading.

When opening a block special or character special file that supports non-blocking opens:

- If O_NONBLOCK is set, the *open*( ) function shall return without blocking for the device to be ready or available. Subsequent behavior of the device is device-specific.
- If O_NONBLOCK is clear, the *open*( ) function shall block the calling thread until the device is ready or available before returning.

Otherwise, the behavior of O_NONBLOCK is unspecified.

SIO O_RSYNC Read I/O operations on the file descriptor shall complete at the same level of integrity as specified by the O_DSYNC and O_SYNC flags. If both O_DSYNC and O_RSYNC are set in *oflag*, all I/O operations on the file descriptor shall complete as defined by synchronized I/O data integrity completion. If both O_SYNC and O_RSYNC are set in flags, all I/O operations on the file descriptor shall complete as defined by synchronized I/O file integrity completion.

SIO O_SYNC Write I/O operations on the file descriptor shall complete as defined by synchronized I/O file integrity completion.

O_TRUNC If the file exists and is a regular file, and the file is successfully opened O_RDWR or O_WRONLY, its length shall be truncated to 0, and the mode and owner shall be unchanged. It shall have no effect on FIFO special files or terminal device files. Its effect on other file types is implementation-defined. The result of using O_TRUNC with O_RDONLY is undefined.

If O_CREAT is set and the file did not previously exist, upon successful completion, *open*( ) shall mark for update the *st_atime*, *st_ctime*, and *st_mtime* fields of the file and the *st_ctime* and *st_mtime* fields of the parent directory.

If O_TRUNC is set and the file did previously exist, upon successful completion, *open*( ) shall mark for update the *st_ctime* and *st_mtime* fields of the file.

SIO If both the O_SYNC and O_DSYNC flags are set, the effect is as if only the O_SYNC flag was set.

XSR If *path* refers to a STREAMS file, *oflag* may be constructed from O_NONBLOCK OR'ed with either O_RDONLY, O_WRONLY, or O_RDWR. Other flag values are not applicable to STREAMS devices and shall have no effect on them. The value O_NONBLOCK affects the operation of STREAMS drivers and certain functions applied to file descriptors associated with STREAMS files. For STREAMS drivers, the implementation of O_NONBLOCK is device-specific.

XSI If *path* names the master side of a pseudo-terminal device, then it is unspecified whether *open*( ) locks the slave side so that it cannot be opened. Conforming applications shall call *unlockpt*( ) before opening the slave side.

The largest value that can be represented correctly in an object of type **off_t** shall be established as the offset maximum in the open file description.

RETURN VALUE

Upon successful completion, the function shall open the file and return a non-negative integer representing the lowest numbered unused file descriptor. Otherwise, −1 shall be returned and *errno* set to indicate the error. No files shall be created or modified if the function returns −1.

ERRORS

The *open*( ) function shall fail if:

	[EACCES]	Search permission is denied on a component of the path prefix, or the file exists and the permissions specified by *oflag* are denied, or the file does not exist and write permission is denied for the parent directory of the file to be created, or O_TRUNC is specified and write permission is denied.
	[EEXIST]	O_CREAT and O_EXCL are set, and the named file exists.
	[EINTR]	A signal was caught during *open*( ).
SIO	[EINVAL]	The implementation does not support synchronized I/O for this file.
XSR	[EIO]	The *path* argument names a STREAMS file and a hangup or error occurred during the *open*( ).
	[EISDIR]	The named file is a directory and *oflag* includes O_WRONLY or O_RDWR.
	[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
	[EMFILE]	{OPEN_MAX} file descriptors are currently open in the calling process.
	[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
	[ENFILE]	The maximum allowable number of files is currently open in the system.
	[ENOENT]	O_CREAT is not set and the named file does not exist; or O_CREAT is set and either the path prefix does not exist or the *path* argument points to an empty string.
XSR	[ENOSR]	The *path* argument names a STREAMS-based file and the system is unable to allocate a STREAM.
	[ENOSPC]	The directory or file system that would contain the new file cannot be expanded, the file does not exist, and O_CREAT is specified.

[ENOTDIR]	A component of the path prefix is not a directory.
[ENXIO]	O_NONBLOCK is set, the named file is a FIFO, O_WRONLY is set, and no process has the file open for reading.
[ENXIO]	The named file is a character special or block special file, and the device associated with this special file does not exist.
[EOVERFLOW]	The named file is a regular file and the size of the file cannot be represented correctly in an object of type **off_t**.
[EROFS]	The named file resides on a read-only file system and either O_WRONLY, O_RDWR, O_CREAT (if file does not exist), or O_TRUNC is set in the *oflag* argument.

The *open*( ) function may fail if:

XSI [EAGAIN]	The *path* argument names the slave side of a pseudo-terminal device that is locked.
[EINVAL]	The value of the *oflag* argument is not valid.
[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[ENAMETOOLONG]	As a result of encountering a symbolic link in resolution of the *path* argument, the length of the substituted pathname string exceeded {PATH_MAX}.
XSR [ENOMEM]	The *path* argument names a STREAMS file and the system is unable to allocate resources.
[ETXTBSY]	The file is a pure procedure (shared text) file that is being executed and *oflag* is O_WRONLY or O_RDWR.

EXAMPLES

Opening a File for Writing by the Owner

The following example opens the file **/tmp/file**, either by creating it (if it does not already exist), or by truncating its length to 0 (if it does exist). In the former case, if the call creates a new file, the access permission bits in the file mode of the file are set to permit reading and writing by the owner, and to permit reading only by group members and others.

If the call to *open*( ) is successful, the file is opened for writing.

```
#include <fcntl.h>
...
int fd;
mode_t mode = S_IRUSR | S_IWUSR | S_IRGRP | S_IROTH;
char *filename = "/tmp/file";
...
fd = open(filename, O_WRONLY | O_CREAT | O_TRUNC, mode);
...
```

Opening a File Using an Existence Check

The following example uses the *open*( ) function to try to create the **LOCKFILE** file and open it for writing. Since the *open*( ) function specifies the O_EXCL flag, the call fails if the file already exists. In that case, the program assumes that someone else is updating the password file and exits.

```
#include <fcntl.h>
#include <stdio.h>
#include <stdlib.h>

#define LOCKFILE "/etc/ptmp"
...
int pfd; /* Integer for file descriptor returned by open() call. */
...
if ((pfd = open(LOCKFILE, O_WRONLY | O_CREAT | O_EXCL,
    S_IRUSR | S_IWUSR | S_IRGRP | S_IROTH)) == -1)
{
    fprintf(stderr, "Cannot open /etc/ptmp. Try again later.\n");
    exit(1);
}
...
```

Opening a File for Writing

The following example opens a file for writing, creating the file if it does not already exist. If the file does exist, the system truncates the file to zero bytes.

```
#include <fcntl.h>
#include <stdio.h>
#include <stdlib.h>

#define LOCKFILE "/etc/ptmp"
...
int pfd;
char filename[PATH_MAX+1];
...
if ((pfd = open(filename, O_WRONLY | O_CREAT | O_TRUNC,
    S_IRUSR | S_IWUSR | S_IRGRP | S_IROTH)) == -1)
{
    perror("Cannot open output file\n"); exit(1);
}
...
```

APPLICATION USAGE

None.

RATIONALE

Except as specified in this volume of IEEE Std 1003.1-200x, the flags allowed in *oflag* are not mutually-exclusive and any number of them may be used simultaneously.

Some implementations permit opening FIFOs with O_RDWR. Since FIFOs could be implemented in other ways, and since two file descriptors can be used to the same effect, this possibility is left as undefined.

See *getgroups*( ) about the group of a newly created file.

The use of *open*( ) to create a regular file is preferable to the use of *creat*( ), because the latter is redundant and included only for historical reasons.

The use of the O_TRUNC flag on FIFOs and directories (pipes cannot be *open*( )-ed) must be permissible without unexpected side effects (for example, *creat*( ) on a FIFO must not remove data). Since terminal special files might have type-ahead data stored in the buffer, O_TRUNC should not affect their content, particularly if a program that normally opens a regular file should open the current controlling terminal instead. Other file types, particularly implementation-defined ones, are left implementation-defined.

IEEE Std 1003.1-200x permits [EACCES] to be returned for conditions other than those explicitly listed.

The O_NOCTTY flag was added to allow applications to avoid unintentionally acquiring a controlling terminal as a side effect of opening a terminal file. This volume of IEEE Std 1003.1-200x does not specify how a controlling terminal is acquired, but it allows an implementation to provide this on *open*( ) if the O_NOCTTY flag is not set and other conditions specified in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface are met. The O_NOCTTY flag is an effective no-op if the file being opened is not a terminal device.

In historical implementations the value of O_RDONLY is zero. Because of that, it is not possible to detect the presence of O_RDONLY and another option. Future implementations should encode O_RDONLY and O_WRONLY as bit flags so that:

```
O_RDONLY | O_WRONLY == O_RDWR
```

In general, the *open*( ) function follows the symbolic link if *path* names a symbolic link. However, the *open*( ) function, when called with O_CREAT and O_EXCL, is required to fail with [EEXIST] if *path* names an existing symbolic link, even if the symbolic link refers to a nonexistent file. This behavior is required so that privileged applications can create a new file in a known location without the possibility that a symbolic link might cause the file to be created in a different location.

For example, a privileged application that must create a file with a predictable name in a user-writable directory, such as the user's home directory, could be compromised if the user creates a symbolic link with that name that refers to a nonexistent file in a system directory. If the user can influence the contents of a file, the user could compromise the system by creating a new system configuration or spool file that would then be interpreted by the system. The test for a symbolic link which refers to a nonexisting file must be atomic with the creation of a new file.

The POSIX.1-1990 standard required that the group ID of a newly created file be set to the group ID of its parent directory or to the effective group ID of the creating process. FIPS 151-2 required that implementations provide a way to have the group ID be set to the group ID of the containing directory, but did not prohibit implementations also supporting a way to set the group ID to the effective group ID of the creating process. Conforming applications should not assume which group ID will be used. If it matters, an application can use *chown*( ) to set the group ID after the file is created, or determine under what conditions the implementation will set the desired group ID.

FUTURE DIRECTIONS

None.

SEE ALSO

chmod( ), *close*( ), *creat*( ), *dup*( ), *fcntl*( ), *lseek*( ), *read*( ), *umask*( ), *unlockpt*( ), *write*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<fcntl.h>**, **<sys/stat.h>**, **<sys/types.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Large File Summit extensions are added.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification: |

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- In the DESCRIPTION, O_CREAT is amended to state that the group ID of the file is set to the group ID of the file's parent directory or to the effective group ID of the process. This is a FIPS requirement.
- In the DESCRIPTION, text is added to indicate setting of the offset maximum in the open file description. This change is to support large files.
- In the ERRORS section, the [EOVERFLOW] condition is added. This change is to support large files.
- The [ENXIO] mandatory error condition is added.
- The [EINVAL], [ENAMETOOLONG], and [ETXTBSY] optional error conditions are added.

The DESCRIPTION and ERRORS sections are updated so that items related to the optional XSI STREAMS Option Group are marked.

The following changes were made to align with the IEEE P1003.1a draft standard:

- An explanation is added of the effect of the O_CREAT and O_EXCL flags when the path refers to a symbolic link.
- The [ELOOP] optional error condition is added.

The DESCRIPTION is updated to avoid use of the term ''must'' for application requirements.

The DESCRIPTION of O_EXCL is updated in response to IEEE PASC Interpretation 1003.1c #48.

NAME

opendir — open a directory

SYNOPSIS

```
#include <dirent.h>

DIR *opendir(const char *dirname);
```

DESCRIPTION

The *opendir*( ) function shall open a directory stream corresponding to the directory named by the *dirname* argument. The directory stream is positioned at the first entry. If the type **DIR** is implemented using a file descriptor, applications shall only be able to open up to a total of {OPEN_MAX} files and directories.

RETURN VALUE

Upon successful completion, *opendir*( ) shall return a pointer to an object of type **DIR**. Otherwise, a null pointer shall be returned and *errno* set to indicate the error.

ERRORS

The *opendir*( ) function shall fail if:

[EACCES]	Search permission is denied for the component of the path prefix of *dirname* or read permission is denied for *dirname*.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *dirname* argument.
[ENAMETOOLONG]	The length of the *dirname* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of *dirname* does not name an existing directory or *dirname* is an empty string.
[ENOTDIR]	A component of *dirname* is not a directory.

The *opendir*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *dirname* argument.
[EMFILE]	{OPEN_MAX} file descriptors are currently open in the calling process.
[ENAMETOOLONG]	As a result of encountering a symbolic link in resolution of the *dirname* argument, the length of the substituted pathname string exceeded {PATH_MAX}.
[ENFILE]	Too many files are currently open in the system.

EXAMPLES

Open a Directory Stream

The following program fragment demonstrates how the *opendir*( ) function is used.

```
#include <sys/types.h>
#include <dirent.h>
#include <libgen.h>
...
    DIR *dir;
    struct dirent *dp;
...
    if ((dir = opendir (".")) == NULL) {
        perror ("Cannot open .");
        exit (1);
    }

    while ((dp = readdir (dir)) != NULL) {
...
```

APPLICATION USAGE

The *opendir*( ) function should be used in conjunction with *readdir*( ), *closedir*( ), and *rewinddir*( ) to examine the contents of the directory (see the EXAMPLES section in *readdir*( )). This method is recommended for portability.

RATIONALE

Based on historical implementations, the rules about file descriptors apply to directory streams as well. However, this volume of IEEE Std 1003.1-200x does not mandate that the directory stream be implemented using file descriptors. The description of *closedir*( ) clarifies that if a file descriptor is used for the directory stream, it is mandatory that *closedir*( ) deallocate the file descriptor. When a file descriptor is used to implement the directory stream, it behaves as if the FD_CLOEXEC had been set for the file descriptor.

The directory entries for dot and dot-dot are optional. This volume of IEEE Std 1003.1-200x does not provide a way to test *a priori* for their existence because an application that is portable must be written to look for (and usually ignore) those entries. Writing code that presumes that they are the first two entries does not always work, as many implementations permit them to be other than the first two entries, with a ''normal'' entry preceding them. There is negligible value in providing a way to determine what the implementation does because the code to deal with dot and dot-dot must be written in any case and because such a flag would add to the list of those flags (which has proven in itself to be objectionable) and might be abused.

Since the structure and buffer allocation, if any, for directory operations are defined by the implementation, this volume of IEEE Std 1003.1-200x imposes no portability requirements for erroneous program constructs, erroneous data, or the use of unspecified values such as the use or referencing of a *dirp* value or a **dirent** structure value after a directory stream has been closed or after a *fork*( ) or one of the *exec* function calls.

FUTURE DIRECTIONS

None.

SEE ALSO

closedir( ), *lstat*( ), *readdir*( ), *rewinddir*( ), *symlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<dirent.h>**, **<limits.h>**, **<sys/types.h>**

CHANGE HISTORY

First released in Issue 2.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- The [ELOOP] mandatory error condition is added.
- A second [ENAMETOOLONG] is added as an optional error condition.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The [ELOOP] optional error condition is added.

NAME

openlog — open a connection to the logging facility

SYNOPSIS

XSI

```
#include <syslog.h>

void openlog(const char *ident, int logopt, int facility);
```

DESCRIPTION

Refer to *closelog*( ).

NAME

optarg, opterr, optind, optopt — options parsing variables

SYNOPSIS

```
#include <unistd.h>

extern char *optarg;
extern int opterr, optind, optopt;
```

DESCRIPTION

Refer to *getopt*( ).

NAME

pathconf — get configurable pathname variables

SYNOPSIS

```
#include <unistd.h>

long pathconf(const char *path, int name);
```

DESCRIPTION

Refer to *fpathconf*( ).

NAME

pause — suspend the thread until a signal is received

SYNOPSIS

```
#include <unistd.h>

int pause(void);
```

DESCRIPTION

The *pause*( ) function shall suspend the calling thread until delivery of a signal whose action is either to execute a signal-catching function or to terminate the process.

If the action is to terminate the process, *pause*( ) shall not return.

If the action is to execute a signal-catching function, *pause*( ) shall return after the signal-catching function returns.

RETURN VALUE

Since *pause*( ) suspends thread execution indefinitely unless interrupted by a signal, there is no successful completion return value. A value of −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *pause*( ) function shall fail if:

[EINTR]	A signal is caught by the calling process and control is returned from the signal-catching function.

EXAMPLES

None.

APPLICATION USAGE

Many common uses of *pause*( ) have timing windows. The scenario involves checking a condition related to a signal and, if the signal has not occurred, calling *pause*( ). When the signal occurs between the check and the call to *pause*( ), the process often blocks indefinitely. The *sigprocmask*( ) and *sigsuspend*( ) functions can be used to avoid this type of problem.

RATIONALE

None.

FUTURE DIRECTIONS

None.

Issue 6

The APPLICATION USAGE section is added.

NAME

pclose — close a pipe stream to or from a process

SYNOPSIS

CX

```
#include <stdio.h>

int pclose(FILE *stream);
```

DESCRIPTION

The *pclose*( ) function shall close a stream that was opened by *popen*( ), wait for the command to terminate, and return the termination status of the process that was running the command language interpreter. However, if a call caused the termination status to be unavailable to *pclose*( ), then *pclose*( ) shall return –1 with *errno* set to [ECHILD] to report this situation. This can happen if the application calls one of the following functions:

- *wait*( )
- *waitpid*( ) with a *pid* argument less than or equal to 0 or equal to the process ID of the command line interpreter
- Any other function not defined in this volume of IEEE Std 1003.1-200x that could do one of the above

In any case, *pclose*( ) shall not return before the child process created by *popen*( ) has terminated.

If the command language interpreter cannot be executed, the child termination status returned by *pclose*( ) shall be as if the command language interpreter terminated using *exit*(127) or *_exit*(127).

The *pclose*( ) function shall not affect the termination status of any child of the calling process other than the one created by *popen*( ) for the associated stream.

If the argument *stream* to *pclose*( ) is not a pointer to a stream created by *popen*( ), the result of *pclose*( ) is undefined.

RETURN VALUE

Upon successful return, *pclose*( ) shall return the termination status of the command language interpreter. Otherwise, *pclose*( ) shall return –1 and set *errno* to indicate the error.

ERRORS

The *pclose*( ) function shall fail if:

[ECHILD]	The status of the child process could not be obtained, as described above.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

There is a requirement that *pclose*( ) not return before the child process terminates. This is intended to disallow implementations that return [EINTR] if a signal is received while waiting. If *pclose*( ) returned before the child terminated, there would be no way for the application to discover which child used to be associated with the stream, and it could not do the cleanup itself.

If the stream pointed to by *stream* was not created by *popen*( ), historical implementations of *pclose*( ) return –1 without setting *errno*. To avoid requiring *pclose*( ) to set *errno* in this case, IEEE Std 1003.1-200x makes the behavior unspecified. An application should not use *pclose*( ) to close any stream that was not created by *popen*( ).

Some historical implementations of *pclose*( ) either block or ignore the signals SIGINT, SIGQUIT, and SIGHUP while waiting for the child process to terminate. Since this behavior is not described for the *pclose*( ) function in IEEE Std 1003.1-200x, such implementations are not conforming. Also, some historical implementations return [EINTR] if a signal is received, even though the child process has not terminated. Such implementations are also considered non-conforming.

Consider, for example, an application that uses:

```
popen("command", "r")
```

to start *command*, which is part of the same application. The parent writes a prompt to its standard output (presumably the terminal) and then reads from the stream. The child reads the response from the user, does some transformation on the response (pathname expansion, perhaps) and writes the result to its standard output. The parent process reads the result from the pipe, does something with it, and prints another prompt. The cycle repeats. Assuming that both processes do appropriate buffer flushing, this would be expected to work.

To conform to IEEE Std 1003.1-200x, *pclose*( ) must use *waitpid*( ), or some similar function, instead of *wait*( ).

The code sample below illustrates how the *pclose*( ) function might be implemented on a system conforming to IEEE Std 1003.1-200x.

```
int pclose(FILE *stream)
{
    int stat;
    pid_t pid;

    pid = <pid for process created for stream by popen()>
    (void) fclose(stream);
    while (waitpid(pid, &stat, 0) == -1) {
        if (errno != EINTR){
            stat = -1;
            break;
        }
    }
    return(stat);
}
```

FUTURE DIRECTIONS

None.

NAME

perror — write error messages to standard error

SYNOPSIS

```
#include <stdio.h>

void perror(const char *s);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *perror*( ) function shall map the error number accessed through the symbol *errno* to a language-dependent error message, which shall be written to the standard error stream as follows: |

- First (if *s* is not a null pointer and the character pointed to by *s* is not the null byte), the string pointed to by *s* followed by a colon and a <space>.
- Then an error message string followed by a <newline>.

The contents of the error message strings shall be the same as those returned by *strerror*( ) with argument *errno*. |

CX The *perror*( ) function shall mark the file associated with the standard error stream as having been written (*st_ctime*, *st_mtime* marked for update) at some time between its successful completion and *exit*( ), *abort*( ), or the completion of *fflush*( ) or *fclose*( ) on *stderr*.

The *perror*( ) function shall not change the orientation of the standard error stream.

RETURN VALUE

The *perror*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

Printing an Error Message for a Function

The following example replaces *bufptr* with a buffer that is the necessary size. If an error occurs, the *perror*( ) function prints a message and the program exits.

```
#include <stdio.h>
#include <stdlib.h>
...
char *bufptr;
size_t szbuf;
...
if ((bufptr = malloc(szbuf)) == NULL) {
    perror("malloc"); exit(2);
}
...
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

strerror( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdio.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

A paragraph is added to the DESCRIPTION indicating that *perror*( ) does not change the orientation of the standard error stream.

Issue 6

Extensions beyond the ISO C standard are now marked.

NAME

pipe — create an interprocess channel

SYNOPSIS

```
#include <unistd.h>

int pipe(int fildes[2]);
```

DESCRIPTION

The *pipe*( ) function shall create a pipe and place two file descriptors, one each into the arguments *fildes*[0] and *fildes*[1], that refer to the open file descriptions for the read and write ends of the pipe. Their integer values shall be the two lowest available at the time of the *pipe*( ) call. The O_NONBLOCK and FD_CLOEXEC flags shall be clear on both file descriptors. (The *fcntl*( ) function can be used to set both these flags.)

Data can be written to the file descriptor *fildes*[1] and read from the file descriptor *fildes*[0]. A read on the file descriptor *fildes*[0] shall access data written to the file descriptor *fildes*[1] on a first-in-first-out basis. It is unspecified whether *fildes*[0] is also open for writing and whether *fildes*[1] is also open for reading.

A process has the pipe open for reading (correspondingly writing) if it has a file descriptor open that refers to the read end, *fildes*[0] (write end, *fildes*[1]).

Upon successful completion, *pipe*( ) shall mark for update the *st_atime*, *st_ctime*, and *st_mtime* fields of the pipe.

RETURN VALUE

Upon successful completion, 0 shall be returned; otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *pipe*( ) function shall fail if:

[EMFILE]	More than {OPEN_MAX} minus two file descriptors are already in use by this process.
[ENFILE]	The number of simultaneously open files in the system would exceed a system-imposed limit.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The wording carefully avoids using the verb ‘‘to open’’ in order to avoid any implication of use of *open*( ); see also *write*( ).

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION is updated to indicate that certain dispositions of *fildes*[0] and *fildes*[1] are unspecified.

NAME

poll — input/output multiplexing

SYNOPSIS

XSI
```
#include <poll.h>

int poll(struct pollfd fds[], nfds_t nfds, int timeout);
```

DESCRIPTION

The *poll*( ) function provides applications with a mechanism for multiplexing input/output over a set of file descriptors. For each member of the array pointed to by *fds*, *poll*( ) shall examine the given file descriptor for the event(s) specified in *events*. The number of **pollfd** structures in the *fds* array is specified by *nfds*. The *poll*( ) function shall identify those file descriptors on which an application can read or write data, or on which certain events have occurred.

The *fds* argument specifies the file descriptors to be examined and the events of interest for each file descriptor. It is a pointer to an array with one member for each open file descriptor of interest. The array's members are **pollfd** structures within which *fd* specifies an open file descriptor and *events* and *revents* are bitmasks constructed by OR'ing a combination of the following event flags:

POLLIN	Data other than high-priority data may be read without blocking. XSR For STREAMS, this flag is set in *revents* even if the message is of zero length. This flag shall be equivalent to POLLRDNORM | POLLRDBAND.
POLLRDNORM	Normal data may be read without blocking. XSR For STREAMS, data on priority band 0 may be read without blocking. This flag is set in *revents* even if the message is of zero length.
POLLRDBAND	Priority data may be read without blocking. XSR For STREAMS, data on priority bands greater than 0 may be read without blocking. This flag is set in *revents* even if the message is of zero length.
POLLPRI	High-priority data may be read without blocking. XSR For STREAMS, this flag is set in *revents* even if the message is of zero length.
POLLOUT	Normal data may be written without blocking. XSR For STREAMS, data on priority band 0 may be written without blocking.
POLLWRNORM	Equivalent to POLLOUT.
POLLWRBAND	Priority data may be written. XSR For STREAMS, data on priority bands greater than 0 may be written without blocking. If any priority band has been written to on this STREAM, this event only examines bands that have been written to at least once.
POLLERR	An error has occurred on the device or stream. This flag is only valid in the *revents* bitmask; it shall be ignored in the *events* member.
POLLHUP	The device has been disconnected. This event and POLLOUT are mutually-exclusive; a stream can never be writable if a hangup has occurred. However, this event and POLLIN, POLLRDNORM, POLLRDBAND, or POLLPRI are not mutually-exclusive. This flag is only valid in the *revents* bitmask; it shall be ignored in the *events* member.

POLLNVAL	The specified *fd* value is invalid. This flag is only valid in the *revents* member; it shall ignored in the *events* member.

The significance and semantics of normal, priority, and high-priority data are file and device-specific.

If the value of *fd* is less than 0, *events* shall be ignored, and *revents* shall be set to 0 in that entry on return from *poll*( ).

In each **pollfd** structure, *poll*( ) shall clear the *revents* member, except that where the application requested a report on a condition by setting one of the bits of *events* listed above, *poll*( ) shall set the corresponding bit in *revents* if the requested condition is true. In addition, *poll*( ) shall set the POLLHUP, POLLERR, and POLLNVAL flag in *revents* if the condition is true, even if the application did not set the corresponding bit in *events*. |

If none of the defined events have occurred on any selected file descriptor, *poll*( ) shall wait at least *timeout* milliseconds for an event to occur on any of the selected file descriptors. If the value of *timeout* is 0, *poll*( ) shall return immediately. If the value of *timeout* is −1, *poll*( ) shall block until a requested event occurs or until the call is interrupted.

Implementations may place limitations on the granularity of timeout intervals. If the requested timeout interval requires a finer granularity than the implementation supports, the actual timeout interval shall be rounded up to the next supported value.

The *poll*( ) function shall not be affected by the O_NONBLOCK flag.

XSR The *poll*( ) function shall support regular files, terminal and pseudo-terminal devices, STREAMS-based files, FIFOs, pipes, and sockets. The behavior of *poll*( ) on elements of *fds* that refer to other types of file is unspecified.

Regular files shall always poll TRUE for reading and writing.

A file descriptor for a socket that is listening for connections shall indicate that it is ready for reading, once connections are available. A file descriptor for a socket that is connecting asynchronously shall indicate that it is ready for writing, once a connection has been established.

RETURN VALUE

Upon successful completion, *poll*( ) shall return a non-negative value. A positive value indicates the total number of file descriptors that have been selected (that is, file descriptors for which the *revents* member is non-zero). A value of 0 indicates that the call timed out and no file descriptors have been selected. Upon failure, *poll*( ) shall return −1 and set *errno* to indicate the error.

ERRORS

The *poll*( ) function shall fail if:

[EAGAIN]	The allocation of internal data structures failed but a subsequent request may succeed.
[EINTR]	A signal was caught during *poll*( ).
XSR [EINVAL]	The *nfds* argument is greater than {OPEN_MAX}, or one of the *fd* members refers to a STREAM or multiplexer that is linked (directly or indirectly) downstream from a multiplexer.

EXAMPLES

Checking for Events on a Stream

The following example opens a pair of STREAMS devices and then waits for either one to become writable. This example proceeds as follows:

1. Sets the *timeout* parameter to 500 milliseconds.
2. Opens the STREAMS devices **/dev/dev0** and **/dev/dev1**, and then polls them, specifying POLLOUT and POLLWRBAND as the events of interest.

   The STREAMS device names **/dev/dev0** and **/dev/dev1** are only examples of how STREAMS devices can be named; STREAMS naming conventions may vary among systems conforming to the IEEE Std 1003.1-200x.
3. Uses the *ret* variable to determine whether an event has occurred on either of the two STREAMS. The *poll*( ) function is given 500 milliseconds to wait for an event to occur (if it has not occurred prior to the *poll*( ) call).
4. Checks the returned value of *ret*. If a positive value is returned, one of the following can be done:
   a. Priority data can be written to the open STREAM on priority bands greater than 0, because the POLLWRBAND event occurred on the open STREAM (*fds*[0] or *fds*[1]).
   b. Data can be written to the open STREAM on priority-band 0, because the POLLOUT event occurred on the open STREAM (*fds*[0] or *fds*[1]).
5. If the returned value is not a positive value, permission to write data to the open STREAM (on any priority band) is denied.
6. If the POLLHUP event occurs on the open STREAM (*fds*[0] or *fds*[1]), the device on the open STREAM has disconnected.

```
#include <stropts.h>
#include <poll.h>
...
struct pollfd fds[2];
int timeout_msecs = 500;
int ret;
    int i;

/* Open STREAMS device. */
fds[0].fd = open("/dev/dev0", ...);
fds[1].fd = open("/dev/dev1", ...);
    fds[0].events = POLLOUT | POLLWRBAND;
    fds[1].events = POLLOUT | POLLWRBAND;

ret = poll(fds, 2, timeout_msecs);

if (ret > 0) {
    /* An event on one of the fds has occurred. */
    for (i=0; i<2; i++) {
        if (fds[i].revents & POLLWRBAND) {
        /* Priority data may be written on device number i. */
...
        }
        if (fds[i].revents & POLLOUT) {
```

```
                /* Data may be written on device number i. */
        ...
                }
                if (fds[i].revents & POLLHUP) {
                /* A hangup has occurred on device number i. */
        ...
                }
            }
        }
```

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

The description of POLLWRBAND is updated.

Issue 6

Text referring to sockets is added to the DESCRIPTION.

Text relating to the XSI STREAMS Option Group is marked.

The Open Group Corrigendum Unnn/nn is applied, updating the DESCRIPTION of POLLWRBAND.

NAME

popen — initiate pipe streams to or from a process

SYNOPSIS

CX
```
#include <stdio.h>

FILE *popen(const char *command, const char *mode);
```

DESCRIPTION

The *popen*( ) function shall execute the command specified by the string *command*. It shall create a pipe between the calling program and the executed command, and shall return a pointer to a stream that can be used to either read from or write to the pipe.

The environment of the executed command shall be as if a child process were created within the *popen*( ) call using the *fork*( ) function, and the child invoked the *sh* utility using the call:

```
execl(shell path, "sh", "-c", command, (char *)0);
```

where *shell path* is an unspecified pathname for the *sh* utility.

The *popen*( ) function shall ensure that any streams from previous *popen*( ) calls that remain open in the parent process are closed in the new child process.

The *mode* argument to *popen*( ) is a string that specifies I/O mode:

1. If *mode* is *r*, when the child process is started, its file descriptor STDOUT_FILENO shall be the writable end of the pipe, and the file descriptor *fileno*(*stream*) in the calling process, where *stream* is the stream pointer returned by *popen*( ), shall be the readable end of the pipe.
2. If *mode* is *w*, when the child process is started its file descriptor STDIN_FILENO shall be the readable end of the pipe, and the file descriptor *fileno*(*stream*) in the calling process, where *stream* is the stream pointer returned by *popen*( ), shall be the writable end of the pipe.
3. If *mode* is any other value, the result is undefined.

After *popen*( ), both the parent and the child process shall be capable of executing independently before either terminates.

Pipe streams are byte-oriented.

RETURN VALUE

Upon successful completion, *popen*( ) shall return a pointer to an open stream that can be used to read or write to the pipe. Otherwise, it shall return a null pointer and may set *errno* to indicate the error.

ERRORS

The *popen*( ) function may fail if:

[EMFILE]	{FOPEN_MAX} or {STREAM_MAX} streams are currently open in the calling process.
[EINVAL]	The *mode* argument is invalid.

The *popen*( ) function may also set *errno* values as described by *fork*( ) or *pipe*( ).

EXAMPLES

None.

APPLICATION USAGE

Since open files are shared, a mode *r* command can be used as an input filter and a mode *w* command as an output filter.

Buffered reading before opening an input filter may leave the standard input of that filter mispositioned. Similar problems with an output filter may be prevented by careful buffer flushing; for example, with *fflush*( ).

A stream opened by *popen*( ) should be closed by *pclose*( ).

The behavior of *popen*( ) is specified for values of *mode* of *r* and *w*. Other modes such as *rb* and *wb* might be supported by specific implementations, but these would not be portable features. Note that historical implementations of *popen*( ) only check to see if the first character of *mode* is *r*. Thus, a *mode* of *robert the robot* would be treated as *mode r*, and a *mode* of *anything else* would be treated as *mode w*.

If the application calls *waitpid*( ) or *waitid*( ) with a *pid* argument greater than 0, and it still has a stream that was called with *popen*( ) open, it must ensure that *pid* does not refer to the process started by *popen*( ).

To determine whether or not the environment specified in the Shell and Utilities volume of IEEE Std 1003.1-200x is present, use the function call:

```
sysconf(_SC_2_VERSION)
```

(See *sysconf*( )).

RATIONALE

The *popen*( ) function should not be used by programs that have set user (or group) ID privileges. The *fork*( ) and *exec* family of functions (except *execlp*( ) and *execvp*( )), should be used instead. This prevents any unforeseen manipulation of the environment of the user that could cause execution of commands not anticipated by the calling program.

If the original and *popen*( )ed processes both intend to read or write or read and write a common file, and either will be using FILE-type C functions (*fread*( ), *fwrite*( ), and so on), the rules for sharing file handles must be observed (see Section 2.5.1 (on page 485)).

Since open files are shared, a mode *r* argument can be used as an input filter and a mode *w* argument as an output filter.

The behavior of *popen*( ) is specified for modes of *r* and *w*. Other modes such as *rb* and *wb* might be supported by specific implementations, but these would not be portable features. Note that historical implementations of *popen*( ) only check to see if the first character of mode is `'r'`. Thus, a mode of *robert the robot* would be treated as mode *r*, and a mode of *anything else* would be treated as mode *w*.

If the application calls *waitpid*( ) with a *pid* argument greater than zero, and it still has a *popen*( )ed stream open, it must ensure that *pid* does not refer to the process started by *popen*( ).

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

A statement is added to the DESCRIPTION indicating that pipe streams are byte-oriented.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The optional [EMFILE] error condition is added.

NAME

posix_fadvise — file advisory information (**ADVANCED REALTIME**)

SYNOPSIS

ADV

```
#include <fcntl.h>

int posix_fadvise(int fd, off_t offset, size_t len, int advice);
```

DESCRIPTION

The *posix_fadvise*( ) function shall advise the implementation on the expected behavior of the application with respect to the data in the file associated with the open file descriptor, *fd*, starting at *offset* and continuing for *len* bytes. The specified range need not currently exist in the file. If *len* is zero, all data following *offset* is specified. The implementation may use this information to optimize handling of the specified data. The *posix_fadvise*( ) function shall have no effect on the semantics of other operations on the specified data, although it may affect the performance of other operations.

The advice to be applied to the data is specified by the *advice* parameter and may be one of the following values:

POSIX_FADV_NORMAL
Specifies that the application has no advice to give on its behavior with respect to the specified data. It is the default characteristic if no advice is given for an open file.

POSIX_FADV_SEQUENTIAL
Specifies that the application expects to access the specified data sequentially from lower offsets to higher offsets.

POSIX_FADV_RANDOM
Specifies that the application expects to access the specified data in a random order.

POSIX_FADV_WILLNEED
Specifies that the application expects to access the specified data in the near future.

POSIX_FADV_DONTNEED
Specifies that the application expects that it will not access the specified data in the near future.

POSIX_FADV_NOREUSE
Specifies that the application expects to access the specified data once and then not reuse it thereafter.

These values are defined in **<fcntl.h>**.

RETURN VALUE

Upon successful completion, *posix_fadvise*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *posix_fadvise*( ) function shall fail if:

[EBADF]	The *fd* argument is not a valid file descriptor.
[EINVAL]	The value of *advice* is invalid.
[ESPIPE]	The *fd* argument is associated with a pipe or FIFO.

EXAMPLES

None.

APPLICATION USAGE

The *posix_fadvise*( ) function is part of the Advisory Information option and need not be provided on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1d-1999.

In the SYNOPSIS, the inclusion of **<sys/types.h>** is no longer required.

NAME

posix_fallocate — file space control (**ADVANCED REALTIME**)

SYNOPSIS

ADV
```
#include <fcntl.h>

int posix_fallocate(int fd, off_t offset, size_t len);
```

DESCRIPTION

The *posix_fallocate*( ) function shall ensure that any required storage for regular file data starting at *offset* and continuing for *len* bytes is allocated on the file system storage media. If *posix_fallocate*( ) returns successfully, subsequent writes to the specified file data shall not fail due to the lack of free space on the file system storage media.

If the *offset*+*len* is beyond the current file size, then *posix_fallocate*( ) shall adjust the file size to *offset*+*len*. Otherwise, the file size shall not be changed.

It is implementation-defined whether a previous *posix_fadvise*( ) call influences allocation strategy.

Space allocated via *posix_fallocate*( ) shall be freed by a successful call to *creat*( ) or *open*( ) that truncates the size of the file. Space allocated via *posix_fallocate*( ) may be freed by a successful call to *ftruncate*( ) that reduces the file size to a size smaller than *offset*+*len*.

RETURN VALUE

Upon successful completion, *posix_fallocate*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *posix_fallocate*( ) function shall fail if:

[EBADF]	The *fd* argument is not a valid file descriptor.
[EBADF]	The *fd* argument references a file that was opened without write permission.
[EFBIG]	The value of *offset*+*len* is greater than the maximum file size.
[EINTR]	A signal was caught during execution.
[EINVAL]	The *len* argument was zero or the *offset* argument was less than zero.
[EIO]	An I/O error occurred while reading from or writing to a file system.
[ENODEV]	The *fd* argument does not refer to a regular file.
[ENOSPC]	There is insufficient free space remaining on the file system storage media.
[ESPIPE]	The *fd* argument is associated with a pipe or FIFO.

EXAMPLES

None.

APPLICATION USAGE

The *posix_fallocate*( ) function is part of the Advisory Information option and need not be provided on all implementations.

In the SYNOPSIS, the inclusion of **<sys/types.h>** is no longer required.

NAME

posix_madvise — memory advisory information and alignment control (**ADVANCED REALTIME**)

SYNOPSIS

ADV

```
#include <sys/mman.h>

int posix_madvise(void *addr, size_t len, int advice);

```

DESCRIPTION

MF|SHM The *posix_madvise*( ) function need only be supported if either the Memory Mapped Files or the Shared Memory Objects options are supported.

The *posix_madvise*( ) function shall advise the implementation on the expected behavior of the application with respect to the data in the memory starting at address *addr*, and continuing for *len* bytes. The implementation may use this information to optimize handling of the specified data. The *posix_madvise*( ) function shall have no effect on the semantics of access to memory in the specified range, although it may affect the performance of access.

The implementation may require that *addr* be a multiple of the page size, which is the value returned by *sysconf*( ) when the name value _SC_PAGESIZE is used.

The advice to be applied to the memory range is specified by the *advice* parameter and may be one of the following values:

POSIX_MADV_NORMAL
Specifies that the application has no advice to give on its behavior with respect to the specified range. It is the default characteristic if no advice is given for a range of memory.

POSIX_MADV_SEQUENTIAL
Specifies that the application expects to access the specified range sequentially from lower addresses to higher addresses.

POSIX_MADV_RANDOM
Specifies that the application expects to access the specified range in a random order.

POSIX_MADV_WILLNEED
Specifies that the application expects to access the specified range in the near future.

POSIX_MADV_DONTNEED
Specifies that the application expects that it will not access the specified range in the near future.

These values are defined in the **<sys/mman.h>** header.

RETURN VALUE

Upon successful completion, *posix_madvise*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *posix_madvise*( ) function shall fail if:

[EINVAL]	The value of *advice* is invalid.
[ENOMEM]	Addresses in the range starting at *addr* and continuing for *len* bytes are partly or completely outside the range allowed for the address space of the calling process.

The *posix_madvise*( ) function may fail if:

[EINVAL] The value of *addr* is not a multiple of the value returned by *sysconf*( ) when the name value _SC_PAGESIZE is used.

[EINVAL] The value of *len* is zero.

EXAMPLES

None.

APPLICATION USAGE

The *posix_madvise*( ) function is part of the Advisory Information option and need not be provided on all implementations.

RATIONALE

NAME

posix_mem_offset — find offset and length of a mapped typed memory block (**ADVANCED REALTIME**)

SYNOPSIS

TYM
```
#include <sys/mman.h>

int posix_mem_offset(const void *restrict addr, size_t len,
    off_t *restrict off, size_t *restrict contig_len,
    int *restrict fildes);
```

DESCRIPTION

The *posix_mem_offset*( ) function shall return in the variable pointed to by *off* a value that identifies the offset (or location), within a memory object, of the memory block currently mapped at *addr*. The function shall return in the variable pointed to by *fildes*, the descriptor used (via *mmap*( )) to establish the mapping which contains *addr*. If that descriptor was closed since the mapping was established, the returned value of *fildes* shall be –1. The *len* argument specifies the length of the block of the memory object the user wishes the offset for; upon return, the value pointed to by *contig_len* shall equal either *len*, or the length of the largest contiguous block of the memory object that is currently mapped to the calling process starting at *addr*, whichever is smaller.

If the memory object mapped at *addr* is a typed memory object, then if the *off* and *contig_len* values obtained by calling *posix_mem_offset*( ) are used in a call to *mmap*( ) with a file descriptor that refers to the same memory pool as *fildes* (either through the same port or through a different port), and that was opened with neither the POSIX_TYPED_MEM_ALLOCATE nor the POSIX_TYPED_MEM_ALLOCATE_CONTIG flag, the typed memory area that is mapped shall be exactly the same area that was mapped at *addr* in the address space of the process that called *posix_mem_offset*( ).

If the memory object specified by *fildes* is not a typed memory object, then the behavior of this function is implementation-defined.

RETURN VALUE

Upon successful completion, the *posix_mem_offset*( ) function shall return zero; otherwise, the corresponding error status value shall be returned.

ERRORS

The *posix_mem_offset*( ) function shall fail if:

[EACCES] The process has not mapped a memory object supported by this function at the given address *addr*.

This function shall not return an error code of [EINTR].

EXAMPLES

NAME

posix_memalign — aligned memory allocation (**ADVANCED REALTIME**)

SYNOPSIS

ADV

```
#include <stdlib.h>

int posix_memalign(void **memptr, size_t alignment, size_t size);

```

DESCRIPTION

The *posix_memalign*( ) function shall allocate *size* bytes aligned on a boundary specified by *alignment*, and shall return a pointer to the allocated memory in *memptr*. The value of *alignment* shall be a multiple of *sizeof*(**void ***), that is also a power of two. Upon successful completion, the value pointed to by *memptr* shall be a multiple of *alignment*.

CX The *free*( ) function shall deallocate memory that has previously been allocated by *posix_memalign*( ).

RETURN VALUE

Upon successful completion, *posix_memalign*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *posix_memalign*( ) function shall fail if:

[EINVAL]	The value of the alignment parameter is not a power of two multiple of *sizeof*(**void ***).
[ENOMEM]	There is insufficient memory available with the requested alignment.

EXAMPLES

None.

APPLICATION USAGE

The *posix_memalign*( ) function is part of the Advisory Information option and need not be provided on all implementations.

NAME

posix_openpt — open a pseudo terminal device

SYNOPSIS

XSI

```
#include <stdlib.h>
#include <fcntl.h>

int posix_openpt(int oflag);
```

DESCRIPTION

The *posix_openpt*( ) function shall establish a connection between a master device for a pseudo-terminal and a file descriptor. The file descriptor is used by other I/O functions that refer to that pseudo-terminal.

The file status flags and file access modes of the open file description shall be set according to the value of *oflag*.

Values for *oflag* are constructed by a bitwise-inclusive OR of flags from the following list, defined in **<fcntl.h>**:

O_RDWR	Open for reading and writing.
O_NOCTTY	If set *posix_openpt*( ) shall not cause the terminal device to become the controlling terminal for the process.

The behavior of other values for the *oflag* argument is unspecified.

RETURN VALUE

Upon successful completion, the *posix_openpt*( ) function shall open a master pseudo-terminal device and return a non-negative integer representing the lowest numbered unused file descriptor. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *posix_openpt*( ) function shall fail if:

[EMFILE]	{OPEN_MAX} file descriptors are currently open in the calling process.
[ENFILE]	The maximum allowable number of files is currently open in the system.

The *posix_openpt*( ) function may fail if:

	[EINVAL]	The value of *oflag* is not valid.
	[EAGAIN]	Out of pseudo-terminal resources.
XSR	[ENOSR]	Out of STREAMS resources.

EXAMPLES

Opening a Pseudo-Terminal and Returning the Name of the Slave Device and a File Descriptor

```
#include <fcntl.h>
#include <stdio.h>

int masterfd, slavefd;
char *slavedevice;

masterfd = posix_openpt(O_RDWR|O_NOCTTY);

if (masterfd == -1
    || grantpt (masterfd) == -1
```

```
            || unlockpt (masterfd) == -1
            || (slavedevice = ptsname (masterfd)) == NULL)
            return -1;

        printf("slave device is: %s\n", slavedevice);

        slavefd = open(slave, O_RDWR|O_NOCTTY);
        if (slavefd < 0)
            return -1;
```

APPLICATION USAGE

This function is a method for portably obtaining a file descriptor of a master terminal device for a pseudo-terminal. The *grantpt*( ) and *ptsname*( ) functions can be used to manipulate mode and ownership permissions, and to obtain the name of the slave device, respectively.

RATIONALE

The standard developers considered the matter of adding a special device for cloning master pseudo-terminals: the **/dev/ptmx** device. However, consensus could not be reached, and it was felt that adding a new function would permit other implementations. The *posix_openpt*( ) function is designed to complement the *grantpt*( ), *ptsname*( ), and *unlockpt*( ) functions.

On implementations supporting the **/dev/ptmx** clone device, opening the master device of a pseudo-terminal is simply:

```
        mfdp = open("/dev/ptmx", oflag );
        if (mfdp < 0)
            return -1;
```

FUTURE DIRECTIONS

None.

SEE ALSO

grantpt( ), *open*( ), *ptsname*( ), *unlockpt*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<fcntl.h>**

CHANGE HISTORY

First released in Issue 6.

NAME

posix_spawn, posix_spawnp — spawn a process (**ADVANCED REALTIME**)

SYNOPSIS

SPN

```
#include <spawn.h>

int posix_spawn(pid_t *restrict pid, const char *restrict path,
    const posix_spawn_file_actions_t *file_actions,
    const posix_spawnattr_t *restrict attrp,
    char *const argv[restrict], char *const envp[restrict]);
int posix_spawnp(pid_t *restrict pid, const char *restrict file,
    const posix_spawn_file_actions_t *file_actions,
    const posix_spawnattr_t *restrict attrp,
    char *const argv[restrict], char * const envp[restrict]);
```

DESCRIPTION

The *posix_spawn*( ) and *posix_spawnp*( ) functions shall create a new process (child process) from the specified process image. The new process image shall be constructed from a regular executable file called the new process image file.

When a C program is executed as the result of this call, it shall be entered as a C language function call as follows:

```
int main(int argc, char *argv[]);
```

where *argc* is the argument count and *argv* is an array of character pointers to the arguments themselves. In addition, the following variable:

```
extern char **environ;
```

shall be initialized as a pointer to an array of character pointers to the environment strings.

The argument *argv* is an array of character pointers to null-terminated strings. The last member of this array shall be a null pointer and is not counted in *argc*. These strings constitute the argument list available to the new process image. The value in *argv*[0] should point to a filename that is associated with the process image being started by the *posix_spawn*( ) or *posix_spawnp*( ) function.

The argument *envp* is an array of character pointers to null-terminated strings. These strings constitute the environment for the new process image. The environment array is terminated by a null pointer.

The number of bytes available for the child process' combined argument and environment lists is {ARG_MAX}. The implementation shall specify in the system documentation (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 2, Conformance) whether any list overhead, such as length words, null terminators, pointers, or alignment bytes, is included in this total.

The *path* argument to *posix_spawn*( ) is a pathname that identifies the new process image file to execute.

The *file* parameter to *posix_spawnp*( ) shall be used to construct a pathname that identifies the new process image file. If the *file* parameter contains a slash character, the *file* parameter shall be used as the pathname for the new process image file. Otherwise, the path prefix for this file shall be obtained by a search of the directories passed as the environment variable *PATH* (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables). If this environment variable is not defined, the results of the search are implementation-defined.

If *file_actions* is a null pointer, then file descriptors open in the calling process shall remain open in the child process, except for those whose close-on-*exec* flag FD_CLOEXEC is set (see *fcntl*( )). For those file descriptors that remain open, all attributes of the corresponding open file descriptions, including file locks (see *fcntl*( )), shall remain unchanged.

If *file_actions* is not NULL, then the file descriptors open in the child process shall be those open in the calling process as modified by the spawn file actions object pointed to by *file_actions* and the FD_CLOEXEC flag of each remaining open file descriptor after the spawn file actions have been processed. The effective order of processing the spawn file actions shall be:

1. The set of open file descriptors for the child process shall initially be the same set as is open for the calling process. All attributes of the corresponding open file descriptions, including file locks (see *fcntl*( )), shall remain unchanged.
2. The signal mask, signal default actions, and the effective user and group IDs for the child process shall be changed as specified in the attributes object referenced by *attrp*.
3. The file actions specified by the spawn file actions object shall be performed in the order in which they were added to the spawn file actions object.
4. Any file descriptor that has its FD_CLOEXEC flag set (see *fcntl*( )) shall be closed.

The **posix_spawnattr_t** spawn attributes object type is defined in **<spawn.h>**. It shall contain at least the attributes defined below. |

If the POSIX_SPAWN_SETPGROUP flag is set in the *spawn-flags* attribute of the object referenced by *attrp*, and the *spawn-pgroup* attribute of the same object is non-zero, then the child's process group shall be as specified in the *spawn-pgroup* attribute of the object referenced by *attrp*.

As a special case, if the POSIX_SPAWN_SETPGROUP flag is set in the *spawn-flags* attribute of the object referenced by *attrp*, and the *spawn-pgroup* attribute of the same object is set to zero, then the child shall be in a new process group with a process group ID equal to its process ID.

If the POSIX_SPAWN_SETPGROUP flag is not set in the *spawn-flags* attribute of the object referenced by *attrp*, the new child process shall inherit the parent's process group.

PS If the POSIX_SPAWN_SETSCHEDPARAM flag is set in the *spawn-flags* attribute of the object referenced by *attrp*, but POSIX_SPAWN_SETSCHEDULER is not set, the new process image shall initially have the scheduling policy of the calling process with the scheduling parameters specified in the *spawn-schedparam* attribute of the object referenced by *attrp*.

If the POSIX_SPAWN_SETSCHEDULER flag is set in *spawn-flags* attribute of the object referenced by *attrp* (regardless of the setting of the POSIX_SPAWN_SETSCHEDPARAM flag), the new process image shall initially have the scheduling policy specified in the *spawn-schedpolicy* attribute of the object referenced by *attrp* and the scheduling parameters specified in the *spawn-schedparam* attribute of the same object.

The POSIX_SPAWN_RESETIDS flag in the *spawn-flags* attribute of the object referenced by *attrp* governs the effective user ID of the child process. If this flag is not set, the child process shall inherit the parent process' effective user ID. If this flag is set, the child process' effective user ID shall be reset to the parent's real user ID. In either case, if the set-user-ID mode bit of the new process image file is set, the effective user ID of the child process shall become that file's owner ID before the new process image begins execution. |

The POSIX_SPAWN_RESETIDS flag in the *spawn-flags* attribute of the object referenced by *attrp* also governs the effective group ID of the child process. If this flag is not set, the child process shall inherit the parent process' effective group ID. If this flag is set, the child process' effective group ID shall be reset to the parent's real group ID. In either case, if the set-group-ID mode bit |

of the new process image file is set, the effective group ID of the child process shall become that file's group ID before the new process image begins execution.

If the POSIX_SPAWN_SETSIGMASK flag is set in the *spawn-flags* attribute of the object referenced by *attrp*, the child process shall initially have the signal mask specified in the *spawn-sigmask* attribute of the object referenced by *attrp*.

If the POSIX_SPAWN_SETSIGDEF flag is set in the *spawn-flags* attribute of the object referenced by *attrp*, the signals specified in the *spawn-sigdefault* attribute of the same object shall be set to their default actions in the child process. Signals set to the default action in the parent process shall be set to the default action in the child process.

Signals set to be caught by the calling process shall be set to the default action in the child process.

Except for SIGCHLD, signals set to be ignored by the calling process image shall be set to be ignored by the child process, unless otherwise specified by the POSIX_SPAWN_SETSIGDEF flag being set in the *spawn-flags* attribute of the object referenced by *attrp* and the signals being indicated in the *spawn-sigdefault* attribute of the object referenced by *attrp*.

If the SIGCHLD signal is set to be ignored by the calling process, it is unspecified whether the SIGCHLD signal is set to be ignored or to the default action in the child process, unless otherwise specified by the POSIX_SPAWN_SETSIGDEF flag being set in the *spawn_flags* attribute of the object referenced by *attrp* and the SIGCHLD signal being indicated in the *spawn_sigdefault* attribute of the object referenced by *attrp*.

If the value of the *attrp* pointer is NULL, then the default values are used.

All process attributes, other than those influenced by the attributes set in the object referenced by *attrp* as specified above or by the file descriptor manipulations specified in *file_actions*, shall appear in the new process image as though *fork*( ) had been called to create a child process and then a member of the *exec* family of functions had been called by the child process to execute the new process image.

THR It is implementation-defined whether the fork handlers are run when *posix_spawn*( ) or *posix_spawnp*( ) is called.

RETURN VALUE

Upon successful completion, *posix_spawn*( ) and *posix_spawnp*( ) shall return the process ID of the child process to the parent process, in the variable pointed to by a non-NULL *pid* argument, and shall return zero as the function return value. Otherwise, no child process shall be created, the value stored into the variable pointed to by a non-NULL *pid* is unspecified, and an error number shall be returned as the function return value to indicate the error. If the *pid* argument is a null pointer, the process ID of the child is not returned to the caller.

ERRORS

The *posix_spawn*( ) and *posix_spawnp*( ) functions may fail if:

[EINVAL]	The value specified by *file_actions* or *attrp* is invalid.

If this error occurs after the calling process successfully returns from the *posix_spawn*( ) or *posix_spawnp*( ) function, the child process may exit with exit status 127.

If *posix_spawn*( ) or *posix_spawnp*( ) fail for any of the reasons that would cause *fork*( ) or one of the *exec* family of functions to fail, an error value shall be returned as described by *fork*( ) and *exec*, respectively (or, if the error occurs after the calling process successfully returns, the child process shall exit with exit status 127).

If POSIX_SPAWN_SETPGROUP is set in the *spawn-flags* attribute of the object referenced by *attrp*, and *posix_spawn*( ) or *posix_spawnp*( ) fails while changing the child's process group, an error value shall be returned as described by *setpgid*( ) (or, if the error occurs after the calling process successfully returns, the child process shall exit with exit status 127).

PS If POSIX_SPAWN_SETSCHEDPARAM is set and POSIX_SPAWN_SETSCHEDULER is not set in the *spawn-flags* attribute of the object referenced by *attrp*, then if *posix_spawn*( ) or *posix_spawnp*( ) fails for any of the reasons that would cause *sched_setparam*( ) to fail, an error value shall be returned as described by *sched_setparam*( ) (or, if the error occurs after the calling process successfully returns, the child process shall exit with exit status 127).

If POSIX_SPAWN_SETSCHEDULER is set in the *spawn-flags* attribute of the object referenced by *attrp*, and if *posix_spawn*( ) or *posix_spawnp*( ) fails for any of the reasons that would cause *sched_setscheduler*( ) to fail, an error value shall be returned as described by *sched_setscheduler*( ) (or, if the error occurs after the calling process successfully returns, the child process shall exit with exit status 127).

If the *file_actions* argument is not NULL, and specifies any *close*, *dup2*, or *open* actions to be performed, and if *posix_spawn*( ) or *posix_spawnp*( ) fails for any of the reasons that would cause *close*( ), *dup2*( ), or *open*( ) to fail, an error value shall be returned as described by *close*( ), *dup2*( ), and *open*( ), respectively (or, if the error occurs after the calling process successfully returns, the child process shall exit with exit status 127). An open file action may, by itself, result in any of the errors described by *close*( ) or *dup2*( ), in addition to those described by *open*( ).

EXAMPLES

None.

APPLICATION USAGE

These functions are part of the Spawn option and need not be provided on all implementations.

RATIONALE

The *posix_spawn*( ) function and its close relation *posix_spawnp*( ) have been introduced to overcome the following perceived difficulties with *fork*( ): the *fork*( ) function is difficult or impossible to implement without swapping or dynamic address translation. |

- Swapping is generally too slow for a realtime environment.
- Dynamic address translation is not available everywhere that POSIX might be useful. |
- Processes are too useful to simply option out of POSIX whenever it must run without address translation or other MMU services,

Thus, POSIX needs process creation and file execution primitives that can be efficiently implemented without address translation or other MMU services. |

The *posix_spawn*( ) function is implementable as a library routine, but both *posix_spawn*( ) and *posix_spawnp*( ) are designed as kernel operations. Also, although they may be an efficient replacement for many *fork*( )/*exec* pairs, their goal is to provide useful process creation primitives for systems that have difficulty with *fork*( ), not to provide drop-in replacements for *fork*( )/*exec*. |

This view of the role of *posix_spawn*( ) and *posix_spawnp*( ) influenced the design of their API. It does not attempt to provide the full functionality of *fork*( )/*exec* in which arbitrary user-specified operations of any sort are permitted between the creation of the child process and the execution of the new process image; any attempt to reach that level would need to provide a programming language as parameters. Instead, *posix_spawn*( ) and *posix_spawnp*( ) are process creation primitives like the *Start_Process* and *Start_Process_Search* Ada language bindings package *POSIX_Process_Primitives* and also like those in many operating systems that are not UNIX systems, but with some POSIX-specific additions.

To achieve its coverage goals, *posix_spawn*( ) and *posix_spawnp*( ) have control of six types of inheritance: file descriptors, process group ID, user and group ID, signal mask, scheduling, and whether each signal ignored in the parent will remain ignored in the child, or be reset to its default action in the child.

Control of file descriptors is required to allow an independently written child process image to access data streams opened by and even generated or read by the parent process without being specifically coded to know which parent files and file descriptors are to be used. Control of the process group ID is required to control how the child process' job control relates to that of the parent.

Control of the signal mask and signal defaulting is sufficient to support the implementation of *system*( ). Although support for *system*( ) is not explicitly one of the goals for *posix_spawn*( ) and *posix_spawnp*( ), it is covered under the ''at least 50%'' coverage goal.

The intention is that the normal file descriptor inheritance across *fork*( ), the subsequent effect of the specified spawn file actions, and the normal file descriptor inheritance across one of the *exec* family of functions should fully specify open file inheritance. The implementation need make no decisions regarding the set of open file descriptors when the child process image begins execution, those decisions having already been made by the caller and expressed as the set of open file descriptors and their FD_CLOEXEC flags at the time of the call and the spawn file actions object specified in the call. We have been assured that in cases where the POSIX *Start_Process* Ada primitives have been implemented in a library, this method of controlling file descriptor inheritance may be implemented very easily.

We can identify several problems with *posix_spawn*( ) and *posix_spawnp*( ), but there does not appear to be a solution that introduces fewer problems. Environment modification for child process attributes not specifiable via the *attrp* or *file_actions* arguments must be done in the parent process, and since the parent generally wants to save its context, it is more costly than similar functionality with *fork*( )/*exec*. It is also complicated to modify the environment of a multi-threaded process temporarily, since all threads must agree when it is safe for the environment to be changed. However, this cost is only borne by those invocations of *posix_spawn*( ) and *posix_spawnp*( ) that use the additional functionality. Since extensive modifications are not the usual case, and are particularly unlikely in time-critical code, keeping much of the environment control out of *posix_spawn*( ) and *posix_spawnp*( ) is appropriate design.

The *posix_spawn*( ) and *posix_spawnp*( ) functions do not have all the power of *fork*( )/*exec*. This is to be expected. The *fork*( ) function is a wonderfully powerful operation. We do not expect to duplicate its functionality in a simple, fast function with no special hardware requirements. It is worth noting that *posix_spawn*( ) and *posix_spawnp*( ) are very similar to the process creation operations on many operating systems that are not UNIX systems.

Requirements

The requirements for *posix_spawn*( ) and *posix_spawnp*( ) are:

- They must be implementable without an MMU or unusual hardware.
- They must be compatible with existing POSIX standards.

Additional goals are:

- They should be efficiently implementable.
- They should be able to replace at least 50% of typical executions of *fork*( ).

- A system with *posix_spawn*( ) and *posix_spawnp*( ) and without *fork*( ) should be useful, at least for realtime applications.
- A system with *fork*( ) and the *exec* family should be able to implement *posix_spawn*( ) and *posix_spawnp*( ) as library routines.

Two-Syntax

POSIX *exec* has several calling sequences with approximately the same functionality. These appear to be required for compatibility with existing practice. Since the existing practice for the *posix_spawn**( ) functions is otherwise substantially unlike POSIX, we feel that simplicity outweighs compatibility. There are, therefore, only two names for the *posix_spawn**( ) functions.

The parameter list does not differ between *posix_spawn*( ) and *posix_spawnp*( ); *posix_spawnp*( ) interprets the second parameter more elaborately than *posix_spawn*( ).

Compatibility with POSIX.5 (Ada)

The *Start_Process* and *Start_Process_Search* procedures from the POSIX_Process_Primitives package from the Ada language binding to POSIX.1 encapsulate *fork*( ) and *exec* functionality in a manner similar to that of *posix_spawn*( ) and *posix_spawnp*( ). Originally, in keeping with our simplicity goal, the standard developers had limited the capabilities of *posix_spawn*( ) and *posix_spawnp*( ) to a subset of the capabilities of *Start_Process* and *Start_Process_Search*; certain non-default capabilities were not supported. However, based on suggestions by the ballot group to improve file descriptor mapping or drop it, and on the advice of an Ada Language Bindings working group member, the standard developers decided that *posix_spawn*( ) and *posix_spawnp*( ) should be sufficiently powerful to implement *Start_Process* and *Start_Process_Search*. The rationale is that if the Ada language binding to such a primitive had already been approved as an IEEE standard, there can be little justification for not approving the functionally-equivalent parts of a C binding. The only three capabilities provided by *posix_spawn*( ) and *posix_spawnp*( ) that are not provided by *Start_Process* and *Start_Process_Search* are optionally specifying the child's process group ID, the set of signals to be reset to default signal handling in the child process, and the child's scheduling policy and parameters.

For the Ada language binding for *Start_Process* to be implemented with *posix_spawn*( ), that binding would need to explicitly pass an empty signal mask and the parent's environment to *posix_spawn*( ) whenever the caller of *Start_Process* allowed these arguments to default, since *posix_spawn*( ) does not provide such defaults. The ability of *Start_Process* to mask user-specified signals during its execution is functionally unique to the Ada language binding and must be dealt with in the binding separately from the call to *posix_spawn*( ).

Process Group

The process group inheritance field can be used to join the child process with an existing process group. By assigning a value of zero to the *spawn-pgroup* attribute of the object referenced by *attrp*, the *setpgid*( ) mechanism will place the child process in a new process group.

Threads

Without the *posix_spawn*( ) and *posix_spawnp*( ) functions, systems without address translation can still use threads to give an abstraction of concurrency. In many cases, thread creation suffices, but it is not always a good substitute. The *posix_spawn*( ) and *posix_spawnp*( ) functions are considerably ‘‘heavier’’ than thread creation. Processes have several important attributes that threads do not. Even without address translation, a process may have base-and-bound memory protection. Each process has a process environment including security attributes and file capabilities, and powerful scheduling attributes. Processes abstract the behavior of non-uniform-memory-architecture multi-processors better than threads, and they are more convenient to use for activities that are not closely linked.

The *posix_spawn*( ) and *posix_spawnp*( ) functions may not bring support for multiple processes to every configuration. Process creation is not the only piece of operating system support required to support multiple processes. The total cost of support for multiple processes may be quite high in some circumstances. Existing practice shows that support for multiple processes is uncommon and threads are common among ‘‘tiny kernels’’. There should, therefore, probably continue to be AEPs for operating systems with only one process.

Asynchronous Error Notification

A library implementation of *posix_spawn*( ) or *posix_spawnp*( ) may not be able to detect all possible errors before it forks the child process. IEEE Std 1003.1-200x provides for an error indication returned from a child process which could not successfully complete the spawn operation via a special exit status which may be detected using the status value returned by *wait*( ) and *waitpid*( ).

The *stat_val* interface and the macros used to interpret it are not well suited to the purpose of returning API errors, but they are the only path available to a library implementation. Thus, an implementation may cause the child process to exit with exit status 127 for any error detected during the spawn process after the *posix_spawn*( ) or *posix_spawnp*( ) function has successfully returned.

The standard developers had proposed using two additional macros to interpret *stat_val*. The first, WIFSPAWNFAIL, would have detected a status that indicated that the child exited because of an error detected during the *posix_spawn*( ) or *posix_spawnp*( ) operations rather than during actual execution of the child process image; the second, WSPAWNERRNO, would have extracted the error value if WIFSPAWNFAIL indicated a failure. Unfortunately, the ballot group strongly opposed this because it would make a library implementation of *posix_spawn*( ) or *posix_spawnp*( ) dependent on kernel modifications to *waitpid*( ) to be able to embed special information in *stat_val* to indicate a spawn failure.

The 8 bits of child process exit status that are guaranteed by IEEE Std 1003.1-200x to be accessible to the waiting parent process are insufficient to disambiguate a spawn error from any other kind of error that may be returned by an arbitrary process image. No other bits of the exit status are required to be visible in *stat_val*, so these macros could not be strictly implemented at the library level. Reserving an exit status of 127 for such spawn errors is consistent with the use of this value by *system*( ) and *popen*( ) to signal failures in these operations that occur after the function has returned but before a shell is able to execute. The exit status of 127 does not uniquely identify this class of error, nor does it provide any detailed information on the nature of the failure. Note that a kernel implementation of *posix_spawn*( ) or *posix_spawnp*( ) is permitted (and encouraged) to return any possible error as the function value, thus providing more detailed failure information to the parent process.

Thus, no special macros are available to isolate asynchronous *posix_spawn*( ) or *posix_spawnp*( ) errors. Instead, errors detected by the *posix_spawn*( ) or *posix_spawnp*( ) operations in the context of the child process before the new process image executes are reported by setting the child's exit status to 127. The calling process may use the WIFEXITED and WEXITSTATUS macros on the *stat_val* stored by the *wait*( ) or *waitpid*( ) functions to detect spawn failures to the extent that other status values with which the child process image may exit (before the parent can conclusively determine that the child process image has begun execution) are distinct from exit status 127.

FUTURE DIRECTIONS

None.

NAME

posix_spawn_file_actions_addclose, posix_spawn_file_actions_addopen — add close or open action to spawn file actions object (**ADVANCED REALTIME**)

SYNOPSIS

SPN

```
#include <spawn.h>

int posix_spawn_file_actions_addclose(posix_spawn_file_actions_t *
    file_actions, int fildes);
int posix_spawn_file_actions_addopen(posix_spawn_file_actions_t *restrict
    file_actions, int fildes, const char *restrict path,
    int oflag, mode_t mode);
```

DESCRIPTION

These functions shall add or delete a close or open action to a spawn file actions object.

A spawn file actions object is of type **posix_spawn_file_actions_t** (defined in **<spawn.h>**) and is used to specify a series of actions to be performed by a *posix_spawn*( ) or *posix_spawnp*( ) operation in order to arrive at the set of open file descriptors for the child process given the set of open file descriptors of the parent. IEEE Std 1003.1-200x does not define comparison or assignment operators for the type **posix_spawn_file_actions_t**.

A spawn file actions object, when passed to *posix_spawn*( ) or *posix_spawnp*( ), shall specify how the set of open file descriptors in the calling process is transformed into a set of potentially open file descriptors for the spawned process. This transformation shall be as if the specified sequence of actions was performed exactly once, in the context of the spawned process (prior to execution of the new process image), in the order in which the actions were added to the object; additionally, when the new process image is executed, any file descriptor (from this new set) which has its FD_CLOEXEC flag set shall be closed (see *posix_spawn*( )).

The *posix_spawn_file_actions_addclose*( ) function shall add a *close* action to the object referenced by *file_actions* that shall cause the file descriptor *fildes* to be closed (as if *close*(*fildes*) had been called) when a new process is spawned using this file actions object.

The *posix_spawn_file_actions_addopen*( ) function shall add an *open* action to the object referenced by *file_actions* that shall cause the file named by *path* to be opened (as if *open*(*path*, *oflag*, *mode*) had been called, and the returned file descriptor, if not *fildes*, had been changed to *fildes*) when a new process is spawned using this file actions object. If *fildes* was already an open file descriptor, it shall be closed before the new file is opened.

The string described by *path* shall be copied by the *posix_spawn_file_actions_addopen*( ) function.

RETURN VALUE

Upon successful completion, these functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

These functions shall fail if:

[EBADF]	The value specified by *fildes* is negative or greater than or equal to {OPEN_MAX}.

These functions may fail if:

[EINVAL]	The value specified by *file_actions* is invalid.
[ENOMEM]	Insufficient memory exists to add to the spawn file actions object.

It shall not be considered an error for the *fildes* argument passed to these functions to specify a file descriptor for which the specified operation could not be performed at the time of the call. Any such error will be detected when the associated file actions object is later used during a *posix_spawn*( ) or *posix_spawnp*( ) operation.

EXAMPLES

None.

APPLICATION USAGE

These functions are part of the Spawn option and need not be provided on all implementations.

RATIONALE

A spawn file actions object may be initialized to contain an ordered sequence of *close*( ), *dup2*( ), and *open*( ) operations to be used by *posix_spawn*( ) or *posix_spawnp*( ) to arrive at the set of open file descriptors inherited by the spawned process from the set of open file descriptors in the parent at the time of the *posix_spawn*( ) or *posix_spawnp*( ) call. It had been suggested that the *close*( ) and *dup2*( ) operations alone are sufficient to rearrange file descriptors, and that files which need to be opened for use by the spawned process can be handled either by having the calling process open them before the *posix_spawn*( ) or *posix_spawnp*( ) call (and close them after), or by passing filenames to the spawned process (in *argv*) so that it may open them itself. The standard developers recommend that applications use one of these two methods when practical, since detailed error status on a failed open operation is always available to the application this way. However, the standard developers feel that allowing a spawn file actions object to specify open operations is still appropriate because:

1. It is consistent with equivalent POSIX.5 (Ada) functionality.
2. It supports the I/O redirection paradigm commonly employed by POSIX programs designed to be invoked from a shell. When such a program is the child process, it may not be designed to open files on its own.
3. It allows file opens that might otherwise fail or violate file ownership/access rights if executed by the parent process.

Regarding 2. above, note that the spawn open file action provides to *posix_spawn*( ) and *posix_spawnp*( ) the same capability that the shell redirection operators provide to *system*( ), only without the intervening execution of a shell; for example:

```
system ("myprog <file1 3<file2");
```

Regarding 3. above, note that if the calling process needs to open one or more files for access by the spawned process, but has insufficient spare file descriptors, then the open action is necessary to allow the *open*( ) to occur in the context of the child process after other file descriptors have been closed (that must remain open in the parent).

Additionally, if a parent is executed from a file having a ''set-user-id'' mode bit set and the POSIX_SPAWN_RESETIDS flag is set in the spawn attributes, a file created within the parent process will (possibly incorrectly) have the parent's effective user ID as its owner, whereas a file created via an *open*( ) action during *posix_spawn*( ) or *posix_spawnp*( ) will have the parent's real ID as its owner; and an open by the parent process may successfully open a file to which the real user should not have access or fail to open a file to which the real user should have access.

File Descriptor Mapping

The standard developers had originally proposed using an array which specified the mapping of child file descriptors back to those of the parent. It was pointed out by the ballot group that it is not possible to reshuffle file descriptors arbitrarily in a library implementation of *posix_spawn*( ) or *posix_spawnp*( ) without provision for one or more spare file descriptor entries (which simply may not be available). Such an array requires that an implementation develop a complex strategy to achieve the desired mapping without inadvertently closing the wrong file descriptor at the wrong time.

It was noted by a member of the Ada Language Bindings working group that the approved Ada Language *Start_Process* family of POSIX process primitives use a caller-specified set of file actions to alter the normal *fork*( )/*exec* semantics for inheritance of file descriptors in a very flexible way, yet no such problems exist because the burden of determining how to achieve the final file descriptor mapping is completely on the application. Furthermore, although the file actions interface appears frightening at first glance, it is actually quite simple to implement in either a library or the kernel.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1d-1999.

IEEE PASC Interpretation 1003.1 #105 is applied, adding a note to the DESCRIPTION that the string pointed to by *path* is copied by the *posix_spawn_file_actions_addopen*( ) function.

NAME

posix_spawn_file_actions_adddup2 — add dup2 action to spawn file actions object (**ADVANCED REALTIME**)

SYNOPSIS

SPN

```
#include <spawn.h>

int posix_spawn_file_actions_adddup2(posix_spawn_file_actions_t *
    file_actions, int fildes, int newfildes);
```

DESCRIPTION

The *posix_spawn_file_actions_adddup2*( ) function shall add a *dup2*( ) action to the object referenced by *file_actions* that shall cause the file descriptor *fildes* to be duplicated as *newfildes* (as if *dup2*(*fildes*, *newfildes*) had been called) when a new process is spawned using this file actions object.

A spawn file actions object is as defined in *posix_spawn_file_actions_addclose*( ).

RETURN VALUE

Upon successful completion, the *posix_spawn_file_actions_adddup2*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *posix_spawn_file_actions_adddup2*( ) function shall fail if:

[EBADF]	The value specified by *fildes* or *newfildes* is negative or greater than or equal to {OPEN_MAX}.
[ENOMEM]	Insufficient memory exists to add to the spawn file actions object.

The *posix_spawn_file_actions_adddup2*( ) function may fail if:

[EINVAL]	The value specified by *file_actions* is invalid.

It shall not be considered an error for the *fildes* argument passed to the *posix_spawn_file_actions_adddup2*( ) function to specify a file descriptor for which the specified operation could not be performed at the time of the call. Any such error will be detected when the associated file actions object is later used during a *posix_spawn*( ) or *posix_spawnp*( ) operation.

EXAMPLES

None.

APPLICATION USAGE

The *posix_spawn_file_actions_adddup2*( ) function is part of the Spawn option and need not be provided on all implementations.

RATIONALE

Refer to the RATIONALE in *posix_spawn_file_actions_addclose*( ).

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1d-1999.

IEEE PASC Interpretation 1003.1 #104 is applied, noting that the [EBADF] error can apply to the *newfildes* argument in addition to *fildes*.

NAME

posix_spawn_file_actions_addopen — add open action to spawn file actions object (**ADVANCED REALTIME**)

SYNOPSIS

SPN

```
#include <spawn.h>

int posix_spawn_file_actions_addopen(posix_spawn_file_actions_t *restrict
    file_actions, int fildes, const char *restrict path,
    int oflag, mode_t mode);

```

DESCRIPTION

Refer to *posix_spawn_file_actions_addclose*( ).

NAME

posix_spawn_file_actions_destroy, posix_spawn_file_actions_init — destroy and initialize spawn file actions object (**ADVANCED REALTIME**)

SYNOPSIS

SPN

```
#include <spawn.h>

int posix_spawn_file_actions_destroy(posix_spawn_file_actions_t *
    file_actions);
int posix_spawn_file_actions_init(posix_spawn_file_actions_t *
    file_actions);
```

DESCRIPTION

The *posix_spawn_file_actions_destroy*( ) function shall destroy the object referenced by *file_actions*; the object becomes, in effect, uninitialized. An implementation may cause *posix_spawn_file_actions_destroy*( ) to set the object referenced by *file_actions* to an invalid value. A destroyed spawn file actions object can be reinitialized using *posix_spawn_file_actions_init*( ); the results of otherwise referencing the object after it has been destroyed are undefined.

The *posix_spawn_file_actions_init*( ) function shall initialize the object referenced by *file_actions* to contain no file actions for *posix_spawn*( ) or *posix_spawnp*( ) to perform.

A spawn file actions object is as defined in *posix_spawn_file_actions_addclose*( ).

The effect of initializing an already initialized spawn file actions object is undefined.

RETURN VALUE

Upon successful completion, these functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *posix_spawn_file_actions_init*( ) function shall fail if:

[ENOMEM] Insufficient memory exists to initialize the spawn file actions object.

The *posix_spawn_file_actions_destroy*( ) function may fail if:

[EINVAL] The value specified by *file_actions* is invalid.

EXAMPLES

None.

APPLICATION USAGE

These functions are part of the Spawn option and need not be provided on all implementations.

RATIONALE

Refer to the RATIONALE in *posix_spawn_file_actions_addclose*( ).

FUTURE DIRECTIONS

None.

posix_spawn( ), *posix_spawnp*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<spawn.h>**

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1d-1999.

In the SYNOPSIS, the inclusion of **<sys/types.h>** is no longer required.

NAME

posix_spawn_file_actions_init — initialize spawn file actions object (**ADVANCED REALTIME**)

SYNOPSIS

SPN

```
#include <spawn.h>

int posix_spawn_file_actions_init(posix_spawn_file_actions_t *
    file_actions);
```

DESCRIPTION

Refer to *posix_spawn_file_actions_destroy*( ).

NAME

posix_spawnattr_destroy, posix_spawnattr_init — destroy and initialize spawn attributes object (**ADVANCED REALTIME**)

SYNOPSIS

SPN

```
#include <spawn.h>

int posix_spawnattr_destroy(posix_spawnattr_t *attr);
int posix_spawnattr_init(posix_spawnattr_t *attr);
```

DESCRIPTION

The *posix_spawnattr_destroy*( ) function shall destroy a spawn attributes object. A destroyed *attr* attributes object can be reinitialized using *posix_spawnattr_init*( ); the results of otherwise referencing the object after it has been destroyed are undefined. An implementation may cause *posix_spawnattr_destroy*( ) to set the object referenced by *attr* to an invalid value.

The *posix_spawnattr_init*( ) function shall initialize a spawn attributes object *attr* with the default value for all of the individual attributes used by the implementation. Results are undefined if *posix_spawnattr_init*( ) is called specifying an already initialized *attr* attributes object.

A spawn attributes object is of type **posix_spawnattr_t** (defined in **<spawn.h>**) and is used to specify the inheritance of process attributes across a spawn operation. IEEE Std 1003.1-200x does not define comparison or assignment operators for the type **posix_spawnattr_t**.

Each implementation shall document the individual attributes it uses and their default values unless these values are defined by IEEE Std 1003.1-200x. Attributes not defined by IEEE Std 1003.1-200x, their default values, and the names of the associated functions to get and set those attribute values are implementation-defined.

The resulting spawn attributes object (possibly modified by setting individual attribute values), is used to modify the behavior of *posix_spawn*( ) or *posix_spawnp*( ). After a spawn attributes object has been used to spawn a process by a call to a *posix_spawn*( ) or *posix_spawnp*( ), any function affecting the attributes object (including destruction) shall not affect any process that has been spawned in this way.

RETURN VALUE

Upon successful completion, *posix_spawnattr_destroy*( ) and *posix_spawnattr_init*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *posix_spawnattr_init*( ) function shall fail if:

[ENOMEM] Insufficient memory exists to initialize the spawn attributes object.

The *posix_spawnattr_destroy*( ) function may fail if:

[EINVAL] The value specified by attr is invalid.

EXAMPLES

None.

APPLICATION USAGE

These functions are part of the Spawn option and need not be provided on all implementations.

RATIONALE

The original spawn interface proposed in IEEE Std 1003.1-200x defined the attributes that specify the inheritance of process attributes across a spawn operation as a structure. In order to be able to separate optional individual attributes under their appropriate options (that is, the *spawn-schedparam* and *spawn-schedpolicy* attributes depending upon the Process Scheduling option), and also for extensibility and consistency with the newer POSIX interfaces, the attributes interface has been changed to an opaque data type. This interface now consists of the type **posix_spawnattr_t**, representing a spawn attributes object, together with associated functions to initialize or destroy the attributes object, and to set or get each individual attribute. Although the new object-oriented interface is more verbose than the original structure, it is simple to use, more extensible, and easy to implement.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1d-1999.

IEEE PASC Interpretation 1003.1 #106 is applied, noting that the effect of initializing an already initialized spawn attributes option is undefined. |

NAME

posix_spawnattr_getflags, posix_spawnattr_setflags — get and set spawn-flags attribute of spawn attributes object (**ADVANCED REALTIME**)

SYNOPSIS

SPN
```
#include <spawn.h>

int posix_spawnattr_getflags(const posix_spawnattr_t *restrict attr,
    short *restrict flags);
int posix_spawnattr_setflags(posix_spawnattr_t *attr, short flags);
```

DESCRIPTION

The *posix_spawnattr_getflags*( ) function shall obtain the value of the *spawn-flags* attribute from the attributes object referenced by *attr*.

The *posix_spawnattr_setflags*( ) function shall set the *spawn-flags* attribute in an initialized attributes object referenced by *attr*.

The *spawn-flags* attribute is used to indicate which process attributes are to be changed in the new process image when invoking *posix_spawn*( ) or *posix_spawnp*( ). It is the bitwise-inclusive OR of zero or more of the following flags:

POSIX_SPAWN_RESETIDS
POSIX_SPAWN_SETPGROUP
POSIX_SPAWN_SETSIGDEF
POSIX_SPAWN_SETSIGMASK
PS POSIX_SPAWN_SETSCHEDPARAM
POSIX_SPAWN_SETSCHEDULER

These flags are defined in **<spawn.h>**. The default value of this attribute shall be as if no flags were set.

RETURN VALUE

Upon successful completion, *posix_spawnattr_getflags*( ) shall return zero and store the value of the *spawn-flags* attribute of *attr* into the object referenced by the *flags* parameter; otherwise, an error number shall be returned to indicate the error.

Upon successful completion, *posix_spawnattr_setflags*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

These functions may fail if:

[EINVAL]	The value specified by *attr* is invalid.

The *posix_spawnattr_setflags*( ) function may fail if:

[EINVAL]	The value of the attribute being set is not valid.

EXAMPLES

None.

APPLICATION USAGE

These functions are part of the Spawn option and need not be provided on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1d-1999.

NAME

posix_spawnattr_getpgroup, posix_spawnattr_setpgroup — get and set spawn-pgroup attribute of spawn attributes object (**ADVANCED REALTIME**)

SYNOPSIS

SPN

```
#include <spawn.h>

int posix_spawnattr_getpgroup(const posix_spawnattr_t *restrict attr,
    pid_t *restrict pgroup);
int posix_spawnattr_setpgroup(posix_spawnattr_t *attr, pid_t pgroup);
```

DESCRIPTION

The *posix_spawnattr_getpgroup*( ) function shall obtain the value of the *spawn-pgroup* attribute from the attributes object referenced by *attr*.

The *posix_spawnattr_setpgroup*( ) function shall set the *spawn-pgroup* attribute in an initialized attributes object referenced by *attr*.

The *spawn-pgroup* attribute represents the process group to be joined by the new process image in a spawn operation (if POSIX_SPAWN_SETPGROUP is set in the *spawn-flags* attribute). The default value of this attribute shall be zero.

RETURN VALUE

Upon successful completion, *posix_spawnattr_getpgroup*( ) shall return zero and store the value of the *spawn-pgroup* attribute of *attr* into the object referenced by the *pgroup* parameter; otherwise, an error number shall be returned to indicate the error.

Upon successful completion, *posix_spawnattr_setpgroup*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

These functions may fail if:

[EINVAL] The value specified by *attr* is invalid.

The *posix_spawnattr_setpgroup*( ) function may fail if:

[EINVAL] The value of the attribute being set is not valid.

EXAMPLES

None.

APPLICATION USAGE

These functions are part of the Spawn option and need not be provided on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

posix_spawnattr_getschedparam, posix_spawnattr_setschedparam — get and set spawn-schedparam attribute of spawn attributes object (**ADVANCED REALTIME**)

SYNOPSIS

SPN PS

```
#include <spawn.h>
#include <sched.h>

int posix_spawnattr_getschedparam(
    const posix_spawnattr_t *restrict attr,
    struct sched_param *restrict schedparam);
int posix_spawnattr_setschedparam(posix_spawnattr_t *restrict attr,
    const struct sched_param *restrict schedparam);
```

DESCRIPTION

The *posix_spawnattr_getschedparam*( ) function shall obtain the value of the *spawn-schedparam* attribute from the attributes object referenced by *attr*.

The *posix_spawnattr_setschedparam*( ) function shall set the *spawn-schedparam* attribute in an initialized attributes object referenced by *attr*.

The *spawn-schedparam* attribute represents the scheduling parameters to be assigned to the new process image in a spawn operation (if POSIX_SPAWN_SETSCHEDULER or POSIX_SPAWN_SETSCHEDPARAM is set in the *spawn-flags* attribute). The default value of this attribute is unspecified.

RETURN VALUE

Upon successful completion, *posix_spawnattr_getschedparam*( ) shall return zero and store the value of the *spawn-schedparam* attribute of *attr* into the object referenced by the *schedparam* parameter; otherwise, an error number shall be returned to indicate the error.

Upon successful completion, *posix_spawnattr_setschedparam*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

These functions may fail if:

[EINVAL] The value specified by *attr* is invalid.

The *posix_spawnattr_setschedparam*( ) function may fail if:

[EINVAL] The value of the attribute being set is not valid.

NAME

posix_spawnattr_getsigdefault, posix_spawnattr_setsigdefault — get and set spawn-sigdefault attribute of spawn attributes object (**ADVANCED REALTIME**)

SYNOPSIS

SPN

```
#include <signal.h>
#include <spawn.h>

int posix_spawnattr_getsigdefault(
    const posix_spawnattr_t *restrict attr,
    sigset_t *restrict sigdefault);
int posix_spawnattr_setsigdefault(posix_spawnattr_t *restrict attr,
    const sigset_t *restrict sigdefault);
```

DESCRIPTION

The *posix_spawnattr_getsigdefault*( ) function shall obtain the value of the *spawn-sigdefault* attribute from the attributes object referenced by *attr*.

The *posix_spawnattr_setsigdefault*( ) function shall set the *spawn-sigdefault* attribute in an initialized attributes object referenced by *attr*.

The *spawn-sigdefault* attribute represents the set of signals to be forced to default signal handling in the new process image (if POSIX_SPAWN_SETSIGDEF is set in the *spawn-flags* attribute) by a spawn operation. The default value of this attribute shall be an empty signal set.

RETURN VALUE

Upon successful completion, *posix_spawnattr_getsigdefault*( ) shall return zero and store the value of the *spawn-sigdefault* attribute of *attr* into the object referenced by the *sigdefault* parameter; otherwise, an error number shall be returned to indicate the error.

Upon successful completion, *posix_spawnattr_setsigdefault*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

These functions may fail if:

[EINVAL]	The value specified by *attr* is invalid.

The *posix_spawnattr_setsigdefault*( ) function may fail if:

[EINVAL]	The value of the attribute being set is not valid.

EXAMPLES

NAME

posix_spawnattr_getsigmask, posix_spawnattr_setsigmask — get and set spawn-sigmask attribute of spawn attributes object (**ADVANCED REALTIME**)

SYNOPSIS

SPN
```
#include <signal.h>
#include <spawn.h>

int posix_spawnattr_getsigmask(const posix_spawnattr_t *restrict attr,
    sigset_t *restrict sigmask);
int posix_spawnattr_setsigmask(posix_spawnattr_t *restrict attr,
    const sigset_t *restrict sigmask);
```

DESCRIPTION

The *posix_spawnattr_getsigmask*( ) function shall obtain the value of the *spawn-sigmask* attribute from the attributes object referenced by *attr*.

The *posix_spawnattr_setsigmask*( ) function shall set the *spawn-sigmask* attribute in an initialized attributes object referenced by *attr*.

The *spawn-sigmask* attribute represents the signal mask in effect in the new process image of a spawn operation (if POSIX_SPAWN_SETSIGMASK is set in the *spawn-flags* attribute). The default value of this attribute is unspecified.

RETURN VALUE

Upon successful completion, *posix_spawnattr_getsigmask*( ) shall return zero and store the value of the *spawn-sigmask* attribute of *attr* into the object referenced by the *sigmask* parameter; otherwise, an error number shall be returned to indicate the error.

Upon successful completion, *posix_spawnattr_setsigmask*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

    const posix_spawn_file_actions_t *file_actions,
    const posix_spawnattr_t *restrict attrp,
    char *const argv[restrict], char *const envp[restrict]);
```

DESCRIPTION

Refer to *posix_spawn*( ).

NAME

posix_trace_attr_destroy, posix_trace_attr_init — trace stream attributes object destroy and initialization (**TRACING**)

SYNOPSIS

TRC

```
#include <trace.h>

int posix_trace_attr_destroy(trace_attr_t *attr);
int posix_trace_attr_init(trace_attr_t *attr);
```

DESCRIPTION

The *posix_trace_attr_destroy*( ) function shall destroy an initialized trace attributes object. A destroyed *attr* attributes object can be reinitialized using *posix_trace_attr_init*( ); the results of otherwise referencing the object after it has been destroyed are undefined.

The *posix_trace_attr_init*( ) function shall initialize a trace attributes object *attr* with the default value for all of the individual attributes used by a given implementation. The read-only *generation-version* and *clock-resolution* attributes of the newly initialized trace attributes object shall be set to their appropriate values (see Section 2.11.1.2 (on page 525)).

Results are undefined if *posix_trace_attr_init*( ) is called specifying an already initialized *attr* attributes object.

Implementations may add extensions to the trace attributes object structure as permitted in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 2, Conformance.

The resulting attributes object (possibly modified by setting individual attributes values), when used by *posix_trace_create*( ), defines the attributes of the trace stream created. A single attributes object can be used in multiple calls to *posix_trace_create*( ). After one or more trace streams have been created using an attributes object, any function affecting that attributes object, including destruction, shall not affect any trace stream previously created. An initialized attributes object also serves to receive the attributes of an existing trace stream or trace log when calling the *posix_trace_get_attr*( ) function.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

ERRORS

The *posix_trace_attr_destroy*( ) function may fail if:

[EINVAL] The value of *attr* is invalid.

The *posix_trace_attr_init*( ) function shall fail if:

[ENOMEM] Insufficient memory exists to initialize the trace attributes object.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

IEEE PASC Interpretation 1003.1 #123 is applied. |

NAME

posix_trace_attr_getclockres, posix_trace_attr_getcreatetime, posix_trace_attr_getgenversion, posix_trace_attr_getname, posix_trace_attr_setname — retrieve and set information about a trace stream (**TRACING**)

SYNOPSIS

TRC

```
#include <time.h>
#include <trace.h>

int posix_trace_attr_getclockres(const trace_attr_t *attr,
    struct timespec *resolution);
int posix_trace_attr_getcreatetime(const trace_attr_t *attr,
    struct timespec *createtime);

#include <trace.h>

int posix_trace_attr_getgenversion(const trace_attr_t *attr,
    char *genversion);
int posix_trace_attr_getname(const trace_attr_t *attr,
    char *tracename);
int posix_trace_attr_setname(trace_attr_t *attr,
    const char *tracename);
```

DESCRIPTION

The *posix_trace_attr_getclockres*( ) function shall copy the clock resolution of the clock used to generate timestamps from the *clock-resolution* attribute of the attributes object pointed to by the *attr* argument into the structure pointed to by the *resolution* argument.

The *posix_trace_attr_getcreatetime*( ) function shall copy the trace stream creation time from the *creation-time* attribute of the attributes object pointed to by the *attr* argument into the structure pointed to by the *createtime* argument. The *creation-time* attribute shall represent the time of creation of the trace stream.

The *posix_trace_attr_getgenversion*( ) function shall copy the string containing version information from the *generation-version* attribute of the attributes object pointed to by the *attr* argument into the string pointed to by the *genversion* argument. The *genversion* argument shall be the address of a character array which can store at least {TRACE_NAME_MAX} characters.

The *posix_trace_attr_getname*( ) function shall copy the string containing the trace name from the *trace-name* attribute of the attributes object pointed to by the *attr* argument into the string pointed to by the *tracename* argument. The *tracename* argument shall be the address of a character array which can store at least {TRACE_NAME_MAX} characters.

The *posix_trace_attr_setname*( ) function shall set the name in the *trace-name* attribute of the attributes object pointed to by the *attr* argument, using the trace name string supplied by the *tracename* argument. If the supplied string contains more than {TRACE_NAME_MAX} characters, the name copied into the *trace-name* attribute may be truncated to one less than the length of {TRACE_NAME_MAX} characters. The default value is a null string.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

If successful, the *posix_trace_attr_getclockres*( ) function stores the *clock-resolution* attribute value in the object pointed to by *resolution*. Otherwise, the content of this object is unspecified.

If successful, the *posix_trace_attr_getcreatetime*( ) function stores the trace stream creation time in the object pointed to by *createtime*. Otherwise, the content of this object is unspecified.

If successful, the *posix_trace_attr_getgenversion*( ) function stores the trace version information in the string pointed to by *genversion*. Otherwise, the content of this string is unspecified.

If successful, the *posix_trace_attr_getname*( ) function stores the trace name in the string pointed to by *tracename*. Otherwise, the content of this string is unspecified.

ERRORS

The *posix_trace_attr_getclockres*( ), *posix_trace_attr_getcreatetime*( ), *posix_trace_attr_getgenversion*( ), and *posix_trace_attr_getname*( ) functions may fail if:

[EINVAL] The value specified by one of the arguments is invalid.

EXAMPLES

None.

APPLICATION USAGE

None.

    int logpolicy);
```
TRC
```
int posix_trace_attr_setstreamfullpolicy(trace_attr_t *attr,
    int streampolicy);
```

DESCRIPTION

TRI The *posix_trace_attr_getinherited*( ) and *posix_trace_attr_setinherited*( ) functions, respectively, shall get and set the inheritance policy stored in the *inheritance* attribute for traced processes across the *fork*( ) and *spawn*( ) operations. The *inheritance* attribute of the attributes object pointed to by the *attr* argument shall be set to one of the following values defined by manifest constants in the **<trace.h>** header:

POSIX_TRACE_CLOSE_FOR_CHILD
: After a *fork*( ) or *spawn*( ) operation, the child shall not be traced, and tracing of the parent shall continue.

POSIX_TRACE_INHERITED
: After a *fork*( ) or *spawn*( ) operation, if the parent is being traced, its child shall be concurrently traced using the same trace stream.

The default value for the *inheritance* attribute is POSIX_TRACE_CLOSE_FOR_CHILD.

TRL The *posix_trace_attr_getlogfullpolicy*( ) and *posix_trace_attr_setlogfullpolicy*( ) functions, respectively, shall get and set the trace log full policy stored in the *log-full-policy* attribute of the attributes object pointed to by the *attr* argument.

The *log-full-policy* attribute shall be set to one of the following values defined by manifest constants in the **<trace.h>** header:

POSIX_TRACE_LOOP
: The trace log shall loop until the associated trace stream is stopped. This policy means that when the trace log gets full, the file system shall reuse the resources allocated to the oldest trace events that were recorded. In this way, the trace log will always contain the most recent trace events flushed.

POSIX_TRACE_UNTIL_FULL
: The trace stream shall be flushed to the trace log until the trace log is full. This condition can be deduced from the *posix_log_full_status* member status (see the *posix_trace_status_info*( ) function). The last recorded trace event shall be the POSIX_TRACE_STOP trace event.

POSIX_TRACE_APPEND

The associated trace stream shall be flushed to the trace log without log size limitation. If the application specifies POSIX_TRACE_APPEND, the implementation shall ignore the *log-max-size* attribute.

The default value for the *log-full-policy* attribute is POSIX_TRACE_LOOP.

The *posix_trace_attr_getstreamfullpolicy*( ) and *posix_trace_attr_setstreamfullpolicy*( ) functions, respectively, shall get and set the trace stream full policy stored in the *stream-full-policy* attribute of the attributes object pointed to by the *attr* argument.

The *stream-full-policy* attribute shall be set to one of the following values defined by manifest constants in the **<trace.h>** header:

POSIX_TRACE_LOOP

The trace stream shall loop until explicitly stopped by the *posix_trace_stop*( ) function. This policy means that when the trace stream is full, the trace system shall reuse the resources allocated to the oldest trace events recorded. In this way, the trace stream will always contain the most recent trace events recorded.

POSIX_TRACE_UNTIL_FULL

The trace stream will run until the trace stream resources are exhausted. Then the trace stream will stop. This condition can be deduced from *posix_stream_status* and *posix_stream_full_status* statuses (see the *posix_trace_status_info*( ) function). When this trace stream is read, a POSIX_TRACE_STOP trace event shall be reported after reporting the last recorded trace event. The trace system shall reuse the resources allocated to any trace events already reported—see the *posix_trace_getnext_event*( ), *posix_trace_trygetnext_event*( ), and *posix_trace_timedgetnext_event*( ) functions—or already flushed for an active trace stream with log if the Trace Log option is supported; see the *posix_trace_flush*( ) function. The trace system shall restart the trace stream when it is empty and may restart it sooner. A POSIX_TRACE_START trace event shall be reported before reporting the next recorded trace event.

TRL POSIX_TRACE_FLUSH

If the Trace Log option is supported, this policy is identical to the POSIX_TRACE_UNTIL_FULL trace stream full policy except that the trace stream shall be flushed regularly as if *posix_trace_flush*( ) had been explicitly called. Defining this policy for an active trace stream without log shall be invalid.

The default value for the *stream-full-policy* attribute shall be POSIX_TRACE_LOOP for an active trace stream without log.

TRL If the Trace Log option is supported, the default value for the *stream-full-policy* attribute shall be POSIX_TRACE_FLUSH for an active trace stream with log.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

TRI If successful, the *posix_trace_attr_getinherited*( ) function shall store the *inheritance* attribute value in the object pointed to by *inheritancepolicy*. Otherwise, the content of this object is undefined.

TRL If successful, the *posix_trace_attr_getlogfullpolicy*( ) function shall store the *log-full-policy* attribute value in the object pointed to by *logpolicy*. Otherwise, the content of this object is undefined.

If successful, the *posix_trace_attr_getstreamfullpolicy*( ) function shall store the *stream-full-policy* attribute value in the object pointed to by *streampolicy*. Otherwise, the content of this object is undefined.

ERRORS

These functions may fail if:

[EINVAL] The value specified by at least one of the arguments is invalid.

    size_t maxdatasize);
int posix_trace_attr_setstreamsize(trace_attr_t *attr,
    size_t streamsize);
```

DESCRIPTION

The *posix_trace_attr_getlogsize*( ) function shall copy the log size, in bytes, from the *log-max-size* attribute of the attributes object pointed to by the *attr* argument into the variable pointed to by the *logsize* argument. This log size is the maximum total of bytes that shall be allocated for system and user trace events in the trace log. The default value for the *log-max-size* attribute is implementation-defined.

The *posix_trace_attr_setlogsize*( ) function shall set the maximum allowed size, in bytes, in the *log-max-size* attribute of the attributes object pointed to by the *attr* argument, using the size value supplied by the *logsize* argument.

The trace log size shall be used if the *log-full-policy* attribute is set to POSIX_TRACE_LOOP or POSIX_TRACE_UNTIL_FULL. If the *log-full-policy* attribute is set to POSIX_TRACE_APPEND, the implementation shall ignore the *log-max-size* attribute.

The *posix_trace_attr_getmaxdatasize*( ) function shall copy the maximum user trace event data size, in bytes, from the *max-data-size* attribute of the attributes object pointed to by the *attr* argument into the variable pointed to by the *maxdatasize* argument. The default value for the *max-data-size* attribute is implementation-defined.

The *posix_trace_attr_getmaxsystemeventsize*( ) function shall calculate the maximum memory size, in bytes, required to store a single system trace event. This value is calculated for the trace stream attributes object pointed to by the *attr* argument and is returned in the variable pointed to by the *eventsize* argument.

The values returned as the maximum memory sizes of the user and system trace events shall be such that if the sum of the maximum memory sizes of a set of the trace events that may be recorded in a trace stream is less than or equal to the *stream-min-size* attribute of that trace stream, the system provides the necessary resources for recording all those trace events, without loss.

The *posix_trace_attr_getmaxusereventsize*( ) function shall calculate the maximum memory size, in bytes, required to store a single user trace event generated by a call to *posix_trace_event*( ) with a *data_len* parameter equal to the *data_len* value specified in this call. This value is calculated for the trace stream attributes object pointed to by the *attr* argument and is returned in the variable pointed to by the *eventsize* argument.

The *posix_trace_attr_getstreamsize*( ) function shall copy the stream size, in bytes, from the *stream-min-size* attribute of the attributes object pointed to by the *attr* argument into the variable pointed to by the *streamsize* argument.

This stream size is the current total memory size reserved for system and user trace events in the trace stream. The default value for the *stream-min-size* attribute is implementation-defined. The stream size refers to memory used to store trace event records. Other stream data (for example, trace attribute values) shall not be included in this size.

The *posix_trace_attr_setmaxdatasize*( ) function shall set the maximum allowed size, in bytes, in the *max-data-size* attribute of the attributes object pointed to by the *attr* argument, using the size value supplied by the *maxdatasize* argument. This maximum size is the maximum allowed size for the user data argument which may be passed to *posix_trace_event*( ). The implementation shall be allowed to truncate data passed to *trace_user_event* which is longer than *maxdatasize*.

The *posix_trace_attr_setstreamsize*( ) function shall set the minimum allowed size, in bytes, in the *stream-min-size* attribute of the attributes object pointed to by the *attr* argument, using the size value supplied by the *streamsize* argument.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

TRL The *posix_trace_attr_getlogsize*( ) function stores the maximum trace log allowed size in the object pointed to by *logsize*, if successful.

The *posix_trace_attr_getmaxdatasize*( ) function stores the maximum trace event record memory size in the object pointed to by *maxdatasize*, if successful.

The *posix_trace_attr_getmaxsystemeventsize*( ) function stores the maximum memory size to store a single system trace event in the object pointed to by *eventsize*, if successful.

The *posix_trace_attr_getmaxusereventsize*( ) function stores the maximum memory size to store a single user trace event in the object pointed to by *eventsize*, if successful.

The *posix_trace_attr_getstreamsize*( ) function stores the maximum trace stream allowed size in the object pointed to by *streamsize*, if successful.

ERRORS

These functions may fail if:

[EINVAL] The value specified by one of the arguments is invalid.

NAME

posix_trace_clear — clear trace stream and trace log (**TRACING**)

SYNOPSIS

TRC
```
#include <sys/types.h>
#include <trace.h>

int posix_trace_clear(trace_id_t trid);

```

DESCRIPTION

The *posix_trace_clear*( ) function shall reinitialize the trace stream identified by the argument *trid* as if it were returning from the *posix_trace_create*( ) function, except that the same allocated resources shall be reused, the mapping of trace event type identifiers to trace event names shall be unchanged, and the trace stream status shall remain unchanged (that is, if it was running, it remains running and if it was suspended, it remains suspended).

All trace events in the trace stream recorded before the call to *posix_trace_clear*( ) shall be lost. The *posix_stream_full_status* status shall be set to POSIX_TRACE_NOT_FULL. There is no guarantee that all trace events that occurred during the *posix_trace_clear*( ) call are recorded; the behavior with respect to trace points that may occur during this call, is unspecified.

TRL If the Trace Log option is supported and the trace stream has been created with a log, the *posix_trace_clear*( ) function shall reinitialize the trace stream with the same behavior as if the trace stream was created without the log, plus it shall reinitialize the trace log associated with the trace stream identified by the argument *trid* as if it were returning from the *posix_trace_create_withlog*( ) function, except that the same allocated resources, for the trace log, may be reused and the associated trace stream status remains unchanged. The first trace event recorded in the trace log after the call to *posix_trace_clear*( ) shall be the same as the first trace event recorded in the active trace stream after the call to *posix_trace_clear*( ). The *posix_log_full_status* status shall be set to POSIX_TRACE_NOT_FULL. There is no guarantee that all trace events that occurred during the *posix_trace_clear*( ) call are recorded in the trace log; the behavior with respect to trace points that may occur during this call is unspecified. If the log full policy is POSIX_TRACE_APPEND, the effect of a call to this function is unspecified for the trace log associated with the trace stream identified by the *trid* argument.

RETURN VALUE

Upon successful completion, the *posix_trace_clear*( ) function shall return a value of zero. Otherwise, it shall return the corresponding error number.

ERRORS

The *posix_trace_clear*( ) function shall fail if:

[EINVAL]	The value of the *trid* argument does not correspond to an active trace stream.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1q-2000.

IEEE PASC Interpretation 1003.1 #123 is applied.

NAME

posix_trace_close, posix_trace_open, posix_trace_rewind — trace log management (**TRACING**)

SYNOPSIS

TRC TRL

```
#include <trace.h>

int posix_trace_close(trace_id_t trid);
int posix_trace_open(int file_desc, trace_id_t *trid);
int posix_trace_rewind(trace_id_t trid);

```

DESCRIPTION

The *posix_trace_close*( ) function shall deallocate the trace log identifier indicated by *trid*, and all of its associated resources. If there is no valid trace log pointed to by the *trid*, this function shall fail.

The *posix_trace_open*( ) function shall allocate the necessary resources and establishes the connection between a trace log identified by the *file_desc* argument and a trace stream identifier identified by the object pointed to by the *trid* argument. The *file_desc* argument should be a valid open file descriptor that corresponds to a trace log. The *file_desc* argument shall be open for reading. The current trace event timestamp, which specifies the timestamp of the trace event that will be read by the next call to *posix_trace_getnext_event*( ), shall be set to the timestamp of the oldest trace event recorded in the trace log identified by *trid*.

The *posix_trace_open*( ) function shall return a trace stream identifier in the variable pointed to by the *trid* argument, that may only be used by the following functions:

posix_trace_close( )
posix_trace_eventid_equal( )
posix_trace_eventid_get_name( )
posix_trace_eventtypelist_getnext_id( )
posix_trace_eventtypelist_rewind( )
posix_trace_get_attr( )
posix_trace_get_status( )
posix_trace_getnext_event( )
posix_trace_rewind( )

In particular, notice that the operations normally used by a trace controller process, such as *posix_trace_start*( ), *posix_trace_stop*( ), or *posix_trace_shutdown*( ), cannot be invoked using the trace stream identifier returned by the *posix_trace_open*( ) function.

The *posix_trace_rewind*( ) function shall reset the current trace event timestamp, which specifies the timestamp of the trace event that will be read by the next call to *posix_trace_getnext_event*( ), to the timestamp of the oldest trace event recorded in the trace log identified by *trid*.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

If successful, the *posix_trace_open*( ) function stores the trace stream identifier value in the object pointed to by *trid*.

ERRORS

The *posix_trace_open*( ) function shall fail if:

[EINTR]	The operation was interrupted by a signal and thus no trace log was opened.
[EINVAL]	The object pointed to by *file_desc* does not correspond to a valid trace log.

The *posix_trace_close*( ) and *posix_trace_rewind*( ) functions may fail if:

[EINVAL]	The object pointed to by *trid* does not correspond to a valid trace log.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

IEEE PASC Interpretation 1003.1 #123 is applied.

NAME

posix_trace_create, posix_trace_create_withlog, posix_trace_flush, posix_trace_shutdown — trace stream initialization, flush, and shutdown from a process (**TRACING**)

SYNOPSIS

```
TRC       #include <sys/types.h>
          #include <trace.h>

          int posix_trace_create(pid_t pid,
              const trace_attr_t *restrict attr,
              trace_id_t *restrict trid);
TRC  TRL  int posix_trace_create_withlog(pid_t pid,
              const trace_attr_t *restrict attr, int file_desc,
              trace_id_t *restrict trid);
          int posix_trace_flush(trace_id_t trid);
TRC       int posix_trace_shutdown(trace_id_t trid);
```

DESCRIPTION

The *posix_trace_create*( ) function shall create an active trace stream. It allocates all the resources needed by the trace stream being created for tracing the process specified by *pid* in accordance with the *attr* argument. The *attr* argument represents the initial attributes of the trace stream and shall have been initialized by the function *posix_trace_attr_init*( ) prior the *posix_trace_create*( ) call. If the argument *attr* is NULL, the default attributes shall be used. The *attr* attributes object shall be manipulated through a set of functions described in the *posix_trace_attr* family of functions. If the attributes of the object pointed to by *attr* are modified later, the attributes of the trace stream shall not be affected. The *creation-time* attribute of the newly created trace stream shall be set to the value of the system clock, if the Timers option is not supported, or to the value of the CLOCK_REALTIME clock, if the Timers option is supported.

The *pid* argument represents the target process to be traced. If the process executing this function does not have appropriate privileges to trace the process identified by *pid*, an error shall be returned. If the *pid* argument is zero, the calling process shall be traced.

The *posix_trace_create*( ) function shall store the trace stream identifier of the new trace stream in the object pointed to by the *trid* argument. This trace stream identifier shall be used in subsequent calls to control tracing. The *trid* argument may only be used by the following functions:

posix_trace_clear( )
posix_trace_eventid_equal( )
posix_trace_eventid_get_name( )
posix_trace_eventtypelist_getnext_id( )
posix_trace_eventtypelist_rewind( )
posix_trace_get_attr( )
posix_trace_get_status( )
posix_trace_getnext_event( )
posix_trace_shutdown( )
posix_trace_start( )
posix_trace_stop( )
posix_trace_timedgetnext_event( )
posix_trace_trid_eventid_open( )
posix_trace_trygetnext_event( )

TEF If the Trace Event Filter option is supported, the following additional functions may use the *trid* argument:

posix_trace_get_filter( ) *posix_trace_set_filter*( )

In particular, notice that the operations normally used by a trace analyzer process, such as *posix_trace_rewind*( ) or *posix_trace_close*( ), cannot be invoked using the trace stream identifier returned by the *posix_trace_create*( ) function.

TEF A trace stream shall be created in a suspended state. If the Trace Event Filter option is supported, its trace event type filter shall be empty.

The *posix_trace_create*( ) function may be called multiple times from the same or different processes, with the system-wide limit indicated by the runtime invariant value {TRACE_SYS_MAX}, which has the minimum value {_POSIX_TRACE_SYS_MAX}.

The trace stream identifier returned by the *posix_trace_create*( ) function in the argument pointed to by *trid* is valid only in the process that made the function call. If it is used from another process, that is a child process, in functions defined in IEEE Std 1003.1-200x, these functions shall return with the error [EINVAL].

TRL The *posix_trace_create_withlog*( ) function shall be equivalent to *posix_trace_create*( ), except that it associates a trace log with this stream. The *file_desc* argument shall be the file descriptor designating the trace log destination. The function shall fail if this file descriptor refers to a file with a file type that is not compatible with the log policy associated with the trace log. The list of the appropriate file types that are compatible with each log policy is implementation-defined.

The *posix_trace_create_withlog*( ) function shall return in the parameter pointed to by *trid* the trace stream identifier, which uniquely identifies the newly created trace stream, and shall be used in subsequent calls to control tracing. The *trid* argument may only be used by the following functions:

posix_trace_clear( )
posix_trace_eventid_equal( )
posix_trace_eventid_get_name( )
posix_trace_eventtypelist_getnext_id( )
posix_trace_eventtypelist_rewind( )
posix_trace_flush( )
posix_trace_get_attr( )
posix_trace_get_status( )
posix_trace_getnext_event( )
posix_trace_shutdown( )
posix_trace_start( )
posix_trace_stop( )
posix_trace_timedgetnext_event( )
posix_trace_trid_eventid_open( )
posix_trace_trygetnext_event( )

TRL TEF If the Trace Event Filter option is supported, the following additional functions may use the *trid* argument:

posix_trace_get_filter( )
posix_trace_set_filter( )

TRL In particular, notice that the operations normally used by a trace analyzer process, such as *posix_trace_rewind*( ) or *posix_trace_close*( ), cannot be invoked using the trace stream identifier returned by the *posix_trace_create_withlog*( ) function.

The *posix_trace_flush*( ) function shall initiate a flush operation which copies the contents of the trace stream identified by the argument *trid* into the trace log associated with the trace stream at the creation time. If no trace log has been associated with the trace stream pointed to by *trid*, this function shall return an error. The termination of the flush operation can be polled by the *posix_trace_get_status*( ) function. During the flush operation, it shall be possible to trace new trace events up to the point when the trace stream becomes full. After flushing is completed, the space used by the flushed trace events shall be available for tracing new trace events.

If flushing the trace stream causes the resulting trace log to become full, the trace log full policy shall be applied. If the trace *log-full-policy* attribute is set, the following occurs:

POSIX_TRACE_UNTIL_FULL
The trace events that have not yet been flushed shall be discarded.

POSIX_TRACE_LOOP
The trace events that have not yet been flushed shall be written to the beginning of the trace log, overwriting previous trace events stored there.

POSIX_TRACE_APPEND
The trace events that had not yet been flushed shall be appended to the trace log.

The *posix_trace_shutdown*( ) function shall stop the tracing of trace events in the trace stream identified by *trid*, as if *posix_trace_stop*( ) had been invoked. The *posix_trace_shutdown*( ) function shall free all the resources associated with the trace stream.

The *posix_trace_shutdown*( ) function shall not return until all the resources associated with the trace stream have been freed. When the *posix_trace_shutdown*( ) function returns, the *trid* argument becomes an invalid trace stream identifier. A call to this function shall unconditionally deallocate the resources regardless of whether all trace events have been retrieved by the analyzer process. Any thread blocked on one of the *trace_getnext_event*( ) functions (which specified this *trid*) before this call is unblocked with the error [EINVAL].

If the process exits, invokes an *exec*( ) call, or is terminated, the trace streams that the process had created and that have not yet been shut down, shall be automatically shut down as if an explicit call were made to the *posix_trace_shutdown*( ) function.

TRL For an active trace stream with log, when the *posix_trace_shutdown*( ) function is called, all trace events that have not yet been flushed to the trace log shall be flushed, as in the *posix_trace_flush*( ) function, and the trace log shall be closed.

When a trace log is closed, all the information that may be retrieved later from the trace log through the trace interface shall have been written to the trace log. This information includes the trace attributes, the list of trace event types (with the mapping between trace event names and trace event type identifiers), and the trace status.

In addition, unspecified information shall be written to the trace log to allow detection of a valid trace log during the *posix_trace_open*( ) operation.

The *posix_trace_shutdown*( ) function shall not return until all trace events have been flushed.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

TRL The *posix_trace_create*( ) and *posix_trace_create_withlog*( ) functions store the trace stream identifier value in the object pointed to by *trid*, if successful.

ERRORS

TRL The *posix_trace_create*( ) and *posix_trace_create_withlog*( ) functions shall fail if:

[EAGAIN]	No more trace streams can be started now. {TRACE_SYS_MAX} has been exceeded.
[EINTR]	The operation was interrupted by a signal. No trace stream was created.
[EINVAL]	One or more of the trace parameters specified by the *attr* parameter is invalid.

[ENOMEM]	The implementation does not currently have sufficient memory to create the trace stream with the specified parameters.
[EPERM]	The caller does not have appropriate privilege to trace the process specified by *pid*.
[ESRCH]	The *pid* argument does not refer to an existing process.

TRL The *posix_trace_create_withlog*( ) function shall fail if:

[EBADF]	The *file_desc* argument is not a valid file descriptor open for writing.
[EINVAL]	The *file_desc* argument refers to a file with a file type that does not support the log policy associated with the trace log.
[ENOSPC]	No space left on device. The device corresponding to the argument *file_desc* does not contain the space required to create this trace log.

TRL The *posix_trace_flush*( ) and *posix_trace_shutdown*( ) functions shall fail if:

[EINVAL]	The value of the *trid* argument does not correspond to an active trace stream with log.
[EFBIG]	The trace log file has attempted to exceed an implementation-defined maximum file size.
[ENOSPC]	No space left on device.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1q-2000.

NAME

posix_trace_event, posix_trace_eventid_open — trace functions for instrumenting application code (**TRACING**)

SYNOPSIS

TRC
```
#include <sys/types.h>
#include <trace.h>
```

```
void posix_trace_event(trace_event_id_t event_id,
    const void *restrictdata_ptr, size_t data_len);
int posix_trace_eventid_open(const char *restrict event_name,
    trace_event_id_t *restrict event_id);
```

DESCRIPTION

The *posix_trace_event*( ) function shall record the *event_id* and the user data pointed to by *data_ptr* in the trace stream into which the calling process is being traced and in which *event_id* is not filtered out. If the total size of the user trace event data represented by *data_len* is not greater than the declared maximum size for user trace event data, then the *truncation-status* attribute of the trace event recorded is POSIX_TRACE_NOT_TRUNCATED. Otherwise, the user trace event data is truncated to this declared maximum size and the *truncation-status* attribute of the trace event recorded is POSIX_TRACE_TRUNCATED_RECORD.

If there is no trace stream created for the process or if the created trace stream is not running or if the trace event specified by *event_id* is filtered out in the trace stream, the *posix_trace_event*( ) function shall have no effect.

The *posix_trace_eventid_open*( ) function shall associate a user trace event name with a trace event type identifier for the calling process. The trace event name is the string pointed to by the argument *event_name*. It shall have a maximum of {TRACE_EVENT_NAME_MAX} characters (which has the minimum value {_POSIX_TRACE_EVENT_NAME_MAX}). The number of user trace event type identifiers that can be defined for any given process is limited by the maximum value {TRACE_USER_EVENT_MAX}, which has the minimum value {POSIX_TRACE_USER_EVENT_MAX}.

If the Trace Inherit option is not supported, the *posix_trace_eventid_open*( ) function shall associate the user trace event name pointed to by the *event_name* argument with a trace event type identifier that is unique for the traced process, and is returned in the variable pointed to by the *event_id* argument. If the user trace event name has already been mapped for the traced process, then the previously assigned trace event type identifier shall be returned. If the per-process user trace event name limit represented by {TRACE_USER_EVENT_MAX} has been reached, the pre-defined POSIX_TRACE_UNNAMED_USEREVENT (see Table 2-7 (on page 529)) user trace event shall be returned.

TRI If the Trace Inherit option is supported, the *posix_trace_eventid_open*( ) function shall associate the user trace event name pointed to by the *event_name* argument with a trace event type identifier that is unique for all the processes being traced in this same trace stream, and is returned in the variable pointed to by the *event_id* argument. If the user trace event name has already been mapped for the traced processes, then the previously assigned trace event type identifier shall be returned. If the per-process user trace event name limit represented by {TRACE_USER_EVENT_MAX} has been reached, the pre-defined POSIX_TRACE_UNNAMED_USEREVENT (Table 2-7 (on page 529)) user trace event shall be returned.

Note: The above procedure, together with the fact that multiple processes can only be traced into the same trace stream by inheritance, ensure that all the processes that are traced into a trace stream have the same mapping of trace event names to trace event type identifiers.

If there is no trace stream created, the *posix_trace_eventid_open*( ) function shall store this information for future trace streams created for this process.

RETURN VALUE

No return value is defined for the *posix_trace_event*( ) function.

Upon successful completion, the *posix_trace_eventid_open*( ) function shall return a value of zero. Otherwise, it shall return the corresponding error number. The *posix_trace_eventid_open*( ) function stores the trace event type identifier value in the object pointed to by *event_id*, if successful.

ERRORS

The *posix_trace_eventid_open*( ) function shall fail if: |

[ENAMETOOLONG]
The size of the name pointed to by *event_name* argument was longer than the implementation-defined value {TRACE_EVENT_NAME_MAX}.

NAME

posix_trace_eventid_equal, posix_trace_eventid_get_name, posix_trace_trid_eventid_open — manipulate trace event type identifier (**TRACING**)

SYNOPSIS

```
#include <trace.h>

int posix_trace_eventid_equal(trace_id_t trid, trace_event_id_t event1,
    trace_event_id_t event2);
int posix_trace_eventid_get_name(trace_id_t trid,
    trace_event_id_t event, char *event_name);
int posix_trace_trid_eventid_open(trace_id_t trid,
    const char *restrict event_name,
    trace_event_id_t *restrict event);
```

DESCRIPTION

The *posix_trace_eventid_equal*( ) function shall compare the trace event type identifiers *event1* and *event2* from the same trace stream or the same trace log identified by the *trid* argument. If the trace event type identifiers *event1* and *event2* are from different trace streams, the return value shall be unspecified.

The *posix_trace_eventid_get_name*( ) function shall return in the argument pointed to by *event_name*, the trace event name associated with the trace event type identifier identified by the argument *event*, for the trace stream or for the trace log identified by the *trid* argument. The name of the trace event shall have a maximum of {TRACE_EVENT_NAME_MAX} characters (which has the minimum value {_POSIX_TRACE_EVENT_NAME_MAX}). Successive calls to this function with the same trace event type identifier and the same trace stream identifier shall return the same event name.

The *posix_trace_trid_eventid_open*( ) function shall associate a user trace event name with a trace event type identifier for a given trace stream. The trace stream is identified by the *trid* argument, and it shall be an active trace stream. The trace event name is the string pointed to by the argument *event_name*. It shall have a maximum of {TRACE_EVENT_NAME_MAX} characters (which has the minimum value {_POSIX_TRACE_EVENT_NAME_MAX}). The number of user trace event type identifiers that can be defined for any given process is limited by the maximum value {TRACE_USER_EVENT_MAX}, which has the minimum value {_POSIX_TRACE_USER_EVENT_MAX}.

If the Trace Inherit option is not supported, the *posix_trace_trid_eventid_open*( ) function shall associate the user trace event name pointed to by the *event_name* argument with a trace event type identifier that is unique for the process being traced in the trace stream identified by the *trid* argument, and is returned in the variable pointed to by the *event* argument. If the user trace event name has already been mapped for the traced process, then the previously assigned trace event type identifier shall be returned. If the per-process user trace event name limit represented by {TRACE_USER_EVENT_MAX} has been reached, the pre-defined POSIX_TRACE_UNNAMED_USEREVENT (see Table 2-7 (on page 529)) user trace event shall be returned.

If the Trace Inherit option is supported, the *posix_trace_trid_eventid_open*( ) function shall associate the user trace event name pointed to by the *event_name* argument with a trace event type identifier that is unique for all the processes being traced in the trace stream identified by the *trid* argument, and is returned in the variable pointed to by the *event* argument. If the user trace event name has already been mapped for the traced processes, then the previously assigned trace event type identifier shall be returned. If the per-process user trace event name limit represented by {TRACE_USER_EVENT_MAX} has been reached, the pre-defined

POSIX_TRACE_UNNAMED_USEREVENT (see Table 2-7 (on page 529)) user trace event shall be returned.

RETURN VALUE

TEF Upon successful completion, the *posix_trace_eventid_get_name*( ) and *posix_trace_trid_eventid_open*( ) functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

The *posix_trace_eventid_equal*( ) function shall return a non-zero value if *event1* and *event2* are equal; otherwise, a value of zero shall be returned. No errors are defined. If either *event1* or *event2* are not valid trace event type identifiers for the trace stream specified by *trid* or if the *trid* is invalid, the behavior shall be unspecified.

The *posix_trace_eventid_get_name*( ) function stores the trace event name value in the object pointed to by *event_name*, if successful.

TEF The *posix_trace_trid_eventid_open*( ) function stores the trace event type identifier value in the object pointed to by *event*, if successful.

ERRORS

TEF The *posix_trace_eventid_get_name*( ) and *posix_trace_trid_eventid_open*( ) functions shall fail if:

[EINVAL] The *trid* argument was not a valid trace stream identifier.

TEF The *posix_trace_trid_eventid_open*( ) function shall fail if:

TEF [ENAMETOOLONG]
The size of the name pointed to by *event_name* argument was longer than the implementation-defined value {TRACE_EVENT_NAME_MAX}.

The *posix_trace_eventid_get_name*( ) function shall fail if:

[EINVAL] The trace event type identifier *event* was not associated with any name.

NAME

posix_trace_eventid_get_name — manipulate trace event type identifier (**TRACING**)

SYNOPSIS

TRC

```
#include <trace.h>

int posix_trace_eventid_get_name(trace_id_t trid,
    trace_event_id_t event, char *event_name);
```

DESCRIPTION

Refer to *posix_trace_eventid_equal*( ).

NAME

posix_trace_eventid_open — trace functions for instrumenting application code (**TRACING**)

SYNOPSIS

TRC
```
#include <sys/types.h>
#include <trace.h>

int posix_trace_eventid_open(const char *restrict event_name,
    trace_event_id_t *restrict event_id);
```

DESCRIPTION

Refer to *posix_trace_event*( ).

NAME

posix_trace_eventset_add, posix_trace_eventset_del, posix_trace_eventset_empty, posix_trace_eventset_fill, posix_trace_eventset_ismember — manipulate trace event type sets (**TRACING**)

SYNOPSIS

TRC TEF

```
#include <trace.h>

int posix_trace_eventset_add(trace_event_id_t event_id,
    trace_event_set_t *set);
int posix_trace_eventset_del(trace_event_id_t event_id,
    trace_event_set_t *set);
int posix_trace_eventset_empty(trace_event_set_t *set);
int posix_trace_eventset_fill(trace_event_set_t *set, int what);
int posix_trace_eventset_ismember(trace_event_id_t event_id,
    const trace_event_set_t *restrict set,
    int *restrict ismember);
```

DESCRIPTION

These primitives manipulate sets of trace event types. They operate on data objects addressable by the application, not on the current trace event filter of any trace stream.

The *posix_trace_eventset_add*( ) and *posix_trace_eventset_del*( ) functions, respectively, shall add or delete the individual trace event type specified by the value of the argument *event_id* to or from the trace event type set pointed to by the argument *set*. Adding a trace event type already in the set or deleting a trace event type not in the set shall not be considered an error.

The *posix_trace_eventset_empty*( ) function shall initialize the trace event type set pointed to by the *set* argument such that all trace event types defined, both system and user, shall be excluded from the set.

The *posix_trace_eventset_fill*( ) function shall initialize the trace event type set pointed to by the argument *set*, such that the set of trace event types defined by the argument *what* shall be included in the set. The value of the argument *what* shall consist of one of the following values, as defined in the **<trace.h>** header:

POSIX_TRACE_WOPID_EVENTS
All the process-independent implementation-defined system trace event types are included in the set.

POSIX_TRACE_SYSTEM_EVENTS All the implementation-defined system trace event types are included in the set, as are those defined in IEEE Std 1003.1-200x.

POSIX_TRACE_ALL_EVENTS All trace event types defined, both system and user, are included in the set.

Applications shall call either *posix_trace_eventset_empty*( ) or *posix_trace_eventset_fill*( ) at least once for each object of type **trace_event_set_t** prior to any other use of that object. If such an object is not initialized in this way, but is nonetheless supplied as an argument to any of the *posix_trace_eventset_add*( ), *posix_trace_eventset_del*( ), or *posix_trace_eventset_ismember*( ) functions, the results are undefined.

The *posix_trace_eventset_ismember*( ) function shall test whether the trace event type specified by the value of the argument *event_id* is a member of the set pointed to by the argument *set*. The value returned in the object pointed to by *ismember* argument is zero if the trace event type identifier is not a member of the set and a value different from zero if it is a member of the set. |

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

ERRORS

These functions may fail if:

[EINVAL] The value of one of the arguments is invalid.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1q-2000.

NAME

posix_trace_eventtypelist_getnext_id, posix_trace_eventtypelist_rewind — iterate over a mapping of trace event types (**TRACING**)

SYNOPSIS

TRC

```
#include <trace.h>

int posix_trace_eventtypelist_getnext_id(trace_id_t trid,
    trace_event_id_t *restrict event, int *restrict unavailable);
int posix_trace_eventtypelist_rewind(trace_id_t trid);
```

DESCRIPTION

The first time *posix_trace_eventtypelist_getnext_id*( ) is called, the function shall return in the variable pointed to by *event* the first trace event type identifier of the list of trace events of the trace stream identified by the *trid* argument. Successive calls to *posix_trace_eventtypelist_getnext_id*( ) return in the variable pointed to by *event* the next trace event type identifier in that same list. Each time a trace event type identifier is successfully written into the variable pointed to by the *event* argument, the variable pointed to by the *unavailable* argument shall be set to zero. When no more trace event type identifiers are available, and so none is returned, the variable pointed to by the *unavailable* argument shall be set to a value different from zero.

The *posix_trace_eventtypelist_rewind*( ) function shall reset the next trace event type identifier to be read to the first trace event type identifier from the list of trace events used in the trace stream identified by *trid*.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

The *posix_trace_eventtypelist_getnext_id*( ) function stores the trace event type identifier value in the object pointed to by *event*, if successful.

ERRORS

These functions shall fail if:

[EINVAL] The *trid* argument was not a valid trace stream identifier.

IEEE PASC Interpretations 1003.1 #123 and #129 are applied.

NAME

posix_trace_flush — trace stream flush from a process (**TRACING**)

SYNOPSIS

TRC
```
#include <sys/types.h>
#include <trace.h>

int posix_trace_flush(trace_id_t trid);
```

DESCRIPTION

Refer to *posix_trace_create*( ).

NAME

posix_trace_get_attr, posix_trace_get_status — retrieve the trace attributes or trace statuses (**TRACING**)

SYNOPSIS

TRC

```
#include <trace.h>

int posix_trace_get_attr(trace_id_t trid, trace_attr_t *attr);
int posix_trace_get_status(trace_id_t trid,
    struct posix_trace_status_info *statusinfo);
```

DESCRIPTION

The *posix_trace_get_attr*( ) function shall copy the attributes of the active trace stream identified by *trid* into the object pointed to by the *attr* argument. TRL If the Trace Log option is supported, *trid* may represent a pre-recorded trace log.

The *posix_trace_get_status*( ) function shall return, in the structure pointed to by the *statusinfo* argument, the current trace status for the trace stream identified by the *trid* argument. These status values returned in the structure pointed to by *statusinfo* shall have been appropriately read to ensure that the returned values are consistent. TRL If the Trace Log option is supported and the *trid* argument refers to a pre-recorded trace stream, the status shall be the status of the completed trace stream.

Each time the *posix_trace_get_status*( ) function is used, the overrun status of the trace stream shall be reset to POSIX_TRACE_NO_OVERRUN immediately after the call completes. TRL If the Trace Log option is supported, the *posix_trace_get_status*( ) function shall behave the same as when the option is not supported except for the following differences:

- If the *trid* argument refers to a trace stream with log, each time the *posix_trace_get_status*( ) function is used, the log overrun status of the trace stream shall be reset to POSIX_TRACE_NO_OVERRUN and the *flush_error* status shall be reset to zero immediately after the call completes.
- If the *trid* argument refers to a pre-recorded trace stream, the status returned shall be the status of the completed trace stream and the status values of the trace stream shall not be reset.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

The *posix_trace_get_attr*( ) function stores the trace attributes in the object pointed to by *attr*, if successful.

The *posix_trace_get_status*( ) function stores the trace status in the object pointed to by *statusinfo*, if successful.

ERRORS

These functions shall fail if:

[EINVAL] The trace stream argument *trid* does not correspond to a valid active trace stream or a valid trace log.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1q-2000.

IEEE PASC Interpretation 1003.1 #123 is applied.

NAME

posix_trace_get_filter, posix_trace_set_filter — retrieve and set filter of an initialized trace stream (**TRACING**)

SYNOPSIS

TRC TEF

```
#include <trace.h>

int posix_trace_get_filter(trace_id_t trid, trace_event_set_t *set);
int posix_trace_set_filter(trace_id_t trid,
    const trace_event_set_t *set, int how);
```

DESCRIPTION

The *posix_trace_get_filter*( ) function shall retrieve, into the argument pointed to by *set*, the actual trace event filter from the trace stream specified by *trid*.

The *posix_trace_set_filter*( ) function shall change the set of filtered trace event types after a trace stream identified by the *trid* argument is created. This function may be called prior to starting the trace stream, or while the trace stream is active. By default, if no call is made to *posix_trace_set_filter*( ), all trace events shall be recorded (that is, none of the trace event types are filtered out).

If this function is called while the trace is in progress, a special system trace event, POSIX_TRACE_FILTER, shall be recorded in the trace indicating both the old and the new sets of filtered trace event types (see Table 2-4 (on page 528) and Table 2-6 (on page 529)).

If the *posix_trace_set_filter*( ) function is interrupted by a signal, an error shall be returned and the filter shall not be changed. In this case, the state of the trace stream shall not be changed.

The value of the argument *how* indicates the manner in which the set is to be changed and shall have one of the following values, as defined in the **<trace.h>** header:

POSIX_TRACE_SET_EVENTSET
The resulting set of trace event types to be filtered shall be the trace event type set pointed to by the argument *set*.

POSIX_TRACE_ADD_EVENTSET
The resulting set of trace event types to be filtered shall be the union of the current set and the trace event type set pointed to by the argument *set*.

POSIX_TRACE_SUB_EVENTSET
The resulting set of trace event types to be filtered shall be all trace event types in the current set that are not in the set pointed to by the argument *set*; that is, remove each element of the specified set from the current filter.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

The *posix_trace_get_filter*( ) function stores the set of filtered trace event types in *set*, if successful.

ERRORS

These functions shall fail if:

[EINVAL]	The value of the *trid* argument does not correspond to an active trace stream or the value of the argument pointed to by *set* is invalid.
[EINTR]	The operation was interrupted by a signal.

posix_trace_get_status — retrieve the trace statuses (**TRACING**)

SYNOPSIS

TRC
```
#include <trace.h>

int posix_trace_get_status(trace_id_t trid,
    struct posix_trace_status_info *statusinfo);
```

DESCRIPTION

Refer to *posix_trace_get_attr*( ).

NAME

posix_trace_getnext_event, posix_trace_timedgetnext_event, posix_trace_trygetnext_event — retrieve a trace event (**TRACING**)

SYNOPSIS

TRC
```
#include <sys/types.h>
#include <trace.h>
```

```
int posix_trace_getnext_event(trace_id_t trid,
    struct posix_trace_event_info *restrict event,
    void *restrict data, size_t num_bytes,
    size_t *restrict data_len, int *restrict unavailable);
```

TRC TMO
```
int posix_trace_timedgetnext_event(trace_id_t trid,
    struct posix_trace_event_info *restrict event,
    void *restrict data, size_t num_bytes,
    size_t *restrict data_len, int *restrict unavailable,
    const struct timespec *restrict abs_timeout);
```

TRC
```
int posix_trace_trygetnext_event(trace_id_t trid,
    struct posix_trace_event_info *restrict event,
    void *restrict data, size_t num_bytes,
    size_t *restrict data_len, int *restrict unavailable);
```

DESCRIPTION

The *posix_trace_getnext_event*( ) function shall report a recorded trace event either from an active trace stream without log TRL or a pre-recorded trace stream identified by the *trid* argument. The *posix_trace_trygetnext_event*( ) function shall report a recorded trace event from an active trace stream without log identified by the *trid* argument.

The trace event information associated with the recorded trace event shall be copied by the function into the structure pointed to by the argument *event* and the data associated with the trace event shall be copied into the buffer pointed to by the *data* argument.

The *posix_trace_getnext_event*( ) function shall block if the *trid* argument identifies an active trace stream and there is currently no trace event ready to be retrieved. When returning, if a recorded trace event was reported, the variable pointed to by the *unavailable* argument shall be set to zero. Otherwise, the variable pointed to by the *unavailable* argument shall be set to a value different from zero.

TMO The *posix_trace_timedgetnext_event*( ) function shall attempt to get another trace event from an active trace stream without log, as in the *posix_trace_getnext_event*( ) function. However, if no trace event is available from the trace stream, the implied wait shall be terminated when the timeout specified by the argument *abs_timeout* expires, and the function shall return the error [ETIMEDOUT].

The timeout shall expire when the absolute time specified by *abs_timeout* passes, as measured by the clock upon which timeouts are based (that is, when the value of that clock equals or exceeds *abs_timeout*), or if the absolute time specified by *abs_timeout* has already passed at the time of the call.

TMO TMR If the Timers option is supported, the timeout shall be based on the CLOCK_REALTIME clock; if the Timers option is not supported, the timeout shall be based on the system clock as returned by the *time*( ) function. The resolution of the timeout shall be the resolution of the clock on which it is based. The **timespec** data type is defined in the **<time.h>** header.

TMO Under no circumstance shall the function fail with a timeout if a trace event is immediately available from the trace stream. The validity of the *abs_timeout* argument need not be checked if a trace event is immediately available from the trace stream.

The behavior of this function for a pre-recorded trace stream is unspecified.

TRL The *posix_trace_trygetnext_event*( ) function shall not block. This function shall return an error if the *trid* argument identifies a pre-recorded trace stream. If a recorded trace event was reported, the variable pointed to by the *unavailable* argument shall be set to zero. Otherwise, if no trace event was reported, the variable pointed to by the *unavailable* argument shall be set to a value different from zero.

The argument *num_bytes* shall be the size of the buffer pointed to by the *data* argument. The argument *data_len* reports to the application the length in bytes of the data record just transferred. If *num_bytes* is greater than or equal to the size of the data associated with the trace event pointed to by the *event* argument, all the recorded data shall be transferred. In this case, the *truncation-status* member of the trace event structure shall be either POSIX_TRACE_NOT_TRUNCATED, if the trace event data was recorded without truncation while tracing, or POSIX_TRACE_TRUNCATED_RECORD, if the trace event data was truncated when it was recorded. If the *num_bytes* argument is less than the length of recorded trace event data, the data transferred shall be truncated to a length of *num_bytes*, the value stored in the variable pointed to by *data_len* shall be equal to *num_bytes*, and the *truncation-status* member of the *event* structure argument shall be set to POSIX_TRACE_TRUNCATED_READ (see the *posix_trace_event_info*( ) function).

The report of a trace event shall be sequential starting from the oldest recorded trace event. Trace events shall be reported in the order in which they were generated, up to an implementation-defined time resolution that causes the ordering of trace events occurring very close to each other to be unknown. Once reported, a trace event cannot be reported again from an active trace stream. Once a trace event is reported from an active trace stream without log, the trace stream shall make the resources associated with that trace event available to record future generated trace events.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

If successful, these functions store:

- The recorded trace event in the object pointed to by *event*
- The trace event information associated with the recorded trace event in the object pointed to by *data*
- The length of this trace event information in the object pointed to by *data_len*
- The value of zero in the object pointed to by *unavailable*

ERRORS

These functions shall fail if: |

[EINVAL] The trace stream identifier argument *trid* is invalid.

The *posix_trace_getnext_event*( ) and *posix_trace_timedgetnext_event*( ) functions shall fail if: |

[EINTR] The operation was interrupted by a signal, and so the call had no effect.

The *posix_trace_trygetnext_event*( ) function shall fail if: |

[EINVAL] The trace stream identifier argument *trid* does not correspond to an active trace stream.

TMO The *posix_trace_timedgetnext_event*( ) function shall fail if:

[EINVAL]	There is no trace event immediately available from the trace stream, and the *timeout* argument is invalid.
[ETIMEDOUT]	No trace event was available from the trace stream before the specified timeout *timeout* expired.

NAME

posix_trace_open — trace log management (**TRACING**)

SYNOPSIS

TCT TRL

```
#include <trace.h>

int posix_trace_open(int file_desc, trace_id_t *trid);
```

DESCRIPTION

Refer to *posix_trace_close*( ).

NAME

posix_trace_rewind — trace log management (**TRACING**)

SYNOPSIS

TCT TRL

```
#include <trace.h>

int posix_trace_rewind(trace_id_t trid);
```

DESCRIPTION

Refer to *posix_trace_close*( ).

NAME

posix_trace_set_filter — set filter of an initialized trace stream (**TRACING**)

SYNOPSIS

TRC TEF

```
#include <trace.h>

int posix_trace_set_filter(trace_id_t trid,
    const trace_event_set_t *set, int how);
```

DESCRIPTION

Refer to *posix_trace_get_filter*( ).

NAME

posix_trace_shutdown — trace stream shutdown from a process (**TRACING**)

SYNOPSIS

TRC
```
#include <sys/types.h>
#include <trace.h>

int posix_trace_shutdown(trace_id_t trid);
```

DESCRIPTION

Refer to *posix_trace_create*( ).

NAME

posix_trace_start, posix_trace_stop — trace start and stop (**TRACING**)

SYNOPSIS

TRC
```
#include <trace.h>

int posix_trace_start(trace_id_t trid);
int posix_trace_stop (trace_id_t trid);
```

DESCRIPTION

The *posix_trace_start*( ) and *posix_trace_stop*( ) functions, respectively, shall start and stop the trace stream identified by the argument *trid*.

The effect of calling the *posix_trace_start*( ) function shall be recorded in the trace stream as the POSIX_TRACE_START system trace event and the status of the trace stream shall become POSIX_TRACE_RUNNING. If the trace stream is in progress when this function is called, the POSIX_TRACE_START system trace event shall not be recorded and the trace stream shall continue to run. If the trace stream is full, the POSIX_TRACE_START system trace event shall not be recorded and the status of the trace stream shall not be changed.

The effect of calling the *posix_trace_stop*( ) function shall be recorded in the trace stream as the POSIX_TRACE_STOP system trace event and the status of the trace stream shall become POSIX_TRACE_SUSPENDED. If the trace stream is suspended when this function is called, the POSIX_TRACE_STOP system trace event shall not be recorded and the trace stream shall remain suspended. If the trace stream is full, the POSIX_TRACE_STOP system trace event shall not be recorded and the status of the trace stream shall not be changed.

RETURN VALUE

Upon successful completion, these functions shall return a value of zero. Otherwise, they shall return the corresponding error number.

ERRORS

These functions shall fail if:

[EINVAL]	The value of the argument *trid* does not correspond to an active trace stream and thus no trace stream was started or stopped.
[EINTR]	The operation was interrupted by a signal and thus the trace stream was not necessarily started or stopped.

```

DESCRIPTION

Refer to *posix_trace_getnext_event*( ).

NAME

posix_typed_mem_get_info — query typed memory information (**ADVANCED REALTIME**)

SYNOPSIS

TYM

```
#include <sys/mman.h>

int posix_typed_mem_get_info(int fildes,
    struct posix_typed_mem_info *info);

```

DESCRIPTION

The *posix_typed_mem_get_info*( ) function shall return, in the *posix_tmi_length* field of the **posix_typed_mem_info** structure pointed to by *info*, the maximum length which may be successfully allocated by the typed memory object designated by *fildes*. This maximum length shall take into account the flag POSIX_TYPED_MEM_ALLOCATE or POSIX_TYPED_MEM_ALLOCATE_CONTIG specified when the typed memory object represented by *fildes* was opened. The maximum length is dynamic; therefore, the value returned is valid only while the current mapping of the corresponding typed memory pool remains unchanged.

If *fildes* represents a typed memory object opened with neither the POSIX_TYPED_MEM_ALLOCATE flag nor the POSIX_TYPED_MEM_ALLOCATE_CONTIG flag specified, the returned value of *info*->*posix_tmi_length* is unspecified.

The *posix_typed_mem_get_info*( ) function may return additional implementation-defined information in other fields of the **posix_typed_mem_info** structure pointed to by *info*.

If the memory object specified by *fildes* is not a typed memory object, then the behavior of this function is undefined.

RETURN VALUE

Upon successful completion, the *posix_typed_mem_get_info*( ) function shall return zero; otherwise, the corresponding error status value shall be returned.

ERRORS

The *posix_typed_mem_get_info*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid open file descriptor.
[ENODEV]	The *fildes* argument is not connected to a memory object supported by this function.

This function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

An application that needs to allocate a block of typed memory with length dependent upon the amount of memory currently available must either query the typed memory object to obtain the amount available, or repeatedly invoke *mmap*( ) attempting to guess an appropriate length. While the latter method is existing practice with *malloc*( ), it is awkward and imprecise. The *posix_typed_mem_get_info*( ) function allows an application to immediately determine available memory. This is particularly important for typed memory objects that may in some cases be scarce resources. Note that when a typed memory pool is a shared resource, some form of mutual exclusion or synchronization may be required while typed memory is being queried and allocated to prevent race conditions.

The existing *fstat*( ) function is not suitable for this purpose. We realize that implementations may wish to provide other attributes of typed memory objects (for example, alignment requirements, page size, and so on). The *fstat*( ) function returns a structure which is not extensible and, furthermore, contains substantial information that is inappropriate for typed memory objects.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1j-2000.

NAME

posix_typed_mem_open — open a typed memory object (**ADVANCED REALTIME**)

SYNOPSIS

TYM

```
#include <sys/mman.h>

int posix_typed_mem_open(const char *name, int oflag, int tflag);
```

DESCRIPTION

The *posix_typed_mem_open*( ) function shall establish a connection between the typed memory object specified by the string pointed to by *name* and a file descriptor. It shall create an open file description that refers to the typed memory object and a file descriptor that refers to that open file description. The file descriptor is used by other functions to refer to that typed memory object. It is unspecified whether the name appears in the file system and is visible to other functions that take pathnames as arguments. The *name* argument shall conform to the construction rules for a pathname. If *name* begins with the slash character, then processes calling *posix_typed_mem_open*( ) with the same value of *name* shall refer to the same typed memory object. If *name* does not begin with the slash character, the effect is implementation-defined. The interpretation of slash characters other than the leading slash character in *name* is implementation-defined.

Each typed memory object supported in a system shall be identified by a name which specifies not only its associated typed memory pool, but also the path or port by which it is accessed. That is, the same typed memory pool accessed via several different ports shall have several different corresponding names. The binding between names and typed memory objects is established in an implementation-defined manner. Unlike shared memory objects, there is no way within IEEE Std 1003.1-200x for a program to create a typed memory object.

The value of *tflag* shall determine how the typed memory object behaves when subsequently mapped by calls to *mmap*( ). At most, one of the following flags defined in **<sys/mman.h>** may be specified:

POSIX_TYPED_MEM_ALLOCATE
Allocate on *mmap*( ).

POSIX_TYPED_MEM_ALLOCATE_CONTIG
Allocate contiguously on *mmap*( ).

POSIX_TYPED_MEM_MAP_ALLOCATABLE
Map on *mmap*( ), without affecting allocatability.

If *tflag* has the flag POSIX_TYPED_MEM_ALLOCATE specified, any subsequent call to *mmap*( ) using the returned file descriptor shall result in allocation and mapping of typed memory from the specified typed memory pool. The allocated memory may be a contiguous previously unallocated area of the typed memory pool or several non-contiguous previously unallocated areas (mapped to a contiguous portion of the process address space). If *tflag* has the flag POSIX_TYPED_MEM_ALLOCATE_CONTIG specified, any subsequent call to *mmap*( ) using the returned file descriptor shall result in allocation and mapping of a single contiguous previously unallocated area of the typed memory pool (also mapped to a contiguous portion of the process address space). If *tflag* has none of the flags POSIX_TYPED_MEM_ALLOCATE or POSIX_TYPED_MEM_ALLOCATE_CONTIG specified, any subsequent call to *mmap*( ) using the returned file descriptor shall map an application-chosen area from the specified typed memory pool such that this mapped area becomes unavailable for allocation until unmapped by all processes. If *tflag* has the flag POSIX_TYPED_MEM_MAP_ALLOCATABLE specified, any subsequent call to *mmap*( ) using the returned file descriptor shall map an application-chosen area from the specified typed memory pool without an effect on the availability of that area for allocation; that is, mapping such an object leaves each byte of the mapped area unallocated if it was unallocated prior to the mapping or allocated if it was allocated prior to the mapping. The appropriate privilege to specify the POSIX_TYPED_MEM_MAP_ALLOCATABLE flag is implementation-defined.

If successful, *posix_typed_mem_open*( ) shall return a file descriptor for the typed memory object that is the lowest numbered file descriptor not currently open for that process. The open file description is new, and therefore the file descriptor shall not share it with any other processes. It is unspecified whether the file offset is set. The FD_CLOEXEC file descriptor flag associated with the new file descriptor shall be cleared.

The behavior of *msync*( ), *ftruncate*( ), and all file operations other than *mmap*( ), *posix_mem_offset*( ), *posix_typed_mem_get_info*( ), *fstat*( ), *dup*( ), *dup2*( ), and *close*( ), is unspecified when passed a file descriptor connected to a typed memory object by this function.

The file status flags of the open file description shall be set according to the value of *oflag*. Applications shall specify exactly one of the three access mode values described below and defined in the **<fcntl.h>** header, as the value of *oflag*.

O_RDONLY	Open for read access only.
O_WRONLY	Open for write access only.
O_RDWR	Open for read or write access.

RETURN VALUE

Upon successful completion, the *posix_typed_mem_open*( ) function shall return a non-negative integer representing the lowest numbered unused file descriptor. Otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *posix_typed_mem_open*( ) function shall fail if:

[EACCES]	The typed memory object exists and the permissions specified by *oflag* are denied.
[EINTR]	The *posix_typed_mem_open*( ) operation was interrupted by a signal.
[EINVAL]	The flags specified in *tflag* are invalid (more than one of POSIX_TYPED_MEM_ALLOCATE, POSIX_TYPED_MEM_ALLOCATE_CONTIG, or POSIX_TYPED_MEM_MAP_ALLOCATABLE is specified).
[EMFILE]	Too many file descriptors are currently in use by this process.
[ENAMETOOLONG]	The length of the *name* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENFILE]	Too many file descriptors are currently open in the system.
[ENOENT]	The named typed memory object does not exist.
[EPERM]	The caller lacks the appropriate privilege to specify the flag POSIX_TYPED_MEM_MAP_ALLOCATABLE in argument *tflag*.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1j-2000.

NAME

pow, powf, powl — power function

SYNOPSIS

```
#include <math.h>

double pow(double x, double y);
float powf(float x, float y);
long double powl(long double x, long double y);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the value of x raised to the power y, x^y. If x is negative, the application shall ensure that y is an integer value.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the value of x raised to the power y.

MX For finite values of $x < 0$, and finite non-integer values of y, a domain error shall occur and either a NaN (if representable), or an implementation-defined value shall be returned.

If the correct value would cause overflow, a range error shall occur and *pow*( ), *powf*( ), and *powl*( ) shall return HUGE_VAL, HUGE_VALF, and HUGE_VALL, respectively.

If the correct value would cause underflow, and is not representable, a range error may occur,
MX and either 0.0 (if supported), or an implementation-defined value shall be returned.

MX If x or y is a NaN, a NaN shall be returned (unless specified elsewhere in this description).

For any value of y (including NaN), if x is +1, 1.0 shall be returned.

For any value of x (including NaN), if y is ±0, 1.0 shall be returned.

For any odd integer value of $y > 0$, if x is ±0, ±0 shall be returned.

For $y > 0$ and not an odd integer, if x is ±0, +0 shall be returned.

If x is –1, and y is ±Inf, 1.0 shall be returned.

For $|x| < 1$, if y is –Inf, +Inf shall be returned.

For $|x| > 1$, if y is –Inf, +0 shall be returned.

For $|x| < 1$, if y is +Inf, +0 shall be returned.

For $|x| > 1$, if y is +Inf, +Inf shall be returned.

For y an odd integer < 0, if x is –Inf, –0 shall be returned.

For $y < 0$ and not an odd integer, if x is –Inf, +0 shall be returned.

For y an odd integer > 0, if x is –Inf, –Inf shall be returned.

For $y > 0$ and not an odd integer, if x is –Inf, +Inf shall be returned.

For $y < 0$, if x is +Inf, +0 shall be returned.

For $y > 0$, if x is +Inf, +Inf shall be returned.

For y an odd integer < 0, if x is ±0, a pole error shall occur and ±HUGE_VAL, ±HUGE_VALF, and ±HUGE_VALL shall be returned for *pow*( ), *powf*( ), and *powl*( ), respectively.

For $y < 0$ and not an odd integer, if x is ±0, a pole error shall occur and HUGE_VAL, HUGE_VALF, and HUGE_VALL shall be returned for *pow*( ), *powf*( ), and *powl*( ), respectively.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value shall be returned.

ERRORS

These functions shall fail if:

Domain Error	The value of x is negative and y is a finite non-integer. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.
MX Pole Error	The value of x is zero and y is negative. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.
Range Error	The result overflows. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

These functions may fail if:

Range Error	The result underflows. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The *powf*( ) and *powl*( ) functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

IEC 60559:1989 standard floating-point extensions over the ISO/IEC 9899:1999 standard are marked.

NAME

pselect, select — synchronous I/O multiplexing

SYNOPSIS

```
#include <sys/select.h>

int pselect(int nfds, fd_set *restrict readfds,
    fd_set *restrict writefds, fd_set *restrict errorfds,
    const struct timespec *restrict timeout,
    const sigset_t *restrict sigmask);
int select(int nfds, fd_set *restrict readfds,
    fd_set *restrict writefds, fd_set *restrict errorfds,
    struct timeval *restrict timeout);
void FD_CLR(int fd, fd_set *fdset);
int FD_ISSET(int fd, fd_set *fdset);
void FD_SET(int fd, fd_set *fdset);
void FD_ZERO(fd_set *fdset);
```

DESCRIPTION

The *pselect*( ) function shall examine the file descriptor sets whose addresses are passed in the *readfds*, *writefds*, and *errorfds* parameters to see if some of their descriptors are ready for reading, are ready for writing, or have an exceptional condition pending, respectively.

The *select*( ) function shall be equivalent to the *pselect*( ) function, except as follows:

- For the *select*( ) function, the timeout period is given in seconds and microseconds in an argument of type **struct timeval**, whereas for the *pselect*( ) function the timeout period is given in seconds and nanoseconds in an argument of type **struct timespec**.
- The *select*( ) function has no *sigmask* argument; it shall behave as *pselect*( ) does when *sigmask* is a null pointer.
- Upon successful completion, the *select*( ) function may modify the object pointed to by the *timeout* argument.

The *pselect*( ) and *select*( ) functions shall support regular files, terminal and pseudo-terminal devices, XSR STREAMS-based files, FIFOs, pipes, and sockets. The behavior of *pselect*( ) and *select*( ) on file descriptors that refer to other types of file is unspecified.

The *nfds* argument specifies the range of descriptors to be tested. The first *nfds* descriptors shall be checked in each set; that is, the descriptors from zero through *nfds*−1 in the descriptor sets shall be examined.

If the *readfds* argument is not a null pointer, it points to an object of type **fd_set** that on input specifies the file descriptors to be checked for being ready to read, and on output indicates which file descriptors are ready to read.

If the *writefds* argument is not a null pointer, it points to an object of type **fd_set** that on input specifies the file descriptors to be checked for being ready to write, and on output indicates which file descriptors are ready to write.

If the *errorfds* argument is not a null pointer, it points to an object of type **fd_set** that on input specifies the file descriptors to be checked for error conditions pending, and on output indicates which file descriptors have error conditions pending.

Upon successful completion, the *pselect*( ) or *select*( ) function shall modify the objects pointed to by the *readfds*, *writefds*, and *errorfds* arguments to indicate which file descriptors are ready for reading, ready for writing, or have an error condition pending, respectively, and shall return the total number of ready descriptors in all the output sets. For each file descriptor less than *nfds*, the corresponding bit shall be set on successful completion if it was set on input and the associated condition is true for that file descriptor.

If none of the selected descriptors are ready for the requested operation, the *pselect*( ) or *select*( ) function shall block until at least one of the requested operations becomes ready, until the *timeout* occurs, or until interrupted by a signal. The *timeout* parameter controls how long the *pselect*( ) or *select*( ) function shall take before timing out. If the *timeout* parameter is not a null pointer, it specifies a maximum interval to wait for the selection to complete. If the specified time interval expires without any requested operation becoming ready, the function shall return. If the *timeout* parameter is a null pointer, then the call to *pselect*( ) or *select*( ) shall block indefinitely until at least one descriptor meets the specified criteria. To effect a poll, the *timeout* parameter should not be a null pointer, and should point to a zero-valued **timespec** structure.

The use of a timeout does not affect any pending timers set up by *alarm*( ), *ualarm*( ), or *setitimer*( ).

Implementations may place limitations on the maximum timeout interval supported. All implementations shall support a maximum timeout interval of at least 31 days. If the *timeout* argument specifies a timeout interval greater than the implementation-defined maximum value, the maximum value shall be used as the actual timeout value. Implementations may also place limitations on the granularity of timeout intervals. If the requested timeout interval requires a finer granularity than the implementation supports, the actual timeout interval shall be rounded up to the next supported value.

If *sigmask* is not a null pointer, then the *pselect*( ) function shall replace the signal mask of the process by the set of signals pointed to by *sigmask* before examining the descriptors, and shall restore the signal mask of the process before returning.

A descriptor shall be considered ready for reading when a call to an input function with O_NONBLOCK clear would not block, whether or not the function would transfer data successfully. (The function might return data, an end-of-file indication, or an error other than one indicating that it is blocked, and in each of these cases the descriptor shall be considered ready for reading.)

A descriptor shall be considered ready for writing when a call to an output function with O_NONBLOCK clear would not block, whether or not the function would transfer data successfully.

If a socket has a pending error, it shall be considered to have an exceptional condition pending. Otherwise, what constitutes an exceptional condition is file type-specific. For a file descriptor for use with a socket, it is protocol-specific except as noted below. For other file types it is implementation-defined. If the operation is meaningless for a particular file type, *pselect*( ) or *select*( ) shall indicate that the descriptor is ready for read or write operations, and shall indicate that the descriptor has no exceptional condition pending.

If a descriptor refers to a socket, the implied input function is the *recvmsg*( ) function with parameters requesting normal and ancillary data, such that the presence of either type shall cause the socket to be marked as readable. The presence of out-of-band data shall be checked if the socket option SO_OOBINLINE has been enabled, as out-of-band data is enqueued with normal data. If the socket is currently listening, then it shall be marked as readable if an incoming connection request has been received, and a call to the *accept*( ) function shall complete without blocking.

If a descriptor refers to a socket, the implied output function is the *sendmsg*( ) function supplying an amount of normal data equal to the current value of the SO_SNDLOWAT option for the socket. If a non-blocking call to the *connect*( ) function has been made for a socket, and the connection attempt has either succeeded or failed leaving a pending error, the socket shall be marked as writable.

A socket shall be considered to have an exceptional condition pending if a receive operation with O_NONBLOCK clear for the open file description and with the MSG_OOB flag set would return out-of-band data without blocking. (It is protocol-specific whether the MSG_OOB flag would be used to read out-of-band data.) A socket shall also be considered to have an exceptional condition pending if an out-of-band data mark is present in the receive queue. Other circumstances under which a socket may be considered to have an exceptional condition pending are protocol-specific and implementation-defined.

If the *readfds*, *writefds*, and *errorfds* arguments are all null pointers and the *timeout* argument is not a null pointer, the *pselect*( ) or *select*( ) function shall block for the time specified, or until interrupted by a signal. If the *readfds*, *writefds*, and *errorfds* arguments are all null pointers and the *timeout* argument is a null pointer, the *pselect*( ) or *select*( ) function shall block until interrupted by a signal.

File descriptors associated with regular files shall always select true for ready to read, ready to write, and error conditions.

On failure, the objects pointed to by the *readfds*, *writefds*, and *errorfds* arguments shall not be modified. If the timeout interval expires without the specified condition being true for any of the specified file descriptors, the objects pointed to by the *readfds*, *writefds*, and *errorfds* arguments shall have all bits set to 0.

File descriptor masks of type **fd_set** can be initialized and tested with *FD_CLR*( ), *FD_ISSET*( ), *FD_SET*( ), and *FD_ZERO*( ). It is unspecified whether each of these is a macro or a function. If a macro definition is suppressed in order to access an actual function, or a program defines an external identifier with any of these names, the behavior is undefined.

FD_CLR(*fd*, *fdsetp*) shall remove the file descriptor *fd* from the set pointed to by *fdsetp*. If *fd* is not a member of this set, there shall be no effect on the set, nor will an error be returned.

FD_ISSET(*fd*, *fdsetp*) shall evaluate to non-zero if the file descriptor *fd* is a member of the set pointed to by *fdsetp*, and shall evaluate to zero otherwise.

FD_SET(*fd*, *fdsetp*) shall add the file descriptor *fd* to the set pointed to by *fdsetp*. If the file descriptor *fd* is already in this set, there shall be no effect on the set, nor will an error be returned.

FD_ZERO(*fdsetp*) shall initialize the descriptor set pointed to by *fdsetp* to the null set. No error is returned if the set is not empty at the time *FD_ZERO*( ) is invoked.

The behavior of these macros is undefined if the *fd* argument is less than 0 or greater than or equal to FD_SETSIZE, or if *fd* is not a valid file descriptor, or if any of the arguments are expressions with side effects.

RETURN VALUE

Upon successful completion, the *pselect*( ) and *select*( ) functions shall return the total number of bits set in the bit masks. Otherwise, −1 shall be returned, and shall set *errno* to indicate the error.

FD_CLR( ), *FD_SET*( ), and *FD_ZERO*( ) not return a value. *FD_ISSET*( ) shall return a non-zero value if the bit for the file descriptor *fd* is set in the file descriptor set pointed to by *fdset*, and 0 otherwise.

ERRORS

Under the following conditions, *pselect*( ) and *select*( ) shall fail and set *errno* to:

[EBADF]	One or more of the file descriptor sets specified a file descriptor that is not a valid open file descriptor.

	[EINTR]	The function was interrupted before any of the selected events occurred and before the timeout interval expired.
XSI		If SA_RESTART has been set for the interrupting signal, it is implementation-defined whether the function restarts or returns with [EINTR].
	[EINVAL]	An invalid timeout interval was specified.
	[EINVAL]	The *nfds* argument is less than 0 or greater than FD_SETSIZE.
XSR	[EINVAL]	One of the specified file descriptors refers to a STREAM or multiplexer that is linked (directly or indirectly) downstream from a multiplexer.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

In previous versions of the Single UNIX Specification, the *select*( ) function was defined in the **<sys/time.h>** header. This is now changed to **<sys/select.h>**. The rationale for this change was as follows: the introduction of the *pselect*( ) function included the **<sys/select.h>** header and the **<sys/select.h>** header defines all the related definitions for the *pselect*( ) and *select*( ) functions. Backwards-compatibility to existing XSI implementations is handled by allowing **<sys/time.h>** to include **<sys/select.h>**.

FUTURE DIRECTIONS

None.

SEE ALSO

accept( ), *alarm*( ), *connect*( ), *fcntl*( ), *poll*( ), *read*( ), *recvmsg*( ), *sendmsg*( ), *setitimer*( ), *ualarm*( ), *write*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/select.h>**, **<sys/time.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

In the ERRORS section, the text has been changed to indicate that [EINVAL] is returned when *nfds* is less than 0 or greater than FD_SETSIZE. It previously stated less than 0, or greater than or equal to FD_SETSIZE.

Text about *timeout* is moved from the APPLICATION USAGE section to the DESCRIPTION.

Issue 6

The Open Group Corrigendum U026/6 is applied, changing the occurrences of *readfs* and *writefs* in the *select*( ) DESCRIPTION to be *readfds* and *writefds*.

Text referring to sockets is added to the DESCRIPTION.

The DESCRIPTION and ERRORS sections are updated so that references to STREAMS are marked as part of the XSI STREAMS Option Group.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- These functions are now mandatory.

The *pselect*( ) function is added for alignment with IEEE Std 1003.1g-2000 and additional detail related to sockets semantics is added to the DESCRIPTION.

The *select*( ) function now requires inclusion of **<sys/select.h>**.

The **restrict** keyword is added to the *select*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

pthread_atfork — register fork handlers

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_atfork(void (*prepare)(void), void (*parent)(void),
    void (*child)(void));
```

DESCRIPTION

The *pthread_atfork*( ) function shall declare fork handlers to be called before and after *fork*( ), in the context of the thread that called *fork*( ). The *prepare* fork handler shall be called before *fork*( ) processing commences. The *parent* fork handle shall be called after *fork*( ) processing completes in the parent process. The *child* fork handler shall be called after *fork*( ) processing completes in the child process. If no handling is desired at one or more of these three points, the corresponding fork handler address(es) may be set to NULL.

The order of calls to *pthread_atfork*( ) is significant. The *parent* and *child* fork handlers shall be called in the order in which they were established by calls to *pthread_atfork*( ). The *prepare* fork handlers shall be called in the opposite order.

RETURN VALUE

Upon successful completion, *pthread_atfork*( ) shall return a value of zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_atfork*( ) function shall fail if:

[ENOMEM]	Insufficient table space exists to record the fork handler addresses.

The *pthread_atfork*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

There are at least two serious problems with the semantics of *fork*( ) in a multi-threaded program. One problem has to do with state (for example, memory) covered by mutexes. Consider the case where one thread has a mutex locked and the state covered by that mutex is inconsistent while another thread calls *fork*( ). In the child, the mutex is in the locked state (locked by a nonexistent thread and thus can never be unlocked). Having the child simply reinitialize the mutex is unsatisfactory since this approach does not resolve the question about how to correct or otherwise deal with the inconsistent state in the child.

It is suggested that programs that use *fork*( ) call an *exec* function very soon afterwards in the child process, thus resetting all states. In the meantime, only a short list of async-signal-safe library routines are promised to be available.

Unfortunately, this solution does not address the needs of multi-threaded libraries. Application programs may not be aware that a multi-threaded library is in use, and they feel free to call any number of library routines between the *fork*( ) and *exec* calls, just as they always have. Indeed, they may be extant single-threaded programs and cannot, therefore, be expected to obey new restrictions imposed by the threads library.

On the other hand, the multi-threaded library needs a way to protect its internal state during *fork*( ) in case it is re-entered later in the child process. The problem arises especially in multi-threaded I/O libraries, which are almost sure to be invoked between the *fork*( ) and *exec* calls to effect I/O redirection. The solution may require locking mutex variables during *fork*( ), or it may entail simply resetting the state in the child after the *fork*( ) processing completes.

The *pthread_atfork*( ) function provides multi-threaded libraries with a means to protect themselves from innocent application programs that call *fork*( ), and it provides multi-threaded application programs with a standard mechanism for protecting themselves from *fork*( ) calls in a library routine or the application itself.

The expected usage is that the *prepare* handler acquires all mutex locks and the other two fork handlers release them.

For example, an application can supply a *prepare* routine that acquires the necessary mutexes the library maintains and supply *child* and *parent* routines that release those mutexes, thus ensuring that the child gets a consistent snapshot of the state of the library (and that no mutexes are left stranded). Alternatively, some libraries might be able to supply just a *child* routine that reinitializes the mutexes in the library and all associated states to some known value (for example, what it was when the image was originally executed).

When *fork*( ) is called, only the calling thread is duplicated in the child process. Synchronization variables remain in the same state in the child as they were in the parent at the time *fork*( ) was called. Thus, for example, mutex locks may be held by threads that no longer exist in the child process, and any associated states may be inconsistent. The parent process may avoid this by explicit code that acquires and releases locks critical to the child via *pthread_atfork*( ). In addition, any critical threads need to be recreated and reinitialized to the proper state in the child (also via *pthread_atfork*( )).

A higher-level package may acquire locks on its own data structures before invoking lower-level packages. Under this scenario, the order specified for fork handler calls allows a simple rule of initialization for avoiding package deadlock: a package initializes all packages on which it depends before it calls the *pthread_atfork*( ) function for itself.

FUTURE DIRECTIONS

None.

atexit( ), *fork*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/types.h>**

CHANGE HISTORY

First released in Issue 5. Derived from the POSIX Threads Extension.

IEEE PASC Interpretation 1003.1c #4 is applied.

Issue 6

The *pthread_atfork*( ) function is marked as part of the Threads option.

The **<pthread.h>** header is added to the SYNOPSIS.

NAME

pthread_attr_destroy, pthread_attr_init — destroy and initialize threads attributes object

SYNOPSIS

THR
```
#include <pthread.h>

int pthread_attr_destroy(pthread_attr_t *attr);
int pthread_attr_init(pthread_attr_t *attr);

```

DESCRIPTION

The *pthread_attr_destroy*( ) function shall destroy a thread attributes object. An implementation may cause *pthread_attr_destroy*( ) to set *attr* to an implementation-defined invalid value. A destroyed *attr* attributes object can be reinitialized using *pthread_attr_init*( ); the results of otherwise referencing the object after it has been destroyed are undefined.

The *pthread_attr_init*( ) function shall initialize a thread attributes object *attr* with the default value for all of the individual attributes used by a given implementation.

The resulting attributes object (possibly modified by setting individual attribute values), when used by *pthread_create*( ) defines the attributes of the thread created. A single attributes object can be used in multiple simultaneous calls to *pthread_create*( ). Results are undefined if *pthread_attr_init*( ) is called specifying an already initialized *attr* attributes object.

RETURN VALUE

Upon successful completion, *pthread_attr_destroy*( ) and *pthread_attr_init*( ) shall return a value of 0; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_attr_init*( ) function shall fail if:

[ENOMEM] Insufficient memory exists to initialize the thread attributes object.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Attributes objects are provided for threads, mutexes, and condition variables as a mechanism to support probable future standardization in these areas without requiring that the function itself be changed.

Attributes objects provide clean isolation of the configurable aspects of threads. For example, ‘‘stack size’’ is an important attribute of a thread, but it cannot be expressed portably. When porting a threaded program, stack sizes often need to be adjusted. The use of attributes objects can help by allowing the changes to be isolated in a single place, rather than being spread across every instance of thread creation.

Attributes objects can be used to set up ‘‘classes’ of threads with similar attributes; for example, ‘‘threads with large stacks and high priority’’ or ‘‘threads with minimal stacks’’. These classes can be defined in a single place and then referenced wherever threads need to be created. Changes to ‘‘class’’ decisions become straightforward, and detailed analysis of each *pthread_create*( ) call is not required.

The attributes objects are defined as opaque types as an aid to extensibility. If these objects had been specified as structures, adding new attributes would force recompilation of all multi-threaded programs when the attributes objects are extended; this might not be possible if different program components were supplied by different vendors.

Additionally, opaque attributes objects present opportunities for improving performance. Argument validity can be checked once when attributes are set, rather than each time a thread is created. Implementations often need to cache kernel objects that are expensive to create. Opaque attributes objects provide an efficient mechanism to detect when cached objects become invalid due to attribute changes.

Since assignment is not necessarily defined on a given opaque type, implementation-defined default values cannot be defined in a portable way. The solution to this problem is to allow attributes objects to be initialized dynamically by attributes object initialization functions, so that default values can be supplied automatically by the implementation.

The following proposal was provided as a suggested alternative to the supplied attributes:

1. Maintain the style of passing a parameter formed by the bitwise-inclusive OR of flags to the initialization routines (*pthread_create*( ), *pthread_mutex_init*( ), *pthread_cond_init*( )). The parameter containing the flags should be an opaque type for extensibility. If no flags are set in the parameter, then the objects are created with default characteristics. An implementation may specify implementation-defined flag values and associated behavior.
2. If further specialization of mutexes and condition variables is necessary, implementations may specify additional procedures that operate on the **pthread_mutex_t** and **pthread_cond_t** objects (instead of on attributes objects).

The difficulties with this solution are:

1. A bitmask is not opaque if bits have to be set into bitvector attributes objects using explicitly-coded bitwise-inclusive OR operations. If the set of options exceeds an **int**, application programmers need to know the location of each bit. If bits are set or read by encapsulation (that is, get and set functions), then the bitmask is merely an implementation of attributes objects as currently defined and should not be exposed to the programmer.
2. Many attributes are not Boolean or very small integral values. For example, scheduling policy may be placed in 3-bit or 4-bit, but priority requires 5-bit or more, thereby taking up at least 8 bits out of a possible 16 bits on machines with 16-bit integers. Because of this, the bitmask can only reasonably control whether particular attributes are set or not, and it cannot serve as the repository of the value itself. The value needs to be specified as a function parameter (which is non-extensible), or by setting a structure field (which is non-opaque), or by get and set functions (making the bitmask a redundant addition to the attributes objects).

Stack size is defined as an optional attribute because the very notion of a stack is inherently machine-dependent. Some implementations may not be able to change the size of the stack, for example, and others may not need to because stack pages may be discontiguous and can be allocated and released on demand.

The attribute mechanism has been designed in large measure for extensibility. Future extensions to the attribute mechanism or to any attributes object defined in this volume of IEEE Std 1003.1-200x has to be done with care so as not to affect binary-compatibility.

Attributes objects, even if allocated by means of dynamic allocation functions such as *malloc*( ), may have their size fixed at compile time. This means, for example, a *pthread_create*( ) in an implementation with extensions to the **pthread_attr_t** cannot look beyond the area that the binary application assumes is valid. This suggests that implementations should maintain a size field in the attributes object, as well as possibly version information, if extensions in different directions (possibly by different vendors) are to be accommodated.

FUTURE DIRECTIONS

None.

SEE ALSO

pthread_attr_getstackaddr( ), *pthread_attr_getstacksize*( ), *pthread_attr_getdetachstate*( ), *pthread_create*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_attr_destroy*( ) and *pthread_attr_init*( ) functions marked as part of the Threads option.

IEEE PASC Interpretation 1003.1 #107 is applied, noting that the effect of initializing an already initialized thread attributes object is undefined.

NAME

pthread_attr_getdetachstate, pthread_attr_setdetachstate — get and set detachstate attribute

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_attr_getdetachstate(const pthread_attr_t *attr,
    int *detachstate);
int pthread_attr_setdetachstate(pthread_attr_t *attr, int detachstate);
```

DESCRIPTION

The *detachstate* attribute controls whether the thread is created in a detached state. If the thread is created detached, then use of the ID of the newly created thread by the *pthread_detach*( ) or *pthread_join*( ) function is an error.

The *pthread_attr_getdetachstate*( ) and *pthread_attr_setdetachstate*( ) functions, respectively, shall get and set the *detachstate* attribute in the *attr* object.

For *pthread_attr_getdetachstate*( ), *detachstate* shall be set to either PTHREAD_CREATE_DETACHED or PTHREAD_CREATE_JOINABLE.

For *pthread_attr_setdetachstate*( ), the application shall set *detachstate* to either PTHREAD_CREATE_DETACHED or PTHREAD_CREATE_JOINABLE.

A value of PTHREAD_CREATE_DETACHED shall cause all threads created with *attr* to be in the detached state, whereas using a value of PTHREAD_CREATE_JOINABLE shall cause all threads created with *attr* to be in the joinable state. The default value of the *detachstate* attribute shall be PTHREAD_CREATE_JOINABLE.

RETURN VALUE

Upon successful completion, *pthread_attr_getdetachstate*( ) and *pthread_attr_setdetachstate*( ) shall return a value of 0; otherwise, an error number shall be returned to indicate the error.

The *pthread_attr_getdetachstate*( ) function stores the value of the *detachstate* attribute in *detachstate* if successful.

ERRORS

The *pthread_attr_setdetachstate*( ) function shall fail if:

[EINVAL] The value of *detachstate* was not valid

These functions shall not return an error code of [EINTR].

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_attr_setdetachstate*( ) and *pthread_attr_getdetachstate*( ) functions are marked as part of the Threads option.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

pthread_attr_getguardsize, pthread_attr_setguardsize — get and set the thread guardsize attribute

SYNOPSIS

XSI

```
#include <pthread.h>

int pthread_attr_getguardsize(const pthread_attr_t *restrict attr,
    size_t *restrict guardsize);
int pthread_attr_setguardsize(pthread_attr_t *attr,
    size_t guardsize);
```

DESCRIPTION

The *pthread_attr_getguardsize*( ) function shall get the *guardsize* attribute in the *attr* object. This attribute shall be returned in the *guardsize* parameter.

The *pthread_attr_setguardsize*( ) function shall set the *guardsize* attribute in the *attr* object. The new value of this attribute shall be obtained from the *guardsize* parameter. If *guardsize* is zero, a guard area shall not be provided for threads created with *attr*. If *guardsize* is greater than zero, a guard area of at least size *guardsize* bytes shall be provided for each thread created with *attr*.

The *guardsize* attribute controls the size of the guard area for the created thread's stack. The *guardsize* attribute provides protection against overflow of the stack pointer. If a thread's stack is created with guard protection, the implementation allocates extra memory at the overflow end of the stack as a buffer against stack overflow of the stack pointer. If an application overflows into this buffer an error shall result (possibly in a SIGSEGV signal being delivered to the thread).

A conforming implementation may round up the value contained in *guardsize* to a multiple of the configurable system variable {PAGESIZE} (see **<sys/mman.h>**). If an implementation rounds up the value of *guardsize* to a multiple of {PAGESIZE}, a call to *pthread_attr_getguardsize*( ) specifying *attr* shall store in the *guardsize* parameter the guard size specified by the previous *pthread_attr_setguardsize*( ) function call.

The default value of the *guardsize* attribute is {PAGESIZE} bytes. The actual value of {PAGESIZE} is implementation-defined.

If the *stackaddr* or *stack* attribute has been set (that is, the caller is allocating and managing its own thread stacks), the *guardsize* attribute shall be ignored and no protection shall be provided by the implementation. It is the responsibility of the application to manage stack overflow along with stack allocation and management in this case.

RETURN VALUE

If successful, the *pthread_attr_getguardsize*( ) and *pthread_attr_setguardsize*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_attr_getguardsize*( ) and *pthread_attr_setguardsize*( ) functions shall fail if:

[EINVAL]	The attribute *attr* is invalid.
[EINVAL]	The parameter *guardsize* is invalid.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The *guardsize* attribute is provided to the application for two reasons:

1. Overflow protection can potentially result in wasted system resources. An application that creates a large number of threads, and which knows its threads never overflow their stack, can save system resources by turning off guard areas.
2. When threads allocate large data structures on the stack, large guard areas may be needed to detect stack overflow.

FUTURE DIRECTIONS

None.

SEE ALSO

The Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**, **<sys/mman.h>**

CHANGE HISTORY

First released in Issue 5.

Issue 6

In the ERRORS section, a third [EINVAL] error condition is removed as it is covered by the second error condition.

The **restrict** keyword is added to the *pthread_attr_getguardsize*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

pthread_attr_getinheritsched, pthread_attr_setinheritsched — get and set inheritsched attribute (**REALTIME THREADS**)

SYNOPSIS

THR TPS

```
#include <pthread.h>

int pthread_attr_getinheritsched(const pthread_attr_t *restrict attr,
    int *restrict inheritsched);
int pthread_attr_setinheritsched(pthread_attr_t *attr,
    int inheritsched);
```

DESCRIPTION

The *pthread_attr_getinheritsched*( ), and *pthread_attr_setinheritsched*( ) functions, respectively, shall get and set the *inheritsched* attribute in the *attr* argument.

When the attributes objects are used by *pthread_create*( ), the *inheritsched* attribute determines how the other scheduling attributes of the created thread shall be set.

PTHREAD_INHERIT_SCHED
: Specifies that the thread scheduling attributes shall be inherited from the creating thread, and the scheduling attributes in this *attr* argument shall be ignored.

PTHREAD_EXPLICIT_SCHED
: Specifies that the thread scheduling attributes shall be set to the corresponding values from this attributes object.

The symbols PTHREAD_INHERIT_SCHED and PTHREAD_EXPLICIT_SCHED are defined in the **<pthread.h>** header.

The following ‘‘thread scheduling attributes’’ defined by IEEE Std 1003.1-200x are affected by the *inheritsched* attribute: scheduling policy (*schedpolicy*), scheduling parameters (*schedparam*), and scheduling contention scope (*contentionscope*).

RETURN VALUE

If successful, the *pthread_attr_getinheritsched*( ) and *pthread_attr_setinheritsched*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_attr_setinheritsched*( ) function may fail if:

[EINVAL]	The value of *inheritsched* is not valid.
[ENOTSUP]	An attempt was made to set the attribute to an unsupported value.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

After these attributes have been set, a thread can be created with the specified attributes using *pthread_create*( ). Using these routines does not affect the current running thread.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

pthread_attr_destroy( ), *pthread_attr_getscope*( ), *pthread_attr_getschedpolicy*( ), *pthread_attr_getschedparam*( ), *pthread_create*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**, **<sched.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Marked as part of the Realtime Threads Feature Group.

Issue 6

The *pthread_attr_getinheritsched*( ) and *pthread_attr_setinheritsched*( ) functions are marked as part of the Threads and Thread Execution Scheduling options.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Thread Execution Scheduling option.

The **restrict** keyword is added to the *pthread_attr_getinheritsched*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

pthread_attr_getschedparam, pthread_attr_setschedparam — get and set schedparam attribute

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_attr_getschedparam(const pthread_attr_t *restrict attr,
    struct sched_param *restrict param);
int pthread_attr_setschedparam(pthread_attr_t *restrict attr,
    const struct sched_param *restrict param);
```

DESCRIPTION

The *pthread_attr_getschedparam*( ), and *pthread_attr_setschedparam*( ) functions, respectively, shall get and set the scheduling parameter attributes in the *attr* argument. The contents of the *param* structure are defined in the **<sched.h>** header. For the SCHED_FIFO and SCHED_RR policies, the only required member of *param* is *sched_priority*. |

TSP For the SCHED_SPORADIC policy, the required members of the *param* structure are *sched_priority*, *sched_ss_low_priority*, *sched_ss_repl_period*, *sched_ss_init_budget*, and *sched_ss_max_repl*. The specified *sched_ss_repl_period* must be greater than or equal to the specified *sched_ss_init_budget* for the function to succeed; if it is not, then the function shall fail. The value of *sched_ss_max_repl* shall be within the inclusive range [1,{SS_REPL_MAX}] for the function to succeed; if not, the function shall fail.

RETURN VALUE

If successful, the *pthread_attr_getschedparam*( ) and *pthread_attr_setschedparam*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_attr_setschedparam*( ) function may fail if:

[EINVAL]	The value of *param* is not valid.
[ENOTSUP]	An attempt was made to set the attribute to an unsupported value.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

After these attributes have been set, a thread can be created with the specified attributes using *pthread_create*( ). Using these routines does not affect the current running thread.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_attr_getschedparam*( ) and *pthread_attr_setschedparam*( ) functions are marked as part of the Threads option.

The SCHED_SPORADIC scheduling policy is added for alignment with IEEE Std 1003.1d-1999.

The **restrict** keyword is added to the *pthread_attr_getschedparam*( ) and *pthread_attr_setschedparam*( ) prototypes for alignment with the ISO/IEC 9899: 1999 standard.

NAME

pthread_attr_getschedpolicy, pthread_attr_setschedpolicy — get and set schedpolicy attribute (**REALTIME THREADS**)

SYNOPSIS

THR TPS
```
#include <pthread.h>

int pthread_attr_getschedpolicy(const pthread_attr_t *restrict attr,
    int *restrict policy);
int pthread_attr_setschedpolicy(pthread_attr_t *attr, int policy);

```

DESCRIPTION

The *pthread_attr_getschedpolicy*( ) and *pthread_attr_setschedpolicy*( ) functions, respectively, shall get and set the *schedpolicy* attribute in the *attr* argument.

The supported values of *policy* shall include SCHED_FIFO, SCHED_RR, and SCHED_OTHER, which are defined in the **<sched.h>** header. When threads executing with the scheduling policy SCHED_FIFO, SCHED_RR, TSP or SCHED_SPORADIC are waiting on a mutex, they shall acquire the mutex in priority order when the mutex is unlocked. |

RETURN VALUE

If successful, the *pthread_attr_getschedpolicy*( ) and *pthread_attr_setschedpolicy*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_attr_setschedpolicy*( ) function may fail if:

[EINVAL]	The value of *policy* is not valid.
[ENOTSUP]	An attempt was made to set the attribute to an unsupported value.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

After these attributes have been set, a thread can be created with the specified attributes using *pthread_create*( ). Using these routines does not affect the current running thread.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Marked as part of the Realtime Threads Feature Group.

Issue 6

The *pthread_attr_getschedpolicy*( ) and *pthread_attr_setschedpolicy*( ) functions are marked as part of the Threads and Thread Execution Scheduling options.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Thread Execution Scheduling option.

The SCHED_SPORADIC scheduling policy is added for alignment with IEEE Std 1003.1d-1999.

The **restrict** keyword is added to the *pthread_attr_getschedpolicy*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

pthread_attr_getscope, pthread_attr_setscope — get and set contentionscope attribute (**REALTIME THREADS**)

SYNOPSIS

THR TPS

```
#include <pthread.h>

int pthread_attr_getscope(const pthread_attr_t *restrict attr,
    int *restrict contentionscope);
int pthread_attr_setscope(pthread_attr_t *attr, int contentionscope);
```

DESCRIPTION

The *pthread_attr_getscope*( ) and *pthread_attr_setscope*( ) functions, respectively, shall get and set the *contentionscope* attribute in the *attr* object.

The *contentionscope* attribute may have the values PTHREAD_SCOPE_SYSTEM, signifying system scheduling contention scope, or PTHREAD_SCOPE_PROCESS, signifying process scheduling contention scope. The symbols PTHREAD_SCOPE_SYSTEM and PTHREAD_SCOPE_PROCESS are defined in the **<pthread.h>** header.

RETURN VALUE

If successful, the *pthread_attr_getscope*( ) and *pthread_attr_setscope*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_attr_setscope*( ) function may fail if:

[EINVAL]	The value of *contentionscope* is not valid.
[ENOTSUP]	An attempt was made to set the attribute to an unsupported value.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

After these attributes have been set, a thread can be created with the specified attributes using *pthread_create*( ). Using these routines does not affect the current running thread.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Marked as part of the Realtime Threads Feature Group.

Issue 6

The *pthread_attr_getscope*( ) and *pthread_attr_setscope*( ) functions are marked as part of the Threads and Thread Execution Scheduling options.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Thread Execution Scheduling option.

The **restrict** keyword is added to the *pthread_attr_getscope*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

pthread_attr_getstack, pthread_attr_setstack — get and set stack attributes

SYNOPSIS

THR

```
#include <pthread.h>
```

TSA TSS

```
int pthread_attr_getstack(const pthread_attr_t *restrict attr,
    void **restrict stackaddr, size_t *restrict stacksize);
int pthread_attr_setstack(pthread_attr_t *attr, void *stackaddr,
    size_t stacksize);
```

DESCRIPTION

The *pthread_attr_getstack*( ) and *pthread_attr_setstack*( ) functions, respectively, shall get and set the thread creation stack attributes *stackaddr* and *stacksize* in the *attr* object.

The stack attributes specify the area of storage to be used for the created thread's stack. The base (lowest addressable byte) of the storage shall be *stackaddr*, and the size of the storage shall be *stacksize* bytes. The *stacksize* shall be at least {PTHREAD_STACK_MIN}. The *stackaddr* shall be aligned appropriately to be used as a stack; for example, *pthread_attr_setstack*( ) may fail with [EINVAL] if (*stackaddr* & 0x7) is not 0. All pages within the stack described by *stackaddr* and *stacksize* shall be both readable and writable by the thread.

RETURN VALUE

Upon successful completion, these functions shall return a value of 0; otherwise, an error number shall be returned to indicate the error.

The *pthread_attr_getstack*( ) function shall store the stack attribute values in *stackaddr* and *stacksize* if successful.

ERRORS

The *pthread_attr_setstack*( ) function shall fail if:

[EINVAL] The value of *stacksize* is less than {PTHREAD_STACK_MIN} or exceeds an implementation-defined limit.

The *pthread_attr_setstack*( ) function may fail if:

[EINVAL] The value of *stackaddr* does not have proper alignment to be used as a stack, or if (*stackaddr* + *stacksize*) lacks proper alignment.

[EACCES] The stack page(s) described by *stackaddr* and *stacksize* are not both readable and writable by the thread.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

These functions are appropriate for use by applications in an environment where the stack for a thread must be placed in some particular region of memory.

While it might seem that an application could detect stack overflow by providing a protected page outside the specified stack region, this cannot be done portably. Implementations are free to place the thread's initial stack pointer anywhere within the specified region to accommodate the machine's stack pointer behavior and allocation requirements. Furthermore, on some architectures, such as the IA-64, ''overflow'' might mean that two separate stack pointers allocated within the region will overlap somewhere in the middle of the region.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Developed as an XSI extension and brought into the BASE by IEEE PASC Interpretation 1003.1 #101.

NAME

pthread_attr_getstackaddr, pthread_attr_setstackaddr — get and set stackaddr attribute

SYNOPSIS

THR TSA

```
#include <pthread.h>
```

OB

```
int pthread_attr_getstackaddr(const pthread_attr_t *restrict attr,
    void **restrict stackaddr);
int pthread_attr_setstackaddr(pthread_attr_t *attr, void *stackaddr);
```

DESCRIPTION

The *pthread_attr_getstackaddr*( ) and *pthread_attr_setstackaddr*( ) functions, respectively, shall get and set the thread creation *stackaddr* attribute in the *attr* object.

The *stackaddr* attribute specifies the location of storage to be used for the created thread's stack. The size of the storage shall be at least {PTHREAD_STACK_MIN}.

RETURN VALUE

Upon successful completion, *pthread_attr_getstackaddr*( ) and *pthread_attr_setstackaddr*( ) shall return a value of 0; otherwise, an error number shall be returned to indicate the error.

The *pthread_attr_getstackaddr*( ) function stores the *stackaddr* attribute value in *stackaddr* if successful.

ERRORS

No errors are defined.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

The specification of the *stackaddr* attribute presents several ambiguities that make portable use of these interfaces impossible. The description of the single address parameter as a ''stack'' does not specify a particular relationship between the address and the ''stack'' implied by that address. For example, the address may be taken as the low memory address of a buffer intended for use as a stack, or it may be taken as the address to be used as the initial stack pointer register value for the new thread. These two are not the same except for a machine on which the stack grows ''up'' from low memory to high, and on which a ''push'' operation first stores the value in memory and then increments the stack pointer register. Further, on a machine where the stack grows ''down'' from high memory to low, interpretation of the address as the ''low memory'' address requires a determination of the intended size of the stack. IEEE Std 1003.1-200x has introduced the new interfaces *pthread_attr_setstack*( ) and *pthread_attr_getstack*( ) to resolve these ambiguities.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_attr_getstackaddr*( ) and *pthread_attr_setstackaddr*( ) functions are marked as part of the Threads and Thread Stack Address Attribute options.

The **restrict** keyword is added to the *pthread_attr_getstackaddr*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

These functions are marked obsolescent.

NAME

pthread_attr_getstacksize, pthread_attr_setstacksize — get and set stacksize attribute

SYNOPSIS

THR TSA

```
#include <pthread.h>

int pthread_attr_getstacksize(const pthread_attr_t *restrict attr,
    size_t *restrict stacksize);
int pthread_attr_setstacksize(pthread_attr_t *attr, size_t stacksize);
```

DESCRIPTION

The *pthread_attr_getstacksize*( ) and *pthread_attr_setstacksize*( ) functions, respectively, shall get and set the thread creation *stacksize* attribute in the *attr* object.

The *stacksize* attribute shall define the minimum stack size (in bytes) allocated for the created threads stack.

RETURN VALUE

Upon successful completion, *pthread_attr_getstacksize*( ) and *pthread_attr_setstacksize*( ) shall return a value of 0; otherwise, an error number shall be returned to indicate the error.

The *pthread_attr_getstacksize*( ) function stores the *stacksize* attribute value in *stacksize* if successful.

ERRORS

The *pthread_attr_setstacksize*( ) function shall fail if:

[EINVAL] The value of *stacksize* is less than {PTHREAD_STACK_MIN} or exceeds a system-imposed limit.

These functions shall not return an error code of [EINTR].

NAME

pthread_barrier_destroy, pthread_barrier_init — destroy and initialize a barrier object (**ADVANCED REALTIME THREADS**)

SYNOPSIS

THR BAR
```
#include <pthread.h>

int pthread_barrier_destroy(pthread_barrier_t *barrier);
int pthread_barrier_init(pthread_barrier_t *restrict barrier,
    const pthread_barrierattr_t *restrict attr, unsigned count);
```

DESCRIPTION

The *pthread_barrier_destroy*( ) function shall destroy the barrier referenced by *barrier* and release any resources used by the barrier. The effect of subsequent use of the barrier is undefined until the barrier is reinitialized by another call to *pthread_barrier_init*( ). An implementation may use this function to set *barrier* to an invalid value. The results are undefined if *pthread_barrier_destroy*( ) is called when any thread is blocked on the barrier, or if this function is called with an uninitialized barrier.

The *pthread_barrier_init*( ) function shall allocate any resources required to use the barrier referenced by *barrier* and shall initialize the barrier with attributes referenced by *attr*. If *attr* is NULL, the default barrier attributes shall be used; the effect is the same as passing the address of a default barrier attributes object. The results are undefined if *pthread_barrier_init*( ) is called when any thread is blocked on the barrier (that is, has not returned from the *pthread_barrier_wait*( ) call). The results are undefined if a barrier is used without first being initialized. The results are undefined if *pthread_barrier_init*( ) is called specifying an already initialized barrier.

The *count* argument specifies the number of threads that must call *pthread_barrier_wait*( ) before any of them successfully return from the call. The value specified by *count* must be greater than zero.

If the *pthread_barrier_init*( ) function fails, the barrier shall not be initialized and the contents of *barrier* are undefined. |

Only the object referenced by *barrier* may be used for performing synchronization. The result of referring to copies of that object in calls to *pthread_barrier_destroy*( ) or *pthread_barrier_wait*( ) is undefined.

RETURN VALUE

Upon successful completion, these functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_barrier_destroy*( ) function may fail if:

[EBUSY]	The implementation has detected an attempt to destroy a barrier while it is in use (for example, while being used in a *pthread_barrier_wait*( ) call) by another thread.
[EINVAL]	The value specified by *barrier* is invalid.

The *pthread_barrier_init*( ) function shall fail if:

[EAGAIN]	The system lacks the necessary resources to initialize another barrier.
[EINVAL]	The value specified by *count* is equal to zero.

[ENOMEM]	Insufficient memory exists to initialize the barrier.

The *pthread_barrier_init*( ) function may fail if:

[EBUSY]	The implementation has detected an attempt to reinitialize a barrier while it is in use (for example, while being used in a *pthread_barrier_wait*( ) call) by another thread.
[EINVAL]	The value specified by *attr* is invalid.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

The *pthread_barrier_destroy*( ) and *pthread_barrier_init*( ) functions are part of the Barriers option and need not be provided on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

pthread_barrier_wait( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1j-2000.

NAME

pthread_barrier_init — initialize a barrier object (**ADVANCED REALTIME THREADS**)

SYNOPSIS

THR BAR
```
#include <pthread.h>

int pthread_barrier_init(pthread_barrier_t *restrict barrier,
    const pthread_barrierattr_t *restrict attr, unsigned count);
```

DESCRIPTION

Refer to *pthread_barrier_destroy*( ).

NAME

pthread_barrier_wait — synchronize at a barrier (**ADVANCED REALTIME THREADS**)

SYNOPSIS

THR BAR
```
#include <pthread.h>

int pthread_barrier_wait(pthread_barrier_t *barrier);
```

DESCRIPTION

The *pthread_barrier_wait*( ) function shall synchronize participating threads at the barrier referenced by *barrier*. The calling thread shall block until the required number of threads have called *pthread_barrier_wait*( ) specifying the barrier.

When the required number of threads have called *pthread_barrier_wait*( ) specifying the barrier, the constant PTHREAD_BARRIER_SERIAL_THREAD shall be returned to one unspecified thread and zero shall be returned to each of the remaining threads. At this point, the barrier shall be reset to the state it had as a result of the most recent *pthread_barrier_init*( ) function that referenced it.

The constant PTHREAD_BARRIER_SERIAL_THREAD is defined in **<pthread.h>** and its value shall be distinct from any other value returned by *pthread_barrier_wait*( ).

The results are undefined if this function is called with an uninitialized barrier.

If a signal is delivered to a thread blocked on a barrier, upon return from the signal handler the thread shall resume waiting at the barrier if the barrier wait has not completed (that is, if the required number of threads have not arrived at the barrier during the execution of the signal handler); otherwise, the thread shall continue as normal from the completed barrier wait. Until the thread in the signal handler returns from it, it is unspecified whether other threads may proceed past the barrier once they have all reached it.

A thread that has blocked on a barrier shall not prevent any unblocked thread that is eligible to use the same processing resources from eventually making forward progress in its execution. Eligibility for processing resources shall be determined by the scheduling policy.

RETURN VALUE

Upon successful completion, the *pthread_barrier_wait*( ) function shall return PTHREAD_BARRIER_SERIAL_THREAD for a single (arbitrary) thread synchronized at the barrier and zero for each of the other threads. Otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_barrier_wait*( ) function may fail if:

[EINVAL] The value specified by *barrier* does not refer to an initialized barrier object.

This function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

Applications using this function may be subject to priority inversion, as discussed in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.285, Priority Inversion.

The *pthread_barrier_wait*( ) function is part of the Barriers option and need not be provided on all implementations.

In the SYNOPSIS, the inclusion of **<sys/types.h>** is no longer required.

NAME

pthread_barrierattr_destroy, pthread_barrierattr_init — destroy and initialize barrier attributes object (**ADVANCED REALTIME THREADS**)

SYNOPSIS

THR BAR

```
#include <pthread.h>

int pthread_barrierattr_destroy(pthread_barrierattr_t *attr);
int pthread_barrierattr_init(pthread_barrierattr_t *attr);
```

DESCRIPTION

The *pthread_barrierattr_destroy*( ) function shall destroy a barrier attributes object. A destroyed *attr* attributes object can be reinitialized using *pthread_barrierattr_init*( ); the results of otherwise referencing the object after it has been destroyed are undefined. An implementation may cause *pthread_barrierattr_destroy*( ) to set the object referenced by *attr* to an invalid value.

The *pthread_barrierattr_init*( ) function shall initialize a barrier attributes object *attr* with the default value for all of the attributes defined by the implementation.

Results are undefined if *pthread_barrierattr_init*( ) is called specifying an already initialized *attr* attributes object.

After a barrier attributes object has been used to initialize one or more barriers, any function affecting the attributes object (including destruction) shall not affect any previously initialized barrier.

RETURN VALUE

If successful, the *pthread_barrierattr_destroy*( ) and *pthread_barrierattr_init*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_barrierattr_destroy*( ) function may fail if:

[EINVAL] The value specified by *attr* is invalid.

The *pthread_barrierattr_init*( ) function shall fail if:

[ENOMEM] Insufficient memory exists to initialize the barrier attributes object.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

The *pthread_barrierattr_destroy*( ) and *pthread_barrierattr_init*( ) functions are part of the Barriers option and need not be provided on all implementations.

First released in Issue 6. Derived from IEEE Std 1003.1j-2000.

In the SYNOPSIS, the inclusion of **<sys/types.h>** is no longer required.

NAME

pthread_barrierattr_getpshared, pthread_barrierattr_setpshared — get and set process-shared attribute of barrier attributes object (**ADVANCED REALTIME THREADS**)

SYNOPSIS

THR
```
#include <pthread.h>
```

BAR TSH
```
int pthread_barrierattr_getpshared(
    const pthread_barrierattr_t *restrict attr,
    int *restrict pshared);
int pthread_barrierattr_setpshared(pthread_barrierattr_t *attr,
    int pshared);
```

DESCRIPTION

The *pthread_barrierattr_getpshared*( ) function shall obtain the value of the process-shared attribute from the attributes object referenced by *attr*. The *pthread_barrierattr_setpshared*( ) function shall set the process-shared attribute in an initialized attributes object referenced by *attr*.

The process-shared attribute is set to PTHREAD_PROCESS_SHARED to permit a barrier to be operated upon by any thread that has access to the memory where the barrier is allocated. If the process-shared attribute is PTHREAD_PROCESS_PRIVATE, the barrier shall only be operated upon by threads created within the same process as the thread that initialized the barrier; if threads of different processes attempt to operate on such a barrier, the behavior is undefined. The default value of the attribute shall be PTHREAD_PROCESS_PRIVATE. Both constants PTHREAD_PROCESS_SHARED and PTHREAD_PROCESS_PRIVATE are defined in **<pthread.h>**.

Additional attributes, their default values, and the names of the associated functions to get and set those attribute values are implementation-defined.

RETURN VALUE

If successful, the *pthread_barrierattr_getpshared*( ) function shall return zero and store the value of the process-shared attribute of *attr* into the object referenced by the *pshared* parameter. Otherwise, an error number shall be returned to indicate the error.

If successful, the *pthread_barrierattr_setpshared*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

These functions may fail if:

[EINVAL]	The value specified by *attr* is invalid.

The *pthread_barrierattr_setpshared*( ) function may fail if:

[EINVAL]	The new value specified for the process-shared attribute is not one of the legal values PTHREAD_PROCESS_SHARED or PTHREAD_PROCESS_PRIVATE.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

The *pthread_barrierattr_getpshared*( ) and *pthread_barrierattr_setpshared*( ) functions are part of the Barriers option and need not be provided on all implementations.

```

DESCRIPTION

Refer to *pthread_barrierattr_getpshared*( ).

NAME

pthread_cancel — cancel execution of a thread

SYNOPSIS

THR
```
#include <pthread.h>

int pthread_cancel(pthread_t thread);
```

DESCRIPTION

The *pthread_cancel*( ) function shall request that *thread* be canceled. The target thread's cancelability state and type determines when the cancelation takes effect. When the cancelation is acted on, the cancelation cleanup handlers for *thread* shall be called. When the last cancelation cleanup handler returns, the thread-specific data destructor functions shall be called for *thread*. When the last destructor function returns, *thread* shall be terminated.

The cancelation processing in the target thread shall run asynchronously with respect to the calling thread returning from *pthread_cancel*( ).

RETURN VALUE

If successful, the *pthread_cancel*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_cancel*( ) function may fail if:

[ESRCH] No thread could be found corresponding to that specified by the given thread ID.

The *pthread_cancel*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Two alternative functions were considered to sending the cancelation notification to a thread. One would be to define a new SIGCANCEL signal that had the cancelation semantics when delivered; the other was to define the new *pthread_cancel*( ) function, which would trigger the cancelation semantics.

The advantage of a new signal was that so much of the delivery criteria were identical to that used when trying to deliver a signal that making cancelation notification a signal was seen as consistent. Indeed, many implementations implement cancelation using a special signal. On the other hand, there would be no signal functions that could be used with this signal except *pthread_kill*( ), and the behavior of the delivered cancelation signal would be unlike any previously existing defined signal.

The benefits of a special function include the recognition that this signal would be defined because of the similar delivery criteria and that this is the only common behavior between a cancelation request and a signal. In addition, the cancelation delivery mechanism does not have to be implemented as a signal. There are also strong, if not stronger, parallels with language exception mechanisms than with signals that are potentially obscured if the delivery mechanism is visibly closer to signals.

In the end, it was considered that as there were so many exceptions to the use of the new signal with existing signals functions that it would be misleading. A special function has resolved this problem. This function was carefully defined so that an implementation wishing to provide the cancelation functions on top of signals could do so. The special function also means that implementations are not obliged to implement cancelation with signals.

FUTURE DIRECTIONS

None.

NAME

pthread_cleanup_pop, pthread_cleanup_push — establish cancelation handlers

SYNOPSIS

THR

```
#include <pthread.h>

void pthread_cleanup_pop(int execute);
void pthread_cleanup_push(void (*routine)(void*), void *arg);
```

DESCRIPTION

The *pthread_cleanup_pop*( ) function shall remove the routine at the top of the calling thread's cancelation cleanup stack and optionally invoke it (if *execute* is non-zero).

The *pthread_cleanup_push*( ) function shall push the specified cancelation cleanup handler *routine* onto the calling thread's cancelation cleanup stack. The cancelation cleanup handler shall be popped from the cancelation cleanup stack and invoked with the argument *arg* when:

- The thread exits (that is, calls *pthread_exit*( )).
- The thread acts upon a cancelation request.
- The thread calls *pthread_cleanup_pop*( ) with a non-zero *execute* argument.

These functions may be implemented as macros. The application shall ensure that they appear as statements, and in pairs within the same lexical scope (that is, the *pthread_cleanup_push*( ) macro may be thought to expand to a token list whose first token is `'{'` with *pthread_cleanup_pop*( ) expanding to a token list whose last token is the corresponding `'}'`).

The effect of calling *longjmp*( ) or *siglongjmp*( ) is undefined if there have been any calls to *pthread_cleanup_push*( ) or *pthread_cleanup_pop*( ) made without the matching call since the jump buffer was filled. The effect of calling *longjmp*( ) or *siglongjmp*( ) from inside a cancelation cleanup handler is also undefined unless the jump buffer was also filled in the cancelation cleanup handler.

RETURN VALUE

The *pthread_cleanup_push*( ) and *pthread_cleanup_pop*( ) functions shall not return a value.

ERRORS

No errors are defined.

These functions shall not return an error code of [EINTR].

EXAMPLES

The following is an example using thread primitives to implement a cancelable, writers-priority read-write lock:

```
typedef struct {
    pthread_mutex_t lock;
    pthread_cond_t rcond,
        wcond;
    int lock_count; /* < 0 .. Held by writer. */
                    /* > 0 .. Held by lock_count readers. */
                    /* = 0 .. Held by nobody. */
    int waiting_writers; /* Count of waiting writers. */
} rwlock;

void
waiting_reader_cleanup(void *arg)
{
```

```
    rwlock *l;

    l = (rwlock *) arg;
    pthread_mutex_unlock(&l->lock);
}

void
lock_for_read(rwlock *l)
{
    pthread_mutex_lock(&l->lock);
    pthread_cleanup_push(waiting_reader_cleanup, l);
    while ((l->lock_count < 0) && (l->waiting_writers != 0))
        pthread_cond_wait(&l->rcond, &l->lock);
    l->lock_count++;
   /*
    * Note the pthread_cleanup_pop executes
    * waiting_reader_cleanup.
    */
    pthread_cleanup_pop(1);
}

void
release_read_lock(rwlock *l)
{
    pthread_mutex_lock(&l->lock);
    if (--l->lock_count == 0)
        pthread_cond_signal(&l->wcond);
    pthread_mutex_unlock(l);
}

void
waiting_writer_cleanup(void *arg)
{
    rwlock *l;

    l = (rwlock *) arg;
    if ((--l->waiting_writers == 0) && (l->lock_count >= 0)) {
       /*
        * This only happens if we have been canceled.
        */
        pthread_cond_broadcast(&l->wcond);
}
    pthread_mutex_unlock(&l->lock);
}

void
lock_for_write(rwlock *l)
{
    pthread_mutex_lock(&l->lock);
    l->waiting_writers++;
    pthread_cleanup_push(waiting_writer_cleanup, l);
    while (l->lock_count != 0)
        pthread_cond_wait(&l->wcond, &l->lock);
    l->lock_count = −1;
   /*
```

```
         * Note the pthread_cleanup_pop executes
         * waiting_writer_cleanup.
         */
        pthread_cleanup_pop(1);
    }
    void
    release_write_lock(rwlock *l)
    {
        pthread_mutex_lock(&l->lock);
        l->lock_count = 0;
        if (l->waiting_writers == 0)
            pthread_cond_broadcast(&l->rcond)
        else
            pthread_cond_signal(&l->wcond);
        pthread_mutex_unlock(&l->lock);
    }
    /*
     * This function is called to initialize the read/write lock.
     */
    void
    initialize_rwlock(rwlock *l)
    {
        pthread_mutex_init(&l->lock, pthread_mutexattr_default);
        pthread_cond_init(&l->wcond, pthread_condattr_default);
        pthread_cond_init(&l->rcond, pthread_condattr_default);
        l->lock_count = 0;
        l->waiting_writers = 0;
    }
    reader_thread()
    {
        lock_for_read(&lock);
        pthread_cleanup_push(release_read_lock, &lock);
       /*
        * Thread has read lock.
        */
        pthread_cleanup_pop(1);
    }
    writer_thread()
    {
        lock_for_write(&lock);
        pthread_cleanup_push(release_write_lock, &lock);
       /*
        * Thread has write lock.
        */
    pthread_cleanup_pop(1);
    }
```

APPLICATION USAGE

The two routines that push and pop cancelation cleanup handlers, *pthread_cleanup_push*( ) and *pthread_cleanup_pop*( ), can be thought of as left and right parentheses. They always need to be matched.

RATIONALE

The restriction that the two routines that push and pop cancelation cleanup handlers, *pthread_cleanup_push*( ) and *pthread_cleanup_pop*( ), have to appear in the same lexical scope allows for efficient macro or compiler implementations and efficient storage management. A sample implementation of these routines as macros might look like this:

```
#define pthread_cleanup_push(rtn,arg) { \
    struct _pthread_handler_rec __cleanup_handler, **__head; \
    __cleanup_handler.rtn = rtn; \
    __cleanup_handler.arg = arg; \
    (void) pthread_getspecific(_pthread_handler_key, &__head); \
    __cleanup_handler.next = *__head; \
    *__head = &__cleanup_handler;

#define pthread_cleanup_pop(ex) \
    *__head = __cleanup_handler.next; \
    if (ex) (*__cleanup_handler.rtn)(__cleanup_handler.arg); \
}
```

A more ambitious implementation of these routines might do even better by allowing the compiler to note that the cancelation cleanup handler is a constant and can be expanded inline.

This volume of IEEE Std 1003.1-200x currently leaves unspecified the effect of calling *longjmp*( ) from a signal handler executing in a POSIX System Interfaces function. If an implementation wants to allow this and give the programmer reasonable behavior, the *longjmp*( ) function has to call all cancelation cleanup handlers that have been pushed but not popped since the time *setjmp*( ) was called.

Consider a multi-threaded function called by a thread that uses signals. If a signal were delivered to a signal handler during the operation of *qsort*( ) and that handler were to call *longjmp*( ) (which, in turn, did *not* call the cancelation cleanup handlers) the helper threads created by the *qsort*( ) function would not be canceled. Instead, they would continue to execute and write into the argument array even though the array might have been popped off of the stack.

Note that the specified cleanup handling mechanism is especially tied to the C language and, while the requirement for a uniform mechanism for expressing cleanup is language-independent, the mechanism used in other languages may be quite different. In addition, this mechanism is really only necessary due to the lack of a real exception mechanism in the C language, which would be the ideal solution.

There is no notion of a cancelation cleanup-safe function. If an application has no cancelation points in its signal handlers, blocks any signal whose handler may have cancelation points while calling async-unsafe functions, or disables cancelation while calling async-unsafe functions, all functions may be safely called from cancelation cleanup routines.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_cleanup_pop*( ) and *pthread_cleanup_push*( ) functions are marked as part of the Threads option.

The APPLICATION USAGE section is added.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

pthread_cond_broadcast, pthread_cond_signal — broadcast or signal a condition

SYNOPSIS

THR
```
#include <pthread.h>

int pthread_cond_broadcast(pthread_cond_t *cond);
int pthread_cond_signal(pthread_cond_t *cond);

```

DESCRIPTION

These functions shall unblock threads blocked on a condition variable.

The *pthread_cond_broadcast*( ) function shall unblock all threads currently blocked on the specified condition variable *cond*.

The *pthread_cond_signal*( ) function shall unblock at least one of the threads that are blocked on the specified condition variable *cond* (if any threads are blocked on *cond*).

If more than one thread is blocked on a condition variable, the scheduling policy shall determine the order in which threads are unblocked. When each thread unblocked as a result of a *pthread_cond_broadcast*( ) or *pthread_cond_signal*( ) returns from its call to *pthread_cond_wait*( ) or *pthread_cond_timedwait*( ), the thread shall own the mutex with which it called *pthread_cond_wait*( ) or *pthread_cond_timedwait*( ). The thread(s) that are unblocked shall contend for the mutex according to the scheduling policy (if applicable), and as if each had called *pthread_mutex_lock*( ).

The *pthread_cond_broadcast*( ) or *pthread_cond_signal*( ) functions may be called by a thread whether or not it currently owns the mutex that threads calling *pthread_cond_wait*( ) or *pthread_cond_timedwait*( ) have associated with the condition variable during their waits; however, if predictable scheduling behavior is required, then that mutex shall be locked by the thread calling *pthread_cond_broadcast*( ) or *pthread_cond_signal*( ).

The *pthread_cond_broadcast*( ) and *pthread_cond_signal*( ) functions shall have no effect if there are no threads currently blocked on *cond*.

RETURN VALUE

If successful, the *pthread_cond_broadcast*( ) and *pthread_cond_signal*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_cond_broadcast*( ) and *pthread_cond_signal*( ) function may fail if:

[EINVAL] The value *cond* does not refer to an initialized condition variable.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

The *pthread_cond_broadcast*( ) function is used whenever the shared-variable state has been changed in a way that more than one thread can proceed with its task. Consider a single producer/multiple consumer problem, where the producer can insert multiple items on a list that is accessed one item at a time by the consumers. By calling the *pthread_cond_broadcast*( ) function, the producer would notify all consumers that might be waiting, and thereby the application would receive more throughput on a multi-processor. In addition, *pthread_cond_broadcast*( ) makes it easier to implement a read-write lock. The *pthread_cond_broadcast*( ) function is needed in order to wake up all waiting readers when a writer releases its lock. Finally, the two-phase commit algorithm can use this broadcast function to notify all clients of an impending transaction commit.

It is not safe to use the *pthread_cond_signal*( ) function in a signal handler that is invoked asynchronously. Even if it were safe, there would still be a race between the test of the Boolean *pthread_cond_wait*( ) that could not be efficiently eliminated.

Mutexes and condition variables are thus not suitable for releasing a waiting thread by signaling from code running in a signal handler.

RATIONALE

Multiple Awakenings by Condition Signal

On a multi-processor, it may be impossible for an implementation of *pthread_cond_signal*( ) to avoid the unblocking of more than one thread blocked on a condition variable. For example, consider the following partial implementation of *pthread_cond_wait*( ) and *pthread_cond_signal*( ), executed by two threads in the order given. One thread is trying to wait on the condition variable, another is concurrently executing *pthread_cond_signal*( ), while a third thread is already waiting.

```
pthread_cond_wait(mutex, cond):
    value = cond->value; /* 1 */
    pthread_mutex_unlock(mutex); /* 2 */
    pthread_mutex_lock(cond->mutex); /* 10 */
    if (value == cond->value) { /* 11 */
        me->next_cond = cond->waiter;
        cond->waiter = me;
        pthread_mutex_unlock(cond->mutex);
        unable_to_run(me);
    } else
        pthread_mutex_unlock(cond->mutex); /* 12 */
    pthread_mutex_lock(mutex); /* 13 */

pthread_cond_signal(cond):
    pthread_mutex_lock(cond->mutex); /* 3 */
    cond->value++; /* 4 */
    if (cond->waiter) { /* 5 */
        sleeper = cond->waiter; /* 6 */
        cond->waiter = sleeper->next_cond; /* 7 */
        able_to_run(sleeper); /* 8 */
    }
    pthread_mutex_unlock(cond->mutex); /* 9 */
```

The effect is that more than one thread can return from its call to *pthread_cond_wait*( ) or *pthread_cond_timedwait*( ) as a result of one call to *pthread_cond_signal*( ). This effect is called ‘‘spurious wakeup’’. Note that the situation is self-correcting in that the number of threads that are so awakened is finite; for example, the next thread to call *pthread_cond_wait*( ) after the sequence of events above blocks.

While this problem could be resolved, the loss of efficiency for a fringe condition that occurs only rarely is unacceptable, especially given that one has to check the predicate associated with a condition variable anyway. Correcting this problem would unnecessarily reduce the degree of concurrency in this basic building block for all higher-level synchronization operations.

An added benefit of allowing spurious wakeups is that applications are forced to code a predicate-testing-loop around the condition wait. This also makes the application tolerate superfluous condition broadcasts or signals on the same condition variable that may be coded in some other part of the application. The resulting applications are thus more robust. Therefore, IEEE Std 1003.1-200x explicitly documents that spurious wakeups may occur.

FUTURE DIRECTIONS

None.

pthread_cond_destroy( ), *pthread_cond_timedwait*( ), *pthread_cond_wait*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_cond_broadcast*( ) and *pthread_cond_signal*( ) functions are marked as part of the Threads option.

The APPLICATION USAGE section is added.

NAME

pthread_cond_destroy, pthread_cond_init — destroy and initialize condition variables

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_cond_destroy(pthread_cond_t *cond);
int pthread_cond_init(pthread_cond_t *restrict cond,
    const pthread_condattr_t *restrict attr);
pthread_cond_t cond = PTHREAD_COND_INITIALIZER;
```

DESCRIPTION

The *pthread_cond_destroy*( ) function shall destroy the given condition variable specified by *cond*; the object becomes, in effect, uninitialized. An implementation may cause *pthread_cond_destroy*( ) to set the object referenced by *cond* to an invalid value. A destroyed condition variable object can be reinitialized using *pthread_cond_init*( ); the results of otherwise referencing the object after it has been destroyed are undefined.

It shall be safe to destroy an initialized condition variable upon which no threads are currently blocked. Attempting to destroy a condition variable upon which other threads are currently blocked results in undefined behavior.

The *pthread_cond_init*( ) function shall initialize the condition variable referenced by *cond* with attributes referenced by *attr*. If *attr* is NULL, the default condition variable attributes shall be used; the effect is the same as passing the address of a default condition variable attributes object. Upon successful initialization, the state of the condition variable shall become initialized.

Only *cond* itself may be used for performing synchronization. The result of referring to copies of *cond* in calls to *pthread_cond_wait*( ), *pthread_cond_timedwait*( ), *pthread_cond_signal*( ), *pthread_cond_broadcast*( ), and *pthread_cond_destroy*( ) is undefined.

Attempting to initialize an already initialized condition variable results in undefined behavior.

In cases where default condition variable attributes are appropriate, the macro PTHREAD_COND_INITIALIZER can be used to initialize condition variables that are statically allocated. The effect shall be equivalent to dynamic initialization by a call to *pthread_cond_init*( ) with parameter *attr* specified as NULL, except that no error checks are performed.

RETURN VALUE

If successful, the *pthread_cond_destroy*( ) and *pthread_cond_init*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

The [EBUSY] and [EINVAL] error checks, if implemented, shall act as if they were performed immediately at the beginning of processing for the function and caused an error return prior to modifying the state of the condition variable specified by *cond*.

ERRORS

The *pthread_cond_destroy*( ) function may fail if:

[EBUSY]	The implementation has detected an attempt to destroy the object referenced by *cond* while it is referenced (for example, while being used in a *pthread_cond_wait*( ) or *pthread_cond_timedwait*( )) by another thread.
[EINVAL]	The value specified by *cond* is invalid.

The *pthread_cond_init*( ) function shall fail if:

[EAGAIN]	The system lacked the necessary resources (other than memory) to initialize another condition variable.

[ENOMEM]	Insufficient memory exists to initialize the condition variable.

The *pthread_cond_init*( ) function may fail if:

[EBUSY]	The implementation has detected an attempt to reinitialize the object referenced by *cond*, a previously initialized, but not yet destroyed, condition variable.
[EINVAL]	The value specified by *attr* is invalid.

These functions shall not return an error code of [EINTR].

EXAMPLES

A condition variable can be destroyed immediately after all the threads that are blocked on it are awakened. For example, consider the following code:

```
struct list {
    pthread_mutex_t lm;
    ...
}
struct elt {
    key k;
    int busy;
    pthread_cond_t notbusy;
    ...
}
/* Find a list element and reserve it. */
struct elt *
list_find(struct list *lp, key k)
{
    struct elt *ep;
    pthread_mutex_lock(&lp->lm);
    while ((ep = find_elt(l, k) != NULL) && ep->busy)
        pthread_cond_wait(&ep->notbusy, &lp->lm);
    if (ep != NULL)
        ep->busy = 1;
    pthread_mutex_unlock(&lp->lm);
    return(ep);
}
delete_elt(struct list *lp, struct elt *ep)
{
    pthread_mutex_lock(&lp->lm);
    assert(ep->busy);
    ... remove ep from list ...
    ep->busy = 0;  /* Paranoid. */
(A) pthread_cond_broadcast(&ep->notbusy);
    pthread_mutex_unlock(&lp->lm);
(B) pthread_cond_destroy(&rp->notbusy);
    free(ep);
}
```

In this example, the condition variable and its list element may be freed (line B) immediately after all threads waiting for it are awakened (line A), since the mutex and the code ensure that no other thread can touch the element to be deleted.

APPLICATION USAGE

None.

RATIONALE

See *pthread_mutex_init*( ); a similar rationale applies to condition variables.

FUTURE DIRECTIONS

None.

    const pthread_condattr_t *restrict attr);
pthread_cond_t cond = PTHREAD_COND_INITIALIZER;
```

DESCRIPTION

Refer to *pthread_cond_destroy*( ).

NAME

pthread_cond_signal — signal a condition

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_cond_signal(pthread_cond_t *cond);
```

DESCRIPTION

Refer to *pthread_cond_broadcast*( ).

NAME

pthread_cond_timedwait, pthread_cond_wait — wait on a condition

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_cond_timedwait(pthread_cond_t *restrict cond,
    pthread_mutex_t *restrict mutex,
    const struct timespec *restrict abstime);
int pthread_cond_wait(pthread_cond_t *restrict cond,
    pthread_mutex_t *restrict mutex);
```

DESCRIPTION

The *pthread_cond_timedwait*( ) and *pthread_cond_wait*( ) functions shall block on a condition variable. They shall be called with *mutex* locked by the calling thread or undefined behavior results.

These functions atomically release *mutex* and cause the calling thread to block on the condition variable *cond*; atomically here means ‘‘atomically with respect to access by another thread to the mutex and then the condition variable’’. That is, if another thread is able to acquire the mutex after the about-to-block thread has released it, then a subsequent call to *pthread_cond_broadcast*( ) or *pthread_cond_signal*( ) in that thread shall behave as if it were issued after the about-to-block thread has blocked.

Upon successful return, the mutex shall have been locked and shall be owned by the calling thread.

When using condition variables there is always a Boolean predicate involving shared variables associated with each condition wait that is true if the thread should proceed. Spurious wakeups from the *pthread_cond_timedwait*( ) or *pthread_cond_wait*( ) functions may occur. Since the return from *pthread_cond_timedwait*( ) or *pthread_cond_wait*( ) does not imply anything about the value of this predicate, the predicate should be re-evaluated upon such return.

The effect of using more than one mutex for concurrent *pthread_cond_timedwait*( ) or *pthread_cond_wait*( ) operations on the same condition variable is undefined; that is, a condition variable becomes bound to a unique mutex when a thread waits on the condition variable, and this (dynamic) binding shall end when the wait returns.

A condition wait (whether timed or not) is a cancelation point. When the cancelability enable state of a thread is set to PTHREAD_CANCEL_DEFERRED, a side effect of acting upon a cancelation request while in a condition wait is that the mutex is (in effect) re-acquired before calling the first cancelation cleanup handler. The effect is as if the thread were unblocked, allowed to execute up to the point of returning from the call to *pthread_cond_timedwait*( ) or *pthread_cond_wait*( ), but at that point notices the cancelation request and instead of returning to the caller of *pthread_cond_timedwait*( ) or *pthread_cond_wait*( ), starts the thread cancelation activities, which includes calling cancelation cleanup handlers.

A thread that has been unblocked because it has been canceled while blocked in a call to *pthread_cond_timedwait*( ) or *pthread_cond_wait*( ) shall not consume any condition signal that may be directed concurrently at the condition variable if there are other threads blocked on the condition variable.

The *pthread_cond_timedwait*( ) function shall be equivalent to *pthread_cond_wait*( ), except that an error is returned if the absolute time specified by *abstime* passes (that is, system time equals or exceeds *abstime*) before the condition *cond* is signaled or broadcasted, or if the absolute time

CS

specified by *abstime* has already been passed at the time of the call. If the Clock Selection option is supported, the condition variable shall have a clock attribute which specifies the clock that shall be used to measure the time specified by the *abstime* argument. When such timeouts occur, *pthread_cond_timedwait*( ) shall nonetheless release and re-acquire the mutex referenced by *mutex*. The *pthread_cond_timedwait*( ) function is also a cancelation point.

If a signal is delivered to a thread waiting for a condition variable, upon return from the signal handler the thread resumes waiting for the condition variable as if it was not interrupted, or it shall return zero due to spurious wakeup.

RETURN VALUE

Except in the case of [ETIMEDOUT], all these error checks shall act as if they were performed immediately at the beginning of processing for the function and shall cause an error return, in effect, prior to modifying the state of the mutex specified by *mutex* or the condition variable specified by *cond*.

Upon successful completion, a value of zero shall be returned; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_cond_timedwait*( ) function shall fail if:

[ETIMEDOUT]	The time specified by *abstime* to *pthread_cond_timedwait*( ) has passed.

The *pthread_cond_timedwait*( ) and *pthread_cond_wait*( ) functions may fail if:

[EINVAL]	The value specified by *cond*, *mutex*, or *abstime* is invalid.
[EINVAL]	Different mutexes were supplied for concurrent *pthread_cond_timedwait*( ) or *pthread_cond_wait*( ) operations on the same condition variable.
[EPERM]	The mutex was not owned by the current thread at the time of the call.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Condition Wait Semantics

It is important to note that when *pthread_cond_wait*( ) and *pthread_cond_timedwait*( ) return without error, the associated predicate may still be false. Similarly, when *pthread_cond_timedwait*( ) returns with the timeout error, the associated predicate may be true due to an unavoidable race between the expiration of the timeout and the predicate state change.

Some implementations, particularly on a multi-processor, may sometimes cause multiple threads to wake up when the condition variable is signaled simultaneously on different processors.

In general, whenever a condition wait returns, the thread has to re-evaluate the predicate associated with the condition wait to determine whether it can safely proceed, should wait again, or should declare a timeout. A return from the wait does not imply that the associated predicate is either true or false.

It is thus recommended that a condition wait be enclosed in the equivalent of a ‘‘while loop’’ that checks the predicate.

Timed Wait Semantics

An absolute time measure was chosen for specifying the timeout parameter for two reasons. First, a relative time measure can be easily implemented on top of a function that specifies absolute time, but there is a race condition associated with specifying an absolute timeout on top of a function that specifies relative timeouts. For example, assume that *clock_gettime*( ) returns the current time and *cond_relative_timed_wait*( ) uses relative timeouts:

```
clock_gettime(CLOCK_REALTIME, &now)
reltime = sleep_til_this_absolute_time -now;
cond_relative_timed_wait(c, m, &reltime);
```

If the thread is preempted between the first statement and the last statement, the thread blocks for too long. Blocking, however, is irrelevant if an absolute timeout is used. An absolute timeout also need not be recomputed if it is used multiple times in a loop, such as that enclosing a condition wait.

For cases when the system clock is advanced discontinuously by an operator, it is expected that implementations process any timed wait expiring at an intervening time as if that time had actually occurred.

Cancelation and Condition Wait

A condition wait, whether timed or not, is a cancelation point. That is, the functions *pthread_cond_wait*( ) or *pthread_cond_timedwait*( ) are points where a pending (or concurrent) cancelation request is noticed. The reason for this is that an indefinite wait is possible at these points—whatever event is being waited for, even if the program is totally correct, might never occur; for example, some input data being awaited might never be sent. By making condition wait a cancelation point, the thread can be canceled and perform its cancelation cleanup handler even though it may be stuck in some indefinite wait.

A side effect of acting on a cancelation request while a thread is blocked on a condition variable is to re-acquire the mutex before calling any of the cancelation cleanup handlers. This is done in order to ensure that the cancelation cleanup handler is executed in the same state as the critical code that lies both before and after the call to the condition wait function. This rule is also required when interfacing to POSIX threads from languages, such as Ada or C++, which may choose to map cancelation onto a language exception; this rule ensures that each exception handler guarding a critical section can always safely depend upon the fact that the associated mutex has already been locked regardless of exactly where within the critical section the exception was raised. Without this rule, there would not be a uniform rule that exception handlers could follow regarding the lock, and so coding would become very cumbersome.

Therefore, since *some* statement has to be made regarding the state of the lock when a cancelation is delivered during a wait, a definition has been chosen that makes application coding most convenient and error free.

When acting on a cancelation request while a thread is blocked on a condition variable, the implementation is required to ensure that the thread does not consume any condition signals directed at that condition variable if there are any other threads waiting on that condition variable. This rule is specified in order to avoid deadlock conditions that could occur if these two independent requests (one acting on a thread and the other acting on the condition variable) were not processed independently.

Performance of Mutexes and Condition Variables

Mutexes are expected to be locked only for a few instructions. This practice is almost automatically enforced by the desire of programmers to avoid long serial regions of execution (which would reduce total effective parallelism).

When using mutexes and condition variables, one tries to ensure that the usual case is to lock the mutex, access shared data, and unlock the mutex. Waiting on a condition variable should be a relatively rare situation. For example, when implementing a read-write lock, code that acquires a read-lock typically needs only to increment the count of readers (under mutual-exclusion) and return. The calling thread would actually wait on the condition variable only when there is already an active writer. So the efficiency of a synchronization operation is bounded by the cost of mutex lock/unlock and not by condition wait. Note that in the usual case there is no context switch.

This is not to say that the efficiency of condition waiting is unimportant. Since there needs to be at least one context switch per Ada rendezvous, the efficiency of waiting on a condition variable is important. The cost of waiting on a condition variable should be little more than the minimal cost for a context switch plus the time to unlock and lock the mutex.

Features of Mutexes and Condition Variables

It had been suggested that the mutex acquisition and release be decoupled from condition wait. This was rejected because it is the combined nature of the operation that, in fact, facilitates realtime implementations. Those implementations can atomically move a high-priority thread between the condition variable and the mutex in a manner that is transparent to the caller. This can prevent extra context switches and provide more deterministic acquisition of a mutex when the waiting thread is signaled. Thus, fairness and priority issues can be dealt with directly by the scheduling discipline. Furthermore, the current condition wait operation matches existing practice.

Scheduling Behavior of Mutexes and Condition Variables

Synchronization primitives that attempt to interfere with scheduling policy by specifying an ordering rule are considered undesirable. Threads waiting on mutexes and condition variables are selected to proceed in an order dependent upon the scheduling policy rather than in some fixed order (for example, FIFO or priority). Thus, the scheduling policy determines which thread(s) are awakened and allowed to proceed.

Timed Condition Wait

The *pthread_cond_timedwait*( ) function allows an application to give up waiting for a particular condition after a given amount of time. An example of its use follows:

```
(void) pthread_mutex_lock(&t.mn);
        t.waiters++;
    clock_gettime(CLOCK_REALTIME, &ts);
    ts.tv_sec += 5;
    rc = 0;
    while (! mypredicate(&t) && rc == 0)
        rc = pthread_cond_timedwait(&t.cond, &t.mn, &ts);
    t.waiters--;
    if (rc == 0) setmystate(&t);
(void) pthread_mutex_unlock(&t.mn);
```

By making the timeout parameter absolute, it does not need to be recomputed each time the program checks its blocking predicate. If the timeout was relative, it would have to be recomputed before each call. This would be especially difficult since such code would need to take into account the possibility of extra wakeups that result from extra broadcasts or signals on the condition variable that occur before either the predicate is true or the timeout is due.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_cond_timedwait*( ) and *pthread_cond_wait*( ) functions are marked as part of the Threads option.

The Open Group Corrigendum U021/9 is applied, correcting the prototype for the *pthread_cond_wait*( ) function.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by adding semantics for the Clock Selection option.

The ERRORS section has an additional case for [EPERM] in response to IEEE PASC Interpretation 1003.1c #28.

The **restrict** keyword is added to the *pthread_cond_timedwait*( ) and *pthread_cond_wait*( ) prototypes for alignment with the ISO/IEC 9899:1999 standard.

NAME

pthread_cond_wait — wait on a condition

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_cond_wait(pthread_cond_t *restrict cond,
    pthread_mutex_t *restrict mutex);
```

DESCRIPTION

Refer to *pthread_cond_timedwait*( ).

NAME

pthread_condattr_destroy, pthread_condattr_init — destroy and initialize condition variable attributes object

SYNOPSIS

THR
```
#include <pthread.h>

int pthread_condattr_destroy(pthread_condattr_t *attr);
int pthread_condattr_init(pthread_condattr_t *attr);
```

DESCRIPTION

The *pthread_condattr_destroy*( ) function shall destroy a condition variable attributes object; the object becomes, in effect, uninitialized. An implementation may cause *pthread_condattr_destroy*( ) to set the object referenced by *attr* to an invalid value. A destroyed *attr* attributes object can be reinitialized using *pthread_condattr_init*( ); the results of otherwise referencing the object after it has been destroyed are undefined. |

The *pthread_condattr_init*( ) function shall initialize a condition variable attributes object *attr* with the default value for all of the attributes defined by the implementation.

Results are undefined if *pthread_condattr_init*( ) is called specifying an already initialized *attr* attributes object. |

After a condition variable attributes object has been used to initialize one or more condition variables, any function affecting the attributes object (including destruction) shall not affect any previously initialized condition variables. |

This volume of IEEE Std 1003.1-200x requires two attributes, the *clock* attribute and the *process-shared* attribute.

Additional attributes, their default values, and the names of the associated functions to get and set those attribute values are implementation-defined.

RETURN VALUE

If successful, the *pthread_condattr_destroy*( ) and *pthread_condattr_init*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_condattr_destroy*( ) function may fail if:

[EINVAL]	The value specified by *attr* is invalid.

The *pthread_condattr_init*( ) function shall fail if:

[ENOMEM]	Insufficient memory exists to initialize the condition variable attributes object.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

See *pthread_attr_init*( ) and *pthread_mutex_init*( ).

A *process-shared* attribute has been defined for condition variables for the same reason it has been defined for mutexes.

NAME

pthread_condattr_getclock, pthread_condattr_setclock — get and set the clock selection condition variable attribute (**ADVANCED REALTIME**)

SYNOPSIS

THR CS

```
#include <pthread.h>

int pthread_condattr_getclock(const pthread_condattr_t *restrict attr,
    clockid_t *restrict clock_id);
int pthread_condattr_setclock(pthread_condattr_t *attr,
    clockid_t clock_id);
```

DESCRIPTION

The *pthread_condattr_getclock*( ) function shall obtain the value of the *clock* attribute from the attributes object referenced by *attr*. The *pthread_condattr_setclock*( ) function shall set the *clock* attribute in an initialized attributes object referenced by *attr*. If *pthread_condattr_setclock*( ) is called with a *clock_id* argument that refers to a CPU-time clock, the call shall fail.

The *clock* attribute is the clock ID of the clock that shall be used to measure the timeout service of *pthread_cond_timedwait*( ). The default value of the *clock* attribute shall refer to the system clock.

RETURN VALUE

If successful, the *pthread_condattr_getclock*( ) function shall return zero and store the value of the clock attribute of *attr* into the object referenced by the *clock_id* argument. Otherwise, an error number shall be returned to indicate the error.

If successful, the *pthread_condattr_setclock*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

These functions may fail if:

[EINVAL]	The value specified by *attr* is invalid.

The *pthread_condattr_setclock*( ) function may fail if:

[EINVAL]	The value specified by *clock_id* does not refer to a known clock, or is a CPU-time clock.

These functions shall not return an error code of [EINTR].

NAME

pthread_condattr_getpshared, pthread_condattr_setpshared — get and set the process-shared condition variable attributes

SYNOPSIS

THR TSH

```
#include <pthread.h>

int pthread_condattr_getpshared(const pthread_condattr_t *restrict attr,
    int *restrict pshared);
int pthread_condattr_setpshared(pthread_condattr_t *attr,
    int pshared);
```

DESCRIPTION

The *pthread_condattr_getpshared*( ) function shall obtain the value of the *process-shared* attribute from the attributes object referenced by *attr*. The *pthread_condattr_setpshared*( ) function shall set the *process-shared* attribute in an initialized attributes object referenced by *attr*.

The *process-shared* attribute is set to PTHREAD_PROCESS_SHARED to permit a condition variable to be operated upon by any thread that has access to the memory where the condition variable is allocated, even if the condition variable is allocated in memory that is shared by multiple processes. If the *process-shared* attribute is PTHREAD_PROCESS_PRIVATE, the condition variable shall only be operated upon by threads created within the same process as the thread that initialized the condition variable; if threads of differing processes attempt to operate on such a condition variable, the behavior is undefined. The default value of the attribute is PTHREAD_PROCESS_PRIVATE.

RETURN VALUE

If successful, the *pthread_condattr_setpshared*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

If successful, the *pthread_condattr_getpshared*( ) function shall return zero and store the value of the *process-shared* attribute of *attr* into the object referenced by the *pshared* parameter. Otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_condattr_getpshared*( ) and *pthread_condattr_setpshared*( ) functions may fail if:

[EINVAL]	The value specified by *attr* is invalid.

The *pthread_condattr_setpshared*( ) function may fail if:

[EINVAL]	The new value specified for the attribute is outside the range of legal values for that attribute.

These functions shall not return an error code of [EINTR].

int pthread_condattr_setpshared(pthread_condattr_t *attr,
    int pshared);
```

DESCRIPTION

Refer to *pthread_condattr_getpshared*( ).

NAME

pthread_create — thread creation

SYNOPSIS

THR
```
#include <pthread.h>

int pthread_create(pthread_t *restrict thread,
    const pthread_attr_t *restrict attr,
    void *(*start_routine)(void*), void *restrict arg);
```

DESCRIPTION

The *pthread_create*( ) function shall create a new thread, with attributes specified by *attr*, within a process. If *attr* is NULL, the default attributes shall be used. If the attributes specified by *attr* are modified later, the thread's attributes shall not be affected. Upon successful completion, *pthread_create*( ) shall store the ID of the created thread in the location referenced by *thread*.

The thread is created executing *start_routine* with *arg* as its sole argument. If the *start_routine* returns, the effect shall be as if there was an implicit call to *pthread_exit*( ) using the return value of *start_routine* as the exit status. Note that the thread in which *main*( ) was originally invoked differs from this. When it returns from *main*( ), the effect shall be as if there was an implicit call to *exit*( ) using the return value of *main*( ) as the exit status.

The signal state of the new thread shall be initialized as follows:

- The signal mask shall be inherited from the creating thread.
- The set of signals pending for the new thread shall be empty.

The floating-point environment shall be inherited from the creating thread.

If *pthread_create*( ) fails, no new thread is created and the contents of the location referenced by *thread* are undefined.

TCT If _POSIX_THREAD_CPUTIME is defined, the new thread shall have a CPU-time clock accessible, and the initial value of this clock shall be set to zero.

RETURN VALUE

If successful, the *pthread_create*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_create*( ) function shall fail if:

[EAGAIN]	The system lacked the necessary resources to create another thread, or the system-imposed limit on the total number of threads in a process PTHREAD_THREADS_MAX would be exceeded.
[EINVAL]	The value specified by *attr* is invalid.
[EPERM]	The caller does not have appropriate permission to set the required scheduling parameters or scheduling policy.

The *pthread_create*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

A suggested alternative to *pthread_create*( ) would be to define two separate operations: create and start. Some applications would find such behavior more natural. Ada, in particular, separates the ''creation'' of a task from its ''activation''.

Splitting the operation was rejected by the standard developers for many reasons:

- The number of calls required to start a thread would increase from one to two and thus place an additional burden on applications that do not require the additional synchronization. The second call, however, could be avoided by the additional complication of a start-up state attribute.
- An extra state would be introduced: ''created but not started''. This would require the standard to specify the behavior of the thread operations when the target has not yet started executing.
- For those applications that require such behavior, it is possible to simulate the two separate steps with the facilities that are currently provided. The *start_routine*( ) can synchronize by waiting on a condition variable that is signaled by the start operation.

An Ada implementor can choose to create the thread at either of two points in the Ada program: when the task object is created, or when the task is activated (generally at a ''begin''). If the first approach is adopted, the *start_routine*( ) needs to wait on a condition variable to receive the order to begin ''activation''. The second approach requires no such condition variable or extra synchronization. In either approach, a separate Ada task control block would need to be created when the task object is created to hold rendezvous queues, and so on.

An extension of the preceding model would be to allow the state of the thread to be modified between the create and start. This would allow the thread attributes object to be eliminated. This has been rejected because:

- All state in the thread attributes object has to be able to be set for the thread. This would require the definition of functions to modify thread attributes. There would be no reduction in the number of function calls required to set up the thread. In fact, for an application that creates all threads using identical attributes, the number of function calls required to set up the threads would be dramatically increased. Use of a thread attributes object permits the application to make one set of attribute setting function calls. Otherwise, the set of attribute setting function calls needs to be made for each thread creation.
- Depending on the implementation architecture, functions to set thread state would require kernel calls, or for other implementation reasons would not be able to be implemented as macros, thereby increasing the cost of thread creation.
- The ability for applications to segregate threads by class would be lost.

Another suggested alternative uses a model similar to that for process creation, such as ''thread fork''. The fork semantics would provide more flexibility and the ''create'' function can be implemented simply by doing a thread fork followed immediately by a call to the desired ''start routine'' for the thread. This alternative has these problems:

- For many implementations, the entire stack of the calling thread would need to be duplicated, since in many architectures there is no way to determine the size of the calling frame.

- Efficiency is reduced since at least some part of the stack has to be copied, even though in most cases the thread never needs the copied context, since it merely calls the desired start routine.

FUTURE DIRECTIONS

None.

SEE ALSO

fork( ), *pthread_exit*( ), *pthread_join*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_create*( ) function is marked as part of the Threads option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The [EPERM] mandatory error condition is added.

The thread CPU-time clock semantics are added for alignment with IEEE Std 1003.1d-1999.

The **restrict** keyword is added to the *pthread_create*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

The DESCRIPTION is updated to make it explicit that the floating-point environment is inherited from the creating thread.

NAME

pthread_detach — detach a thread

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_detach(pthread_t thread);
```

DESCRIPTION

The *pthread_detach*( ) function shall indicate to the implementation that storage for the thread *thread* can be reclaimed when that thread terminates. If *thread* has not terminated, *pthread_detach*( ) shall not cause it to terminate. The effect of multiple *pthread_detach*( ) calls on the same target thread is unspecified. |

RETURN VALUE

If the call succeeds, *pthread_detach*( ) shall return 0; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_detach*( ) function shall fail if:

[EINVAL]	The implementation has detected that the value specified by *thread* does not refer to a joinable thread.
[ESRCH]	No thread could be found corresponding to that specified by the given thread ID.

The *pthread_detach*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The *pthread_join*( ) or *pthread_detach*( ) functions should eventually be called for every thread that is created so that storage associated with the thread may be reclaimed.

It has been suggested that a ‘‘detach’’ function is not necessary; the *detachstate* thread creation attribute is sufficient, since a thread need never be dynamically detached. However, need arises in at least two cases:

1. In a cancelation handler for a *pthread_join*( ) it is nearly essential to have a *pthread_detach*( ) function in order to detach the thread on which *pthread_join*( ) was waiting. Without it, it would be necessary to have the handler do another *pthread_join*( ) to attempt to detach the thread, which would both delay the cancelation processing for an unbounded period and introduce a new call to *pthread_join*( ), which might itself need a cancelation handler. A dynamic detach is nearly essential in this case.
2. In order to detach the ‘‘initial thread’’ (as may be desirable in processes that set up server threads).

FUTURE DIRECTIONS

None.

NAME

pthread_equal — compare thread IDs

SYNOPSIS

THR
```
#include <pthread.h>

int pthread_equal(pthread_t t1, pthread_t t2);
```

DESCRIPTION

This function shall compare the thread IDs *t1* and *t2*.

RETURN VALUE

The *pthread_equal*( ) function shall return a non-zero value if *t1* and *t2* are equal; otherwise, zero shall be returned.

If either *t1* or *t2* are not valid thread IDs, the behavior is undefined.

ERRORS

No errors are defined.

The *pthread_equal*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Implementations may choose to define a thread ID as a structure. This allows additional flexibility and robustness over using an **int**. For example, a thread ID could include a sequence number that allows detection of ‘‘dangling IDs’’ (copies of a thread ID that has been detached). Since the C language does not support comparison on structure types, the *pthread_equal*( ) function is provided to compare thread IDs.

FUTURE DIRECTIONS

None.

The *pthread_equal*( ) function is marked as part of the Threads option.

NAME

pthread_exit — thread termination

SYNOPSIS

THR

```
#include <pthread.h>

void pthread_exit(void *value_ptr);
```

DESCRIPTION

The *pthread_exit*( ) function shall terminate the calling thread and make the value *value_ptr* available to any successful join with the terminating thread. Any cancelation cleanup handlers that have been pushed and not yet popped shall be popped in the reverse order that they were pushed and then executed. After all cancelation cleanup handlers have been executed, if the thread has any thread-specific data, appropriate destructor functions shall be called in an unspecified order. Thread termination does not release any application visible process resources, including, but not limited to, mutexes and file descriptors, nor does it perform any process-level cleanup actions, including, but not limited to, calling any *atexit*( ) routines that may exist.

An implicit call to *pthread_exit*( ) is made when a thread other than the thread in which *main*( ) was first invoked returns from the start routine that was used to create it. The function's return value shall serve as the thread's exit status.

The behavior of *pthread_exit*( ) is undefined if called from a cancelation cleanup handler or destructor function that was invoked as a result of either an implicit or explicit call to *pthread_exit*( ).

After a thread has terminated, the result of access to local (auto) variables of the thread is undefined. Thus, references to local variables of the exiting thread should not be used for the *pthread_exit*( ) *value_ptr* parameter value.

The process shall exit with an exit status of 0 after the last thread has been terminated. The behavior shall be as if the implementation called *exit*( ) with a zero argument at thread termination time.

RETURN VALUE

The *pthread_exit*( ) function cannot return to its caller.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The normal mechanism by which a thread terminates is to return from the routine that was specified in the *pthread_create*( ) call that started it. The *pthread_exit*( ) function provides the capability for a thread to terminate without requiring a return from the start routine of that thread, thereby providing a function analogous to *exit*( ).

Regardless of the method of thread termination, any cancelation cleanup handlers that have been pushed and not yet popped are executed, and the destructors for any existing thread-specific data are executed. This volume of IEEE Std 1003.1-200x requires that cancelation cleanup handlers be popped and called in order. After all cancelation cleanup handlers have been executed, thread-specific data destructors are called, in an unspecified order, for each item of thread-specific data that exists in the thread. This ordering is necessary because cancelation cleanup handlers may rely on thread-specific data.

As the meaning of the status is determined by the application (except when the thread has been canceled, in which case it is PTHREAD_CANCELED), the implementation has no idea what an illegal status value is, which is why no address error checking is done.

FUTURE DIRECTIONS

None.

NAME

pthread_getconcurrency, pthread_setconcurrency — get and set level of concurrency

SYNOPSIS

XSI

```
#include <pthread.h>

int pthread_getconcurrency(void);
int pthread_setconcurrency(int new_level);

```

DESCRIPTION

Unbound threads in a process may or may not be required to be simultaneously active. By default, the threads implementation ensures that a sufficient number of threads are active so that the process can continue to make progress. While this conserves system resources, it may not produce the most effective level of concurrency.

The *pthread_setconcurrency*( ) function allows an application to inform the threads implementation of its desired concurrency level, *new_level*. The actual level of concurrency provided by the implementation as a result of this function call is unspecified.

If *new_level* is zero, it causes the implementation to maintain the concurrency level at its discretion as if *pthread_setconcurrency*( ) had never been called.

The *pthread_getconcurrency*( ) function shall return the value set by a previous call to the *pthread_setconcurrency*( ) function. If the *pthread_setconcurrency*( ) function was not previously called, this function shall return zero to indicate that the implementation is maintaining the concurrency level.

A call to *pthread_setconcurrency*( ) shall inform the implementation of its desired concurrency level. The implementation shall use this as a hint, not a requirement.

If an implementation does not support multiplexing of user threads on top of several kernel-scheduled entities, the *pthread_setconcurrency*( ) and *pthread_getconcurrency*( ) functions are provided for source code compatibility but they shall have no effect when called. To maintain the function semantics, the *new_level* parameter is saved when *pthread_setconcurrency*( ) is called so that a subsequent call to *pthread_getconcurrency*( ) shall return the same value.

RETURN VALUE

If successful, the *pthread_setconcurrency*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

The *pthread_getconcurrency*( ) function shall always return the concurrency level set by a previous call to *pthread_setconcurrency*( ). If the *pthread_setconcurrency*( ) function has never been called, *pthread_getconcurrency*( ) shall return zero.

ERRORS

The *pthread_setconcurrency*( ) function shall fail if:

[EINVAL]	The value specified by *new_level* is negative.
[EAGAIN]	The value specific by *new_level* would cause a system resource to be exceeded.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

Use of these functions changes the state of the underlying concurrency upon which the application depends. Library developers are advised to not use the *pthread_getconcurrency*( ) and *pthread_setconcurrency*( ) functions since their use may conflict with an applications use of these functions.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1d-1999.

In the SYNOPSIS, the inclusion of **<sys/types.h>** is no longer required.

NAME

pthread_getschedparam, pthread_setschedparam — dynamic thread scheduling parameters access (**REALTIME THREADS**)

SYNOPSIS

THR TPS

```
#include <pthread.h>

int pthread_getschedparam(pthread_t thread, int *restrict policy,
    struct sched_param *restrict param);
int pthread_setschedparam(pthread_t thread, int policy,
    const struct sched_param *param);
```

DESCRIPTION

The *pthread_getschedparam*( ) and *pthread_setschedparam*( ) functions shall, respectively, get and set the scheduling policy and parameters of individual threads within a multi-threaded process to be retrieved and set. For SCHED_FIFO and SCHED_RR, the only required member of the **sched_param** structure is the priority *sched_priority*. For SCHED_OTHER, the affected scheduling parameters are implementation-defined.

The *pthread_getschedparam*( ) function shall retrieve the scheduling policy and scheduling parameters for the thread whose thread ID is given by *thread* and shall store those values in *policy* and *param*, respectively. The priority value returned from *pthread_getschedparam*( ) shall be the value specified by the most recent *pthread_setschedparam*( ), *pthread_setschedprio*( ), or *pthread_create*( ) call affecting the target thread. It shall not reflect any temporary adjustments to its priority as a result of any priority inheritance or ceiling functions. The *pthread_setschedparam*( ) function shall set the scheduling policy and associated scheduling parameters for the thread whose thread ID is given by *thread* to the policy and associated parameters provided in *policy* and *param*, respectively.

The *policy* parameter may have the value SCHED_OTHER, SCHED_FIFO, or SCHED_RR. The scheduling parameters for the SCHED_OTHER policy are implementation-defined. The SCHED_FIFO and SCHED_RR policies shall have a single scheduling parameter, *priority*.

TSP If _POSIX_THREAD_SPORADIC_SERVER is defined, then the *policy* argument may have the value SCHED_SPORADIC, with the exception for the *pthread_setschedparam*( ) function that if the scheduling policy was not SCHED_SPORADIC at the time of the call, it is implementation-defined whether the function is supported; in other words, the implementation need not allow the application to dynamically change the scheduling policy to SCHED_SPORADIC. The sporadic server scheduling policy has the associated parameters *sched_ss_low_priority*, *sched_ss_repl_period*, *sched_ss_init_budget*, *sched_priority*, and *sched_ss_max_repl*. The specified *sched_ss_repl_period* shall be greater than or equal to the specified *sched_ss_init_budget* for the function to succeed; if it is not, then the function shall fail. The value of *sched_ss_max_repl* shall be within the inclusive range [1,{SS_REPL_MAX}] for the function to succeed; if not, the function shall fail.

If the *pthread_setschedparam*( ) function fails, the scheduling parameters shall not be changed for the target thread.

RETURN VALUE

If successful, the *pthread_getschedparam*( ) and *pthread_setschedparam*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_getschedparam*( ) function may fail if:

[ESRCH]	The value specified by *thread* does not refer to a existing thread.

The *pthread_setschedparam*( ) function may fail if:

[EINVAL]	The value specified by *policy* or one of the scheduling parameters associated with the scheduling policy *policy* is invalid.
[ENOTSUP]	An attempt was made to set the policy or scheduling parameters to an unsupported value.
TSP [ENOTSUP]	An attempt was made to dynamically change the scheduling policy to SCHED_SPORADIC, and the implementation does not support this change.
[EPERM]	The caller does not have the appropriate permission to set either the scheduling parameters or the scheduling policy of the specified thread.
[EPERM]	The implementation does not allow the application to modify one of the parameters to the value specified.
[ESRCH]	The value specified by *thread* does not refer to a existing thread.

These functions shall not return an error code of [EINTR].

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_getschedparam*( ) and *pthread_setschedparam*( ) functions are marked as part of the Threads and Thread Execution Scheduling options.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Thread Execution Scheduling option.

The Open Group Corrigendum U026/2 is applied, correcting the prototype for the *pthread_setschedparam*( ) function so that its second argument is of type **int**.

The SCHED_SPORADIC scheduling policy is added for alignment with IEEE Std 1003.1d-1999.

The **restrict** keyword is added to the *pthread_getschedparam*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

The Open Group Corrigendum U047/1 is applied. |

IEEE PASC Interpretation 1003.1 #96 is applied, noting that priority values can also be set by a call to the *pthread_setschedprio*( ) function.

NAME

pthread_getspecific, pthread_setspecific — thread-specific data management

SYNOPSIS

THR

```
#include <pthread.h>

void *pthread_getspecific(pthread_key_t key);
int pthread_setspecific(pthread_key_t key, const void *value);
```

DESCRIPTION

The *pthread_getspecific*( ) function shall return the value currently bound to the specified *key* on behalf of the calling thread.

The *pthread_setspecific*( ) function shall associate a thread-specific *value* with a *key* obtained via a previous call to *pthread_key_create*( ). Different threads may bind different values to the same key. These values are typically pointers to blocks of dynamically allocated memory that have been reserved for use by the calling thread.

The effect of calling *pthread_getspecific*( ) or *pthread_setspecific*( ) with a *key* value not obtained from *pthread_key_create*( ) or after *key* has been deleted with *pthread_key_delete*( ) is undefined.

Both *pthread_getspecific*( ) and *pthread_setspecific*( ) may be called from a thread-specific data destructor function. A call to *pthread_getspecific*( ) for the thread-specific data key being destroyed shall return the value NULL, unless the value is changed (after the destructor starts) by a call to *pthread_setspecific*( ). Calling *pthread_setspecific*( ) from a thread-specific data destructor routine may result either in lost storage (after at least PTHREAD_DESTRUCTOR_ITERATIONS attempts at destruction) or in an infinite loop.

Both functions may be implemented as macros.

RETURN VALUE

The *pthread_getspecific*( ) function shall return the thread-specific data value associated with the given *key*. If no thread-specific data value is associated with *key*, then the value NULL shall be returned.

If successful, the *pthread_setspecific*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

No errors are returned from *pthread_getspecific*( ).

The *pthread_setspecific*( ) function shall fail if:

[ENOMEM]	Insufficient memory exists to associate the value with the key.

The *pthread_setspecific*( ) function may fail if:

[EINVAL]	The key value is invalid.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Performance and ease-of-use of *pthread_getspecific*( ) is critical for functions that rely on maintaining state in thread-specific data. Since no errors are required to be detected by it, and since the only error that could be detected is the use of an invalid key, the function to *pthread_getspecific*( ) has been designed to favor speed and simplicity over error reporting.

FUTURE DIRECTIONS

None.

The *pthread_getspecific*( ) and *pthread_setspecific*( ) functions are marked as part of the Threads option.

IEEE PASC Interpretation 1003.1c #3 (Part 6) is applied, updating the DESCRIPTION.

NAME

pthread_join — wait for thread termination

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_join(pthread_t thread, void **value_ptr);
```

DESCRIPTION

The *pthread_join*( ) function shall suspend execution of the calling thread until the target *thread* terminates, unless the target *thread* has already terminated. On return from a successful *pthread_join*( ) call with a non-NULL *value_ptr* argument, the value passed to *pthread_exit*( ) by the terminating thread shall be made available in the location referenced by *value_ptr*. When a *pthread_join*( ) returns successfully, the target thread has been terminated. The results of multiple simultaneous calls to *pthread_join*( ) specifying the same target thread are undefined. If the thread calling *pthread_join*( ) is canceled, then the target thread shall not be detached.

It is unspecified whether a thread that has exited but remains unjoined counts against _PTHREAD_THREADS_MAX.

RETURN VALUE

If successful, the *pthread_join*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_join*( ) function shall fail if:

[EINVAL]	The implementation has detected that the value specified by *thread* does not refer to a joinable thread.
[ESRCH]	No thread could be found corresponding to that specified by the given thread ID.

The *pthread_join*( ) function may fail if:

[EDEADLK]	A deadlock was detected or the value of *thread* specifies the calling thread.

The *pthread_join*( ) function shall not return an error code of [EINTR].

EXAMPLES

An example of thread creation and deletion follows:

```
typedef struct {
    int *ar;
    long n;
} subarray;

void *
incer(void *arg)
{
    long i;

    for (i = 0; i < ((subarray *)arg)->n; i++)
        ((subarray *)arg)->ar[i]++;
}

main()
{
    int        ar[1000000];
```

```
        pthread_t  th1, th2;
        subarray   sb1, sb2;

        sb1.ar = &ar[0];
        sb1.n  = 500000;
        (void) pthread_create(&th1, NULL, incer, &sb1);

        sb2.ar = &ar[500000];
        sb2.n  = 500000;
        (void) pthread_create(&th2, NULL, incer, &sb2);

        (void) pthread_join(th1, NULL);
        (void) pthread_join(th2, NULL);
    }
```

APPLICATION USAGE

None.

RATIONALE

The *pthread_join*( ) function is a convenience that has proven useful in multi-threaded applications. It is true that a programmer could simulate this function if it were not provided by passing extra state as part of the argument to the *start_routine*( ). The terminating thread would set a flag to indicate termination and broadcast a condition that is part of that state; a joining thread would wait on that condition variable. While such a technique would allow a thread to wait on more complex conditions (for example, waiting for multiple threads to terminate), waiting on individual thread termination is considered widely useful. Also, including the *pthread_join*( ) function in no way precludes a programmer from coding such complex waits. Thus, while not a primitive, including *pthread_join*( ) in this volume of IEEE Std 1003.1-200x was considered valuable.

The *pthread_join*( ) function provides a simple mechanism allowing an application to wait for a thread to terminate. After the thread terminates, the application may then choose to clean up resources that were used by the thread. For instance, after *pthread_join*( ) returns, any application-provided stack storage could be reclaimed.

The *pthread_join*( ) or *pthread_detach*( ) function should eventually be called for every thread that is created with the *detachstate* attribute set to PTHREAD_CREATE_JOINABLE so that storage associated with the thread may be reclaimed.

The interaction between *pthread_join*( ) and cancelation is well-defined for the following reasons:

- The *pthread_join*( ) function, like all other non-async-cancel-safe functions, can only be called with deferred cancelability type.
- Cancelation cannot occur in the disabled cancelability state.

Thus, only the default cancelability state need be considered. As specified, either the *pthread_join*( ) call is canceled, or it succeeds, but not both. The difference is obvious to the application, since either a cancelation handler is run or *pthread_join*( ) returns. There are no race conditions since *pthread_join*( ) was called in the deferred cancelability state.

The *pthread_join*( ) function is marked as part of the Threads option.

NAME

pthread_key_create — thread-specific data key creation

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_key_create(pthread_key_t *key, void (*destructor)(void*));
```

DESCRIPTION

The *pthread_key_create*( ) function shall create a thread-specific data key visible to all threads in the process. Key values provided by *pthread_key_create*( ) are opaque objects used to locate thread-specific data. Although the same key value may be used by different threads, the values bound to the key by *pthread_setspecific*( ) are maintained on a per-thread basis and persist for the life of the calling thread.

Upon key creation, the value NULL shall be associated with the new key in all active threads. Upon thread creation, the value NULL shall be associated with all defined keys in the new thread.

An optional destructor function may be associated with each key value. At thread exit, if a key value has a non-NULL destructor pointer, and the thread has a non-NULL value associated with that key, the value of the key is set to NULL, and then the function pointed to is called with the previously associated value as its sole argument. The order of destructor calls is unspecified if more than one destructor exists for a thread when it exits.

If, after all the destructors have been called for all non-NULL values with associated destructors, there are still some non-NULL values with associated destructors, then the process is repeated. If, after at least {PTHREAD_DESTRUCTOR_ITERATIONS} iterations of destructor calls for outstanding non-NULL values, there are still some non-NULL values with associated destructors, implementations may stop calling destructors, or they may continue calling destructors until no non-NULL values with associated destructors exist, even though this might result in an infinite loop.

RETURN VALUE

If successful, the *pthread_key_create*( ) function shall store the newly created key value at **key* and shall return zero. Otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_key_create*( ) function shall fail if:

[EAGAIN]	The system lacked the necessary resources to create another thread-specific data key, or the system-imposed limit on the total number of keys per process PTHREAD_KEYS_MAX has been exceeded.
[ENOMEM]	Insufficient memory exists to create the key.

The *pthread_key_create*( ) function shall not return an error code of [EINTR].

EXAMPLES

The following example demonstrates a function that initializes a thread-specific data key when it is first called, and associates a thread-specific object with each calling thread, initializing this object when necessary.

```
static pthread_key_t key;
static pthread_once_t key_once = PTHREAD_ONCE_INIT;

static void
make_key()
{
    (void) pthread_key_create(&key, NULL);
}

func()
{
    void *ptr;

    (void) pthread_once(&key_once, make_key);
    if ((ptr = pthread_getspecific(key)) == NULL) {
        ptr = malloc(OBJECT_SIZE);
        ...
        (void) pthread_setspecific(key, ptr);
    }
    ...
}
```

Note that the key has to be initialized before *pthread_getspecific*( ) or *pthread_setspecific*( ) can be used. The *pthread_key_create*( ) call could either be explicitly made in a module initialization routine, or it can be done implicitly by the first call to a module as in this example. Any attempt to use the key before it is initialized is a programming error, making the code below incorrect.

```
static pthread_key_t key;

func()
{
    void *ptr;

   /* KEY NOT INITIALIZED!!!  THIS WON'T WORK!!! */
    if ((ptr = pthread_getspecific(key)) == NULL &&
        pthread_setspecific(key, NULL) != 0) {
        pthread_key_create(&key, NULL);
        ...
    }
}
```

APPLICATION USAGE

None.

RATIONALE

Destructor Functions

Normally, the value bound to a key on behalf of a particular thread is a pointer to storage allocated dynamically on behalf of the calling thread. The destructor functions specified with *pthread_key_create*( ) are intended to be used to free this storage when the thread exits. Thread cancelation cleanup handlers cannot be used for this purpose because thread-specific data may persist outside the lexical scope in which the cancelation cleanup handlers operate.

If the value associated with a key needs to be updated during the lifetime of the thread, it may be necessary to release the storage associated with the old value before the new value is bound. Although the *pthread_setspecific*( ) function could do this automatically, this feature is not needed often enough to justify the added complexity. Instead, the programmer is responsible for freeing the stale storage:

```
pthread_getspecific(key, &old);
new = allocate();
destructor(old);
pthread_setspecific(key, new);
```

Note: The above example could leak storage if run with asynchronous cancelation enabled. No such problems occur in the default cancelation state if no cancelation points occur between the get and set.

There is no notion of a destructor-safe function. If an application does not call *pthread_exit*( ) from a signal handler, or if it blocks any signal whose handler may call *pthread_exit*( ) while calling async-unsafe functions, all functions may be safely called from destructors.

Non-Idempotent Data Key Creation

There were requests to make *pthread_key_create*( ) idempotent with respect to a given *key* address parameter. This would allow applications to call *pthread_key_create*( ) multiple times for a given *key* address and be guaranteed that only one key would be created. Doing so would require the key value to be previously initialized (possibly at compile time) to a known null value and would require that implicit mutual-exclusion be performed based on the address and contents of the *key* parameter in order to guarantee that exactly one key would be created.

Unfortunately, the implicit mutual-exclusion would not be limited to only *pthread_key_create*( ). On many implementations, implicit mutual-exclusion would also have to be performed by *pthread_getspecific*( ) and *pthread_setspecific*( ) in order to guard against using incompletely stored or not-yet-visible key values. This could significantly increase the cost of important operations, particularly *pthread_getspecific*( ).

Thus, this proposal was rejected. The *pthread_key_create*( ) function performs no implicit synchronization. It it the responsibility of the programmer to ensure that it is called exactly once per key before use of the key. Several straightforward mechanisms can already be used to accomplish this, including calling explicit module initialization functions, using mutexes, and using *pthread_once*( ). This places no significant burden on the programmer, introduces no possibly confusing *ad hoc* implicit synchronization mechanism, and potentially allows commonly used thread-specific data operations to be more efficient.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_key_create*( ) function is marked as part of the Threads option.

IEEE PASC Interpretation 1003.1c #8 is applied, updating the DESCRIPTION.

NAME

pthread_key_delete — thread-specific data key deletion

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_key_delete(pthread_key_t key);
```

DESCRIPTION

The *pthread_key_delete*( ) function shall delete a thread-specific data key previously returned by *pthread_key_create*( ). The thread-specific data values associated with *key* need not be NULL at the time *pthread_key_delete*( ) is called. It is the responsibility of the application to free any application storage or perform any cleanup actions for data structures related to the deleted key or associated thread-specific data in any threads; this cleanup can be done either before or after *pthread_key_delete*( ) is called. Any attempt to use *key* following the call to *pthread_key_delete*( ) results in undefined behavior.

The *pthread_key_delete*( ) function shall be callable from within destructor functions. No destructor functions shall be invoked by *pthread_key_delete*( ). Any destructor function that may have been associated with *key* shall no longer be called upon thread exit.

RETURN VALUE

If successful, the *pthread_key_delete*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_key_delete*( ) function may fail if:

[EINVAL]	The *key* value is invalid.

The *pthread_key_delete*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

A thread-specific data key deletion function has been included in order to allow the resources associated with an unused thread-specific data key to be freed. Unused thread-specific data keys can arise, among other scenarios, when a dynamically loaded module that allocated a key is unloaded.

Conforming applications are responsible for performing any cleanup actions needed for data structures associated with the key to be deleted, including data referenced by thread-specific data values. No such cleanup is done by *pthread_key_delete*( ). In particular, destructor functions are not called. There are several reasons for this division of responsibility: |

1. The associated destructor functions used to free thread-specific data at thread exit time are only guaranteed to work correctly when called in the thread that allocated the thread-specific data. (Destructors themselves may utilize thread-specific data.) Thus, they cannot be used to free thread-specific data in other threads at key deletion time. Attempting to have them called by other threads at key deletion time would require other threads to be asynchronously interrupted. But since interrupted threads could be in an arbitrary state, including holding locks necessary for the destructor to run, this approach would fail. In general, there is no safe mechanism whereby an implementation could free thread-specific data at key deletion time.

2. Even if there were a means of safely freeing thread-specific data associated with keys to be deleted, doing so would require that implementations be able to enumerate the threads with non-NULL data and potentially keep them from creating more thread-specific data while the key deletion is occurring. This special case could cause extra synchronization in the normal case, which would otherwise be unnecessary.

For an application to know that it is safe to delete a key, it has to know that all the threads that might potentially ever use the key do not attempt to use it again. For example, it could know this if all the client threads have called a cleanup procedure declaring that they are through with the module that is being shut down, perhaps by zero'ing a reference count.

FUTURE DIRECTIONS

None.

The *pthread_key_delete*( ) function is marked as part of the Threads option.

NAME

pthread_kill — send a signal to a thread

SYNOPSIS

THR

```
#include <signal.h>

int pthread_kill(pthread_t thread, int sig);
```

DESCRIPTION

The *pthread_kill*( ) function shall request that a signal be delivered to the specified thread. |

As in *kill*( ), if *sig* is zero, error checking shall be performed but no signal shall actually be sent. |

RETURN VALUE

Upon successful completion, the function shall return a value of zero. Otherwise, the function shall return an error number. If the *pthread_kill*( ) function fails, no signal shall be sent.

ERRORS

The *pthread_kill*( ) function shall fail if:

[ESRCH]	No thread could be found corresponding to that specified by the given thread ID.
[EINVAL]	The value of the *sig* argument is an invalid or unsupported signal number.

The *pthread_kill*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

The *pthread_kill*( ) function provides a mechanism for asynchronously directing a signal at a thread in the calling process. This could be used, for example, by one thread to affect broadcast delivery of a signal to a set of threads.

Note that *pthread_kill*( ) only causes the signal to be handled in the context of the given thread; the signal action (termination or stopping) affects the process as a whole.

Issue 6

The *pthread_kill*( ) function is marked as part of the Threads option.

The APPLICATION USAGE section is added.

NAME

pthread_mutex_destroy, pthread_mutex_init — destroy and initialize a mutex

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_mutex_destroy(pthread_mutex_t *mutex);
int pthread_mutex_init(pthread_mutex_t *restrict mutex,
    const pthread_mutexattr_t *restrict attr);
pthread_mutex_t mutex = PTHREAD_MUTEX_INITIALIZER;
```

DESCRIPTION

The *pthread_mutex_destroy*( ) function shall destroy the mutex object referenced by *mutex*; the mutex object becomes, in effect, uninitialized. An implementation may cause *pthread_mutex_destroy*( ) to set the object referenced by *mutex* to an invalid value. A destroyed mutex object can be reinitialized using *pthread_mutex_init*( ); the results of otherwise referencing the object after it has been destroyed are undefined.

It shall be safe to destroy an initialized mutex that is unlocked. Attempting to destroy a locked mutex results in undefined behavior.

The *pthread_mutex_init*( ) function shall initialize the mutex referenced by *mutex* with attributes specified by *attr*. If *attr* is NULL, the default mutex attributes are used; the effect shall be the same as passing the address of a default mutex attributes object. Upon successful initialization, the state of the mutex becomes initialized and unlocked.

Only *mutex* itself may be used for performing synchronization. The result of referring to copies of *mutex* in calls to *pthread_mutex_lock*( ), *pthread_mutex_trylock*( ), *pthread_mutex_unlock*( ), and *pthread_mutex_destroy*( ) is undefined.

Attempting to initialize an already initialized mutex results in undefined behavior.

In cases where default mutex attributes are appropriate, the macro PTHREAD_MUTEX_INITIALIZER can be used to initialize mutexes that are statically allocated. The effect shall be equivalent to dynamic initialization by a call to *pthread_mutex_init*( ) with parameter *attr* specified as NULL, except that no error checks are performed.

RETURN VALUE

If successful, the *pthread_mutex_destroy*( ) and *pthread_mutex_init*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

The [EBUSY] and [EINVAL] error checks, if implemented, act as if they were performed immediately at the beginning of processing for the function and shall cause an error return prior to modifying the state of the mutex specified by *mutex*.

ERRORS

The *pthread_mutex_destroy*( ) function may fail if:

[EBUSY]	The implementation has detected an attempt to destroy the object referenced by *mutex* while it is locked or referenced (for example, while being used in a *pthread_cond_timedwait*( ) or *pthread_cond_wait*( )) by another thread.
[EINVAL]	The value specified by *mutex* is invalid.

The *pthread_mutex_init*( ) function shall fail if:

[EAGAIN]	The system lacked the necessary resources (other than memory) to initialize another mutex.

[ENOMEM]	Insufficient memory exists to initialize the mutex.
[EPERM]	The caller does not have the privilege to perform the operation.

The *pthread_mutex_init*( ) function may fail if:

[EBUSY]	The implementation has detected an attempt to reinitialize the object referenced by *mutex*, a previously initialized, but not yet destroyed, mutex.
[EINVAL]	The value specified by *attr* is invalid.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Alternate Implementations Possible

This volume of IEEE Std 1003.1-200x supports several alternative implementations of mutexes. An implementation may store the lock directly in the object of type **pthread_mutex_t**. Alternatively, an implementation may store the lock in the heap and merely store a pointer, handle, or unique ID in the mutex object. Either implementation has advantages or may be required on certain hardware configurations. So that portable code can be written that is invariant to this choice, this volume of IEEE Std 1003.1-200x does not define assignment or equality for this type, and it uses the term ‘‘initialize’’ to reinforce the (more restrictive) notion that the lock may actually reside in the mutex object itself.

Note that this precludes an over-specification of the type of the mutex or condition variable and motivates the opacity of the type.

An implementation is permitted, but not required, to have *pthread_mutex_destroy*( ) store an illegal value into the mutex. This may help detect erroneous programs that try to lock (or otherwise reference) a mutex that has already been destroyed.

Tradeoff Between Error Checks and Performance Supported

Many of the error checks were made optional in order to let implementations trade off performance *versus* degree of error checking according to the needs of their specific applications and execution environment. As a general rule, errors or conditions caused by the system (such as insufficient memory) always need to be reported, but errors due to an erroneously coded application (such as failing to provide adequate synchronization to prevent a mutex from being deleted while in use) are made optional.

A wide range of implementations is thus made possible. For example, an implementation intended for application debugging may implement all of the error checks, but an implementation running a single, provably correct application under very tight performance constraints in an embedded computer might implement minimal checks. An implementation might even be provided in two versions, similar to the options that compilers provide: a full-checking, but slower version; and a limited-checking, but faster version. To forbid this optionality would be a disservice to users.

By carefully limiting the use of ‘‘undefined behavior’’ only to things that an erroneous (badly coded) application might do, and by defining that resource-not-available errors are mandatory, this volume of IEEE Std 1003.1-200x ensures that a fully-conforming application is portable across the full range of implementations, while not forcing all implementations to add overhead to check for numerous things that a correct program never does.

Why No Limits Defined

Defining symbols for the maximum number of mutexes and condition variables was considered but rejected because the number of these objects may change dynamically. Furthermore, many implementations place these objects into application memory; thus, there is no explicit maximum.

Static Initializers for Mutexes and Condition Variables

Providing for static initialization of statically allocated synchronization objects allows modules with private static synchronization variables to avoid runtime initialization tests and overhead. Furthermore, it simplifies the coding of self-initializing modules. Such modules are common in C libraries, where for various reasons the design calls for self-initialization instead of requiring an explicit module initialization function to be called. An example use of static initialization follows.

Without static initialization, a self-initializing routine *foo*( ) might look as follows:

```
static pthread_once_t foo_once = PTHREAD_ONCE_INIT;
static pthread_mutex_t foo_mutex;

void foo_init()
{
    pthread_mutex_init(&foo_mutex, NULL);
}

void foo()
{
    pthread_once(&foo_once, foo_init);
    pthread_mutex_lock(&foo_mutex);
   /* Do work. */
    pthread_mutex_unlock(&foo_mutex);
}
```

With static initialization, the same routine could be coded as follows:

```
static pthread_mutex_t foo_mutex = PTHREAD_MUTEX_INITIALIZER;

void foo()
{
    pthread_mutex_lock(&foo_mutex);
   /* Do work. */
    pthread_mutex_unlock(&foo_mutex);
}
```

Note that the static initialization both eliminates the need for the initialization test inside *pthread_once*( ) and the fetch of &*foo_mutex* to learn the address to be passed to *pthread_mutex_lock*( ) or *pthread_mutex_unlock*( ).

Thus, the C code written to initialize static objects is simpler on all systems and is also faster on a large class of systems; those where the (entire) synchronization object can be stored in application memory.

Yet the locking performance question is likely to be raised for machines that require mutexes to be allocated out of special memory. Such machines actually have to have mutexes and possibly condition variables contain pointers to the actual hardware locks. For static initialization to work on such machines, *pthread_mutex_lock*( ) also has to test whether or not the pointer to the actual lock has been allocated. If it has not, *pthread_mutex_lock*( ) has to initialize it before use. The reservation of such resources can be made when the program is loaded, and hence return codes have not been added to mutex locking and condition variable waiting to indicate failure to complete initialization.

This runtime test in *pthread_mutex_lock*( ) would at first seem to be extra work; an extra test is required to see whether the pointer has been initialized. On most machines this would actually be implemented as a fetch of the pointer, testing the pointer against zero, and then using the pointer if it has already been initialized. While the test might seem to add extra work, the extra effort of testing a register is usually negligible since no extra memory references are actually done. As more and more machines provide caches, the real expenses are memory references, not instructions executed.

Alternatively, depending on the machine architecture, there are often ways to eliminate *all* overhead in the most important case: on the lock operations that occur *after* the lock has been initialized. This can be done by shifting more overhead to the less frequent operation: initialization. Since out-of-line mutex allocation also means that an address has to be dereferenced to find the actual lock, one technique that is widely applicable is to have static initialization store a bogus value for that address; in particular, an address that causes a machine fault to occur. When such a fault occurs upon the first attempt to lock such a mutex, validity checks can be done, and then the correct address for the actual lock can be filled in. Subsequent lock operations incur no extra overhead since they do not ‘‘fault’’. This is merely one technique that can be used to support static initialization, while not adversely affecting the performance of lock acquisition. No doubt there are other techniques that are highly machine-dependent.

The locking overhead for machines doing out-of-line mutex allocation is thus similar for modules being implicitly initialized, where it is improved for those doing mutex allocation entirely inline. The inline case is thus made much faster, and the out-of-line case is not significantly worse.

Besides the issue of locking performance for such machines, a concern is raised that it is possible that threads would serialize contending for initialization locks when attempting to finish initializing statically allocated mutexes. (Such finishing would typically involve taking an internal lock, allocating a structure, storing a pointer to the structure in the mutex, and releasing the internal lock.) First, many implementations would reduce such serialization by hashing on the mutex address. Second, such serialization can only occur a bounded number of times. In particular, it can happen at most as many times as there are statically allocated synchronization objects. Dynamically allocated objects would still be initialized via *pthread_mutex_init*( ) or *pthread_cond_init*( ).

Finally, if none of the above optimization techniques for out-of-line allocation yields sufficient performance for an application on some implementation, the application can avoid static initialization altogether by explicitly initializing all synchronization objects with the corresponding *pthread_*_init*( ) functions, which are supported by all implementations. An implementation can also document the tradeoffs and advise which initialization technique is more efficient for that particular implementation.

Destroying Mutexes

A mutex can be destroyed immediately after it is unlocked. For example, consider the following code:

```
struct obj {
pthread_mutex_t om;
    int refcnt;
    ...
};

obj_done(struct obj *op)
{
    pthread_mutex_lock(&op->om);
    if (--op->refcnt == 0) {
        pthread_mutex_unlock(&op->om);
(A)     pthread_mutex_destroy(&op->om);
(B)     free(op);
    } else
(C)     pthread_mutex_unlock(&op->om);
}
```

In this case *obj* is reference counted and *obj_done*( ) is called whenever a reference to the object is dropped. Implementations are required to allow an object to be destroyed and freed and potentially unmapped (for example, lines A and B) immediately after the object is unlocked (line C).

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_mutex_destroy*( ) and *pthread_mutex_init*( ) functions are marked as part of the Threads option.

The *pthread_mutex_timedlock*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

IEEE PASC Interpretation 1003.1c #34 is applied, updating the DESCRIPTION.

The **restrict** keyword is added to the *pthread_mutex_init*( ) prototype for alignment with the ISO/IEC 9899: 1999 standard.

NAME

pthread_mutex_getprioceiling, pthread_mutex_setprioceiling — get and set the priority ceiling of a mutex (**REALTIME THREADS**)

SYNOPSIS

THR TPP

```
#include <pthread.h>

int pthread_mutex_getprioceiling(const pthread_mutex_t *restrict mutex,
    int *restrict prioceiling);
int pthread_mutex_setprioceiling(pthread_mutex_t *restrict mutex,
    int prioceiling, int *restrict old_ceiling);
```

DESCRIPTION

The *pthread_mutex_getprioceiling*( ) function shall return the current priority ceiling of the mutex.

The *pthread_mutex_setprioceiling*( ) function shall either lock the mutex if it is unlocked, or block until it can successfully lock the mutex, then it shall change the mutex's priority ceiling and release the mutex. When the change is successful, the previous value of the priority ceiling shall be returned in *old_ceiling*. The process of locking the mutex need not adhere to the priority protect protocol.

If the *pthread_mutex_setprioceiling*( ) function fails, the mutex priority ceiling shall not be changed.

RETURN VALUE

If successful, the *pthread_mutex_getprioceiling*( ) and *pthread_mutex_setprioceiling*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_mutex_getprioceiling*( ) and *pthread_mutex_setprioceiling*( ) functions may fail if:

[EINVAL]	The priority requested by *prioceiling* is out of range.
[EINVAL]	The value specified by *mutex* does not refer to a currently existing mutex.
[EPERM]	The caller does not have the privilege to perform the operation.

These functions shall not return an error code of [EINTR].

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Marked as part of the Realtime Threads Feature Group.

Issue 6

The *pthread_mutex_getprioceiling*( ) and *pthread_mutex_setprioceiling*( ) functions are marked as part of the Threads and Thread Priority Protection options.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Thread Priority Protection option.

The [ENOSYS] error denoting non-support of the priority ceiling protocol for mutexes has been removed. This is since if the implementation provides the functions (regardless of whether _POSIX_PTHREAD_PRIO_PROTECT is defined), they must function as in the DESCRIPTION and therefore the priority ceiling protocol for mutexes is supported.

The *pthread_mutex_timedlock*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

The **restrict** keyword is added to the *pthread_mutex_getprioceiling*( ) and *pthread_mutex_setprioceiling*( ) prototypes for alignment with the ISO/IEC 9899:1999 standard.

NAME

pthread_mutex_init — initialize a mutex

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_mutex_init(pthread_mutex_t *restrict mutex,
    const pthread_mutexattr_t *restrict attr);
pthread_mutex_t mutex = PTHREAD_MUTEX_INITIALIZER;
```

DESCRIPTION

Refer to *pthread_mutex_destroy*( ).

NAME

pthread_mutex_lock, pthread_mutex_trylock, pthread_mutex_unlock — lock and unlock a mutex

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_mutex_lock(pthread_mutex_t *mutex);
int pthread_mutex_trylock(pthread_mutex_t *mutex);
int pthread_mutex_unlock(pthread_mutex_t *mutex);
```

DESCRIPTION

The mutex object referenced by *mutex* shall be locked by calling *pthread_mutex_lock*( ). If the mutex is already locked, the calling thread shall block until the mutex becomes available. This operation shall return with the mutex object referenced by *mutex* in the locked state with the calling thread as its owner.

XSI If the mutex type is PTHREAD_MUTEX_NORMAL, deadlock detection shall not be provided. Attempting to relock the mutex causes deadlock. If a thread attempts to unlock a mutex that it has not locked or a mutex which is unlocked, undefined behavior results.

If the mutex type is PTHREAD_MUTEX_ERRORCHECK, then error checking shall be provided. If a thread attempts to relock a mutex that it has already locked, an error shall be returned. If a thread attempts to unlock a mutex that it has not locked or a mutex which is unlocked, an error shall be returned.

If the mutex type is PTHREAD_MUTEX_RECURSIVE, then the mutex shall maintain the concept of a lock count. When a thread successfully acquires a mutex for the first time, the lock count shall be set to one. Every time a thread relocks this mutex, the lock count shall be incremented by one. Each time the thread unlocks the mutex, the lock count shall be decremented by one. When the lock count reaches zero, the mutex shall become available for other threads to acquire. If a thread attempts to unlock a mutex that it has not locked or a mutex which is unlocked, an error shall be returned.

If the mutex type is PTHREAD_MUTEX_DEFAULT, attempting to recursively lock the mutex results in undefined behavior. Attempting to unlock the mutex if it was not locked by the calling thread results in undefined behavior. Attempting to unlock the mutex if it is not locked results in undefined behavior.

The *pthread_mutex_trylock*( ) function shall be equivalent to *pthread_mutex_lock*( ), except that if the mutex object referenced by *mutex* is currently locked (by any thread, including the current thread), the call shall return immediately. If the mutex type is PTHREAD_MUTEX_RECURSIVE and the mutex is currently owned by the calling thread, the mutex lock count shall be incremented by one and the *pthread_mutex_trylock*( ) function shall immediately return success.

XSI The *pthread_mutex_unlock*( ) function shall release the mutex object referenced by *mutex*. The manner in which a mutex is released is dependent upon the mutex's type attribute. If there are threads blocked on the mutex object referenced by *mutex* when *pthread_mutex_unlock*( ) is called, resulting in the mutex becoming available, the scheduling policy shall determine which thread shall acquire the mutex.

XSI (In the case of PTHREAD_MUTEX_RECURSIVE mutexes, the mutex shall become available when the count reaches zero and the calling thread no longer has any locks on this mutex).

If a signal is delivered to a thread waiting for a mutex, upon return from the signal handler the thread shall resume waiting for the mutex as if it was not interrupted.

RETURN VALUE

If successful, the *pthread_mutex_lock*( ) and *pthread_mutex_unlock*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

The *pthread_mutex_trylock*( ) function shall return zero if a lock on the mutex object referenced by *mutex* is acquired. Otherwise, an error number is returned to indicate the error.

ERRORS

The *pthread_mutex_lock*( ) and *pthread_mutex_trylock*( ) functions shall fail if:

[EINVAL]	The *mutex* was created with the protocol attribute having the value PTHREAD_PRIO_PROTECT and the calling thread's priority is higher than the mutex's current priority ceiling.

The *pthread_mutex_trylock*( ) function shall fail if:

[EBUSY]	The *mutex* could not be acquired because it was already locked.

The *pthread_mutex_lock*( ), *pthread_mutex_trylock*( ), and *pthread_mutex_unlock*( ) functions may fail if:

[EINVAL]	The value specified by *mutex* does not refer to an initialized mutex object.
XSI [EAGAIN]	The mutex could not be acquired because the maximum number of recursive locks for *mutex* has been exceeded.

The *pthread_mutex_lock*( ) function may fail if:

[EDEADLK]	The current thread already owns the mutex.

The *pthread_mutex_unlock*( ) function may fail if:

[EPERM]	The current thread does not own the mutex.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Mutex objects are intended to serve as a low-level primitive from which other thread synchronization functions can be built. As such, the implementation of mutexes should be as efficient as possible, and this has ramifications on the features available at the interface.

The mutex functions and the particular default settings of the mutex attributes have been motivated by the desire to not preclude fast, inlined implementations of mutex locking and unlocking.

For example, deadlocking on a double-lock is explicitly allowed behavior in order to avoid requiring more overhead in the basic mechanism than is absolutely necessary. (More ‘‘friendly’’ mutexes that detect deadlock or that allow multiple locking by the same thread are easily constructed by the user via the other mechanisms provided. For example, *pthread_self*( ) can be used to record mutex ownership.) Implementations might also choose to provide such extended features as options via special mutex attributes.

Since most attributes only need to be checked when a thread is going to be blocked, the use of attributes does not slow the (common) mutex-locking case.

Likewise, while being able to extract the thread ID of the owner of a mutex might be desirable, it would require storing the current thread ID when each mutex is locked, and this could incur unacceptable levels of overhead. Similar arguments apply to a *mutex_tryunlock* operation.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_mutex_lock*( ), *pthread_mutex_trylock*( ), and *pthread_mutex_unlock*( ) functions are marked as part of the Threads option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The behavior when attempting to relock a mutex is defined.

The *pthread_mutex_timedlock*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

NAME

pthread_mutex_setprioceiling — change the priority ceiling of a mutex (**REALTIME THREADS**)

SYNOPSIS

THR TPP

```
#include <pthread.h>

int pthread_mutex_setprioceiling(pthread_mutex_t *restrict mutex,
    int prioceiling, int *restrict old_ceiling);
```

DESCRIPTION

Refer to *pthread_mutex_getprioceiling*( ).

NAME

pthread_mutex_timedlock — lock a mutex (**ADVANCED REALTIME**)

SYNOPSIS

THR TMO

```
#include <pthread.h>
#include <time.h>

int pthread_mutex_timedlock(pthread_mutex_t *restrict mutex,
    const struct timespec *restrict abs_timeout);
```

DESCRIPTION

The *pthread_mutex_timedlock*( ) function shall lock the mutex object referenced by *mutex*. If the mutex is already locked, the calling thread shall block until the mutex becomes available as in the *pthread_mutex_lock*( ) function. If the mutex cannot be locked without waiting for another thread to unlock the mutex, this wait shall be terminated when the specified timeout expires.

The timeout shall expire when the absolute time specified by *abs_timeout* passes, as measured by the clock on which timeouts are based (that is, when the value of that clock equals or exceeds *abs_timeout*), or if the absolute time specified by *abs_timeout* has already been passed at the time of the call.

TMR If the Timers option is supported, the timeout shall be based on the CLOCK_REALTIME clock; if the Timers option is not supported, the timeout shall be based on the system clock as returned by the *time*( ) function.

The resolution of the timeout shall be the resolution of the clock on which it is based. The **timespec** data type is defined in the **<time.h>** header.

Under no circumstance shall the function fail with a timeout if the mutex can be locked immediately. The validity of the *abs_timeout* parameter need not be checked if the mutex can be locked immediately.

As a consequence of the priority inheritance rules (for mutexes initialized with the PRIO_INHERIT protocol), if a timed mutex wait is terminated because its timeout expires, the priority of the owner of the mutex shall be adjusted as necessary to reflect the fact that this thread is no longer among the threads waiting for the mutex.

RETURN VALUE

If successful, the *pthread_mutex_timedlock*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_mutex_timedlock*( ) function shall fail if:

[EINVAL]	The mutex was created with the protocol attribute having the value PTHREAD_PRIO_PROTECT and the calling thread's priority is higher than the mutex' current priority ceiling.
[EINVAL]	The process or thread would have blocked, and the *abs_timeout* parameter specified a nanoseconds field value less than zero or greater than or equal to 1 000 million.
[ETIMEDOUT]	The mutex could not be locked before the specified timeout expired.

The *pthread_mutex_timedlock*( ) function may fail if:

[EINVAL]	The value specified by mutex does not refer to an initialized mutex object.

XSI [EAGAIN]	The mutex could not be acquired because the maximum number of recursive locks for mutex has been exceeded.
[EDEADLK]	The current thread already owns the mutex.

This function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

The *pthread_mutex_timedlock*( ) function is part of the Threads and Timeouts options and need not be provided on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1d-1999.

NAME

pthread_mutex_trylock, pthread_mutex_unlock — lock and unlock a mutex

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_mutex_trylock(pthread_mutex_t *mutex);
int pthread_mutex_unlock(pthread_mutex_t *mutex);
```

DESCRIPTION

Refer to *pthread_mutex_lock*( ).

NAME

pthread_mutexattr_destroy, pthread_mutexattr_init — destroy and initialize mutex attributes object

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_mutexattr_destroy(pthread_mutexattr_t *attr);
int pthread_mutexattr_init(pthread_mutexattr_t *attr);
```

DESCRIPTION

The *pthread_mutexattr_destroy*( ) function shall destroy a mutex attributes object; the object becomes, in effect, uninitialized. An implementation may cause *pthread_mutexattr_destroy*( ) to set the object referenced by *attr* to an invalid value. A destroyed *attr* attributes object can be reinitialized using *pthread_mutexattr_init*( ); the results of otherwise referencing the object after it has been destroyed are undefined.

The *pthread_mutexattr_init*( ) function shall initialize a mutex attributes object *attr* with the default value for all of the attributes defined by the implementation.

Results are undefined if *pthread_mutexattr_init*( ) is called specifying an already initialized *attr* attributes object.

After a mutex attributes object has been used to initialize one or more mutexes, any function affecting the attributes object (including destruction) shall not affect any previously initialized mutexes.

RETURN VALUE

Upon successful completion, *pthread_mutexattr_destroy*( ) and *pthread_mutexattr_init*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_mutexattr_destroy*( ) function may fail if:

[EINVAL]	The value specified by *attr* is invalid.

The *pthread_mutexattr_init*( ) function shall fail if:

[ENOMEM]	Insufficient memory exists to initialize the mutex attributes object.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

See *pthread_attr_init*( ) for a general explanation of attributes. Attributes objects allow implementations to experiment with useful extensions and permit extension of this volume of IEEE Std 1003.1-200x without changing the existing functions. Thus, they provide for future extensibility of this volume of IEEE Std 1003.1-200x and reduce the temptation to standardize prematurely on semantics that are not yet widely implemented or understood.

Examples of possible additional mutex attributes that have been discussed are *spin_only*, *limited_spin*, *no_spin*, *recursive*, and *metered*. (To explain what the latter attributes might mean: recursive mutexes would allow for multiple re-locking by the current owner; metered mutexes would transparently keep records of queue length, wait time, and so on.) Since there is not yet wide agreement on the usefulness of these resulting from shared implementation and usage experience, they are not yet specified in this volume of IEEE Std 1003.1-200x. Mutex attributes objects, however, make it possible to test out these concepts for possible standardization at a later time.

Mutex Attributes and Performance

Care has been taken to ensure that the default values of the mutex attributes have been defined such that mutexes initialized with the defaults have simple enough semantics so that the locking and unlocking can be done with the equivalent of a test-and-set instruction (plus possibly a few other basic instructions).

There is at least one implementation method that can be used to reduce the cost of testing at lock-time if a mutex has non-default attributes. One such method that an implementation can employ (and this can be made fully transparent to fully conforming POSIX applications) is to secretly pre-lock any mutexes that are initialized to non-default attributes. Any later attempt to lock such a mutex causes the implementation to branch to the ‘‘slow path’’ as if the mutex were unavailable; then, on the slow path, the implementation can do the ‘‘real work’’ to lock a non-default mutex. The underlying unlock operation is more complicated since the implementation never really wants to release the pre-lock on this kind of mutex. This illustrates that, depending on the hardware, there may be certain optimizations that can be used so that whatever mutex attributes are considered ‘‘most frequently used’’ can be processed most efficiently.

Process Shared Memory and Synchronization

The existence of memory mapping functions in this volume of IEEE Std 1003.1-200x leads to the possibility that an application may allocate the synchronization objects from this section in memory that is accessed by multiple processes (and therefore, by threads of multiple processes).

In order to permit such usage, while at the same time keeping the usual case (that is, usage within a single process) efficient, a process-shared option has been defined.

If an implementation supports the _POSIX_THREAD_PROCESS_SHARED option, then the *process-shared* attribute can be used to indicate that mutexes or condition variables may be accessed by threads of multiple processes.

The default setting of PTHREAD_PROCESS_PRIVATE has been chosen for the *process-shared* attribute so that the most efficient forms of these synchronization objects are created by default.

Synchronization variables that are initialized with the PTHREAD_PROCESS_PRIVATE *process-shared* attribute may only be operated on by threads in the process that initialized them. Synchronization variables that are initialized with the PTHREAD_PROCESS_SHARED *process-shared* attribute may be operated on by any thread in any process that has access to it. In particular, these processes may exist beyond the lifetime of the initializing process. For example, the following code implements a simple counting semaphore in a mapped file that may be used by many processes.

```
/* sem.h */
struct semaphore {
    pthread_mutex_t lock;
    pthread_cond_t nonzero;
    unsigned count;
};
typedef struct semaphore semaphore_t;

semaphore_t *semaphore_create(char *semaphore_name);
semaphore_t *semaphore_open(char *semaphore_name);
```

```
void semaphore_post(semaphore_t *semap);
void semaphore_wait(semaphore_t *semap);
void semaphore_close(semaphore_t *semap);

/* sem.c */
#include <sys/types.h>
#include <sys/stat.h>
#include <sys/mman.h>
#include <fcntl.h>
#include <pthread.h>
#include "sem.h"

semaphore_t *
semaphore_create(char *semaphore_name)
{
int fd;
    semaphore_t *semap;
    pthread_mutexattr_t psharedm;
    pthread_condattr_t psharedc;

    fd = open(semaphore_name, O_RDWR | O_CREAT | O_EXCL, 0666);
    if (fd < 0)
        return (NULL);
    (void) ftruncate(fd, sizeof(semaphore_t));
    (void) pthread_mutexattr_init(&psharedm);
    (void) pthread_mutexattr_setpshared(&psharedm,
        PTHREAD_PROCESS_SHARED);
    (void) pthread_condattr_init(&psharedc);
    (void) pthread_condattr_setpshared(&psharedc,
        PTHREAD_PROCESS_SHARED);
    semap = (semaphore_t *) mmap(NULL, sizeof(semaphore_t),
            PROT_READ | PROT_WRITE, MAP_SHARED,
            fd, 0);
    close (fd);
    (void) pthread_mutex_init(&semap->lock, &psharedm);
    (void) pthread_cond_init(&semap->nonzero, &psharedc);
    semap->count = 0;
    return (semap);
}

semaphore_t *
semaphore_open(char *semaphore_name)
{
    int fd;
    semaphore_t *semap;

    fd = open(semaphore_name, O_RDWR, 0666);
    if (fd < 0)
        return (NULL);
    semap = (semaphore_t *) mmap(NULL, sizeof(semaphore_t),
            PROT_READ | PROT_WRITE, MAP_SHARED,
            fd, 0);
    close (fd);
    return (semap);
}
```

```
void
semaphore_post(semaphore_t *semap)
{
    pthread_mutex_lock(&semap->lock);
    if (semap->count == 0)
        pthread_cond_signal(&semapx->nonzero);
    semap->count++;
    pthread_mutex_unlock(&semap->lock);
}

void
semaphore_wait(semaphore_t *semap)
{
    pthread_mutex_lock(&semap->lock);
    while (semap->count == 0)
        pthread_cond_wait(&semap->nonzero, &semap->lock);
    semap->count--;
    pthread_mutex_unlock(&semap->lock);
}

void
semaphore_close(semaphore_t *semap)
{
    munmap((void *) semap, sizeof(semaphore_t));
}
```

The following code is for three separate processes that create, post, and wait on a semaphore in the file **/tmp/semaphore**. Once the file is created, the post and wait programs increment and decrement the counting semaphore (waiting and waking as required) even though they did not initialize the semaphore.

```
/* create.c */
#include "pthread.h"
#include "sem.h"

int
main()
{
    semaphore_t *semap;

    semap = semaphore_create("/tmp/semaphore");
    if (semap == NULL)
        exit(1);
    semaphore_close(semap);
    return (0);
}

/* post */
#include "pthread.h"
#include "sem.h"

int
main()
{
    semaphore_t *semap;
```

```
    semap = semaphore_open("/tmp/semaphore");
    if (semap == NULL)
        exit(1);
    semaphore_post(semap);
    semaphore_close(semap);
    return (0);
}

/* wait */
#include "pthread.h"
#include "sem.h"

int
main()
{
    semaphore_t *semap;

    semap = semaphore_open("/tmp/semaphore");
    if (semap == NULL)
        exit(1);
    semaphore_wait(semap);
    semaphore_close(semap);
    return (0);
}
```

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_mutexattr_destroy*( ) and *pthread_mutexattr_init*( ) functions are marked as part of the Threads option.

IEEE PASC Interpretation 1003.1c #27 is applied, updating the ERRORS section.

NAME

pthread_mutexattr_getprioceiling, pthread_mutexattr_setprioceiling — get and set prioceiling attribute of mutex attributes object (**REALTIME THREADS**)

SYNOPSIS

THR TPP

```
#include <pthread.h>

int pthread_mutexattr_getprioceiling(
    const pthread_mutexattr_t *restrict attr,
    int *restrict prioceiling);
int pthread_mutexattr_setprioceiling(pthread_mutexattr_t *attr,
    int prioceiling);
```

DESCRIPTION

The *pthread_mutexattr_getprioceiling*( ) and *pthread_mutexattr_setprioceiling*( ) functions, respectively, shall get and set the priority ceiling attribute of a mutex attributes object pointed to by *attr* which was previously created by the function *pthread_mutexattr_init*( ).

The *prioceiling* attribute contains the priority ceiling of initialized mutexes. The values of *prioceiling* are within the maximum range of priorities defined by SCHED_FIFO.

The *prioceiling* attribute defines the priority ceiling of initialized mutexes, which is the minimum priority level at which the critical section guarded by the mutex is executed. In order to avoid priority inversion, the priority ceiling of the mutex shall be set to a priority higher than or equal to the highest priority of all the threads that may lock that mutex. The values of *prioceiling* are within the maximum range of priorities defined under the SCHED_FIFO scheduling policy.

RETURN VALUE

Upon successful completion, the *pthread_mutexattr_getprioceiling*( ) and *pthread_mutexattr_setprioceiling*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_mutexattr_getprioceiling*( ) and *pthread_mutexattr_setprioceiling*( ) functions may fail if:

[EINVAL]	The value specified by *attr* or *prioceiling* is invalid.
[EPERM]	The caller does not have the privilege to perform the operation.

These functions shall not return an error code of [EINTR].

SEE ALSO

pthread_cond_destroy( ), *pthread_create*( ), *pthread_mutex_destroy*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Marked as part of the Realtime Threads Feature Group.

Issue 6

The *pthread_mutexattr_getprioceiling*( ) and *pthread_mutexattr_setprioceiling*( ) functions are marked as part of the Threads and Thread Priority Protection options.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Thread Priority Protection option.

The [ENOTSUP] error condition has been removed since these functions do not have a *protocol* argument.

The **restrict** keyword is added to the *pthread_mutexattr_getprioceiling*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

pthread_mutexattr_getprotocol, pthread_mutexattr_setprotocol — get and set protocol attribute of mutex attributes object (**REALTIME THREADS**)

SYNOPSIS

THR
```
#include <pthread.h>
```

TPP|TPI
```
int pthread_mutexattr_getprotocol(
    const pthread_mutexattr_t *restrict attr,
    int *restrict protocol);
int pthread_mutexattr_setprotocol(pthread_mutexattr_t *attr,
    int protocol);
```

DESCRIPTION

The *pthread_mutexattr_getprotocol*( ) and *pthread_mutexattr_setprotocol*( ) functions, respectively, shall get and set the protocol attribute of a mutex attributes object pointed to by *attr* which was previously created by the function *pthread_mutexattr_init*( ).

The *protocol* attribute defines the protocol to be followed in utilizing mutexes. The value of *protocol* may be one of:

PTHREAD_PRIO_NONE
TPI PTHREAD_PRIO_INHERIT
TPP PTHREAD_PRIO_PROTECT

which are defined in the **<pthread.h>** header.

When a thread owns a mutex with the PTHREAD_PRIO_NONE *protocol* attribute, its priority and scheduling shall not be affected by its mutex ownership.

TPI When a thread is blocking higher priority threads because of owning one or more mutexes with the PTHREAD_PRIO_INHERIT protocol attribute, it shall execute at the higher of its priority or the priority of the highest priority thread waiting on any of the mutexes owned by this thread and initialized with this protocol.

TPP When a thread owns one or more mutexes initialized with the PTHREAD_PRIO_PROTECT protocol, it shall execute at the higher of its priority or the highest of the priority ceilings of all the mutexes owned by this thread and initialized with this attribute, regardless of whether other threads are blocked on any of these mutexes or not.

While a thread is holding a mutex which has been initialized with the PTHREAD_PRIO_INHERIT or PTHREAD_PRIO_PROTECT protocol attributes, it shall not be subject to being moved to the tail of the scheduling queue at its priority in the event that its original priority is changed, such as by a call to *sched_setparam*( ). Likewise, when a thread unlocks a mutex that has been initialized with the PTHREAD_PRIO_INHERIT or PTHREAD_PRIO_PROTECT protocol attributes, it shall not be subject to being moved to the tail of the scheduling queue at its priority in the event that its original priority is changed.

If a thread simultaneously owns several mutexes initialized with different protocols, it shall execute at the highest of the priorities that it would have obtained by each of these protocols.

TPI When a thread makes a call to *pthread_mutex_lock*( ), the mutex was initialized with the protocol attribute having the value PTHREAD_PRIO_INHERIT, when the calling thread is blocked because the mutex is owned by another thread, that owner thread shall inherit the priority level of the calling thread as long as it continues to own the mutex. The implementation shall update its execution priority to the maximum of its assigned priority and all its inherited priorities.

Furthermore, if this owner thread itself becomes blocked on another mutex, the same priority inheritance effect shall be propagated to this other owner thread, in a recursive manner.

RETURN VALUE

Upon successful completion, the *pthread_mutexattr_getprotocol*( ) and *pthread_mutexattr_setprotocol*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_mutexattr_setprotocol*( ) function shall fail if:

[ENOTSUP]	The value specified by *protocol* is an unsupported value.

The *pthread_mutexattr_getprotocol*( ) and *pthread_mutexattr_setprotocol*( ) functions may fail if:

[EINVAL]	The value specified by *attr* or *protocol* is invalid.
[EPERM]	The caller does not have the privilege to perform the operation.

These functions shall not return an error code of [EINTR].

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Marked as part of the Realtime Threads Feature Group.

Issue 6

The *pthread_mutexattr_getprotocol*( ) and *pthread_mutexattr_setprotocol*( ) functions are marked as part of the Threads option and either the Thread Priority Protection or Thread Priority Inheritance options.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Thread Priority Protection or Thread Priority Inheritance options.

The **restrict** keyword is added to the *pthread_mutexattr_getprotocol*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

pthread_mutexattr_getpshared, pthread_mutexattr_setpshared — get and set process-shared attribute

SYNOPSIS

THR TSH
```
#include <pthread.h>

int pthread_mutexattr_getpshared(
    const pthread_mutexattr_t *restrict attr,
    int *restrict pshared);
int pthread_mutexattr_setpshared(pthread_mutexattr_t *attr,
    int pshared);
```

DESCRIPTION

The *pthread_mutexattr_getpshared*( ) function shall obtain the value of the *process-shared* attribute from the attributes object referenced by *attr*. The *pthread_mutexattr_setpshared*( ) function shall set the *process-shared* attribute in an initialized attributes object referenced by *attr*.

The *process-shared* attribute is set to PTHREAD_PROCESS_SHARED to permit a mutex to be operated upon by any thread that has access to the memory where the mutex is allocated, even if the mutex is allocated in memory that is shared by multiple processes. If the *process-shared* attribute is PTHREAD_PROCESS_PRIVATE, the mutex shall only be operated upon by threads created within the same process as the thread that initialized the mutex; if threads of differing processes attempt to operate on such a mutex, the behavior is undefined. The default value of the attribute shall be PTHREAD_PROCESS_PRIVATE.

RETURN VALUE

Upon successful completion, *pthread_mutexattr_setpshared*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

Upon successful completion, *pthread_mutexattr_getpshared*( ) shall return zero and stores the value of the *process-shared* attribute of *attr* into the object referenced by the *pshared* parameter. Otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_mutexattr_getpshared*( ) and *pthread_mutexattr_setpshared*( ) functions may fail if:

[EINVAL]	The value specified by *attr* is invalid.

The *pthread_mutexattr_setpshared*( ) function may fail if:

[EINVAL]	The new value specified for the attribute is outside the range of legal values for that attribute.

These functions shall not return an error code of [EINTR].

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_mutexattr_getpshared*( ) and *pthread_mutexattr_setpshared*( ) functions are marked as part of the Threads and Thread Process-Shared Synchronization options.

The **restrict** keyword is added to the *pthread_mutexattr_getpshared*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

pthread_mutexattr_gettype, pthread_mutexattr_settype — get and set a mutex type attribute

SYNOPSIS

XSI

```
#include <pthread.h>

int pthread_mutexattr_gettype(const pthread_mutexattr_t *restrict attr,
    int *restrict type);
int pthread_mutexattr_settype(pthread_mutexattr_t *attr, int type);
```

DESCRIPTION

The *pthread_mutexattr_gettype*( ) and *pthread_mutexattr_settype*( ) functions, respectively, shall get and set the mutex *type* attribute. This attribute is set in the *type* parameter to these functions. The default value of the *type* attribute is PTHREAD_MUTEX_DEFAULT.

The type of mutex is contained in the *type* attribute of the mutex attributes. Valid mutex types include:

PTHREAD_MUTEX_NORMAL

This type of mutex does not detect deadlock. A thread attempting to relock this mutex without first unlocking it shall deadlock. Attempting to unlock a mutex locked by a different thread results in undefined behavior. Attempting to unlock an unlocked mutex results in undefined behavior.

PTHREAD_MUTEX_ERRORCHECK

This type of mutex provides error checking. A thread attempting to relock this mutex without first unlocking it shall return with an error. A thread attempting to unlock a mutex which another thread has locked shall return with an error. A thread attempting to unlock an unlocked mutex shall return with an error.

PTHREAD_MUTEX_RECURSIVE

A thread attempting to relock this mutex without first unlocking it shall succeed in locking the mutex. The relocking deadlock which can occur with mutexes of type PTHREAD_MUTEX_NORMAL cannot occur with this type of mutex. Multiple locks of this mutex shall require the same number of unlocks to release the mutex before another thread can acquire the mutex. A thread attempting to unlock a mutex which another thread has locked shall return with an error. A thread attempting to unlock an unlocked mutex shall return with an error.

PTHREAD_MUTEX_DEFAULT

Attempting to recursively lock a mutex of this type results in undefined behavior. Attempting to unlock a mutex of this type which was not locked by the calling thread results in undefined behavior. Attempting to unlock a mutex of this type which is not locked results in undefined behavior. An implementation may map this mutex to one of the other mutex types.

RETURN VALUE

Upon successful completion, the *pthread_mutexattr_gettype*( ) function shall return zero and store the value of the *type* attribute of *attr* into the object referenced by the *type* parameter. Otherwise, an error shall be returned to indicate the error.

If successful, the *pthread_mutexattr_settype*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_mutexattr_settype*( ) function shall fail if:

[EINVAL] The value *type* is invalid.

The *pthread_mutexattr_gettype*( ) and *pthread_mutexattr_settype*( ) functions may fail if:

[EINVAL] The value specified by *attr* is invalid.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

It is advised that an application should not use a PTHREAD_MUTEX_RECURSIVE mutex with condition variables because the implicit unlock performed for a *pthread_cond_timedwait*( ) or *pthread_cond_wait*( ) may not actually release the mutex (if it had been locked multiple times). If this happens, no other thread can satisfy the condition of the predicate.

RATIONALE

None.

FUTURE DIRECTIONS

None.

int pthread_mutexattr_settype(pthread_mutexattr_t *attr, int type);
```

DESCRIPTION

Refer to *pthread_mutexattr_gettype*( ).

NAME

pthread_once — dynamic package initialization

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_once(pthread_once_t *once_control,
    void (*init_routine)(void));
pthread_once_t once_control = PTHREAD_ONCE_INIT;
```

DESCRIPTION

The first call to *pthread_once*( ) by any thread in a process, with a given *once_control*, shall call the *init_routine* with no arguments. Subsequent calls of *pthread_once*( ) with the same *once_control* shall not call the *init_routine*. On return from *pthread_once*( ), *init_routine* shall have completed. | The *once_control* parameter shall determine whether the associated initialization routine has | been called.

The *pthread_once*( ) function is not a cancelation point. However, if *init_routine* is a cancelation point and is canceled, the effect on *once_control* shall be as if *pthread_once*( ) was never called.

The constant PTHREAD_ONCE_INIT is defined in the **<pthread.h>** header. |

The behavior of *pthread_once*( ) is undefined if *once_control* has automatic storage duration or is not initialized by PTHREAD_ONCE_INIT.

RETURN VALUE

Upon successful completion, *pthread_once*( ) shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_once*( ) function may fail if:

[EINVAL] If either *once_control* or *init_routine* is invalid.

The *pthread_once*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Some C libraries are designed for dynamic initialization. That is, the global initialization for the library is performed when the first procedure in the library is called. In a single-threaded program, this is normally implemented using a static variable whose value is checked on entry to a routine, as follows:

```
static int random_is_initialized = 0;
extern int initialize_random();

int random_function()
{
    if (random_is_initialized == 0) {
        initialize_random();
        random_is_initialized = 1;
    }
    ... /* Operations performed after initialization. */
}
```

To keep the same structure in a multi-threaded program, a new primitive is needed. Otherwise, library initialization has to be accomplished by an explicit call to a library-exported initialization function prior to any use of the library.

For dynamic library initialization in a multi-threaded process, a simple initialization flag is not sufficient; the flag needs to be protected against modification by multiple threads simultaneously calling into the library. Protecting the flag requires the use of a mutex; however, mutexes have to be initialized before they are used. Ensuring that the mutex is only initialized once requires a recursive solution to this problem.

The use of *pthread_once*( ) not only supplies an implementation-guaranteed means of dynamic initialization, it provides an aid to the reliable construction of multi-threaded and realtime systems. The preceding example then becomes:

```
#include <pthread.h>
static pthread_once_t random_is_initialized = PTHREAD_ONCE_INIT;
extern int initialize_random();

int random_function()
{
    (void) pthread_once(&random_is_initialized, initialize_random);
    ... /* Operations performed after initialization. */
}
```

Note that a **pthread_once_t** cannot be an array because some compilers do not accept the construct **&<array_name>**.

FUTURE DIRECTIONS

None.

SEE ALSO

The Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_once*( ) function is marked as part of the Threads option.

The [EINVAL] error is added as a may fail case for if either argument is invalid.

NAME

pthread_rwlock_destroy, pthread_rwlock_init — destroy and initialize a read-write lock object

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_rwlock_destroy(pthread_rwlock_t *rwlock);
int pthread_rwlock_init(pthread_rwlock_t *restrict rwlock,
    const pthread_rwlockattr_t *restrict attr);
```

DESCRIPTION

The *pthread_rwlock_destroy*( ) function shall destroy the read-write lock object referenced by *rwlock* and release any resources used by the lock. The effect of subsequent use of the lock is undefined until the lock is reinitialized by another call to *pthread_rwlock_init*( ). An implementation may cause *pthread_rwlock_destroy*( ) to set the object referenced by *rwlock* to an invalid value. Results are undefined if *pthread_rwlock_destroy*( ) is called when any thread holds *rwlock*. Attempting to destroy an uninitialized read-write lock results in undefined behavior.

The *pthread_rwlock_init*( ) function shall allocate any resources required to use the read-write lock referenced by *rwlock* and initializes the lock to an unlocked state with attributes referenced by *attr*. If *attr* is NULL, the default read-write lock attributes shall be used; the effect is the same as passing the address of a default read-write lock attributes object. Once initialized, the lock can be used any number of times without being reinitialized. Results are undefined if *pthread_rwlock_init*( ) is called specifying an already initialized read-write lock. Results are undefined if a read-write lock is used without first being initialized.

If the *pthread_rwlock_init*( ) function fails, *rwlock* shall not be initialized and the contents of *rwlock* are undefined.

Only the object referenced by *rwlock* may be used for performing synchronization. The result of referring to copies of that object in calls to *pthread_rwlock_destroy*( ), *pthread_rwlock_rdlock*( ), *pthread_rwlock_timedrdlock*( ), *pthread_rwlock_timedwrlock*( ), *pthread_rwlock_tryrdlock*( ), *pthread_rwlock_trywrlock*( ), *pthread_rwlock_unlock*( ), or *pthread_rwlock_wrlock*( ) is undefined.

RETURN VALUE

If successful, the *pthread_rwlock_destroy*( ) and *pthread_rwlock_init*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

The [EBUSY] and [EINVAL] error checks, if implemented, act as if they were performed immediately at the beginning of processing for the function and caused an error return prior to modifying the state of the read-write lock specified by *rwlock*.

ERRORS

The *pthread_rwlock_destroy*( ) function may fail if:

[EBUSY]	The implementation has detected an attempt to destroy the object referenced by *rwlock* while it is locked.
[EINVAL]	The value specified by *rwlock* is invalid.

The *pthread_rwlock_init*( ) function shall fail if:

[EAGAIN]	The system lacked the necessary resources (other than memory) to initialize another read-write lock.
[ENOMEM]	Insufficient memory exists to initialize the read-write lock.
[EPERM]	The caller does not have the privilege to perform the operation.

The *pthread_rwlock_init*( ) function may fail if:

[EBUSY]	The implementation has detected an attempt to reinitialize the object referenced by *rwlock*, a previously initialized but not yet destroyed read-write lock.
[EINVAL]	The value specified by *attr* is invalid.

These functions shall not return an error code of [EINTR].

EXAMPLES

CHANGE HISTORY

First released in Issue 5.

Issue 6

The following changes are made for alignment with IEEE Std 1003.1j-2000:

- The margin code in the SYNOPSIS is changed to THR to indicate that the functionality is now part of the Threads option (previously it was part of the Read-Write Locks option in IEEE Std 1003.1j-2000 and also part of the XSI extension). The initializer macro is also deleted from the SYNOPSIS.
- The DESCRIPTION is updated as follows:
  - — It explicitly notes allocation of resources upon initialization of a read-write lock object.
  - — A paragraph is added specifying that copies of read-write lock objects may not be used.
- An [EINVAL] error is added to the ERRORS section for *pthread_rwlock_init*( ), indicating that the *rwlock* value is invalid.
- The SEE ALSO section is updated.

The **restrict** keyword is added to the *pthread_rwlock_init*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

pthread_rwlock_init — initialize a read-write lock object

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_rwlock_init(pthread_rwlock_t *restrict rwlock,
    const pthread_rwlockattr_t *restrict attr);
```

DESCRIPTION

Refer to *pthread_rwlock_destroy*( ).

NAME

pthread_rwlock_rdlock, pthread_rwlock_tryrdlock — lock a read-write lock object for reading

SYNOPSIS

THR
```
#include <pthread.h>

int pthread_rwlock_rdlock(pthread_rwlock_t *rwlock);
int pthread_rwlock_tryrdlock(pthread_rwlock_t *rwlock);
```

DESCRIPTION

The *pthread_rwlock_rdlock*( ) function shall apply a read lock to the read-write lock referenced by *rwlock*. The calling thread acquires the read lock if a writer does not hold the lock and there are no writers blocked on the lock.

TPS If the Thread Execution Scheduling option is supported, and the threads involved in the lock are executing with the scheduling policies SCHED_FIFO or SCHED_RR, the calling thread shall not acquire the lock if a writer holds the lock or if writers of higher or equal priority are blocked on the lock; otherwise, the calling thread shall acquire the lock.

TPS TSP If the Threads Execution Scheduling option is supported, and the threads involved in the lock are executing with the SCHED_SPORADIC scheduling policy, the calling thread shall not acquire the lock if a writer holds the lock or if writers of higher or equal priority are blocked on the lock; otherwise, the calling thread shall acquire the lock.

If the Thread Execution Scheduling option is not supported, it is implementation-defined whether the calling thread acquires the lock when a writer does not hold the lock and there are writers blocked on the lock. If a writer holds the lock, the calling thread shall not acquire the read lock. If the read lock is not acquired, the calling thread shall block until it can acquire the lock. The calling thread may deadlock if at the time the call is made it holds a write lock.

A thread may hold multiple concurrent read locks on *rwlock* (that is, successfully call the *pthread_rwlock_rdlock*( ) function *n* times). If so, the application shall ensure that the thread performs matching unlocks (that is, it calls the *pthread_rwlock_unlock*( ) function *n* times).

The maximum number of simultaneous read locks that an implementation guarantees can be applied to a read-write lock shall be implementation-defined. The *pthread_rwlock_rdlock*( ) function may fail if this maximum would be exceeded.

The *pthread_rwlock_tryrdlock*( ) function shall apply a read lock as in the *pthread_rwlock_rdlock*( ) function, with the exception that the function shall fail if the equivalent *pthread_rwlock_rdlock*( ) call would have blocked the calling thread. In no case shall the *pthread_rwlock_tryrdlock*( ) function ever block; it always either acquires the lock or fails and returns immediately.

Results are undefined if any of these functions are called with an uninitialized read-write lock.

If a signal is delivered to a thread waiting for a read-write lock for reading, upon return from the signal handler the thread resumes waiting for the read-write lock for reading as if it was not interrupted.

RETURN VALUE

If successful, the *pthread_rwlock_rdlock*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

The *pthread_rwlock_tryrdlock*( ) function shall return zero if the lock for reading on the read-write lock object referenced by *rwlock* is acquired. Otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_rwlock_tryrdlock*( ) function shall fail if:

[EBUSY] The read-write lock could not be acquired for reading because a writer holds the lock or a writer with the appropriate priority was blocked on it.

The *pthread_rwlock_rdlock*( ) and *pthread_rwlock_tryrdlock*( ) functions may fail if:

[EINVAL] The value specified by *rwlock* does not refer to an initialized read-write lock object.

[EAGAIN] The read lock could not be acquired because the maximum number of read locks for *rwlock* has been exceeded.

The *pthread_rwlock_rdlock*( ) function may fail if:

[EDEADLK] The current thread already owns the read-write lock for writing.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

Applications using these functions may be subject to priority inversion, as discussed in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.285, Priority Inversion.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5.

Issue 6

The following changes are made for alignment with IEEE Std 1003.1j-2000:

- The margin code in the SYNOPSIS is changed to THR to indicate that the functionality is now part of the Threads option (previously it was part of the Read-Write Locks option in IEEE Std 1003.1j-2000 and also part of the XSI extension).
- The DESCRIPTION is updated as follows:
  - Conditions under which writers have precedence over readers are specified.
  - Failure of *pthread_rwlock_tryrdlock*( ) is clarified.
  - A paragraph on the maximum number of read locks is added.
- In the ERRORS sections, [EBUSY] is modified to take into account write priority, and [EDEADLK] is deleted as a *pthread_rwlock_tryrdlock*( ) error.
- The SEE ALSO section is updated.

NAME

pthread_rwlock_timedrdlock — lock a read-write lock for reading

SYNOPSIS

THR TMO

```
#include <pthread.h>
#include <time.h>

int pthread_rwlock_timedrdlock(pthread_rwlock_t *restrict rwlock,
    const struct timespec *restrict abs_timeout);
```

DESCRIPTION

The *pthread_rwlock_timedrdlock*( ) function shall apply a read lock to the read-write lock referenced by *rwlock* as in the *pthread_rwlock_rdlock*( ) function. However, if the lock cannot be acquired without waiting for other threads to unlock the lock, this wait shall be terminated when the specified timeout expires. The timeout shall expire when the absolute time specified by *abs_timeout* passes, as measured by the clock on which timeouts are based (that is, when the value of that clock equals or exceeds *abs_timeout*), or if the absolute time specified by *abs_timeout* has already been passed at the time of the call. |

TMR If the Timers option is supported, the timeout shall be based on the CLOCK_REALTIME clock. If the Timers option is not supported, the timeout shall be based on the system clock as returned by the *time*( ) function. The resolution of the timeout shall be the resolution of the clock on which it is based. The **timespec** data type is defined in the **<time.h>** header. Under no circumstances shall the function fail with a timeout if the lock can be acquired immediately. The validity of the *abs_timeout* parameter need not be checked if the lock can be immediately acquired. |

If a signal that causes a signal handler to be executed is delivered to a thread blocked on a read-write lock via a call to *pthread_rwlock_timedrdlock*( ), upon return from the signal handler the thread shall resume waiting for the lock as if it was not interrupted.

The calling thread may deadlock if at the time the call is made it holds a write lock on *rwlock*. The results are undefined if this function is called with an uninitialized read-write lock.

RETURN VALUE

The *pthread_rwlock_timedrdlock*( ) function shall return zero if the lock for reading on the read-write lock object referenced by *rwlock* is acquired. Otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_rwlock_timedrdlock*( ) function shall fail if:

[ETIMEDOUT]	The lock could not be acquired before the specified timeout expired.

The *pthread_rwlock_timedrdlock*( ) function may fail if:

[EAGAIN]	The read lock could not be acquired because the maximum number of read locks for lock would be exceeded.
[EDEADLK]	The calling thread already holds a write lock on *rwlock*.
[EINVAL]	The value specified by *rwlock* does not refer to an initialized read-write lock object, or the *abs_timeout* nanosecond value is less than zero or greater than or equal to 1 000 million.

This function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

Applications using this function may be subject to priority inversion, as discussed in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.285, Priority Inversion.

The *pthread_rwlock_timedrdlock*( ) function is part of the Threads and Timeouts options and need not be provided on all implementations.

RATIONALE

NAME

pthread_rwlock_timedwrlock — lock a read-write lock for writing

SYNOPSIS

THR TMO

```
#include <pthread.h>
#include <time.h>

int pthread_rwlock_timedwrlock(pthread_rwlock_t *restrict rwlock,
    const struct timespec *restrict abs_timeout);
```

DESCRIPTION

The *pthread_rwlock_timedwrlock*( ) function shall apply a write lock to the read-write lock referenced by *rwlock* as in the *pthread_rwlock_wrlock*( ) function. However, if the lock cannot be acquired without waiting for other threads to unlock the lock, this wait shall be terminated when the specified timeout expires. The timeout shall expire when the absolute time specified by *abs_timeout* passes, as measured by the clock on which timeouts are based (that is, when the value of that clock equals or exceeds *abs_timeout*), or if the absolute time specified by *abs_timeout* has already been passed at the time of the call.

TMR If the Timers option is supported, the timeout shall be based on the CLOCK_REALTIME clock. If the Timers option is not supported, the timeout shall be based on the system clock as returned by the *time*( ) function. The resolution of the timeout shall be the resolution of the clock on which it is based. The **timespec** data type is defined in the **<time.h>** header. Under no circumstances shall the function fail with a timeout if the lock can be acquired immediately. The validity of the *abs_timeout* parameter need not be checked if the lock can be immediately acquired.

If a signal that causes a signal handler to be executed is delivered to a thread blocked on a read-write lock via a call to *pthread_rwlock_timedwrlock*( ), upon return from the signal handler the thread shall resume waiting for the lock as if it was not interrupted.

The calling thread may deadlock if at the time the call is made it holds the read-write lock. The results are undefined if this function is called with an uninitialized read-write lock.

RETURN VALUE

The *pthread_rwlock_timedwrlock*( ) function shall return zero if the lock for writing on the read-write lock object referenced by *rwlock* is acquired. Otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_rwlock_timedwrlock*( ) function shall fail if:

[ETIMEDOUT]	The lock could not be acquired before the specified timeout expired.

The *pthread_rwlock_timedwrlock*( ) function may fail if:

[EDEADLK]	The calling thread already holds the *rwlock*.
[EINVAL]	The value specified by rwlock does not refer to an initialized read-write lock object, or the *abs_timeout* nanosecond value is less than zero or greater than or equal to 1 000 million.

This function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

Applications using this function may be subject to priority inversion, as discussed in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.285, Priority Inversion.

The *pthread_rwlock_timedwrlock*( ) function is part of the Threads and Timeouts options and need not be provided on all implementations.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1j-2000.

NAME

pthread_rwlock_tryrdlock — lock a read-write lock object for reading

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_rwlock_tryrdlock(pthread_rwlock_t *rwlock);
```

DESCRIPTION

Refer to *pthread_rwlock_rdlock*( ).

NAME

pthread_rwlock_trywrlock, pthread_rwlock_wrlock — lock a read-write lock object for writing

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_rwlock_trywrlock(pthread_rwlock_t *rwlock);
int pthread_rwlock_wrlock(pthread_rwlock_t *rwlock);

```

DESCRIPTION

The *pthread_rwlock_trywrlock*( ) function shall apply a write lock like the *pthread_rwlock_wrlock*( ) function, with the exception that the function shall fail if any thread currently holds *rwlock* (for reading or writing).

The *pthread_rwlock_wrlock*( ) function shall apply a write lock to the read-write lock referenced by *rwlock*. The calling thread acquires the write lock if no other thread (reader or writer) holds the read-write lock *rwlock*. Otherwise, the thread shall block until it can acquire the lock. The calling thread may deadlock if at the time the call is made it holds the read-write lock (whether a read or write lock).

Implementations may favor writers over readers to avoid writer starvation.

Results are undefined if any of these functions are called with an uninitialized read-write lock.

If a signal is delivered to a thread waiting for a read-write lock for writing, upon return from the signal handler the thread resumes waiting for the read-write lock for writing as if it was not interrupted.

RETURN VALUE

The *pthread_rwlock_trywrlock*( ) function shall return zero if the lock for writing on the read-write lock object referenced by *rwlock* is acquired. Otherwise, an error number shall be returned to indicate the error.

If successful, the *pthread_rwlock_wrlock*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_rwlock_trywrlock*( ) function shall fail if:

[EBUSY]	The read-write lock could not be acquired for writing because it was already locked for reading or writing.

The *pthread_rwlock_trywrlock*( ) and *pthread_rwlock_wrlock*( ) functions may fail if:

[EINVAL]	The value specified by *rwlock* does not refer to an initialized read-write lock object.

The *pthread_rwlock_wrlock*( ) function may fail if:

[EDEADLK]	The current thread already owns the read-write lock for writing or reading.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

Applications using these functions may be subject to priority inversion, as discussed in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.285, Priority Inversion.

RATIONALE

None.

FUTURE DIRECTIONS

None.

pthread_rwlock_destroy( ), *pthread_rwlock_init*( ), *pthread_rwlock_rdlock*( ), *pthread_rwlock_timedrdlock*( ), *pthread_rwlock_timedwrlock*( ), *pthread_rwlock_tryrdlock*( ), *pthread_rwlock_unlock*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**

CHANGE HISTORY

First released in Issue 5.

Issue 6

The following changes are made for alignment with IEEE Std 1003.1j-2000:

- The margin code in the SYNOPSIS is changed to THR to indicate that the functionality is now part of the Threads option (previously it was part of the Read-Write Locks option in IEEE Std 1003.1j-2000 and also part of the XSI extension).
- The [EDEADLK] error is deleted as a *pthread_rwlock_trywrlock*( ) error.
- The SEE ALSO section is updated.

NAME

pthread_rwlock_unlock — unlock a read-write lock object

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_rwlock_unlock(pthread_rwlock_t *rwlock);
```

DESCRIPTION

The *pthread_rwlock_unlock*( ) function shall release a lock held on the read-write lock object referenced by *rwlock*. Results are undefined if the read-write lock *rwlock* is not held by the calling thread.

If this function is called to release a read lock from the read-write lock object and there are other read locks currently held on this read-write lock object, the read-write lock object remains in the read locked state. If this function releases the last read lock for this read-write lock object, the read-write lock object shall be put in the unlocked state with no owners.

If this function is called to release a write lock for this read-write lock object, the read-write lock object shall be put in the unlocked state.

If there are threads blocked on the lock when it becomes available, the scheduling policy shall determine which thread(s) shall acquire the lock. TPS If the Thread Execution Scheduling option is supported, when threads executing with the scheduling policies SCHED_FIFO, SCHED_RR, or SCHED_SPORADIC are waiting on the lock, they shall acquire the lock in priority order when the lock becomes available. For equal priority threads, write locks shall take precedence over read locks. If the Thread Execution Scheduling option is not supported, it is implementation-defined whether write locks take precedence over read locks.

Results are undefined if any of these functions are called with an uninitialized read-write lock.

RETURN VALUE

If successful, the *pthread_rwlock_unlock*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_rwlock_unlock*( ) function may fail if:

[EINVAL]	The value specified by *rwlock* does not refer to an initialized read-write lock object.
[EPERM]	The current thread does not hold a lock on the read-write lock.

The *pthread_rwlock_unlock*( ) function shall not return an error code of [EINTR].

EXAMPLES

CHANGE HISTORY

First released in Issue 5.

Issue 6

The following changes are made for alignment with IEEE Std 1003.1j-2000:

- The margin code in the SYNOPSIS is changed to THR to indicate that the functionality is now part of the Threads option (previously it was part of the Read-Write Locks option in IEEE Std 1003.1j-2000 and also part of the XSI extension).
- The DESCRIPTION is updated as follows:
  - The conditions under which writers have precedence over readers are specified.
  - The concept of read-write lock owner is deleted.
- The SEE ALSO section is updated.

NAME

pthread_rwlock_wrlock — lock a read-write lock object for writing

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_rwlock_wrlock(pthread_rwlock_t *rwlock);
```

DESCRIPTION

Refer to *pthread_rwlock_trywrlock*( ).

NAME

pthread_rwlockattr_destroy, pthread_rwlockattr_init — destroy and initialize read-write lock attributes object

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_rwlockattr_destroy(pthread_rwlockattr_t *attr);
int pthread_rwlockattr_init(pthread_rwlockattr_t *attr);
```

DESCRIPTION

The *pthread_rwlockattr_destroy*( ) function shall destroy a read-write lock attributes object. A destroyed *attr* attributes object can be reinitialized using *pthread_rwlockattr_init*( ); the results of otherwise referencing the object after it has been destroyed are undefined. An implementation may cause *pthread_rwlockattr_destroy*( ) to set the object referenced by *attr* to an invalid value.

The *pthread_rwlockattr_init*( ) function shall initialize a read-write lock attributes object *attr* with the default value for all of the attributes defined by the implementation.

Results are undefined if *pthread_rwlockattr_init*( ) is called specifying an already initialized *attr* attributes object.

After a read-write lock attributes object has been used to initialize one or more read-write locks, any function affecting the attributes object (including destruction) shall not affect any previously initialized read-write locks.

RETURN VALUE

If successful, the *pthread_rwlockattr_destroy*( ) and *pthread_rwlockattr_init*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_rwlockattr_destroy*( ) function may fail if:

[EINVAL]	The value specified by *attr* is invalid.

The *pthread_rwlockattr_init*( ) function shall fail if:

[ENOMEM]	Insufficient memory exists to initialize the read-write lock attributes object.

These functions shall not return an error code of [EINTR].

CHANGE HISTORY

First released in Issue 5.

Issue 6

The following changes are made for alignment with IEEE Std 1003.1j-2000:

- The margin code in the SYNOPSIS is changed to THR to indicate that the functionality is now part of the Threads option (previously it was part of the Read-Write Locks option in IEEE Std 1003.1j-2000 and also part of the XSI extension).
- The SEE ALSO section is updated.

NAME

pthread_rwlockattr_getpshared, pthread_rwlockattr_setpshared — get and set process-shared attribute of read-write lock attributes object

SYNOPSIS

THR TSH

```
#include <pthread.h>

int pthread_rwlockattr_getpshared(
    const pthread_rwlockattr_t *restrict attr,
    int *restrict pshared);
int pthread_rwlockattr_setpshared(pthread_rwlockattr_t *attr,
    int pshared);
```

DESCRIPTION

The *pthread_rwlockattr_getpshared*( ) function shall obtain the value of the *process-shared* attribute from the initialized attributes object referenced by *attr*. The *pthread_rwlockattr_setpshared*( ) function shall set the *process-shared* attribute in an initialized attributes object referenced by *attr*.

The *process-shared* attribute shall be set to PTHREAD_PROCESS_SHARED to permit a read-write lock to be operated upon by any thread that has access to the memory where the read-write lock is allocated, even if the read-write lock is allocated in memory that is shared by multiple processes. If the *process-shared* attribute is PTHREAD_PROCESS_PRIVATE, the read-write lock shall only be operated upon by threads created within the same process as the thread that initialized the read-write lock; if threads of differing processes attempt to operate on such a read-write lock, the behavior is undefined. The default value of the *process-shared* attribute shall be PTHREAD_PROCESS_PRIVATE.

Additional attributes, their default values, and the names of the associated functions to get and set those attribute values are implementation-defined.

RETURN VALUE

Upon successful completion, the *pthread_rwlockattr_getpshared*( ) shall return zero and store the value of the *process-shared* attribute of *attr* into the object referenced by the *pshared* parameter. Otherwise, an error number shall be returned to indicate the error.

If successful, the *pthread_rwlockattr_setpshared*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_rwlockattr_getpshared*( ) and *pthread_rwlockattr_setpshared*( ) functions may fail if:

[EINVAL]	The value specified by *attr* is invalid.

The *pthread_rwlockattr_setpshared*( ) function may fail if:

[EINVAL]	The new value specified for the attribute is outside the range of legal values for that attribute.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5.

Issue 6

The following changes are made for alignment with IEEE Std 1003.1j-2000:

- The margin code in the SYNOPSIS is changed to THR TSH to indicate that the functionality is now part of the Threads option (previously it was part of the Read-Write Locks option in IEEE Std 1003.1j-2000 and also part of the XSI extension).
- The DESCRIPTION notes that additional attributes are implementation-defined.
- The SEE ALSO section is updated.

The **restrict** keyword is added to the *pthread_rwlockattr_getpshared*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

pthread_rwlockattr_init — initialize read-write lock attributes object

SYNOPSIS

XSI

```
#include <pthread.h>

int pthread_rwlockattr_init(pthread_rwlockattr_t *attr);
```

DESCRIPTION

Refer to *pthread_rwlockattr_destroy*( ).

NAME

pthread_rwlockattr_setpshared — set process-shared attribute of read-write lock attributes object

SYNOPSIS

XSI

```
#include <pthread.h>

int pthread_rwlockattr_setpshared(pthread_rwlockattr_t *attr,
    int pshared);
```

DESCRIPTION

Refer to *pthread_rwlockattr_getpshared*( ).

NAME

pthread_self — get calling thread's ID

SYNOPSIS

THR
```
#include <pthread.h>

pthread_t pthread_self(void);
```

DESCRIPTION

The *pthread_self*( ) function shall return the thread ID of the calling thread.

RETURN VALUE

Refer to the DESCRIPTION.

ERRORS

No errors are defined.

The *pthread_self*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The *pthread_self*( ) function provides a capability similar to the *getpid*( ) function for processes and the rationale is the same: the creation call does not provide the thread ID to the created thread.

FUTURE DIRECTIONS

None.

SEE ALSO

pthread_create( ), *pthread_equal*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_self*( ) function is marked as part of the Threads option.

NAME

pthread_setcancelstate, pthread_setcanceltype, pthread_testcancel — set cancelability state

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_setcancelstate(int state, int *oldstate);
int pthread_setcanceltype(int type, int *oldtype);
void pthread_testcancel(void);
```

DESCRIPTION

The *pthread_setcancelstate*( ) function shall atomically both set the calling thread's cancelability state to the indicated *state* and return the previous cancelability state at the location referenced by *oldstate*. Legal values for *state* are PTHREAD_CANCEL_ENABLE and PTHREAD_CANCEL_DISABLE.

The *pthread_setcanceltype*( ) function shall atomically both set the calling thread's cancelability type to the indicated *type* and return the previous cancelability type at the location referenced by *oldtype*. Legal values for *type* are PTHREAD_CANCEL_DEFERRED and PTHREAD_CANCEL_ASYNCHRONOUS.

The cancelability state and type of any newly created threads, including the thread in which *main*( ) was first invoked, shall be PTHREAD_CANCEL_ENABLE and PTHREAD_CANCEL_DEFERRED respectively.

The *pthread_testcancel*( ) function shall create a cancelation point in the calling thread. The *pthread_testcancel*( ) function shall have no effect if cancelability is disabled.

RETURN VALUE

If successful, the *pthread_setcancelstate*( ) and *pthread_setcanceltype*( ) functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_setcancelstate*( ) function may fail if:

[EINVAL]	The specified state is not PTHREAD_CANCEL_ENABLE or PTHREAD_CANCEL_DISABLE.

The *pthread_setcanceltype*( ) function may fail if:

[EINVAL]	The specified type is not PTHREAD_CANCEL_DEFERRED or PTHREAD_CANCEL_ASYNCHRONOUS.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The *pthread_setcancelstate*( ) and *pthread_setcanceltype*( ) functions control the points at which a thread may be asynchronously canceled. For cancelation control to be usable in modular fashion, some rules need to be followed.

An object can be considered to be a generalization of a procedure. It is a set of procedures and global variables written as a unit and called by clients not known by the object. Objects may depend on other objects.

First, cancelability should only be disabled on entry to an object, never explicitly enabled. On exit from an object, the cancelability state should always be restored to its value on entry to the object.

This follows from a modularity argument: if the client of an object (or the client of an object that uses that object) has disabled cancelability, it is because the client does not want to be concerned about cleaning up if the thread is canceled while executing some sequence of actions. If an object is called in such a state and it enables cancelability and a cancelation request is pending for that thread, then the thread is canceled, contrary to the wish of the client that disabled.

Second, the cancelability type may be explicitly set to either *deferred* or *asynchronous* upon entry to an object. But as with the cancelability state, on exit from an object the cancelability type should always be restored to its value on entry to the object.

Finally, only functions that are cancel-safe may be called from a thread that is asynchronously cancelable.

FUTURE DIRECTIONS

None.

SEE ALSO

pthread_cancel( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_setcancelstate*( ), *pthread_setcanceltype*( ), and *pthread_testcancel*( ) functions are marked as part of the Threads option.

NAME

pthread_setconcurrency — set level of concurrency

SYNOPSIS

XSI

```
#include <pthread.h>

int pthread_setconcurrency(int new_level);

```

DESCRIPTION

Refer to *pthread_getconcurrency*( ).

NAME

pthread_setschedparam — dynamic thread scheduling parameters access (**REALTIME THREADS**)

SYNOPSIS

THR TPS

```
#include <pthread.h>

int pthread_setschedparam(pthread_t thread, int policy,
    const struct sched_param *param);
```

DESCRIPTION

Refer to *pthread_getschedparam*( ).

NAME

pthread_setschedprio — dynamic thread scheduling parameters access (**REALTIME THREADS**)

SYNOPSIS

THR TPS
```
#include <pthread.h>

int pthread_setschedprio(pthread_t thread, int prio);
```

DESCRIPTION

The *pthread_setschedprio*( ) function shall set the scheduling priority for the thread whose thread ID is given by *thread* to the value given by *prio*. See **Scheduling Policies** (on page 494) for a description on how this function call affects the ordering of the thread in the thread list for its new priority.

If the *pthread_setschedprio*( ) function fails, the scheduling priority of the target thread shall not be changed.

RETURN VALUE

If successful, the *pthread_setschedprio*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_setschedprio*( ) function may fail if:

[EINVAL]	The value of *prio* is invalid for the scheduling policy of the specified thread.
[ENOTSUP]	An attempt was made to set the priority to an unsupported value.
[EPERM]	The caller does not have the appropriate permission to set the scheduling policy of the specified thread.
[EPERM]	The implementation does not allow the application to modify the priority to the value specified.
[ESRCH]	The value specified by *thread* does not refer to an existing thread.

The *pthread_setschedprio*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The *pthread_setschedprio*( ) function provides a way for an application to temporarily raise its priority and then lower it again, without having the undesired side effect of yielding to other threads of the same priority. This is necessary if the application is to implement its own strategies for bounding priority inversion, such as priority inheritance or priority ceilings. This capability is especially important if the implementation does not support the Thread Priority Protection or Thread Priority Inheritance options, but even if those options are supported it is needed if the application is to bound priority inheritance for other resources, such as semaphores.

The standard developers considered that while it might be preferable conceptually to solve this problem by modifying the specification of *pthread_setschedparam*( ), it was too late to make such a change, as there may be implementations that would need to be changed. Therefore, this new function was introduced.

FUTURE DIRECTIONS

None.

SEE ALSO

pthread_getschedparam( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<pthread.h>**

CHANGE HISTORY

First released in Issue 6. Included as a response to IEEE PASC Interpretation 1003.1 #96.

NAME

pthread_setspecific — thread-specific data management

SYNOPSIS

THR

```
#include <pthread.h>

int pthread_setspecific(pthread_key_t key, const void *value);
```

DESCRIPTION

Refer to *pthread_getspecific*( ).

NAME

pthread_sigmask, sigprocmask — examine and change blocked signals

SYNOPSIS

```
#include <signal.h>

int pthread_sigmask(int how, const sigset_t *restrict set,
    sigset_t *restrict oset);
int sigprocmask(int how, const sigset_t *restrict set,
    sigset_t *restrict oset);
```

DESCRIPTION

THR The *pthread_sigmask*( ) function shall examine or change (or both) the calling thread's signal mask, regardless of the number of threads in the process. The function shall be equivalent to *sigprocmask*( ), without the restriction that the call be made in a single-threaded process.

In a single-threaded process, the *sigprocmask*( ) function shall examine or change (or both) the signal mask of the calling thread.

If the argument *set* is not a null pointer, it points to a set of signals to be used to change the currently blocked set.

The argument *how* indicates the way in which the set is changed, and the application shall ensure it consists of one of the following values:

SIG_BLOCK	The resulting set shall be the union of the current set and the signal set pointed to by *set*.
SIG_SETMASK	The resulting set shall be the signal set pointed to by *set*.
SIG_UNBLOCK	The resulting set shall be the intersection of the current set and the complement of the signal set pointed to by *set*.

If the argument *oset* is not a null pointer, the previous mask shall be stored in the location pointed to by *oset*. If *set* is a null pointer, the value of the argument *how* is not significant and the process' signal mask shall be unchanged; thus the call can be used to enquire about currently blocked signals.

If there are any pending unblocked signals after the call to *sigprocmask*( ), at least one of those signals shall be delivered before the call to *sigprocmask*( ) returns.

It is not possible to block those signals which cannot be ignored. This shall be enforced by the system without causing an error to be indicated.

If any of the SIGFPE, SIGILL, SIGSEGV, or SIGBUS signals are generated while they are blocked, the result is undefined, unless the signal was generated by the *kill*( ) function, the *sigqueue*( ) function, or the *raise*( ) function.

If *sigprocmask*( ) fails, the thread's signal mask shall not be changed.

The use of the *sigprocmask*( ) function is unspecified in a multi-threaded process.

RETURN VALUE

THR Upon successful completion *pthread_sigmask*( ) shall return 0; otherwise, it shall return the corresponding error number.

Upon successful completion, *sigprocmask*( ) shall return 0; otherwise, −1 shall be returned, *errno* shall be set to indicate the error, and the process' signal mask shall be unchanged.

ERRORS

THR The *pthread_sigmask*( ) and *sigprocmask*( ) functions shall fail if:

[EINVAL] The value of the *how* argument is not equal to one of the defined values.

THR The *pthread_sigmask*( ) function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

When a process' signal mask is changed in a signal-catching function that is installed by *sigaction*( ), the restoration of the signal mask on return from the signal-catching function overrides that change (see *sigaction*( )). If the signal-catching function was installed with *signal*( ), it is unspecified whether this occurs.

See *kill*( ) for a discussion of the requirement on delivery of signals.

FUTURE DIRECTIONS

None.

SEE ALSO

sigaction( ), *sigaddset*( ), *sigdelset*( ), *sigemptyset*( ), *sigfillset*( ), *sigismember*( ), *sigpending*( ), *sigqueue*( ), *sigsuspend*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<signal.h>**

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

The *pthread_sigmask*( ) function is added for alignment with the POSIX Threads Extension.

Issue 6

The *pthread_sigmask*( ) function is marked as part of the Threads option.

The SYNOPSIS for *sigprocmask*( ) is marked as a CX extension to note that the presence of this function in the **<signal.h>** header is an extension to the ISO C standard. |

The following changes are made for alignment with the ISO POSIX-1: 1996 standard: |

- The DESCRIPTION is updated to explicitly state the functions which may generate the signal.

The DESCRIPTION is updated to avoid use of the term ''must'' for application requirements.

The **restrict** keyword is added to the *pthread_sigmask*( ) and *sigprocmask*( ) prototypes for alignment with the ISO / IEC 9899: 1999 standard.

NAME

pthread_spin_destroy, pthread_spin_init — destroy or initialize a spin lock object (**ADVANCED REALTIME THREADS**)

SYNOPSIS

THR SPI
```
#include <pthread.h>

int pthread_spin_destroy(pthread_spinlock_t *lock);
int pthread_spin_init(pthread_spinlock_t *lock, int pshared);
```

DESCRIPTION

The *pthread_spin_destroy*( ) function shall destroy the spin lock referenced by *lock* and release any resources used by the lock. The effect of subsequent use of the lock is undefined until the lock is reinitialized by another call to *pthread_spin_init*( ). The results are undefined if *pthread_spin_destroy*( ) is called when a thread holds the lock, or if this function is called with an uninitialized thread spin lock.

The *pthread_spin_init*( ) function shall allocate any resources required to use the spin lock referenced by *lock* and initialize the lock to an unlocked state.

TSH If the Thread Process-Shared Synchronization option is supported and the value of *pshared* is PTHREAD_PROCESS_SHARED, the implementation shall permit the spin lock to be operated upon by any thread that has access to the memory where the spin lock is allocated, even if it is allocated in memory that is shared by multiple processes.

If the Thread Process-Shared Synchronization option is supported and the value of *pshared* is PTHREAD_PROCESS_PRIVATE, or if the option is not supported, the spin lock shall only be operated upon by threads created within the same process as the thread that initialized the spin lock. If threads of differing processes attempt to operate on such a spin lock, the behavior is undefined.

The results are undefined if *pthread_spin_init*( ) is called specifying an already initialized spin lock. The results are undefined if a spin lock is used without first being initialized.

If the *pthread_spin_init*( ) function fails, the lock is not initialized and the contents of *lock* are undefined.

Only the object referenced by *lock* may be used for performing synchronization.

The result of referring to copies of that object in calls to *pthread_spin_destroy*( ), *pthread_spin_lock*( ), *pthread_spin_trylock*( ), or *pthread_spin_unlock*( ) is undefined.

RETURN VALUE

Upon successful completion, these functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

These functions may fail if:

[EBUSY]	The implementation has detected an attempt to initialize or destroy a spin lock while it is in use (for example, while being used in a *pthread_spin_lock*( ) call) by another thread.
[EINVAL]	The value specified by *lock* is invalid.

The *pthread_spin_init*( ) function shall fail if:

[EAGAIN]	The system lacks the necessary resources to initialize another spin lock.

[ENOMEM] Insufficient memory exists to initialize the lock.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

The *pthread_spin_destroy*( ) and *pthread_spin_init*( ) functions are part of the Spin Locks option and need not be provided on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

pthread_spin_lock( ), *pthread_spin_trylock*( ), *pthread_spin_unlock*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<<pthread.h>>**

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1j-2000.

In the SYNOPSIS, the inclusion of **<sys/types.h>** is no longer required.

NAME

pthread_spin_init — initialize a spin lock object (**ADVANCED REALTIME THREADS**)

SYNOPSIS

THR SPI

```
#include <pthread.h>

int pthread_spin_init(pthread_spinlock_t *lock, int pshared);
```

DESCRIPTION

Refer to *pthread_spin_destroy*( ).

NAME

pthread_spin_lock, pthread_spin_trylock — lock a spin lock object (**ADVANCED REALTIME THREADS**)

SYNOPSIS

THR SPI

```
#include <pthread.h>

int pthread_spin_lock(pthread_spinlock_t *lock);
int pthread_spin_trylock(pthread_spinlock_t *lock);
```

DESCRIPTION

The *pthread_spin_lock*( ) function shall lock the spin lock referenced by *lock*. The calling thread shall acquire the lock if it is not held by another thread. Otherwise, the thread shall spin (that is, shall not return from the *pthread_spin_lock*( ) call) until the lock becomes available. The results are undefined if the calling thread holds the lock at the time the call is made. The *pthread_spin_trylock*( ) function shall lock the spin lock referenced by *lock* if it is not held by any thread. Otherwise, the function shall fail.

The results are undefined if any of these functions is called with an uninitialized spin lock.

RETURN VALUE

Upon successful completion, these functions shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

These functions may fail if:

[EINVAL] The value specified by *lock* does not refer to an initialized spin lock object.

The *pthread_spin_lock*( ) function may fail if:

[EDEADLK] The calling thread already holds the lock.

The *pthread_spin_trylock*( ) function shall fail if:

[EBUSY] A thread currently holds the lock.

These functions shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

Applications using this function may be subject to priority inversion, as discussed in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.285, Priority Inversion.

The *pthread_spin_lock*( ) and *pthread_spin_trylock*( ) functions are part of the Spin Locks option and need not be provided on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1j-2000.

In the SYNOPSIS, the inclusion of **<sys/types.h>** is no longer required.

NAME

pthread_spin_trylock — lock a spin lock object (**ADVANCED REALTIME THREADS**)

SYNOPSIS

THR SPI

```
#include <pthread.h>

int pthread_spin_trylock(pthread_spinlock_t *lock);

```

DESCRIPTION

Refer to *pthread_spin_lock*( ).

NAME

pthread_spin_unlock — unlock a spin lock object (**ADVANCED REALTIME THREADS**)

SYNOPSIS

THR SPI

```
#include <pthread.h>

int pthread_spin_unlock(pthread_spinlock_t *lock);

```

DESCRIPTION

The *pthread_spin_unlock*( ) function shall release the spin lock referenced by *lock* which was locked via the *pthread_spin_lock*( ) or *pthread_spin_trylock*( ) functions. The results are undefined if the lock is not held by the calling thread. If there are threads spinning on the lock when *pthread_spin_unlock*( ) is called, the lock becomes available and an unspecified spinning thread shall acquire the lock.

The results are undefined if this function is called with an uninitialized thread spin lock.

RETURN VALUE

Upon successful completion, the *pthread_spin_unlock*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *pthread_spin_unlock*( ) function may fail if:

[EINVAL]	An invalid argument was specified.
[EPERM]	The calling thread does not hold the lock.

This function shall not return an error code of [EINTR].

EXAMPLES

None.

APPLICATION USAGE

The *pthread_spin_unlock*( ) function is part of the Spin Locks option and need not be provided on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

pthread_testcancel — set cancelability state

SYNOPSIS

THR
```
#include <pthread.h>

void pthread_testcancel(void);
```

DESCRIPTION

Refer to *pthread_setcancelstate*( ).

NAME

ptsname — get name of the slave pseudo-terminal device

SYNOPSIS

XSI
```
#include <stdlib.h>

char *ptsname(int fildes);
```

DESCRIPTION

The *ptsname*( ) function shall return the name of the slave pseudo-terminal device associated with a master pseudo-terminal device. The *fildes* argument is a file descriptor that refers to the master device. The *ptsname*( ) function shall return a pointer to a string containing the pathname of the corresponding slave device. |

The *ptsname*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

Upon successful completion, *ptsname*( ) shall return a pointer to a string which is the name of the pseudo-terminal slave device. Upon failure, *ptsname*( ) shall return a null pointer. This could occur if *fildes* is an invalid file descriptor or if the slave device name does not exist in the file system.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The value returned may point to a static data area that is overwritten by each call to *ptsname*( ).

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

grantpt( ), *open*( ), *ttyname*( ), *unlockpt*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdlib.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

A note indicating that this function need not be reentrant is added to the DESCRIPTION.

NAME

putc — put byte on a stream

SYNOPSIS

```
#include <stdio.h>

int putc(int c, FILE *stream);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *putc*( ) function shall be equivalent to *fputc*( ), except that if it is implemented as a macro it may evaluate *stream* more than once, so the argument should never be an expression with side effects.

RETURN VALUE

Refer to *fputc*( ).

ERRORS

Refer to *fputc*( ).

EXAMPLES

None.

APPLICATION USAGE

Since it may be implemented as a macro, *putc*( ) may treat a *stream* argument with side effects incorrectly. In particular, *putc*(*c*,**f*++) does not necessarily work correctly. Therefore, use of this function is not recommended in such situations; *fputc*( ) should be used instead. |

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

fputc( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdio.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

NAME

putc_unlocked — stdio with explicit client locking

SYNOPSIS

TSF

```
#include <stdio.h>

int putc_unlocked(int c, FILE *stream);
```

DESCRIPTION

Refer to *getc_unlocked*( ).

NAME

putchar — put byte on stdout stream

SYNOPSIS

```
#include <stdio.h>

int putchar(int c);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The function call *putchar*(*c*) shall be equivalent to *putc*(*c*,*stdout*).

RETURN VALUE

Refer to *fputc*( ).

ERRORS

Refer to *fputc*( ).

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

putc( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdio.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

NAME

putchar_unlocked — stdio with explicit client locking

SYNOPSIS

TSF

```
#include <stdio.h>

int putchar_unlocked(int c);
```

DESCRIPTION

Refer to *getc_unlocked*( ).

NAME

putenv — change or add a value to environment

SYNOPSIS

XSI

```
#include <stdlib.h>

int putenv(char *string);
```

DESCRIPTION

The *putenv*( ) function shall use the *string* argument to set environment variable values. The *string* argument should point to a string of the form "*name*=*value*. The *putenv*( ) function shall make the value of the environment variable *name* equal to *value* by altering an existing variable or creating a new one. In either case, the string pointed to by *string* shall become part of the environment, so altering the string shall change the environment. The space used by *string* is no longer used once a new string-defining *name* is passed to *putenv*( ).

The *putenv*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

Upon successful completion, *putenv*( ) shall return 0; otherwise, it shall return a non-zero value and set *errno* to indicate the error.

ERRORS

The *putenv*( ) function may fail if:

[ENOMEM]	Insufficient memory was available.

EXAMPLES

Changing the Value of an Environment Variable

The following example changes the value of the *HOME* environment variable to the value **/usr/home**.

```
#include <stdlib.h>
...
static char *var = "HOME=/usr/home";
int ret;

ret = putenv(var);
```

APPLICATION USAGE

The *putenv*( ) function manipulates the environment pointed to by *environ*, and can be used in conjunction with *getenv*( ).

This routine may use *malloc*( ) to enlarge the environment.

A potential error is to call *putenv*( ) with an automatic variable as the argument, then return from the calling function while *string* is still part of the environment.

The *setenv*( ) function is preferred over this function.

RATIONALE

The standard developers noted that *putenv*( ) is the only function available to add to the environment without permitting memory leaks.

FUTURE DIRECTIONS

None.

SEE ALSO

exec, *getenv*( ), *malloc*( ), *setenv*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdlib.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The type of the argument to this function is changed from **const char *** to **char ***. This was indicated as a FUTURE DIRECTION in previous issues.

A note indicating that this function need not be reentrant is added to the DESCRIPTION.

NAME

putmsg, putpmsg — send a message on a STREAM (**STREAMS**)

SYNOPSIS

XSR
```
#include <stropts.h>

int putmsg(int fildes, const struct strbuf *ctlptr,
    const struct strbuf *dataptr, int flags);
int putpmsg(int fildes, const struct strbuf *ctlptr,
    const struct strbuf *dataptr, int band, int flags);
```

DESCRIPTION

The *putmsg*( ) function shall create a message from a process buffer(s) and send the message to a STREAMS file. The message may contain either a data part, a control part, or both. The data and control parts are distinguished by placement in separate buffers, as described below. The semantics of each part are defined by the STREAMS module that receives the message.

The *putpmsg*( ) function is equivalent o *putmsg*( ), except that the process can send messages in different priority bands. Except where noted, all requirements on *putmsg*( ) also pertain to *putpmsg*( ).

The *fildes* argument specifies a file descriptor referencing an open STREAM. The *ctlptr* and *dataptr* arguments each point to a **strbuf** structure.

The *ctlptr* argument points to the structure describing the control part, if any, to be included in the message. The *buf* member in the **strbuf** structure points to the buffer where the control information resides, and the *len* member indicates the number of bytes to be sent. The *maxlen* member is not used by *putmsg*( ). In a similar manner, the argument *dataptr* specifies the data, if any, to be included in the message. The *flags* argument indicates what type of message should be sent and is described further below.

To send the data part of a message, the application shall ensure that *dataptr* is not a null pointer and the *len* member of *dataptr* is 0 or greater. To send the control part of a message, the application shall ensure that the corresponding values are set for *ctlptr*. No data (control) part shall be sent if either *dataptr*(*ctlptr*) is a null pointer or the *len* member of *dataptr*(*ctlptr*) is set to −1.

For *putmsg*( ), if a control part is specified and *flags* is set to RS_HIPRI, a high priority message shall be sent. If no control part is specified, and *flags* is set to RS_HIPRI, *putmsg*( ) shall fail and set *errno* to [EINVAL]. If *flags* is set to 0, a normal message (priority band equal to 0) shall be sent. If a control part and data part are not specified and *flags* is set to 0, no message shall be sent and 0 shall be returned. |

For *putpmsg*( ), the flags are different. The *flags* argument is a bitmask with the following mutually-exclusive flags defined: MSG_HIPRI and MSG_BAND. If *flags* is set to 0, *putpmsg*( ) shall fail and set *errno* to [EINVAL]. If a control part is specified and *flags* is set to MSG_HIPRI and *band* is set to 0, a high-priority message shall be sent. If *flags* is set to MSG_HIPRI and either no control part is specified or *band* is set to a non-zero value, *putpmsg*( ) shall fail and set *errno* to [EINVAL]. If *flags* is set to MSG_BAND, then a message shall be sent in the priority band specified by *band*. If a control part and data part are not specified and *flags* is set to MSG_BAND, no message shall be sent and 0 shall be returned. |

The *putmsg*( ) function shall block if the STREAM write queue is full due to internal flow control conditions, with the following exceptions: |

- For high-priority messages, *putmsg*( ) shall not block on this condition and continues processing the message. |

- For other messages, *putmsg*( ) shall not block but shall fail when the write queue is full and O_NONBLOCK is set.

The *putmsg*( ) function shall also block, unless prevented by lack of internal resources, while waiting for the availability of message blocks in the STREAM, regardless of priority or whether O_NONBLOCK has been specified. No partial message shall be sent.

RETURN VALUE

Upon successful completion, *putmsg*( ) and *putpmsg*( ) shall return 0; otherwise, they shall return −1 and set *errno* to indicate the error.

ERRORS

The *putmsg*( ) and *putpmsg*( ) functions shall fail if:

[EAGAIN]	A non-priority message was specified, the O_NONBLOCK flag is set, and the STREAM write queue is full due to internal flow control conditions; or buffers could not be allocated for the message that was to be created.
[EBADF]	*fildes* is not a valid file descriptor open for writing.
[EINTR]	A signal was caught during *putmsg*( ).
[EINVAL]	An undefined value is specified in *flags*, or *flags* is set to RS_HIPRI or MSG_HIPRI and no control part is supplied, or the STREAM or multiplexer referenced by *fildes* is linked (directly or indirectly) downstream from a multiplexer, or *flags* is set to MSG_HIPRI and *band* is non-zero (for *putpmsg*( ) only).
[ENOSR]	Buffers could not be allocated for the message that was to be created due to insufficient STREAMS memory resources.
[ENOSTR]	A STREAM is not associated with *fildes*.
[ENXIO]	A hangup condition was generated downstream for the specified STREAM.
[EPIPE] or [EIO]	The *fildes* argument refers to a STREAMS-based pipe and the other end of the pipe is closed. A SIGPIPE signal is generated for the calling thread.
[ERANGE]	The size of the data part of the message does not fall within the range specified by the maximum and minimum packet sizes of the topmost STREAM module. This value is also returned if the control part of the message is larger than the maximum configured size of the control part of a message, or if the data part of a message is larger than the maximum configured size of the data part of a message.

In addition, *putmsg*( ) and *putpmsg*( ) shall fail if the STREAM head had processed an asynchronous error before the call. In this case, the value of *errno* does not reflect the result of *putmsg*( ) or *putpmsg*( ), but reflects the prior error.

EXAMPLES

Sending a High-Priority Message

The value of *fd* is assumed to refer to an open STREAMS file. This call to *putmsg*( ) does the following:

1. Creates a high-priority message with a control part and a data part, using the buffers pointed to by *ctrlbuf* and *databuf*, respectively.
2. Sends the message to the STREAMS file identified by *fd*.

```
#include <stropts.h>
#include <string.h>
...
int fd;
char *ctrlbuf = "This is the control part";
char *databuf = "This is the data part";
struct strbuf ctrl;
struct strbuf data;
int ret;

ctrl.buf = ctrlbuf;
ctrl.len = strlen(ctrlbuf);

data.buf = databuf;
data.len = strlen(databuf);

ret = putmsg(fd, &ctrl, &data, MSG_HIPRI);
```

Using putpmsg( )

This example has the same effect as the previous example. In this example, however, the *putpmsg*( ) function creates and sends the message to the STREAMS file.

```
#include <stropts.h>
#include <string.h>
...
int fd;
char *ctrlbuf = "This is the control part";
char *databuf = "This is the data part";
struct strbuf ctrl;
struct strbuf data;
int ret;

ctrl.buf = ctrlbuf;
ctrl.len = strlen(ctrlbuf);

data.buf = databuf;
data.len = strlen(databuf);

ret = putpmsg(fd, &ctrl, &data, 0, MSG_HIPRI);
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

The following text is removed from the DESCRIPTION: ‘‘The STREAM head guarantees that the control part of a message generated by *putmsg*( ) is at least 64 bytes in length’’.

Issue 6

This function is marked as part of the XSI STREAMS Option Group.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

putpmsg — send a message on a STREAM (**STREAMS**)

SYNOPSIS

XSR

```
#include <stropts.h>

int putpmsg(int fildes, const struct strbuf *ctlptr,
    const struct strbuf *dataptr, int band, int flags);
```

DESCRIPTION

Refer to *putmsg*( ).

NAME

puts — put a string on standard output

SYNOPSIS

```
#include <stdio.h>

int puts(const char *s);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *puts*( ) function shall write the string pointed to by *s*, followed by a <newline>, to the standard output stream *stdout*. The terminating null byte shall not be written.

CX The *st_ctime* and *st_mtime* fields of the file shall be marked for update between the successful execution of *puts*( ) and the next successful completion of a call to *fflush*( ) or *fclose*( ) on the same stream or a call to *exit*( ) or *abort*( ).

RETURN VALUE

Upon successful completion, *puts*( ) shall return a non-negative number. Otherwise, it shall return EOF, shall set an error indicator for the stream, and *errno* shall be set to indicate the error. CX

ERRORS

Refer to *fputc*( ).

EXAMPLES

Printing to Standard Output

The following example gets the current time, converts it to a string using *localtime*( ) and *asctime*( ), and prints it to standard output using *puts*( ). It then prints the number of minutes to an event for which it is waiting.

```
#include <time.h>
#include <stdio.h>
...
time_t now;
int minutes_to_event;
...
time(&now);
printf("The time is ");
puts(asctime(localtime(&now)));
printf("There are %d minutes to the event.\n",
    minutes_to_event);
...
```

APPLICATION USAGE

The *puts*( ) function appends a <newline>, while *fputs*( ) does not.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

Extensions beyond the ISO C standard are now marked.

NAME

pututxline — put an entry into user accounting database

SYNOPSIS

XSI

```
#include <utmpx.h>

struct utmpx *pututxline(const struct utmpx *utmpx);
```

DESCRIPTION

Refer to *endutxent*( ).

NAME

putwc — put a wide character on a stream

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

wint_t putwc(wchar_t wc, FILE *stream);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *putwc*( ) function shall be equivalent to *fputwc*( ), except that if it is implemented as a macro it may evaluate *stream* more than once, so the argument should never be an expression with side effects.

RETURN VALUE

Refer to *fputwc*( ).

ERRORS

Refer to *fputwc*( ).

EXAMPLES

None.

APPLICATION USAGE

Since it may be implemented as a macro, *putwc*( ) may treat a *stream* argument with side effects incorrectly. In particular, *putwc*(*wc*,**f*++) need not work correctly. Therefore, use of this function is not recommended; *fputwc*( ) should be used instead. |

CHANGE HISTORY

First released in Issue 4.

Issue 5

Aligned with ISO/IEC 9899:1990/Amendment 1:1995 (E). Specifically, the type of argument *wc* is changed from **wint_t** to **wchar_t**.

NAME

pwrite — write on a file

SYNOPSIS

```
#include <unistd.h>
```

XSI
```
ssize_t pwrite(int fildes, const void *buf, size_t nbyte,
    off_t offset);
```

DESCRIPTION

Refer to *write*( ).

NAME

qsort — sort a table of data

SYNOPSIS

```
#include <stdlib.h>

void qsort(void *base, size_t nel, size_t width,
    int (*compar)(const void *, const void *));
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *qsort*( ) function shall sort an array of *nel* objects, the initial element of which is pointed to by *base*. The size of each object, in bytes, is specified by the *width* argument.

The contents of the array shall be sorted in ascending order according to a comparison function. The *compar* argument is a pointer to the comparison function, which is called with two arguments that point to the elements being compared. The application shall ensure that the function returns an integer less than, equal to, or greater than 0, if the first argument is considered respectively less than, equal to, or greater than the second. If two members compare as equal, their order in the sorted array is unspecified.

RETURN VALUE

The *qsort*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

raise — send a signal to the executing process

SYNOPSIS

```
#include <signal.h>

int raise(int sig);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

CX The *raise*( ) function shall send the signal *sig* to the executing thread or process. If a signal handler is called, the *raise*( ) function shall not return until after the signal handler does.

THR If the implementation supports the Threads option, the effect of the *raise*( ) function shall be equivalent to calling: |

```
pthread_kill(pthread_self(), sig);
```

CX Otherwise, the effect of the *raise*( ) function shall be equivalent to calling: |

```
kill(getpid(), sig);
```

RETURN VALUE

CX Upon successful completion, 0 shall be returned. Otherwise, a non-zero value shall be returned and *errno* shall be set to indicate the error.

ERRORS

The *raise*( ) function shall fail if:

CX [EINVAL] The value of the *sig* argument is an invalid signal number.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The term ‘‘thread’’ is an extension to the ISO C standard.

FUTURE DIRECTIONS

None.

SEE ALSO

kill( ), *sigaction*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<signal.h>**, **<sys/types.h>**

CHANGE HISTORY

First released in Issue 4. Derived from the ANSI C standard.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE section, the requirement to set *errno* on error is added.
- The [EINVAL] error condition is added.

NAME

rand, rand_r, srand — pseudo-random number generator

SYNOPSIS

```
#include <stdlib.h>

int rand(void);
int rand_r(unsigned *seed);
void srand(unsigned seed);
```

TSF (rand_r)

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

XSI The *rand*( ) function shall compute a sequence of pseudo-random integers in the range 0 to {RAND_MAX} with a period of at least 2^{32}.

CX The *rand*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

TSF The *rand_r*( ) function shall compute a sequence of pseudo-random integers in the range 0 to {RAND_MAX}. (The value of the {RAND_MAX} macro shall be at least 32 767.)

If *rand_r*( ) is called with the same initial value for the object pointed to by *seed* and that object is not modified between successive returns and calls to *rand_r*( ), the same sequence shall be generated.

The *srand*( ) function uses the argument as a seed for a new sequence of pseudo-random numbers to be returned by subsequent calls to *rand*( ). If *srand*( ) is then called with the same seed value, the sequence of pseudo-random numbers shall be repeated. If *rand*( ) is called before any calls to *srand*( ) are made, the same sequence shall be generated as when *srand*( ) is first called with a seed value of 1.

The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *rand*( ) or *srand*( ).

RETURN VALUE

The *rand*( ) function shall return the next pseudo-random number in the sequence.

TSF The *rand_r*( ) function shall return a pseudo-random integer.

The *srand*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

Generating a Pseudo-Random Number Sequence

The following example demonstrates how to generate a sequence of pseudo-random numbers.

```
#include <stdio.h>
#include <stdlib.h>
...
    long count, i;
    char *keystr;
    int elementlen, len;
    char c;
```

```
...
/* Initial random number generator. */
    srand(1);

    /* Create keys using only lower case characters */
    len = 0;
    for (i=0; i<count; i++) {
        while (len < elementlen) {
            c = (char) (rand() % 128);
            if (islower(c))
                keystr[len++] = c;
        }

        keystr[len] = '\0';
        printf("%s Element%0*ld\n", keystr, elementlen, i);
        len = 0;
    }
```

Generating the Same Sequence on Different Machines

The following code defines a pair of functions that could be incorporated into applications wishing to ensure that the same sequence of numbers is generated across different machines.

```
static unsigned long next = 1;
int myrand(void)  /* RAND_MAX assumed to be 32767. */
{
    next = next * 1103515245 + 12345;
    return((unsigned)(next/65536) % 32768);
}

void mysrand(unsigned seed)
{
    next = seed;
}
```

APPLICATION USAGE

The *drand48*( ) function provides a much more elaborate random number generator.

RATIONALE

The ISO C standard *rand*( ) and *srand*( ) functions allow per-process pseudo-random streams shared by all threads. Those two functions need not change, but there has to be mutual-exclusion that prevents interference between two threads concurrently accessing the random number generator.

With regard to *rand*( ), there are two different behaviors that may be wanted in a multi-threaded program:

1. A single per-process sequence of pseudo-random numbers that is shared by all threads that call *rand*( )

2. A different sequence of pseudo-random numbers for each thread that calls *rand*( )

This is provided by the modified thread-safe function based on whether the seed value is global to the entire process or local to each thread.

This does not address the known deficiencies of the *rand*( ) function implementations, which have been approached by maintaining more state. In effect, this specifies new thread-safe forms of a deficient function. |

FUTURE DIRECTIONS

None.

SEE ALSO

drand48( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdlib.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The *rand_r*( ) function is included for alignment with the POSIX Threads Extension.

A note indicating that the *rand*( ) function need not be reentrant is added to the DESCRIPTION.

Issue 6

Extensions beyond the ISO C standard are now marked.

The *rand_r*( ) function is marked as part of the Thread-Safe Functions option.

NAME

random — generate pseudo-random number

SYNOPSIS

XSI

```
#include <stdlib.h>

long random(void);
```

DESCRIPTION

Refer to *initstate*( ).

NAME

pread, read — read from a file

SYNOPSIS

```
#include <unistd.h>

XSI ssize_t pread(int fildes, void *buf, size_t nbyte, off_t offset);
ssize_t read(int fildes, void *buf, size_t nbyte);
```

DESCRIPTION

The *read*( ) function shall attempt to read *nbyte* bytes from the file associated with the open file descriptor, *fildes*, into the buffer pointed to by *buf*. The behavior of multiple concurrent reads on the same pipe, FIFO, or terminal device is unspecified.

Before any action described below is taken, and if *nbyte* is zero, the *read*( ) function may detect and return errors as described below. In the absence of errors, or if error detection is not performed, the *read*( ) function shall return zero and have no other results.

On files that support seeking (for example, a regular file), the *read*( ) shall start at a position in the file given by the file offset associated with *fildes*. The file offset shall be incremented by the number of bytes actually read.

Files that do not support seeking—for example, terminals—always read from the current position. The value of a file offset associated with such a file is undefined.

No data transfer shall occur past the current end-of-file. If the starting position is at or after the end-of-file, 0 shall be returned. If the file refers to a device special file, the result of subsequent *read*( ) requests is implementation-defined.

If the value of *nbyte* is greater than {SSIZE_MAX}, the result is implementation-defined.

When attempting to read from an empty pipe or FIFO:

- If no process has the pipe open for writing, *read*( ) shall return 0 to indicate end-of-file.
- If some process has the pipe open for writing and O_NONBLOCK is set, *read*( ) shall return −1 and set *errno* to [EAGAIN].
- If some process has the pipe open for writing and O_NONBLOCK is clear, *read*( ) shall block the calling thread until some data is written or the pipe is closed by all processes that had the pipe open for writing.

When attempting to read a file (other than a pipe or FIFO) that supports non-blocking reads and has no data currently available:

- If O_NONBLOCK is set, *read*( ) shall return −1 and set *errno* to [EAGAIN].
- If O_NONBLOCK is clear, *read*( ) shall block the calling thread until some data becomes available.
- The use of the O_NONBLOCK flag has no effect if there is some data available.

The *read*( ) function reads data previously written to a file. If any portion of a regular file prior to the end-of-file has not been written, *read*( ) shall return bytes with value 0. For example, *lseek*( ) allows the file offset to be set beyond the end of existing data in the file. If data is later written at this point, subsequent reads in the gap between the previous end of data and the newly written data shall return bytes with value 0 until data is written into the gap.

Upon successful completion, where *nbyte* is greater than 0, *read*( ) shall mark for update the *st_atime* field of the file, and shall return the number of bytes read. This number shall never be greater than *nbyte*. The value returned may be less than *nbyte* if the number of bytes left in the file is less than *nbyte*, if the *read*( ) request was interrupted by a signal, or if the file is a pipe or FIFO or special file and has fewer than *nbyte* bytes immediately available for reading. For example, a *read*( ) from a file associated with a terminal may return one typed line of data.

If a *read*( ) is interrupted by a signal before it reads any data, it shall return −1 with *errno* set to [EINTR].

If a *read*( ) is interrupted by a signal after it has successfully read some data, it shall return the number of bytes read.

For regular files, no data transfer shall occur past the offset maximum established in the open file description associated with *fildes*.

If *fildes* refers to a socket, *read*( ) shall be equivalent to *recv*( ) with no flags set.

SIO If the O_DSYNC and O_RSYNC bits have been set, read I/O operations on the file descriptor shall complete as defined by synchronized I/O data integrity completion. If the O_SYNC and O_RSYNC bits have been set, read I/O operations on the file descriptor shall complete as defined by synchronized I/O file integrity completion.

SHM If *fildes* refers to a shared memory object, the result of the *read*( ) function is unspecified.

TYM If *fildes* refers to a typed memory object, the result of the *read*( ) function is unspecified.

XSR A *read*( ) from a STREAMS file can read data in three different modes: *byte-stream* mode, *message-nondiscard* mode, and *message-discard* mode. The default shall be byte-stream mode. This can be changed using the I_SRDOPT *ioctl*( ) request, and can be tested with the I_GRDOPT *ioctl*( ). In byte-stream mode, *read*( ) shall retrieve data from the STREAM until as many bytes as were requested are transferred, or until there is no more data to be retrieved. Byte-stream mode ignores message boundaries.

In STREAMS message-nondiscard mode, *read*( ) shall retrieve data until as many bytes as were requested are transferred, or until a message boundary is reached. If *read*( ) does not retrieve all the data in a message, the remaining data shall be left on the STREAM, and can be retrieved by the next *read*( ) call. Message-discard mode also retrieves data until as many bytes as were requested are transferred, or a message boundary is reached. However, unread data remaining in a message after the *read*( ) returns shall be discarded, and shall not be available for a subsequent *read*( ), *getmsg*( ), or *getpmsg*( ) call.

How *read*( ) handles zero-byte STREAMS messages is determined by the current read mode setting. In byte-stream mode, *read*( ) shall accept data until it has read *nbyte* bytes, or until there is no more data to read, or until a zero-byte message block is encountered. The *read*( ) function shall then return the number of bytes read, and place the zero-byte message back on the STREAM to be retrieved by the next *read*( ), *getmsg*( ), or *getpmsg*( ). In message-nondiscard mode or message-discard mode, a zero-byte message shall return 0 and the message shall be removed from the STREAM. When a zero-byte message is read as the first message on a STREAM, the message shall be removed from the STREAM and 0 shall be returned, regardless of the read mode.

A *read*( ) from a STREAMS file shall return the data in the message at the front of the STREAM head read queue, regardless of the priority band of the message.

By default, STREAMs are in control-normal mode, in which a *read*( ) from a STREAMS file can only process messages that contain a data part but do not contain a control part. The *read*( ) shall fail if a message containing a control part is encountered at the STREAM head. This default action can be changed by placing the STREAM in either control-data mode or control-discard mode with the I_SRDOPT *ioctl*( ) command. In control-data mode, *read*( ) shall convert any control part to data and pass it to the application before passing any data part originally present in the same message. In control-discard mode, *read*( ) shall discard message control parts but return to the process any data part in the message.

In addition, *read*( ) shall fail if the STREAM head had processed an asynchronous error before the call. In this case, the value of *errno* shall not reflect the result of *read*( ), but reflects the prior error. If a hangup occurs on the STREAM being read, *read*( ) shall continue to operate normally until the STREAM head read queue is empty. Thereafter, it shall return 0.

XSI The *pread*( ) function shall be equivalent to *read*( ), except that it shall read from a given position in the file without changing the file pointer. The first three arguments to *pread*( ) are the same as *read*( ) with the addition of a fourth argument offset for the desired position inside the file. An attempt to perform a *pread*( ) on a file that is incapable of seeking shall result in an error.

RETURN VALUE

XSI Upon successful completion, *read*( ) and *pread*( ) shall return a non-negative integer indicating the number of bytes actually read. Otherwise, the functions shall return −1 and set *errno* to indicate the error.

ERRORS

XSI The *read*( ) and *pread*( ) functions shall fail if:

	[EAGAIN]	The O_NONBLOCK flag is set for the file descriptor and the process would be delayed.
	[EBADF]	The *fildes* argument is not a valid file descriptor open for reading.
XSR	[EBADMSG]	The file is a STREAM file that is set to control-normal mode and the message waiting to be read includes a control part.
	[EINTR]	The read operation was terminated due to the receipt of a signal, and no data was transferred.
XSR	[EINVAL]	The STREAM or multiplexer referenced by *fildes* is linked (directly or indirectly) downstream from a multiplexer.
	[EIO]	The process is a member of a background process attempting to read from its controlling terminal, the process is ignoring or blocking the SIGTTIN signal, or the process group is orphaned. This error may also be generated for implementation-defined reasons.
XSI	[EISDIR]	The *fildes* argument refers to a directory and the implementation does not allow the directory to be read using *read*( ) or *pread*( ). The *readdir*( ) function should be used instead.
	[EOVERFLOW]	The file is a regular file, *nbyte* is greater than 0, the starting position is before the end-of-file, and the starting position is greater than or equal to the offset maximum established in the open file description associated with *fildes*.

The *read*( ) function shall fail if:

[EAGAIN] or [EWOULDBLOCK]	The file descriptor is for a socket, is marked O_NONBLOCK, and no data is waiting to be received.
[ECONNRESET]	A read was attempted on a socket and the connection was forcibly closed by its peer.
[ENOTCONN]	A read was attempted on a socket that is not connected.
[ETIMEDOUT]	A read was attempted on a socket and a transmission timeout occurred.

XSI The *read*( ) and *pread*( ) functions may fail if:

[EIO]	A physical I/O error has occurred.
[ENOBUFS]	Insufficient resources were available in the system to perform the operation.
[ENOMEM]	Insufficient memory was available to fulfill the request.
[ENXIO]	A request was made of a nonexistent device, or the request was outside the capabilities of the device.

The *pread*( ) function shall fail, and the file pointer shall remain unchanged, if:

XSI	[EINVAL]	The *offset* argument is invalid. The value is negative.
XSI	[EOVERFLOW]	The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the file.
XSI	[ENXIO]	A request was outside the capabilities of the device.
XSI	[ESPIPE]	*fildes* is associated with a pipe or FIFO.

EXAMPLES

Reading Data into a Buffer

The following example reads data from the file associated with the file descriptor *fd* into the buffer pointed to by *buf*.

```
#include <sys/types.h>
#include <unistd.h>
...
char buf[20];
size_t nbytes;
ssize_t bytes_read;
int fd;
...
nbytes = sizeof(buf);
bytes_read = read(fd, buf, nbytes);
...
```

APPLICATION USAGE

None.

RATIONALE

This volume of IEEE Std 1003.1-200x does not specify the value of the file offset after an error is returned; there are too many cases. For programming errors, such as [EBADF], the concept is meaningless since no file is involved. For errors that are detected immediately, such as [EAGAIN], clearly the pointer should not change. After an interrupt or hardware error, however, an updated value would be very useful and is the behavior of many implementations.

Note that a *read*( ) of zero bytes does not modify *st_atime*. A *read*( ) that requests more than zero bytes, but returns zero, shall modify *st_atime*.

Implementations are allowed, but not required, to perform error checking for *read*( ) requests of zero bytes.

Input and Output

The use of I/O with large byte counts has always presented problems. Ideas such as *lread*( ) and *lwrite*( ) (using and returning **long**s) were considered at one time. The current solution is to use abstract types on the ISO C standard function to *read*( ) and *write*( ). The abstract types can be declared so that existing functions work, but can also be declared so that larger types can be represented in future implementations. It is presumed that whatever constraints limit the maximum range of **size_t** also limit portable I/O requests to the same range. This volume of IEEE Std 1003.1-200x also limits the range further by requiring that the byte count be limited so that a signed return value remains meaningful. Since the return type is also a (signed) abstract type, the byte count can be defined by the implementation to be larger than an **int** can hold.

The standard developers considered adding atomicity requirements to a pipe or FIFO, but recognized that due to the nature of pipes and FIFOs there could be no guarantee of atomicity of reads of {PIPE_BUF} or any other size that would be an aid to applications portability.

This volume of IEEE Std 1003.1-200x requires that no action be taken for *read*( ) or *write*( ) when *nbyte* is zero. This is not intended to take precedence over detection of errors (such as invalid buffer pointers or file descriptors). This is consistent with the rest of this volume of IEEE Std 1003.1-200x, but the phrasing here could be misread to require detection of the zero case before any other errors. A value of zero is to be considered a correct value, for which the semantics are a no-op.

I/O is intended to be atomic to ordinary files and pipes and FIFOs. Atomic means that all the bytes from a single operation that started out together end up together, without interleaving from other I/O operations. It is a known attribute of terminals that this is not honored, and terminals are explicitly (and implicitly permanently) excepted, making the behavior unspecified. The behavior for other device types is also left unspecified, but the wording is intended to imply that future standards might choose to specify atomicity (or not).

There were recommendations to add format parameters to *read*( ) and *write*( ) in order to handle networked transfers among heterogeneous file system and base hardware types. Such a facility may be required for support by the OSI presentation of layer services. However, it was determined that this should correspond with similar C-language facilities, and that is beyond the scope of this volume of IEEE Std 1003.1-200x. The concept was suggested to the developers of the ISO C standard for their consideration as a possible area for future work.

In 4.3 BSD, a *read*( ) or *write*( ) that is interrupted by a signal before transferring any data does not by default return an [EINTR] error, but is restarted. In 4.2 BSD, 4.3 BSD, and the Eighth Edition, there is an additional function, *select*( ), whose purpose is to pause until specified activity (data to read, space to write, and so on) is detected on specified file descriptors. It is common in applications written for those systems for *select*( ) to be used before *read*( ) in situations (such as keyboard input) where interruption of I/O due to a signal is desired.

The issue of which files or file types are interruptible is considered an implementation design issue. This is often affected primarily by hardware and reliability issues.

There are no references to actions taken following an ‘‘unrecoverable error’’. It is considered beyond the scope of this volume of IEEE Std 1003.1-200x to describe what happens in the case of hardware errors.

Previous versions of IEEE Std 1003.1-200x allowed two very different behaviors with regard to the handling of interrupts. In order to minimize the resulting confusion, it was decided that IEEE Std 1003.1-200x should support only one of these behaviors. Historical practice on AT&T-derived systems was to have *read*( ) and *write*( ) return −1 and set *errno* to [EINTR] when interrupted after some, but not all, of the data requested had been transferred. However, the U.S. Department of Commerce FIPS 151-1 and FIPS 151-2 require the historical BSD behavior, in which *read*( ) and *write*( ) return the number of bytes actually transferred before the interrupt. If –1 is returned when any data is transferred, it is difficult to recover from the error on a seekable device and impossible on a non-seekable device. Most new implementations support this behavior. The behavior required by IEEE Std 1003.1-200x is to return the number of bytes transferred.

IEEE Std 1003.1-200x does not specify when an implementation that buffers *read*( )s actually moves the data into the user-supplied buffer, so an implementation may chose to do this at the latest possible moment. Therefore, an interrupt arriving earlier may not cause *read*( ) to return a partial byte count, but rather to return –1 and set *errno* to [EINTR].

Consideration was also given to combining the two previous options, and setting *errno* to [EINTR] while returning a short count. However, not only is there no existing practice that implements this, it is also contradictory to the idea that when *errno* is set, the function responsible shall return –1.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Large File Summit extensions are added.

The *pread*( ) function is added.

Issue 6

The DESCRIPTION and ERRORS sections are updated so that references to STREAMS are marked as part of the XSI STREAMS Option Group.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION now states that if *read*( ) is interrupted by a signal after it has successfully read some data, it returns the number of bytes read. In Issue 3, it was optional whether *read*( ) returned the number of bytes read, or whether it returned –1 with *errno* set to [EINTR]. This is a FIPS requirement.
- In the DESCRIPTION, text is added to indicate that for regular files, no data transfer occurs past the offset maximum established in the open file description associated with *fildes*. This change is to support large files.
- The [EOVERFLOW] mandatory error condition is added.
- The [ENXIO] optional error condition is added.

Text referring to sockets is added to the DESCRIPTION.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The effect of reading zero bytes is clarified.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that *read*( ) results are unspecified for typed memory objects.

New RATIONALE is added to explain the atomicity requirements for input and output operations.

The following error conditions are added for operations on sockets: [EAGAIN], [ECONNRESET], [ENOTCONN], and [ETIMEDOUT].

The [EIO] error is changed to ‘‘may fail’’.

The following error conditions are added for operations on sockets: [ENOBUFS] and [ENOMEM]. |

The *readv*( ) function is split out into a separate reference page. |

NAME

readdir, readdir_r — read directory

SYNOPSIS

```
#include <dirent.h>

struct dirent *readdir(DIR *dirp);
int readdir_r(DIR *restrict dirp, struct dirent *restrict entry,
    struct dirent **restrict result);
```

DESCRIPTION

The type **DIR**, which is defined in the **<dirent.h>** header, represents a *directory stream*, which is an ordered sequence of all the directory entries in a particular directory. Directory entries represent files; files may be removed from a directory or added to a directory asynchronously to the operation of *readdir*( ).

The *readdir*( ) function shall return a pointer to a structure representing the directory entry at the current position in the directory stream specified by the argument *dirp*, and position the directory stream at the next entry. It shall return a null pointer upon reaching the end of the directory stream. The structure **dirent** defined in the **<dirent.h>** header describes a directory entry. |

The *readdir*( ) function shall not return directory entries containing empty names. If entries for dot or dot-dot exist, one entry shall be returned for dot and one entry shall be returned for dot-dot; otherwise, they shall not be returned.

The pointer returned by *readdir*( ) points to data which may be overwritten by another call to *readdir*( ) on the same directory stream. This data is not overwritten by another call to *readdir*( ) on a different directory stream.

If a file is removed from or added to the directory after the most recent call to *opendir*( ) or *rewinddir*( ), whether a subsequent call to *readdir*( ) returns an entry for that file is unspecified.

The *readdir*( ) function may buffer several directory entries per actual read operation; *readdir*( ) shall mark for update the *st_atime* field of the directory each time the directory is actually read.

After a call to *fork*( ), either the parent or child (but not both) may continue processing the directory stream using *readdir*( ), *rewinddir*( ), or *seekdir*( ). If both the parent and child processes use these functions, the result is undefined.

If the entry names a symbolic link, the value of the *d_ino* member is unspecified.

The *readdir*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

The *readdir_r*( ) function shall initialize the **dirent** structure referenced by *entry* to represent the directory entry at the current position in the directory stream referred to by *dirp*, store a pointer to this structure at the location referenced by *result*, and position the directory stream at the next entry.

The storage pointed to by *entry* shall be large enough for a **dirent** with an array of **char** *d_name* members containing at least {NAME_MAX} plus one elements.

Upon successful return, the pointer returned at **result* shall have the same value as the argument *entry*. Upon reaching the end of the directory stream, this pointer shall have the value NULL.

The *readdir_r*( ) function shall not return directory entries containing empty names.

If a file is removed from or added to the directory after the most recent call to *opendir*( ) or *rewinddir*( ), whether a subsequent call to *readdir_r*( ) returns an entry for that file is unspecified.

The *readdir_r*( ) function may buffer several directory entries per actual read operation; the *readdir_r*( ) function shall mark for update the *st_atime* field of the directory each time the directory is actually read.

Applications wishing to check for error situations should set *errno* to 0 before calling *readdir*( ). If *errno* is set to non-zero on return, an error occurred.

RETURN VALUE

Upon successful completion, *readdir*( ) shall return a pointer to an object of type **struct dirent**. When an error is encountered, a null pointer shall be returned and *errno* shall be set to indicate the error. When the end of the directory is encountered, a null pointer shall be returned and *errno* is not changed.

TSF If successful, the *readdir_r*( ) function shall return zero; otherwise, an error number shall be returned to indicate the error.

ERRORS

The *readdir*( ) function shall fail if:

[EOVERFLOW] One of the values in the structure to be returned cannot be represented correctly.

The *readdir*( ) function may fail if:

[EBADF] The *dirp* argument does not refer to an open directory stream.

[ENOENT] The current position of the directory stream is invalid.

The *readdir_r*( ) function may fail if:

[EBADF] The *dirp* argument does not refer to an open directory stream.

EXAMPLES

The following sample code searches the current directory for the entry *name*:

```
dirp = opendir(".");

while (dirp) {
    errno = 0;
    if ((dp = readdir(dirp)) != NULL) {
        if (strcmp(dp->d_name, name) == 0) {
            closedir(dirp);
            return FOUND;
        }
    } else {
        if (errno == 0) {
            closedir(dirp);
            return NOT_FOUND;
        }
        closedir(dirp);
        return READ_ERROR;
    }
}

return OPEN_ERROR;
```

APPLICATION USAGE

The *readdir*( ) function should be used in conjunction with *opendir*( ), *closedir*( ), and *rewinddir*( ) to examine the contents of the directory.

The *readdir_r*( ) function is thread-safe and shall return values in a user-supplied buffer instead of possibly using a static data area that may be overwritten by each call.

RATIONALE

The returned value of *readdir*( ) merely *represents* a directory entry. No equivalence should be inferred.

Historical implementations of *readdir*( ) obtain multiple directory entries on a single read operation, which permits subsequent *readdir*( ) operations to operate from the buffered information. Any wording that required each successful *readdir*( ) operation to mark the directory *st_atime* field for update would militate against the historical performance-oriented implementations.

Since *readdir*( ) returns NULL when it detects an error and when the end of the directory is encountered, an application that needs to tell the difference must set *errno* to zero before the call and check it if NULL is returned. Since the function must not change *errno* in the second case and must set it to a non-zero value in the first case, a zero *errno* after a call returning NULL indicates end of directory; otherwise, an error.

Routines to deal with this problem more directly were proposed:

```
int derror (dirp)
DIR *dirp;
```

```
void clearderr (dirp)
DIR *dirp;
```

The first would indicate whether an error had occurred, and the second would clear the error indication. The simpler method involving *errno* was adopted instead by requiring that *readdir*( ) not change *errno* when end-of-directory is encountered.

An error or signal indicating that a directory has changed while open was considered but rejected.

The thread-safe version of the directory reading function returns values in a user-supplied buffer instead of possibly using a static data area that may be overwritten by each call. Either the {NAME_MAX} compile-time constant or the corresponding *pathconf*( ) option can be used to determine the maximum sizes of returned pathnames.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 2.

Issue 5

Large File Summit extensions are added.

The *readdir_r*( ) function is included for alignment with the POSIX Threads Extension.

A note indicating that the *readdir*( ) function need not be reentrant is added to the DESCRIPTION.

Issue 6

The *readdir_r*( ) function is marked as part of the Thread-Safe Functions option.

The Open Group Corrigendum U026/7 is applied, correcting the prototype for *readdir_r*( ).

The Open Group Corrigendum U026/8 is applied, clarifying the wording of the successful return for the *readdir_r*( ) function.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- A statement is added to the DESCRIPTION indicating the disposition of certain fields in **struct dirent** when an entry refers to a symbolic link.
- The [EOVERFLOW] mandatory error condition is added. This change is to support large files.
- The [ENOENT] optional error condition is added.

The APPLICATION USAGE section is updated to include a note on the thread-safe function and its avoidance of possibly using a static data area.

The **restrict** keyword is added to the *readdir_r*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

readlink — read the contents of a symbolic link

SYNOPSIS

```
#include <unistd.h>

ssize_t readlink(const char *restrict path, char *restrict buf,
    size_t bufsize);
```

DESCRIPTION

The *readlink*( ) function shall place the contents of the symbolic link referred to by *path* in the buffer *buf* which has size *bufsize*. If the number of bytes in the symbolic link is less than *bufsize*, the contents of the remainder of *buf* are unspecified. If the *buf* argument is not large enough to contain the link content, the first *bufsize* bytes shall be placed in *buf*.

If the value of *bufsize* is greater than {SSIZE_MAX}, the result is implementation-defined.

RETURN VALUE

Upon successful completion, *readlink*( ) shall return the count of bytes placed in the buffer. Otherwise, it shall return a value of −1, leave the buffer unchanged, and set *errno* to indicate the error.

ERRORS

The *readlink*( ) function shall fail if:

[EACCES]	Search permission is denied for a component of the path prefix of *path*.
[EINVAL]	The *path* argument names a file that is not a symbolic link.
[EIO]	An I/O error occurred while reading from the file system.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of *path* does not name an existing file or *path* is an empty string.
[ENOTDIR]	A component of the path prefix is not a directory.

The *readlink*( ) function may fail if:

[EACCES]	Read permission is denied for the directory.
[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[ENAMETOOLONG]	As a result of encountering a symbolic link in resolution of the *path* argument, the length of the substituted pathname string exceeded {PATH_MAX}.

EXAMPLES

Reading the Name of a Symbolic Link

The following example shows how to read the name of a symbolic link named **/modules/pass1**.

```
#include <unistd.h>

char buf[1024];
int len;
...
if ((len = readlink("/modules/pass1", buf, sizeof(buf)-1)) != -1);
buf[len] = '\0';
```

APPLICATION USAGE

Conforming applications should not assume that the returned contents of the symbolic link are null-terminated.

RATIONALE

Since IEEE Std 1003.1-200x does not require any association of file times with symbolic links, there is no requirement that file times be updated by *readlink*( ). The type associated with *bufsiz* is a **size_t** in order to be consistent with both the ISO C standard and the definition of *read*( ). The behavior specified for *readlink*( ) when *bufsiz* is zero represents historical practice. For this case, the standard developers considered a change whereby *readlink*( ) would return the number of non-null bytes contained in the symbolic link with the buffer *buf* remaining unchanged; however, since the **stat** structure member *st_size* value can be used to determine the size of buffer necessary to contain the contents of the symbolic link as returned by *readlink*( ), this proposal was rejected, and the historical practice retained.

FUTURE DIRECTIONS

None.

SEE ALSO

lstat( ), *stat*( ), *symlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<unistd.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

The return type is changed to **ssize_t**, to align with the IEEE P1003.1a draft standard.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- This function is made mandatory.
- In this function it is possible for the return value to exceed the range of the type **ssize_t** (since **size_t** has a larger range of positive values than **ssize_t**). A sentence restricting the size of the **size_t** object is added to the description to resolve this conflict.

The following changes are made for alignment with the ISO POSIX-1:1996 standard:

- The FUTURE DIRECTIONS section is changed to None.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The [ELOOP] optional error condition is added.

The **restrict** keyword is added to the *readlink*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

readv — read a vector

SYNOPSIS

XSI

```
#include <sys/uio.h>

ssize_t readv(int fildes, const struct iovec *iov, int iovcnt);
```

DESCRIPTION

The *readv*( ) function shall be equivalent to *read*( ), except as described below. The *readv*( ) function shall place the input data into the *iovcnt* buffers specified by the members of the *iov* array: *iov*[0], *iov*[1], . . ., *iov*[*iovcnt*−1]. The *iovcnt* argument is valid if greater than 0 and less than or equal to {IOV_MAX}.

Each *iovec* entry specifies the base address and length of an area in memory where data should be placed. The *readv*( ) function shall always fill an area completely before proceeding to the next.

Upon successful completion, *readv*( ) shall mark for update the *st_atime* field of the file.

RETURN VALUE

Refer to *read*( ).

ERRORS

Refer to *read*( ).

In addition, the *readv*( ) function shall fail if:

[EINVAL] The sum of the *iov_len* values in the *iov* array overflowed an **ssize_t**.

The *readv*( ) function may fail if:

[EINVAL] The *iovcnt* argument was less than or equal to 0, or greater than {IOV_MAX}.

EXAMPLES

Reading Data into an Array

The following example reads data from the file associated with the file descriptor *fd* into the buffers specified by members of the *iov* array.

```
#include <sys/types.h>
#include <sys/uio.h>
#include <unistd.h>
...
ssize_t bytes_read;
int fd;
char buf0[20];
char buf1[30];
char buf2[40];
int iovcnt;
struct iovec iov[3];

iov[0].iov_base = buf0;
iov[0].iov_len = sizeof(buf0);
iov[1].iov_base = buf1;
iov[1].iov_len = sizeof(buf1);
iov[2].iov_base = buf2;
iov[2].iov_len = sizeof(buf2);
```

```
...
iovcnt = sizeof(iov) / sizeof(struct iovec);
bytes_read = readv(fd, iov, iovcnt);
...
```

APPLICATION USAGE

None.

RATIONALE

Refer to *read*( ).

FUTURE DIRECTIONS

Issue 6

Split out from the *read*( ) reference page.

NAME

realloc — memory reallocator

SYNOPSIS

```
#include <stdlib.h>

void *realloc(void *ptr, size_t size);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *realloc*( ) function shall change the size of the memory object pointed to by *ptr* to the size specified by *size*. The contents of the object shall remain unchanged up to the lesser of the new and old sizes. If the new size of the memory object would require movement of the object, the space for the previous instantiation of the object is freed. If the new size is larger, the contents of the newly allocated portion of the object are unspecified. If *size* is 0 and *ptr* is not a null pointer, the object pointed to is freed. If the space cannot be allocated, the object shall remain unchanged.

If *ptr* is a null pointer, *realloc*( ) shall be equivalent to *malloc*( ) for the specified size.

If *ptr* does not match a pointer returned earlier by *calloc*( ), *malloc*( ), or *realloc*( ) or if the space has previously been deallocated by a call to *free*( ) or *realloc*( ), the behavior is undefined.

The order and contiguity of storage allocated by successive calls to *realloc*( ) is unspecified. The pointer returned if the allocation succeeds shall be suitably aligned so that it may be assigned to a pointer to any type of object and then used to access such an object in the space allocated (until the space is explicitly freed or reallocated). Each such allocation shall yield a pointer to an object disjoint from any other object. The pointer returned shall point to the start (lowest byte address) of the allocated space. If the space cannot be allocated, a null pointer shall be returned.

RETURN VALUE

Upon successful completion with a size not equal to 0, *realloc*( ) shall return a pointer to the (possibly moved) allocated space. If *size* is 0, either a null pointer or a unique pointer that can be successfully passed to *free*( ) shall be returned. If there is not enough available memory, *realloc*( ) shall return a null pointer CX and set *errno* to [ENOMEM].

ERRORS

The *realloc*( ) function shall fail if:

CX [ENOMEM] Insufficient memory is available.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

calloc( ), *free*( ), *malloc*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdlib.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE section, if there is not enough available memory, the setting of *errno* to [ENOMEM] is added.
- The [ENOMEM] error condition is added.

NAME

realpath — resolve a pathname

SYNOPSIS

```
#include <stdlib.h>

char *realpath(const char *restrict file_name,
    char *restrict resolved_name);
```

DESCRIPTION

The *realpath*( ) function shall derive, from the pathname pointed to by *file_name*, an absolute pathname that names the same file, whose resolution does not involve `'.'`, `'..'`, or symbolic links. The generated pathname shall be stored as a null-terminated string, up to a maximum of {PATH_MAX} bytes, in the buffer pointed to by *resolved_name*.

RETURN VALUE

Upon successful completion, *realpath*( ) shall return a pointer to the resolved name. Otherwise, *realpath*( ) shall return a null pointer and set *errno* to indicate the error, and the contents of the buffer pointed to by *resolved_name* are undefined.

ERRORS

The *realpath*( ) function shall fail if:

[EACCES]	Read or search permission was denied for a component of *file_name*.
[EINVAL]	Either the *file_name* or *resolved_name* argument is a null pointer.
[EIO]	An error occurred while reading from the file system.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of the *file_name* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of *file_name* does not name an existing file or *file_name* points to an empty string.
[ENOTDIR]	A component of the path prefix is not a directory.

The *realpath*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[ENAMETOOLONG]	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds {PATH_MAX}.
[ENOMEM]	Insufficient storage space is available.

EXAMPLES

Generating an Absolute Pathname

The following example generates an absolute pathname for the file identified by the *symlinkpath* argument. The generated pathname is stored in the *actualpath* array.

```
#include <stdlib.h>
...
char *symlinkpath = "/tmp/symlink/file";
char actualpath [PATH_MAX+1];
char *ptr;

ptr = realpath(symlinkpath, actualpath);
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

The **restrict** keyword is added to the *realpath*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.

NAME

recv — receive a message from a connected socket

SYNOPSIS

```
#include <sys/socket.h>

ssize_t recv(int socket, void *buffer, size_t length, int flags);
```

DESCRIPTION

The *recv*( ) function shall receive a message from a connection-mode or connectionless-mode socket. It is normally used with connected sockets because it does not permit the application to retrieve the source address of received data.

The *recv*( ) function takes the following arguments:

socket	Specifies the socket file descriptor.
buffer	Points to a buffer where the message should be stored.
length	Specifies the length in bytes of the buffer pointed to by the *buffer* argument.
flags	Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:

MSG_PEEK	Peeks at an incoming message. The data is treated as unread and the next *recv*( ) or similar function shall still return this data.
MSG_OOB	Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific.
MSG_WAITALL	On SOCK_STREAM sockets this requests that the function block until the full amount of data can be returned. The function may return the smaller amount of data if the socket is a message-based socket, if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if an error is pending for the socket.

The *recv*( ) function shall return the length of the message written to the buffer pointed to by the *buffer* argument. For message-based sockets, such as SOCK_DGRAM and SOCK_SEQPACKET, the entire message shall be read in a single operation. If a message is too long to fit in the supplied buffer, and MSG_PEEK is not set in the *flags* argument, the excess bytes shall be discarded. For stream-based sockets, such as SOCK_STREAM, message boundaries shall be ignored. In this case, data shall be returned to the user as soon as it becomes available, and no data shall be discarded.

If the MSG_WAITALL flag is not set, data shall be returned only up to the end of the first message.

If no messages are available at the socket and O_NONBLOCK is not set on the socket's file descriptor, *recv*( ) shall block until a message arrives. If no messages are available at the socket and O_NONBLOCK is set on the socket's file descriptor, *recv*( ) shall fail and set *errno* to [EAGAIN] or [EWOULDBLOCK].

RETURN VALUE

Upon successful completion, *recv*( ) shall return the length of the message in bytes. If no messages are available to be received and the peer has performed an orderly shutdown, *recv*( ) shall return 0. Otherwise, –1 shall be returned and *errno* set to indicate the error.

ERRORS

The *recv*( ) function shall fail if:

[EAGAIN] or [EWOULDBLOCK]	The socket's file descriptor is marked O_NONBLOCK and no data is waiting to be received; or MSG_OOB is set and no out-of-band data is available and either the socket's file descriptor is marked O_NONBLOCK or the socket does not support blocking to await out-of-band data.
[EBADF]	The *socket* argument is not a valid file descriptor.
[ECONNRESET]	A connection was forcibly closed by a peer.
[EINTR]	The *recv*( ) function was interrupted by a signal that was caught, before any data was available.
[EINVAL]	The MSG_OOB flag is set and no out-of-band data is available.
[ENOTCONN]	A receive is attempted on a connection-mode socket that is not connected.
[ENOTSOCK]	The *socket* argument does not refer to a socket.
[EOPNOTSUPP]	The specified flags are not supported for this socket type or protocol.
[ETIMEDOUT]	The connection timed out during connection establishment, or due to a transmission timeout on active connection.

The *recv*( ) function may fail if:

[EIO]	An I/O error occurred while reading from or writing to the file system.
[ENOBUFS]	Insufficient resources were available in the system to perform the operation.
[ENOMEM]	Insufficient memory was available to fulfill the request.

EXAMPLES

None.

APPLICATION USAGE

The *recv*( ) function is equivalent to *recvfrom*( ) with a zero *address_len* argument, and to *read*( ) if no flags are used.

The *select*( ) and *poll*( ) functions can be used to determine when data is available to be received.

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

NAME

recvfrom — receive a message from a socket

SYNOPSIS

```
#include <sys/socket.h>

ssize_t recvfrom(int socket, void *restrict buffer, size_t length,
    int flags, struct sockaddr *restrict address,
    socklen_t *restrict address_len);
```

DESCRIPTION

The *recvfrom*( ) function shall receive a message from a connection-mode or connectionless-mode socket. It is normally used with connectionless-mode sockets because it permits the application to retrieve the source address of received data.

The *recvfrom*( ) function takes the following arguments:

socket	Specifies the socket file descriptor.	
buffer	Points to the buffer where the message should be stored.	
length	Specifies the length in bytes of the buffer pointed to by the *buffer* argument.	
flags	Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:	
	MSG_PEEK	Peeks at an incoming message. The data is treated as unread and the next *recvfrom*( ) or similar function shall still return this data.
	MSG_OOB	Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific.
	MSG_WAITALL	On SOCK_STREAM sockets this requests that the function block until the full amount of data can be returned. The function may return the smaller amount of data if the socket is a message-based socket, if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if an error is pending for the socket.
address	A null pointer, or points to a **sockaddr** structure in which the sending address is to be stored. The length and format of the address depend on the address family of the socket.	
address_len	Specifies the length of the **sockaddr** structure pointed to by the *address* argument.	

The *recvfrom*( ) function shall return the length of the message written to the buffer pointed to by the *buffer* argument. For message-based sockets, such as SOCK_RAW, SOCK_DGRAM, and SOCK_SEQPACKET, the entire message shall be read in a single operation. If a message is too long to fit in the supplied buffer, and MSG_PEEK is not set in the *flags* argument, the excess bytes shall be discarded. For stream-based sockets, such as SOCK_STREAM, message boundaries shall be ignored. In this case, data shall be returned to the user as soon as it becomes available, and no data shall be discarded.

If the MSG_WAITALL flag is not set, data shall be returned only up to the end of the first message.

Not all protocols provide the source address for messages. If the *address* argument is not a null pointer and the protocol provides the source address of messages, the source address of the received message shall be stored in the **sockaddr** structure pointed to by the *address* argument, and the length of this address shall be stored in the object pointed to by the *address_len* argument.

If the actual length of the address is greater than the length of the supplied **sockaddr** structure, the stored address shall be truncated.

If the *address* argument is not a null pointer and the protocol does not provide the source address of messages, the value stored in the object pointed to by *address* is unspecified.

If no messages are available at the socket and O_NONBLOCK is not set on the socket's file descriptor, *recvfrom*( ) shall block until a message arrives. If no messages are available at the socket and O_NONBLOCK is set on the socket's file descriptor, *recvfrom*( ) shall fail and set *errno* to [EAGAIN] or [EWOULDBLOCK].

RETURN VALUE

Upon successful completion, *recvfrom*( ) shall return the length of the message in bytes. If no messages are available to be received and the peer has performed an orderly shutdown, *recvfrom*( ) shall return 0. Otherwise, the function shall return −1 and set *errno* to indicate the error.

ERRORS

The *recvfrom*( ) function shall fail if:

[EAGAIN] or [EWOULDBLOCK]	The socket's file descriptor is marked O_NONBLOCK and no data is waiting to be received; or MSG_OOB is set and no out-of-band data is available and either the socket's file descriptor is marked O_NONBLOCK or the socket does not support blocking to await out-of-band data.
[EBADF]	The *socket* argument is not a valid file descriptor.
[ECONNRESET]	A connection was forcibly closed by a peer.
[EINTR]	A signal interrupted *recvfrom*( ) before any data was available.
[EINVAL]	The MSG_OOB flag is set and no out-of-band data is available.
[ENOTCONN]	A receive is attempted on a connection-mode socket that is not connected.
[ENOTSOCK]	The *socket* argument does not refer to a socket.
[EOPNOTSUPP]	The specified flags are not supported for this socket type.
[ETIMEDOUT]	The connection timed out during connection establishment, or due to a transmission timeout on active connection.

The *recvfrom*( ) function may fail if:

[EIO]	An I/O error occurred while reading from or writing to the file system.
[ENOBUFS]	Insufficient resources were available in the system to perform the operation.
[ENOMEM]	Insufficient memory was available to fulfill the request.

EXAMPLES

None.

APPLICATION USAGE

The *select*( ) and *poll*( ) functions can be used to determine when data is available to be received.

NAME

recvmsg — receive a message from a socket

SYNOPSIS

```
#include <sys/socket.h>

ssize_t recvmsg(int socket, struct msghdr *message, int flags);
```

DESCRIPTION

The *recvmsg*( ) function shall receive a message from a connection-mode or connectionless-mode socket. It is normally used with connectionless-mode sockets because it permits the application to retrieve the source address of received data.

The *recvmsg*( ) function takes the following arguments:

socket	Specifies the socket file descriptor.
message	Points to a **msghdr** structure, containing both the buffer to store the source address and the buffers for the incoming message. The length and format of the address depend on the address family of the socket. The *msg_flags* member is ignored on input, but may contain meaningful values on output.
flags	Specifies the type of message reception. Values of this argument are formed by logically OR'ing zero or more of the following values:

MSG_OOB	Requests out-of-band data. The significance and semantics of out-of-band data are protocol-specific.
MSG_PEEK	Peeks at the incoming message.
MSG_WAITALL	On SOCK_STREAM sockets this requests that the function block until the full amount of data can be returned. The function may return the smaller amount of data if the socket is a message-based socket, if a signal is caught, if the connection is terminated, if MSG_PEEK was specified, or if an error is pending for the socket.

The *recvmsg*( ) function shall receive messages from unconnected or connected sockets and shall return the length of the message.

The *recvmsg*( ) function shall return the total length of the message. For message-based sockets, such as SOCK_DGRAM and SOCK_SEQPACKET, the entire message shall be read in a single operation. If a message is too long to fit in the supplied buffers, and MSG_PEEK is not set in the *flags* argument, the excess bytes shall be discarded, and MSG_TRUNC shall be set in the *msg_flags* member of the **msghdr** structure. For stream-based sockets, such as SOCK_STREAM, message boundaries shall be ignored. In this case, data shall be returned to the user as soon as it becomes available, and no data shall be discarded.

If the MSG_WAITALL flag is not set, data shall be returned only up to the end of the first message.

If no messages are available at the socket and O_NONBLOCK is not set on the socket's file descriptor, *recvmsg*( ) shall block until a message arrives. If no messages are available at the socket and O_NONBLOCK is set on the socket's file descriptor, *recvmsg*( ) function shall fail and set *errno* to [EAGAIN] or [EWOULDBLOCK].

In the **msghdr** structure, the *msg_name* and *msg_namelen* members specify the source address if the socket is unconnected. If the socket is connected, the *msg_name* and *msg_namelen* members shall be ignored. The *msg_name* member may be a null pointer if no names are desired or required. The *msg_iov* and *msg_iovlen* fields are used to specify where the received data shall be stored. *msg_iov* points to an array of **iovec** structures; *msg_iovlen* shall be set to the dimension of this array. In each **iovec** structure, the *iov_base* field specifies a storage area and the *iov_len* field gives its size in bytes. Each storage area indicated by *msg_iov* is filled with received data in turn until all of the received data is stored or all of the areas have been filled.

Upon successful completion, the *msg_flags* member of the message header shall be the bitwise-inclusive OR of all of the following flags that indicate conditions detected for the received message:

MSG_EOR	End of record was received (if supported by the protocol).
MSG_OOB	Out-of-band data was received.
MSG_TRUNC	Normal data was truncated.
MSG_CTRUNC	Control data was truncated.

RETURN VALUE

Upon successful completion, *recvmsg*( ) shall return the length of the message in bytes. If no messages are available to be received and the peer has performed an orderly shutdown, *recvmsg*( ) shall return 0. Otherwise, –1 shall be returned and *errno* set to indicate the error.

ERRORS

The *recvmsg*( ) function shall fail if:

[EAGAIN] or [EWOULDBLOCK]	The socket's file descriptor is marked O_NONBLOCK and no data is waiting to be received; or MSG_OOB is set and no out-of-band data is available and either the socket's file descriptor is marked O_NONBLOCK or the socket does not support blocking to await out-of-band data.
[EBADF]	The *socket* argument is not a valid open file descriptor.
[ECONNRESET]	A connection was forcibly closed by a peer.
[EINTR]	This function was interrupted by a signal before any data was available.
[EINVAL]	The sum of the *iov_len* values overflows a **ssize_t**, or the MSG_OOB flag is set and no out-of-band data is available.
[EMSGSIZE]	The *msg_iovlen* member of the **msghdr** structure pointed to by *message* is less than or equal to 0, or is greater than {IOV_MAX}.
[ENOTCONN]	A receive is attempted on a connection-mode socket that is not connected.
[ENOTSOCK]	The *socket* argument does not refer to a socket.
[EOPNOTSUPP]	The specified flags are not supported for this socket type.
[ETIMEDOUT]	The connection timed out during connection establishment, or due to a transmission timeout on active connection.

The *recvmsg*( ) function may fail if:

[EIO]	An I/O error occurred while reading from or writing to the file system.
[ENOBUFS]	Insufficient resources were available in the system to perform the operation.
[ENOMEM]	Insufficient memory was available to fulfill the request.

EXAMPLES

None.

APPLICATION USAGE

The *select*( ) and *poll*( ) functions can be used to determine when data is available to be received.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

NAME

regcomp, regerror, regexec, regfree — regular expression matching

SYNOPSIS

```
#include <regex.h>

int regcomp(regex_t *restrict preg, const char *restrict pattern, int cflags);
size_t regerror(int errcode, const regex_t *restrict preg,
    char *restrict errbuf, size_t errbuf_size);
int regexec(const regex_t *restrict preg, const char *restrict string,
    size_t nmatch, regmatch_t pmatch[restrict], int eflags);
void regfree(regex_t *preg);
```

DESCRIPTION

These functions interpret *basic* and *extended* regular expressions as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 9, Regular Expressions.

The **regex_t** structure is defined in **<regex.h>** and contains at least the following member:

Member Type	Member Name	Description
`size_t`	`re_nsub`	Number of parenthesized subexpressions.

The **regmatch_t** structure is defined in **<regex.h>** and contains at least the following members:

Member Type	Member Name	Description
regoff_t	*rm_so*	Byte offset from start of *string* to start of substring.
regoff_t	*rm_eo*	Byte offset from start of *string* of the first character after the end of substring.

The *regcomp*( ) function shall compile the regular expression contained in the string pointed to by the *pattern* argument and place the results in the structure pointed to by *preg*. The *cflags* argument is the bitwise-inclusive OR of zero or more of the following flags, which are defined in the **<regex.h>** header:

REG_EXTENDED	Use Extended Regular Expressions.
REG_ICASE	Ignore case in match. (See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 9, Regular Expressions.)
REG_NOSUB	Report only success / fail in *regexec*( ).
REG_NEWLINE	Change the handling of <newline>s, as described in the text.

The default regular expression type for *pattern* is a Basic Regular Expression. The application can specify Extended Regular Expressions using the REG_EXTENDED *cflags* flag.

If the REG_NOSUB flag was not set in *cflags*, then *regcomp*( ) shall set *re_nsub* to the number of parenthesized subexpressions (delimited by `"\(\)"` in basic regular expressions or `"( )"` in extended regular expressions) found in *pattern*.

The *regexec*( ) function compares the null-terminated string specified by *string* with the compiled regular expression *preg* initialized by a previous call to *regcomp*( ). If it finds a match, *regexec*( ) shall return 0; otherwise, it shall return non-zero indicating either no match or an error. The *eflags* argument is the bitwise-inclusive OR of zero or more of the following flags, which are defined in the **<regex.h>** header:

REG_NOTBOL	The first character of the string pointed to by *string* is not the beginning of the line. Therefore, the circumflex character (`'^'`), when taken as a special character, shall not match the beginning of *string*.
REG_NOTEOL	The last character of the string pointed to by *string* is not the end of the line. Therefore, the dollar sign (`'$'`), when taken as a special character, shall not match the end of *string*.

If *nmatch* is 0 or REG_NOSUB was set in the *cflags* argument to *regcomp*( ), then *regexec*( ) shall ignore the *pmatch* argument. Otherwise, the application shall ensure that the *pmatch* argument points to an array with at least *nmatch* elements, and *regexec*( ) shall fill in the elements of that array with offsets of the substrings of *string* that correspond to the parenthesized subexpressions of *pattern*: *pmatch*[*i*].*rm_so* shall be the byte offset of the beginning and *pmatch*[*i*].*rm_eo* shall be one greater than the byte offset of the end of substring *i*. (Subexpression *i* begins at the *i*th matched open parenthesis, counting from 1.) Offsets in *pmatch*[0] identify the substring that corresponds to the entire regular expression. Unused elements of *pmatch* up to *pmatch*[*nmatch*−1] shall be filled with −1. If there are more than *nmatch* subexpressions in *pattern* (*pattern* itself counts as a subexpression), then *regexec*( ) shall still do the match, but shall record only the first *nmatch* substrings.

When matching a basic or extended regular expression, any given parenthesized subexpression of *pattern* might participate in the match of several different substrings of *string*, or it might not match any substring even though the pattern as a whole did match. The following rules shall be used to determine which substrings to report in *pmatch* when matching regular expressions:

1. If subexpression *i* in a regular expression is not contained within another subexpression, and it participated in the match several times, then the byte offsets in *pmatch*[*i*] shall delimit the last such match.

2. If subexpression *i* is not contained within another subexpression, and it did not participate in an otherwise successful match, the byte offsets in *pmatch*[*i*] shall be −1. A subexpression does not participate in the match when:

   `'*'` or `"\{\}"` appears immediately after the subexpression in a basic regular expression, or `'*'`, `'?'`, or `"{}"` appears immediately after the subexpression in an extended regular expression, and the subexpression did not match (matched 0 times)

   or:

   `'|'` is used in an extended regular expression to select this subexpression or another, and the other subexpression matched.

3. If subexpression *i* is contained within another subexpression *j*, and *i* is not contained within any other subexpression that is contained within *j*, and a match of subexpression *j* is reported in *pmatch*[*j*], then the match or non-match of subexpression *i* reported in *pmatch*[*i*] shall be as described in 1. and 2. above, but within the substring reported in *pmatch*[*j*] rather than the whole string. The offsets in *pmatch*[*i*] are still relative to the start of string.

4. If subexpression *i* is contained in subexpression *j*, and the byte offsets in *pmatch*[*j*] are −1, then the pointers in *pmatch*[*i*] shall also be −1.

5. If subexpression *i* matched a zero-length string, then both byte offsets in *pmatch*[*i*] shall be the byte offset of the character or null terminator immediately following the zero-length string.

If, when *regexec*( ) is called, the locale is different from when the regular expression was compiled, the result is undefined.

If REG_NEWLINE is not set in *cflags*, then a <newline> in *pattern* or *string* shall be treated as an ordinary character. If REG_NEWLINE is set, then <newline> shall be treated as an ordinary character except as follows:

1. A <newline> in *string* shall not be matched by a period outside a bracket expression or by any form of a non-matching list (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 9, Regular Expressions).
2. A circumflex (`'^'`) in *pattern*, when used to specify expression anchoring (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3.8, BRE Expression Anchoring), shall match the zero-length string immediately after a <newline> in *string*, regardless of the setting of REG_NOTBOL.
3. A dollar sign (`'$'`) in *pattern*, when used to specify expression anchoring, shall match the zero-length string immediately before a <newline> in *string*, regardless of the setting of REG_NOTEOL.

The *regfree*( ) function frees any memory allocated by *regcomp*( ) associated with *preg*.

The following constants are defined as error return values:

REG_NOMATCH	*regexec*( ) failed to match.
REG_BADPAT	Invalid regular expression.
REG_ECOLLATE	Invalid collating element referenced.
REG_ECTYPE	Invalid character class type referenced.
REG_EESCAPE	Trailing `'\'` in pattern.
REG_ESUBREG	Number in `"\digit"` invalid or in error.
REG_EBRACK	`"[]"` imbalance.
REG_EPAREN	`"\(\)"` or `"()"` imbalance.
REG_EBRACE	`"\{\}"` imbalance.
REG_BADBR	Content of `"\{\}"` invalid: not a number, number too large, more than two numbers, first larger than second.
REG_ERANGE	Invalid endpoint in range expression.
REG_ESPACE	Out of memory.
REG_BADRPT	`'?'`, `'*'`, or `'+'` not preceded by valid regular expression.

The *regerror*( ) function provides a mapping from error codes returned by *regcomp*( ) and *regexec*( ) to unspecified printable strings. It generates a string corresponding to the value of the *errcode* argument, which the application shall ensure is the last non-zero value returned by *regcomp*( ) or *regexec*( ) with the given value of *preg*. If *errcode* is not such a value, the content of the generated string is unspecified.

If *preg* is a null pointer, but *errcode* is a value returned by a previous call to *regexec*( ) or *regcomp*( ), the *regerror*( ) still generates an error string corresponding to the value of *errcode*, but it might not be as detailed under some implementations.

If the *errbuf_size* argument is not 0, *regerror*( ) shall place the generated string into the buffer of size *errbuf_size* bytes pointed to by *errbuf*. If the string (including the terminating null) cannot fit in the buffer, *regerror*( ) shall truncate the string and null-terminates the result.

If *errbuf_size* is 0, *regerror*( ) shall ignore the *errbuf* argument, and return the size of the buffer needed to hold the generated string.

If the *preg* argument to *regexec*( ) or *regfree*( ) is not a compiled regular expression returned by *regcomp*( ), the result is undefined. A *preg* is no longer treated as a compiled regular expression after it is given to *regfree*( ).

RETURN VALUE

Upon successful completion, the *regcomp*( ) function shall return 0. Otherwise, it shall return an integer value indicating an error as described in **<regex.h>**, and the content of *preg* is undefined. If a code is returned, the interpretation shall be as given in **<regex.h>**.

If *regcomp*( ) detects an invalid RE, it may return REG_BADPAT, or it may return one of the error codes that more precisely describes the error.

Upon successful completion, the *regexec*( ) function shall return 0. Otherwise, it shall return REG_NOMATCH to indicate no match.

Upon successful completion, the *regerror*( ) function shall return the number of bytes needed to hold the entire generated string, including the null termination. If the return value is greater than *errbuf_size*, the string returned in the buffer pointed to by *errbuf* has been truncated.

The *regfree*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

```
#include <regex.h>

/*
 * Match string against the extended regular expression in
 * pattern, treating errors as no match.
 *
 * Return 1 for match, 0 for no match.
 */

int
match(const char *string, char *pattern)
{
    int    status;
    regex_t    re;

    if (regcomp(&re, pattern, REG_EXTENDED|REG_NOSUB) != 0) {
        return(0);      /* Report error. */
    }
    status = regexec(&re, string, (size_t) 0, NULL, 0);
    regfree(&re);
    if (status != 0) {
        return(0);      /* Report error. */
    }
    return(1);
}
```

The following demonstrates how the REG_NOTBOL flag could be used with *regexec*( ) to find all substrings in a line that match a pattern supplied by a user. (For simplicity of the example, very little error checking is done.)

```
(void) regcomp (&re, pattern, 0);
/* This call to regexec() finds the first match on the line. */
error = regexec (&re, &buffer[0], 1, &pm, 0);
while (error == 0) {  /* While matches found. */
    /* Substring found between pm.rm_so and pm.rm_eo. */
    /* This call to regexec() finds the next match. */
    error = regexec (&re, buffer + pm.rm_eo, 1, &pm, REG_NOTBOL);
}
```

APPLICATION USAGE

An application could use:

```
regerror(code,preg,(char *)NULL,(size_t)0)
```

to find out how big a buffer is needed for the generated string, *malloc*( ) a buffer to hold the string, and then call *regerror*( ) again to get the string. Alternatively, it could allocate a fixed, static buffer that is big enough to hold most strings, and then use *malloc*( ) to allocate a larger buffer if it finds that this is too small.

To match a pattern as described in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.13, Pattern Matching Notation, use the *fnmatch*( ) function.

RATIONALE

The *regmatch*( ) function must fill in all *nmatch* elements of *pmatch*, where *nmatch* and *pmatch* are supplied by the application, even if some elements of *pmatch* do not correspond to subexpressions in *pattern*. The application writer should note that there is probably no reason for using a value of *nmatch* that is larger than *preg*−>*re_nsub*+1.

The REG_NEWLINE flag supports a use of RE matching that is needed in some applications like text editors. In such applications, the user supplies an RE asking the application to find a line that matches the given expression. An anchor in such an RE anchors at the beginning or end of any line. Such an application can pass a sequence of <newline>-separated lines to *regexec*( ) as a single long string and specify REG_NEWLINE to *regcomp*( ) to get the desired behavior. The application must ensure that there are no explicit <newline>s in *pattern* if it wants to ensure that any match occurs entirely within a single line.

The REG_NEWLINE flag affects the behavior of *regexec*( ), but it is in the *cflags* parameter to *regcomp*( ) to allow flexibility of implementation. Some implementations will want to generate the same compiled RE in *regcomp*( ) regardless of the setting of REG_NEWLINE and have *regexec*( ) handle anchors differently based on the setting of the flag. Other implementations will generate different compiled REs based on the REG_NEWLINE.

The REG_ICASE flag supports the operations taken by the *grep* −**i** option and the historical implementations of *ex* and *vi*. Including this flag will make it easier for application code to be written that does the same thing as these utilities.

The substrings reported in *pmatch*[ ] are defined using offsets from the start of the string rather than pointers. Since this is a new interface, there should be no impact on historical implementations or applications, and offsets should be just as easy to use as pointers. The change to offsets was made to facilitate future extensions in which the string to be searched is presented to *regexec*( ) in blocks, allowing a string to be searched that is not all in memory at once.

A new type **regoff_t** is used for the elements of *pmatch*[ ] to ensure that the application can represent either the largest possible array in memory (important for an application conforming to the Shell and Utilities volume of IEEE Std 1003.1-200x) or the largest possible file (important for an application using the extension where a file is searched in chunks).

The standard developers rejected the inclusion of a *regsub*( ) function that would be used to do substitutions for a matched RE. While such a routine would be useful to some applications, its utility would be much more limited than the matching function described here. Both RE parsing and substitution are possible to implement without support other than that required by the ISO C standard, but matching is much more complex than substituting. The only difficult part of substitution, given the information supplied by *regexec*( ), is finding the next character in a string when there can be multi-byte characters. That is a much larger issue, and one that needs a more general solution.

The *errno* variable has not been used for error returns to avoid filling the *errno* name space for this feature.

The interface is defined so that the matched substrings *rm_sp* and *rm_ep* are in a separate **regmatch_t** structure instead of in **regex_t**. This allows a single compiled RE to be used simultaneously in several contexts; in *main*( ) and a signal handler, perhaps, or in multiple threads of lightweight processes. (The *preg* argument to *regexec*( ) is declared with type **const**, so the implementation is not permitted to use the structure to store intermediate results.) It also allows an application to request an arbitrary number of substrings from an RE. The number of subexpressions in the RE is reported in *re_nsub* in *preg*. With this change to *regexec*( ), consideration was given to dropping the REG_NOSUB flag since the user can now specify this with a zero *nmatch* argument to *regexec*( ). However, keeping REG_NOSUB allows an implementation to use a different (perhaps more efficient) algorithm if it knows in *regcomp*( ) that no subexpressions need be reported. The implementation is only required to fill in *pmatch* if *nmatch* is not zero and if REG_NOSUB is not specified. Note that the **size_t** type, as defined in the ISO C standard, is unsigned, so the description of *regexec*( ) does not need to address negative values of *nmatch*.

REG_NOTBOL was added to allow an application to do repeated searches for the same pattern in a line. If the pattern contains a circumflex character that should match the beginning of a line, then the pattern should only match when matched against the beginning of the line. Without the REG_NOTBOL flag, the application could rewrite the expression for subsequent matches, but in the general case this would require parsing the expression. The need for REG_NOTEOL is not as clear; it was added for symmetry.

The addition of the *regerror*( ) function addresses the historical need for conforming application programs to have access to error information more than ‘‘Function failed to compile/match your RE for unknown reasons’’. |

This interface provides for two different methods of dealing with error conditions. The specific error codes (REG_EBRACE, for example), defined in **<regex.h>**, allow an application to recover from an error if it is so able. Many applications, especially those that use patterns supplied by a user, will not try to deal with specific error cases, but will just use *regerror*( ) to obtain a human-readable error message to present to the user.

The *regerror*( ) function uses a scheme similar to *confstr*( ) to deal with the problem of allocating memory to hold the generated string. The scheme used by *strerror*( ) in the ISO C standard was considered unacceptable since it creates difficulties for multi-threaded applications.

The *preg* argument is provided to *regerror*( ) to allow an implementation to generate a more descriptive message than would be possible with *errcode* alone. An implementation might, for example, save the character offset of the offending character of the pattern in a field of *preg*, and then include that in the generated message string. The implementation may also ignore *preg*.

A REG_FILENAME flag was considered, but omitted. This flag caused *regexec*( ) to match patterns as described in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.13, Pattern Matching Notation instead of REs. This service is now provided by the *fnmatch*( )

function.

Notice that there is a difference in philosophy between the ISO POSIX-2:1993 standard and IEEE Std 1003.1-200x in how to handle a bad regular expression. The ISO POSIX-2:1993 standard says that many bad constructs produce undefined results, or that the interpretation is undefined. IEEE Std 1003.1-200x, however, says that the interpretation of such REs is unspecified. The term ‘‘undefined’’ means that the action by the application is an error, of similar severity to passing a bad pointer to a function.

The *regcomp*( ) and *regexec*( ) functions are required to accept any null-terminated string as the *pattern* argument. If the meaning of the string is undefined, the behavior of the function is unspecified. IEEE Std 1003.1-200x does not specify how the functions will interpret the pattern; they might return error codes, or they might do pattern matching in some completely unexpected way, but they should not do something like abort the process.

FUTURE DIRECTIONS

None.

SEE ALSO

fnmatch( ), *glob*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<regex.h>**, **<sys/types.h>**

CHANGE HISTORY

First released in Issue 4. Derived from the ISO POSIX-2 standard.

Issue 5

Moved from POSIX2 C-language Binding to BASE.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The REG_ENOSYS constant is removed.

The **restrict** keyword is added to the *regcomp*( ), *regerror*( ), and *regexec*( ) prototypes for alignment with the ISO/IEC 9899:1999 standard.

NAME

remainder, remainderf, remainderl — remainder function

SYNOPSIS

```
#include <math.h>

double remainder(double x, double y);
float remainderf(float x, float y);
long double remainderl(long double x, long double y);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall return the floating-point remainder $r=x-ny$ when *y* is non-zero. The value *n* is the integral value nearest the exact value x/y. When $|n-x/y|=\frac{1}{2}$, the value *n* is chosen to be even.

The behavior of *remainder*( ) shall be independent of the rounding mode.

RETURN VALUE

Upon successful completion, these functions shall return the floating-point remainder $r=x-ny$ when *y* is non-zero.

MX If *x* or *y* is NaN, a NaN shall be returned.

If *x* is infinite or *y* is 0 and the other is non-NaN, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

ERRORS

These functions shall fail if:

MX Domain Error	The *x* argument is ±Inf, or the *y* argument is ±0 and the other argument is non-NaN.
	If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

abs( ), *div*( ), *feclearexcept*( ), *fetestexcept*( ), *ldiv*( ), the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.18, Treatment of Error Conditions for Mathematical Functions, **<math.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

The *remainder*( ) function is no longer marked as an extension.

The *remainderf*( ) and *remainderl*( ) functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

IEC 60559:1989 standard floating-point extensions over the ISO/IEC 9899:1999 standard are marked.

NAME

remove — remove a file

SYNOPSIS

```
#include <stdio.h>

int remove(const char *path);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *remove*( ) function shall cause the file named by the pathname pointed to by path to be no longer accessible by that name. A subsequent attempt to open that file using that name shall fail, unless it is created anew.

CX If *path* does not name a directory, *remove*(*path*) shall be equivalent to *unlink*(*path*).

If *path* names a directory, *remove*(*path*) shall be equivalent to *rmdir*(*path*).

RETURN VALUE

CX Refer to *rmdir*( ) or *unlink*( ).

ERRORS

CX Refer to *rmdir*( ) or *unlink*( ).

EXAMPLES

Removing Access to a File

The following example shows how to remove access to a file named **/home/cnd/old_mods**.

```
#include <stdio.h>

int status;
...
status = remove("/home/cnd/old_mods");
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

rmdir( ), *unlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdio.h>**

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard and the ISO C standard.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION, RETURN VALUE, and ERRORS sections are updated so that if *path* is not a directory, *remove*( ) is equivalent to *unlink*( ), and if it is a directory, it is equivalent to *rmdir*( ).

NAME

remque — remove an element from a queue

SYNOPSIS

XSI
```
#include <search.h>

void remque(void *element);
```

DESCRIPTION

Refer to *insque*( ).

NAME

remquo, remquof, remquol — remainder functions

SYNOPSIS

```
#include <math.h>

double remquo(double x, double y, int *quo);
float remquof(float x, float y, int *quo);
long double remquol(long double x, long double y, int *quo);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *remquo*( ), *remquof*( ), and *remquol*( ) functions shall compute the same remainder as the *remainder*( ), *remainderf*( ), and *remainderl*( ) functions, respectively. In the object pointed to by *quo*, they store a value whose sign is the sign of x/y and whose magnitude is congruent modulo 2^n to the magnitude of the integral quotient of x/y, where n is an implementation-defined integer greater than or equal to 3.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

These functions shall return *x* REM *y*.

MX If *x* or *y* is NaN, a NaN shall be returned.

If *x* is ±Inf or *y* is zero and the other argument is non-NaN, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

ERRORS

These functions shall fail if:

MX Domain Error	The *x* argument is ±Inf, or the *y* argument is ±0 and the other argument is non-NaN.
	If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

These functions are intended for implementing argument reductions which can exploit a few low-order bits of the quotient. Note that *x* may be so large in magnitude relative to *y* that an exact representation of the quotient is not practical.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 6. Derived from the ISO/IEC 9899:1999 standard.

NAME

rename — rename a file

SYNOPSIS

```
#include <stdio.h>

int rename(const char *old, const char *new);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *rename*( ) function shall change the name of a file. The *old* argument points to the pathname of the file to be renamed. The *new* argument points to the new pathname of the file.

CX If either the *old* or *new* argument names a symbolic link, *rename*( ) shall operate on the symbolic link itself, and shall not resolve the last component of the argument. If the *old* argument and the *new* argument resolve to the same existing file, *rename*( ) shall return successfully and perform no other action.

If the *old* argument points to the pathname of a file that is not a directory, the *new* argument shall not point to the pathname of a directory. If the link named by the *new* argument exists, it shall be removed and *old* renamed to *new*. In this case, a link named *new* shall remain visible to other processes throughout the renaming operation and refer either to the file referred to by *new* or *old* before the operation began. Write access permission is required for both the directory containing *old* and the directory containing *new*.

If the *old* argument points to the pathname of a directory, the *new* argument shall not point to the pathname of a file that is not a directory. If the directory named by the *new* argument exists, it shall be removed and *old* renamed to *new*. In this case, a link named *new* shall exist throughout the renaming operation and shall refer either to the directory referred to by *new* or *old* before the operation began. If *new* names an existing directory, it shall be required to be an empty directory.

If the *old* argument points to a pathname of a symbolic link, the symbolic link shall be renamed. If the *new* argument points to a pathname of a symbolic link, the symbolic link shall be removed.

The *new* pathname shall not contain a path prefix that names *old*. Write access permission is required for the directory containing *old* and the directory containing *new*. If the *old* argument points to the pathname of a directory, write access permission may be required for the directory named by *old*, and, if it exists, the directory named by *new*.

If the link named by the *new* argument exists and the file's link count becomes 0 when it is removed and no process has the file open, the space occupied by the file shall be freed and the file shall no longer be accessible. If one or more processes have the file open when the last link is removed, the link shall be removed before *rename*( ) returns, but the removal of the file contents shall be postponed until all references to the file are closed.

Upon successful completion, *rename*( ) shall mark for update the *st_ctime* and *st_mtime* fields of the parent directory of each file.

If the *rename*( ) function fails for any reason other than [EIO], any file named by *new* shall be unaffected.

RETURN VALUE

CX Upon successful completion, *rename*( ) shall return 0; otherwise, −1 shall be returned, *errno* shall be set to indicate the error, and neither the file named by *old* nor the file named by *new* shall be changed or created.

ERRORS

The *rename*( ) function shall fail if:

CX	[EACCES]	A component of either path prefix denies search permission; or one of the directories containing *old* or *new* denies write permissions; or, write permission is required and is denied for a directory pointed to by the *old* or *new* arguments.
CX	[EBUSY]	The directory named by *old* or *new* is currently in use by the system or another process, and the implementation considers this an error.
CX	[EEXIST] or [ENOTEMPTY]	The link named by *new* is a directory that is not an empty directory.
CX	[EINVAL]	The *new* directory pathname contains a path prefix that names the *old* directory.
CX	[EIO]	A physical I/O error has occurred.
CX	[EISDIR]	The *new* argument points to a directory and the *old* argument points to a file that is not a directory.
CX	[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
CX	[EMLINK]	The file named by *old* is a directory, and the link count of the parent directory of *new* would exceed {LINK_MAX}.
CX	[ENAMETOOLONG]	The length of the *old* or *new* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
CX	[ENOENT]	The link named by *old* does not name an existing file, or either *old* or *new* points to an empty string.
CX	[ENOSPC]	The directory that would contain *new* cannot be extended.
CX	[ENOTDIR]	A component of either path prefix is not a directory; or the *old* argument names a directory and *new* argument names a non-directory file.
XSI	[EPERM] or [EACCES]	The S_ISVTX flag is set on the directory containing the file referred to by *old* and the caller is not the file owner, nor is the caller the directory owner, nor does the caller have appropriate privileges; or *new* refers to an existing file, the S_ISVTX flag is set on the directory containing this file, and the caller is not the file owner, nor is the caller the directory owner, nor does the caller have appropriate privileges.
CX	[EROFS]	The requested operation requires writing in a directory on a read-only file system.
CX	[EXDEV]	The links named by *new* and *old* are on different file systems and the implementation does not support links between file systems.

The *rename*( ) function may fail if:

XSI	[EBUSY]	The file named by the *old* or *new* arguments is a named STREAM.
CX	[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.

CX [ENAMETOOLONG]
As a result of encountering a symbolic link in resolution of the *path* argument, the length of the substituted pathname string exceeded {PATH_MAX}.

CX [ETXTBSY] The file to be renamed is a pure procedure (shared text) file that is being executed.

EXAMPLES

Renaming a File

The following example shows how to rename a file named **/home/cnd/mod1** to **/home/cnd/mod2**.

```
#include <stdio.h>

int status;
...
status = rename("/home/cnd/mod1", "/home/cnd/mod2");
```

APPLICATION USAGE

Some implementations mark for update the *st_ctime* field of renamed files and some do not. Applications which make use of the *st_ctime* field may behave differently with respect to renamed files unless they are designed to allow for either behavior.

RATIONALE

This *rename*( ) function is equivalent for regular files to that defined by the ISO C standard. Its inclusion here expands that definition to include actions on directories and specifies behavior when the *new* parameter names a file that already exists. That specification requires that the action of the function be atomic.

One of the reasons for introducing this function was to have a means of renaming directories while permitting implementations to prohibit the use of *link*( ) and *unlink*( ) with directories, thus constraining links to directories to those made by *mkdir*( ).

The specification that if *old* and *new* refer to the same file is intended to guarantee that:

```
rename("x", "x");
```

does not remove the file.

Renaming dot or dot-dot is prohibited in order to prevent cyclical file system paths.

See also the descriptions of [ENOTEMPTY] and [ENAMETOOLONG] in *rmdir*( ) and [EBUSY] in *unlink*( ). For a discussion of [EXDEV], see *link*( ).

FUTURE DIRECTIONS

None.

SEE ALSO

link( ), *rmdir*( ), *symlink*( ), *unlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdio.h>**

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 5

The [EBUSY] error is added to the ‘‘may fail’’ part of the ERRORS section.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The [EIO] mandatory error condition is added.
- The [ELOOP] mandatory error condition is added.
- A second [ENAMETOOLONG] is added as an optional error condition.
- The [ETXTBSY] optional error condition is added.

The following changes were made to align with the IEEE P1003.1a draft standard:

- Details are added regarding the treatment of symbolic links.
- The [ELOOP] optional error condition is added.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

rewind — reset file position indicator in a stream

SYNOPSIS

```
#include <stdio.h>

void rewind(FILE *stream);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The call:

```
rewind(stream)
```

shall be equivalent to:

```
(void) fseek(stream, 0L, SEEK_SET)
```

except that *rewind*( ) shall also clear the error indicator. |

CX Since *rewind*( ) does not return a value, an application wishing to detect errors should clear *errno*, then call *rewind*( ), and if *errno* is non-zero, assume an error has occurred. |

RETURN VALUE

The *rewind*( ) function shall not return a value.

ERRORS

CX Refer to *fseek*( ) with the exception of [EINVAL] which does not apply.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

Extensions beyond the ISO C standard are now marked.

NAME

rewinddir — reset position of directory stream to the beginning of a directory

SYNOPSIS

```
#include <dirent.h>

void rewinddir(DIR *dirp);
```

DESCRIPTION

The *rewinddir*( ) function shall reset the position of the directory stream to which *dirp* refers to the beginning of the directory. It shall also cause the directory stream to refer to the current state of the corresponding directory, as a call to *opendir*( ) would have done. If *dirp* does not refer to a directory stream, the effect is undefined.

After a call to the *fork*( ) function, either the parent or child (but not both) may continue XSI processing the directory stream using *readdir*( ), *rewinddir*( ), or *seekdir*( ). If both the parent and child processes use these functions, the result is undefined.

RETURN VALUE

The *rewinddir*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The *rewinddir*( ) function should be used in conjunction with *opendir*( ), *readdir*( ), and *closedir*( ) to examine the contents of the directory. This method is recommended for portability.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

closedir( ), *opendir*( ), *readdir*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<dirent.h>** **<sys/types.h>**

CHANGE HISTORY

First released in Issue 2.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

NAME

rindex — character string operations (**LEGACY**)

SYNOPSIS

XSI
```
#include <strings.h>

char *rindex(const char *s, int c);
```

DESCRIPTION

The *rindex*( ) function shall be equivalent to *strrchr*( ).

RETURN VALUE

Refer to *strrchr*( ).

ERRORS

Refer to *strrchr*( ).

EXAMPLES

None.

APPLICATION USAGE

strrchr( ) is preferred over this function.

For maximum portability, it is recommended to replace the function call to *rindex*( ) as follows:

```
#define rindex(a,b) strrchr((a),(b))
```

RATIONALE

None.

FUTURE DIRECTIONS

This function may be withdrawn in a future version.

SEE ALSO

strrchr( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<strings.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

This function is marked LEGACY.

NAME

rint, rintf, rintl — round-to-nearest integral value

SYNOPSIS

```
#include <math.h>

double rint(double x);
float rintf(float x);
long double rintl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall return the integral value (represented as a **double**) nearest *x* in the direction of the current rounding mode. The current rounding mode is implementation-defined.

If the current rounding mode rounds toward negative infinity, then *rint*( ) shall be equivalent to *floor*( ). If the current rounding mode rounds toward positive infinity, then *rint*( ) shall be equivalent to *ceil*( ).

These functions differ from the *nearbyint*( ), *nearbyintf*( ), and *nearbyintl*( ) functions only in that they may raise the inexact floating-point exception if the result differs in value from the argument.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the integer (represented as a double precision number) nearest *x* in the direction of the current rounding mode.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0, or ±Inf, *x* shall be returned.

XSI If the correct value would cause overflow, a range error shall occur and *rint*( ), *rintf*( ), and *rintl*( ) shall return the value of the macro HUGE_VAL, HUGE_VALF, and HUGE_VALL, respectively.

ERRORS

These functions shall fail if:

XSI

Range Error	The result would cause an overflow.
	If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

abs( ), *ceil*( ), *feclearexcept*( ), *fetestexcept*( ), *nearbyint*( ), *floor*( ), *isnan*( ), the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.18, Treatment of Error Conditions for Mathematical Functions, **<math.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

- The *rintf*( ) and *rintl*( ) functions are added.
- The *rint*( ) function is no longer marked as an extension.
- The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

IEC 60559:1989 standard floating-point extensions over the ISO/IEC 9899:1999 standard are marked.

NAME

rmdir — remove a directory

SYNOPSIS

```
#include <unistd.h>

int rmdir(const char *path);
```

DESCRIPTION

The *rmdir*( ) function shall remove a directory whose name is given by *path*. The directory shall be removed only if it is an empty directory.

If the directory is the root directory or the current working directory of any process, it is unspecified whether the function succeeds, or whether it shall fail and set *errno* to [EBUSY].

If *path* names a symbolic link, then *rmdir*( ) shall fail and set *errno* to [ENOTDIR].

If the *path* argument refers to a path whose final component is either dot or dot-dot, *rmdir*( ) shall fail.

If the directory's link count becomes 0 and no process has the directory open, the space occupied by the directory shall be freed and the directory shall no longer be accessible. If one or more processes have the directory open when the last link is removed, the dot and dot-dot entries, if present, shall be removed before *rmdir*( ) returns and no new entries may be created in the directory, but the directory shall not be removed until all references to the directory are closed.

If the directory is not an empty directory, *rmdir*( ) shall fail and set *errno* to [EEXIST] or [ENOTEMPTY].

Upon successful completion, the *rmdir*( ) function shall mark for update the *st_ctime* and *st_mtime* fields of the parent directory.

RETURN VALUE

Upon successful completion, the function *rmdir*( ) shall return 0. Otherwise, –1 shall be returned, and *errno* set to indicate the error. If –1 is returned, the named directory shall not be changed.

ERRORS

The *rmdir*( ) function shall fail if:

[EACCES]	Search permission is denied on a component of the path prefix, or write permission is denied on the parent directory of the directory to be removed.
[EBUSY]	The directory to be removed is currently in use by the system or some process and the implementation considers this to be an error.
[EEXIST] or [ENOTEMPTY]	The *path* argument names a directory that is not an empty directory, or there are hard links to the directory other than dot or a single entry in dot-dot.
[EINVAL]	The *path* argument contains a last component that is dot.
[EIO]	A physical I/O error has occurred.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than

NAME_MAX

[ENOENT]	A component of *path* does not name an existing file, or the *path* argument names a nonexistent directory or points to an empty string.
[ENOTDIR]	A component of *path* is not a directory.
XSI [EPERM] or [EACCES]	The S_ISVTX flag is set on the parent directory of the directory to be removed and the caller is not the owner of the directory to be removed, nor is the caller the owner of the parent directory, nor does the caller have the appropriate privileges.
[EROFS]	The directory entry to be removed resides on a read-only file system.

The *rmdir*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[ENAMETOOLONG]	As a result of encountering a symbolic link in resolution of the *path* argument, the length of the substituted pathname string exceeded {PATH_MAX}.

EXAMPLES

Removing a Directory

The following example shows how to remove a directory named **/home/cnd/mod1**.

```
#include <unistd.h>

int status;
...
status = rmdir("/home/cnd/mod1");
```

APPLICATION USAGE

None.

RATIONALE

The *rmdir*( ) and *rename*( ) functions originated in 4.2 BSD, and they used [ENOTEMPTY] for the condition when the directory to be removed does not exist or *new* already exists. When the 1984 /usr/group standard was published, it contained [EEXIST] instead. When these functions were adopted into System V, the 1984 /usr/group standard was used as a reference. Therefore, several existing applications and implementations support/use both forms, and no agreement could be reached on either value. All implementations are required to supply both [EEXIST] and [ENOTEMPTY] in **<errno.h>** with distinct values, so that applications can use both values in C-language **case** statements.

The meaning of deleting *pathname*/**dot** is unclear, because the name of the file (directory) in the parent directory to be removed is not clear, particularly in the presence of multiple links to a directory.

IEEE Std 1003.1-200x was silent with regard to the behavior of *rmdir*( ) when there are multiple hard links to the directory being removed. The requirement to set *errno* to [EEXIST] or [ENOTEMPTY] clarifies the behavior in this case.

If the process' current working directory is being removed, that should be an allowed error.

Virtually all existing implementations detect [ENOTEMPTY] or the case of dot-dot. The text in Section 2.3 (on page 471) about returning any one of the possible errors permits that behavior to continue. The [ELOOP] error may be returned if more than {SYMLOOP_MAX} symbolic links are encountered during resolution of the *path* argument.

FUTURE DIRECTIONS

None.

SEE ALSO

mkdir( ), *remove*( ), *unlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<unistd.h>**

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification: |

- The DESCRIPTION is updated to indicate the results of naming a symbolic link in *path*.
- The [EIO] mandatory error condition is added.
- The [ELOOP] mandatory error condition is added.
- A second [ENAMETOOLONG] is added as an optional error condition.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The [ELOOP] optional error condition is added.

NAME

round, roundf, roundl — round to nearest integer value in floating-point format

SYNOPSIS

```
#include <math.h>

double round(double x);
float roundf(float x);
long double roundl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall round their argument to the nearest integer value in floating-point format, rounding halfway cases away from zero, regardless of the current rounding direction.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the rounded integer value.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0, or ±Inf, *x* shall be returned.

XSI If the correct value would cause overflow, a range error shall occur and *round*( ), *roundf*( ), and *roundl*( ) shall return the value of the macro HUGE_VAL, HUGE_VALF, and HUGE_VALL, respectively.

ERRORS

These functions may fail if:

XSI Range Error The result overflows.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from the ISO / IEC 9899: 1999 standard.

NAME

scalb — load exponent of a radix-independent floating-point number

SYNOPSIS

OB XSI

```
#include <math.h>

double scalb(double x, double n);
```

DESCRIPTION

The *scalb*( ) function shall compute $x*r^n$, where r is the radix of the machine's floating-point arithmetic. When r is 2, *scalb*( ) shall be equivalent to *ldexp*( ). The value of r is FLT_RADIX which is defined in **<float.h>**.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, the *scalb*( ) function shall return $x*r^n$.

If x or n is NaN, a NaN shall be returned.

If n is zero, x shall be returned.

If x is ±Inf and n is not −Inf, x shall be returned.

If x is ±0 and n is not +Inf, x shall be returned.

If x is ±0 and n is +Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If x is ±Inf and n is −Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If the result would cause an overflow, a range error shall occur and ±HUGE_VAL (according to the sign of x) shall be returned.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value shall be returned.

If the correct value would cause underflow, and is not representable, a range error may occur, and 0.0 shall be returned.

ERRORS

The *scalb*( ) function shall fail if:

Domain Error	If x is zero and n is +Inf, or x is Inf and n is −Inf. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.
Range Error	The result would overflow. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

The *scalb*( ) function may fail if:

Range Error	The result underflows. If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

Applications should use either *scalbln*( ), *scalblnf*( ), or *scalblnl*( ) in preference to this function.

IEEE Std 1003.1-200x only defines the behavior for the *scalb*( ) function when the *n* argument is an integer, a NaN, or Inf. The behavior of other values for the *n* argument is unspecified.

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6

This function is marked obsolescent.

Although this function is not part of the ISO/IEC 9899:1999 standard, the RETURN VALUE and ERROR sections are updated to align with the error handling in ISO/IEC 9899:1999 standard.

NAME

scalbln, scalblnf, scalblnl, scalbn, scalbnf, scalbnl, — compute exponent using FLT_RADIX

SYNOPSIS

```
#include <math.h>

double scalbln(double x, long n);
float scalblnf(float x, long n);
long double scalblnl(long double x, long n);
double scalbn(double x, int n);
float scalbnf(float x, int n);
long double scalbnl(long double x, int n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute $x * \text{FLT\_RADIX}^n$ efficiently, not normally by computing FLT_RADIX^n explicitly.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return $x * \text{FLT\_RADIX}^n$.

If the result would cause overflow, a range error shall occur and these functions shall return ±HUGE_VAL, ±HUGE_VALF, and ±HUGE_VALL (according to the sign of *x*) as appropriate for the return type of the function.

MX If the correct value would cause underflow, and is not representable, a range error may occur, and either 0.0 (if supported), or an implementation-defined value shall be returned.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0, or ±Inf, *x* shall be returned.

If *n* is 0, *x* shall be returned.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value shall be returned.

ERRORS

These functions shall fail if:

Range Error The result overflows.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

These functions may fail if:

Range Error The result underflows.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

These functions are named so as to avoid conflicting with the historical definition of the *scalb*( ) function from the Single UNIX Specification. The difference is that the *scalb*( ) function has second argument of **double** instead of **int**. The *scalb*( ) function is not part of ISO C standard. The three functions whose second type is **long** are provided because the factor required to scale from the smallest positive floating-point value to the largest finite one, on many implementations, is too large to represent in the minimum-width **int** format.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 6. Derived from the ISO / IEC 9899: 1999 standard.

NAME

scalbn, scalbnf, scalbnl, — compute exponent using FLT_RADIX

SYNOPSIS

```
#include <math.h>

double scalbn(double x, int n);
float scalbnf(float x, int n);
long double scalbnl(long double x, int n);
```

DESCRIPTION

Refer to *scalbln*( ).

NAME

scanf — convert formatted input

SYNOPSIS

```
#include <stdio.h>

int scanf(const char *restrict format, ... );
```

DESCRIPTION

Refer to *fscanf*( ).

NAME

sched_get_priority_max, sched_get_priority_min — get priority limits (**REALTIME**)

SYNOPSIS

PS

```
#include <sched.h>

int sched_get_priority_max(int policy);
int sched_get_priority_min(int policy);
```

DESCRIPTION

The *sched_get_priority_max*( ) and *sched_get_priority_min*( ) functions shall return the appropriate maximum or minimum, respectively, for the scheduling policy specified by *policy*.

The value of *policy* shall be one of the scheduling policy values defined in **<sched.h>**.

RETURN VALUE

If successful, the *sched_get_priority_max*( ) and *sched_get_priority_min*( ) functions shall return the appropriate maximum or minimum values, respectively. If unsuccessful, they shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *sched_get_priority_max*( ) and *sched_get_priority_min*( ) functions shall fail if:

[EINVAL] The value of the *policy* parameter does not represent a defined scheduling policy.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

sched_getparam( ), *sched_setparam*( ), *sched_getscheduler*( ), *sched_rr_get_interval*( ), *sched_setscheduler*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sched.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

These functions are marked as part of the Process Scheduling option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Process Scheduling option.

The [ESRCH] error condition has been removed since these functions do not take a *pid* argument.

NAME

sched_getparam — get scheduling parameters (**REALTIME**)

SYNOPSIS

PS

```
#include <sched.h>

int sched_getparam(pid_t pid, struct sched_param *param);
```

DESCRIPTION

The *sched_getparam*( ) function shall return the scheduling parameters of a process specified by *pid* in the **sched_param** structure pointed to by *param*.

If a process specified by *pid* exists, and if the calling process has permission, the scheduling parameters for the process whose process ID is equal to *pid* shall be returned.

If *pid* is zero, the scheduling parameters for the calling process shall be returned. The behavior of the *sched_getparam*( ) function is unspecified if the value of *pid* is negative.

RETURN VALUE

Upon successful completion, the *sched_getparam*( ) function shall return zero. If the call to *sched_getparam*( ) is unsuccessful, the function shall return a value of –1 and set *errno* to indicate the error.

ERRORS

The *sched_getparam*( ) function shall fail if:

[EPERM]	The requesting process does not have permission to obtain the scheduling parameters of the specified process.
[ESRCH]	No process can be found corresponding to that specified by *pid*.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

Issue 6

The *sched_getparam*( ) function is marked as part of the Process Scheduling option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Process Scheduling option.

NAME

sched_getscheduler — get scheduling policy (**REALTIME**)

SYNOPSIS

PS

```
#include <sched.h>

int sched_getscheduler(pid_t pid);
```

DESCRIPTION

The *sched_getscheduler*( ) function shall return the scheduling policy of the process specified by *pid*. If the value of *pid* is negative, the behavior of the *sched_getscheduler*( ) function is unspecified.

The values that can be returned by *sched_getscheduler*( ) are defined in the **<sched.h>** header. |

If a process specified by *pid* exists, and if the calling process has permission, the scheduling policy shall be returned for the process whose process ID is equal to *pid*.

If *pid* is zero, the scheduling policy shall be returned for the calling process.

RETURN VALUE

Upon successful completion, the *sched_getscheduler*( ) function shall return the scheduling policy of the specified process. If unsuccessful, the function shall return −1 and set *errno* to indicate the error.

ERRORS

The *sched_getscheduler*( ) function shall fail if:

[EPERM]	The requesting process does not have permission to determine the scheduling policy of the specified process.
[ESRCH]	No process can be found corresponding to that specified by *pid*.

Issue 6

The *sched_getscheduler*( ) function is marked as part of the Process Scheduling option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Process Scheduling option.

NAME

sched_rr_get_interval — get execution time limits (**REALTIME**)

SYNOPSIS

PS
```
#include <sched.h>

int sched_rr_get_interval(pid_t pid, struct timespec *interval);
```

DESCRIPTION

The *sched_rr_get_interval*( ) function shall update the **timespec** structure referenced by the *interval* argument to contain the current execution time limit (that is, time quantum) for the process specified by *pid*. If *pid* is zero, the current execution time limit for the calling process shall be returned.

RETURN VALUE

If successful, the *sched_rr_get_interval*( ) function shall return zero. Otherwise, it shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *sched_rr_get_interval*( ) function shall fail if:

[ESRCH] No process can be found corresponding to that specified by *pid*.

The *sched_rr_get_interval*( ) function is marked as part of the Process Scheduling option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Process Scheduling option.

NAME

sched_setparam — set scheduling parameters (**REALTIME**)

SYNOPSIS

PS

```
#include <sched.h>

int sched_setparam(pid_t pid, const struct sched_param *param);
```

DESCRIPTION

The *sched_setparam*( ) function shall set the scheduling parameters of the process specified by *pid* to the values specified by the **sched_param** structure pointed to by *param*. The value of the *sched_priority* member in the **sched_param** structure shall be any integer within the inclusive priority range for the current scheduling policy of the process specified by *pid*. Higher numerical values for the priority represent higher priorities. If the value of *pid* is negative, the behavior of the *sched_setparam*( ) function is unspecified.

If a process specified by *pid* exists, and if the calling process has permission, the scheduling parameters shall be set for the process whose process ID is equal to *pid*.

If *pid* is zero, the scheduling parameters shall be set for the calling process.

The conditions under which one process has permission to change the scheduling parameters of another process are implementation-defined.

Implementations may require the requesting process to have the appropriate privilege to set its own scheduling parameters or those of another process.

The target process, whether it is running or not running, shall be moved to the tail of the thread list for its priority.

If the priority of the process specified by the *pid* argument is set higher than that of the lowest priority running process and if the specified process is ready to run, the process specified by the *pid* argument shall preempt a lowest priority running process. Similarly, if the process calling *sched_setparam*( ) sets its own priority lower than that of one or more other non-empty process lists, then the process that is the head of the highest priority list shall also preempt the calling process. Thus, in either case, the originating process might not receive notification of the completion of the requested priority change until the higher priority process has executed.

SS If the scheduling policy of the target process is SCHED_SPORADIC, the value specified by the *sched_ss_low_priority* member of the *param* argument shall be any integer within the inclusive priority range for the sporadic server policy. The *sched_ss_repl_period* and *sched_ss_init_budget* members of the *param* argument shall represent the time parameters to be used by the sporadic server scheduling policy for the target process. The *sched_ss_max_repl* member of the *param* argument shall represent the maximum number of replenishments that are allowed to be pending simultaneously for the process scheduled under this scheduling policy.

The specified *sched_ss_repl_period* shall be greater than or equal to the specified *sched_ss_init_budget* for the function to succeed; if it is not, then the function shall fail.

The value of *sched_ss_max_repl* shall be within the inclusive range [1,{SS_REPL_MAX}] for the function to succeed; if not, the function shall fail.

If the scheduling policy of the target process is either SCHED_FIFO or SCHED_RR, the *sched_ss_low_priority*, *sched_ss_repl_period*, and *sched_ss_init_budget* members of the *param* argument shall have no effect on the scheduling behavior. If the scheduling policy of this process is not SCHED_FIFO, SCHED_RR, or SCHED_SPORADIC, the effects of these members are implementation-defined; this case includes the SCHED_OTHER policy.

SS If the current scheduling policy for the process specified by *pid* is not SCHED_FIFO, SCHED_RR, or SCHED_SPORADIC, the result is implementation-defined; this case includes the SCHED_OTHER policy.

The effect of this function on individual threads is dependent on the scheduling contention scope of the threads:

- For threads with system scheduling contention scope, these functions shall have no effect on their scheduling.
- For threads with process scheduling contention scope, the threads' scheduling parameters shall not be affected. However, the scheduling of these threads with respect to threads in other processes may be dependent on the scheduling parameters of their process, which are governed using these functions.

If an implementation supports a two-level scheduling model in which library threads are multiplexed on top of several kernel-scheduled entities, then the underlying kernel-scheduled entities for the system contention scope threads shall not be affected by these functions.

The underlying kernel-scheduled entities for the process contention scope threads shall have their scheduling parameters changed to the value specified in *param*. Kernel scheduled entities for use by process contention scope threads that are created after this call completes shall inherit their scheduling policy and associated scheduling parameters from the process.

This function is not atomic with respect to other threads in the process. Threads may continue to execute while this function call is in the process of changing the scheduling policy for the underlying kernel-scheduled entities used by the process contention scope threads.

RETURN VALUE

If successful, the *sched_setparam*( ) function shall return zero.

If the call to *sched_setparam*( ) is unsuccessful, the priority shall remain unchanged, and the function shall return a value of –1 and set *errno* to indicate the error.

ERRORS

The *sched_setparam*( ) function shall fail if:

[EINVAL]	One or more of the requested scheduling parameters is outside the range defined for the scheduling policy of the specified *pid*.
[EPERM]	The requesting process does not have permission to set the scheduling parameters for the specified process, or does not have the appropriate privilege to invoke *sched_setparam*( ).
[ESRCH]	No process can be found corresponding to that specified by *pid*.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

sched_getparam( ), *sched_getscheduler*( ), *sched_setscheduler*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sched.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *sched_setparam*( ) function is marked as part of the Process Scheduling option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Process Scheduling option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the effect of this function on a thread's scheduling parameters is added.
- Sections describing two-level scheduling and atomicity of the function are added.

The SCHED_SPORADIC scheduling policy is added for alignment with IEEE Std 1003.1d-1999.

IEEE PASC Interpretation 1003.1 #100 is applied.

NAME

sched_setscheduler — set scheduling policy and parameters (**REALTIME**)

SYNOPSIS

PS

```
#include <sched.h>

int sched_setscheduler(pid_t pid, int policy,
    const struct sched_param *param);
```

DESCRIPTION

The *sched_setscheduler*( ) function shall set the scheduling policy and scheduling parameters of the process specified by *pid* to *policy* and the parameters specified in the **sched_param** structure pointed to by *param*, respectively. The value of the *sched_priority* member in the **sched_param** structure shall be any integer within the inclusive priority range for the scheduling policy specified by *policy*. If the value of *pid* is negative, the behavior of the *sched_setscheduler*( ) function is unspecified.

The possible values for the *policy* parameter are defined in the **<sched.h>** header. |

If a process specified by *pid* exists, and if the calling process has permission, the scheduling policy and scheduling parameters shall be set for the process whose process ID is equal to *pid*.

If *pid* is zero, the scheduling policy and scheduling parameters shall be set for the calling process.

The conditions under which one process has the appropriate privilege to change the scheduling parameters of another process are implementation-defined.

Implementations may require that the requesting process have permission to set its own scheduling parameters or those of another process. Additionally, implementation-defined restrictions may apply as to the appropriate privileges required to set a process' own scheduling policy, or another process' scheduling policy, to a particular value.

The *sched_setscheduler*( ) function shall be considered successful if it succeeds in setting the scheduling policy and scheduling parameters of the process specified by *pid* to the values specified by *policy* and the structure pointed to by *param*, respectively. |

SS If the scheduling policy specified by *policy* is SCHED_SPORADIC, the value specified by the *sched_ss_low_priority* member of the *param* argument shall be any integer within the inclusive priority range for the sporadic server policy. The *sched_ss_repl_period* and *sched_ss_init_budget* members of the *param* argument shall represent the time parameters used by the sporadic server scheduling policy for the target process. The *sched_ss_max_repl* member of the *param* argument shall represent the maximum number of replenishments that are allowed to be pending simultaneously for the process scheduled under this scheduling policy.

The specified *sched_ss_repl_period* shall be greater than or equal to the specified *sched_ss_init_budget* for the function to succeed; if it is not, then the function shall fail.

The value of *sched_ss_max_repl* shall be within the inclusive range [1,{SS_REPL_MAX}] for the function to succeed; if not, the function shall fail.

If the scheduling policy specified by *policy* is either SCHED_FIFO or SCHED_RR, the *sched_ss_low_priority*, *sched_ss_repl_period*, and *sched_ss_init_budget* members of the *param* argument shall have no effect on the scheduling behavior.

The effect of this function on individual threads is dependent on the scheduling contention scope of the threads:

- For threads with system scheduling contention scope, these functions shall have no effect on their scheduling.
- For threads with process scheduling contention scope, the threads' scheduling policy and associated parameters shall not be affected. However, the scheduling of these threads with respect to threads in other processes may be dependent on the scheduling parameters of their process, which are governed using these functions.

If an implementation supports a two-level scheduling model in which library threads are multiplexed on top of several kernel-scheduled entities, then the underlying kernel-scheduled entities for the system contention scope threads shall not be affected by these functions.

The underlying kernel-scheduled entities for the process contention scope threads shall have their scheduling policy and associated scheduling parameters changed to the values specified in *policy* and *param*, respectively. Kernel scheduled entities for use by process contention scope threads that are created after this call completes shall inherit their scheduling policy and associated scheduling parameters from the process.

This function is not atomic with respect to other threads in the process. Threads may continue to execute while this function call is in the process of changing the scheduling policy and associated scheduling parameters for the underlying kernel-scheduled entities used by the process contention scope threads.

RETURN VALUE

Upon successful completion, the function shall return the former scheduling policy of the specified process. If the *sched_setscheduler*( ) function fails to complete successfully, the policy and scheduling paramenters shall remain unchanged, and the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *sched_setscheduler*( ) function shall fail if:

[EINVAL]	The value of the *policy* parameter is invalid, or one or more of the parameters contained in *param* is outside the valid range for the specified scheduling policy.
[EPERM]	The requesting process does not have permission to set either or both of the scheduling parameters or the scheduling policy of the specified process.
[ESRCH]	No process can be found corresponding to that specified by *pid*.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *sched_setscheduler*( ) function is marked as part of the Process Scheduling option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Process Scheduling option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the effect of this function on a thread's scheduling parameters is added.
- Sections describing two-level scheduling and atomicity of the function are added.

The SCHED_SPORADIC scheduling policy is added for alignment with IEEE Std 1003.1d-1999.

NAME

sched_yield — yield processor

SYNOPSIS

PS|THR
```
#include <sched.h>

int sched_yield(void);
```

DESCRIPTION

The *sched_yield*( ) function shall force the running thread to relinquish the processor until it again becomes the head of its thread list. It takes no arguments.

RETURN VALUE

The *sched_yield*( ) function shall return 0 if it completes successfully; otherwise, it shall return a value of −1 and set *errno* to indicate the error.

ERRORS

No errors are defined.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Issue 6

The *sched_yield*( ) function is now marked as part of the Process Scheduling and Threads options.

NAME

seed48 — seed uniformly distributed pseudo-random non-negative long integer generator

SYNOPSIS

XSI
```
#include <stdlib.h>

unsigned short *seed48(unsigned short seed16v[3]);
```

DESCRIPTION

Refer to *drand48*( ).

NAME

seekdir — set position of directory stream

SYNOPSIS

XSI
```
#include <dirent.h>

void seekdir(DIR *dirp, long loc);
```

DESCRIPTION

The *seekdir*( ) function shall set the position of the next *readdir*( ) operation on the directory stream specified by *dirp* to the position specified by *loc*. The value of *loc* should have been returned from an earlier call to *telldir*( ). The new position reverts to the one associated with the directory stream when *telldir*( ) was performed.

If the value of *loc* was not obtained from an earlier call to *telldir*( ), or if a call to *rewinddir*( ) occurred between the call to *telldir*( ) and the call to *seekdir*( ), the results of subsequent calls to *readdir*( ) are unspecified.

RETURN VALUE

The *seekdir*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The original standard developers perceived that there were restrictions on the use of the *seekdir*( ) and *telldir*( ) functions related to implementation details, and for that reason these functions need not be supported on all POSIX-conforming systems. They are required on implementations supporting the XSI extension.

One of the perceived problems of implementation is that returning to a given point in a directory is quite difficult to describe formally, in spite of its intuitive appeal, when systems that use B-trees, hashing functions, or other similar mechanisms to order their directories are considered. The definition of *seekdir*( ) and *telldir*( ) does not specify whether, when using these interfaces, a given directory entry will be seen at all, or more than once.

On systems not supporting these functions, their capability can sometimes be accomplished by saving a filename found by *readdir*( ) and later using *rewinddir*( ) and a loop on *readdir*( ) to relocate the position from which the filename was saved.

FUTURE DIRECTIONS

None.

SEE ALSO

opendir( ), *readdir*( ), *telldir*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<dirent.h>**, **<stdio.h>**, **<sys/types.h>**

CHANGE HISTORY

First released in Issue 2.

Issue 6

In the SYNOPSIS, the inclusion of **<sys/types.h>** is no longer required.

NAME

select — synchronous I/O multiplexing

SYNOPSIS

```
#include <sys/time.h>

int select(int nfds, fd_set *restrict readfds,
    fd_set *restrict writefds, fd_set *restrict errorfds,
    struct timeval *restrict timeout);
```

DESCRIPTION

Refer to *pselect*( ).

NAME

sem_close — close a named semaphore (**REALTIME**)

SYNOPSIS

SEM

```
#include <semaphore.h>

int sem_close(sem_t *sem);
```

DESCRIPTION

The *sem_close*( ) function shall indicate that the calling process is finished using the named semaphore indicated by *sem*. The effects of calling *sem_close*( ) for an unnamed semaphore (one created by *sem_init*( )) are undefined. The *sem_close*( ) function shall deallocate (that is, make available for reuse by a subsequent *sem_open*( ) by this process) any system resources allocated by the system for use by this process for this semaphore. The effect of subsequent use of the semaphore indicated by *sem* by this process is undefined. If the semaphore has not been removed with a successful call to *sem_unlink*( ), then *sem_close*( ) has no effect on the state of the semaphore. If the *sem_unlink*( ) function has been successfully invoked for *name* after the most recent call to *sem_open*( ) with O_CREAT for this semaphore, then when all processes that have opened the semaphore close it, the semaphore is no longer accessible.

RETURN VALUE

Upon successful completion, a value of zero shall be returned. Otherwise, a value of −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *sem_close*( ) function shall fail if:

[EINVAL]	The *sem* argument is not a valid semaphore descriptor.

EXAMPLES

None.

APPLICATION USAGE

The *sem_close*( ) function is part of the Semaphores option and need not be available on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

semctl( ), *semget*( ), *semop*( ), *sem_init*( ), *sem_open*( ), *sem_unlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<semaphore.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *sem_close*( ) function is marked as part of the Semaphores option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Semaphores option.

NAME

sem_destroy — destroy an unnamed semaphore (**REALTIME**)

SYNOPSIS

SEM
```
#include <semaphore.h>

int sem_destroy(sem_t *sem);
```

DESCRIPTION

The *sem_destroy*( ) function shall destroy the unnamed semaphore indicated by *sem*. Only a semaphore that was created using *sem_init*( ) may be destroyed using *sem_destroy*( ); the effect of calling *sem_destroy*( ) with a named semaphore is undefined. The effect of subsequent use of the semaphore *sem* is undefined until *sem* is reinitialized by another call to *sem_init*( ).

It is safe to destroy an initialized semaphore upon which no threads are currently blocked. The effect of destroying a semaphore upon which other threads are currently blocked is undefined.

RETURN VALUE

Upon successful completion, a value of zero shall be returned. Otherwise, a value of −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *sem_destroy*( ) function shall fail if:

[EINVAL]	The *sem* argument is not a valid semaphore.

The *sem_destroy*( ) function may fail if:

[EBUSY]	There are currently processes blocked on the semaphore.

EXAMPLES

None.

APPLICATION USAGE

The *sem_destroy*( ) function is part of the Semaphores option and need not be available on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

semctl( ), *semget*( ), *semop*( ), *sem_init*( ), *sem_open*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<semaphore.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *sem_destroy*( ) function is marked as part of the Semaphores option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Semaphores option.

NAME

sem_getvalue — get the value of a semaphore (**REALTIME**)

SYNOPSIS

SEM
```
#include <semaphore.h>

int sem_getvalue(sem_t *restrict sem, int *restrict sval);
```

DESCRIPTION

The *sem_getvalue*( ) function shall update the location referenced by the *sval* argument to have the value of the semaphore referenced by *sem* without affecting the state of the semaphore. The updated value represents an actual semaphore value that occurred at some unspecified time during the call, but it need not be the actual value of the semaphore when it is returned to the calling process.

If *sem* is locked, then the value returned by *sem_getvalue*( ) is either zero or a negative number whose absolute value represents the number of processes waiting for the semaphore at some unspecified time during the call.

RETURN VALUE

Upon successful completion, the *sem_getvalue*( ) function shall return a value of zero. Otherwise, it shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *sem_getvalue*( ) function shall fail if:

[EINVAL]	The *sem* argument does not refer to a valid semaphore.

EXAMPLES

None.

APPLICATION USAGE

The *sem_getvalue*( ) function is part of the Semaphores option and need not be available on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

semctl( ), *semget*( ), *semop*( ), *sem_post*( ), *sem_timedwait*( ), *sem_trywait*( ), *sem_wait*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<semaphore.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *sem_getvalue*( ) function is marked as part of the Semaphores option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Semaphores option.

The *sem_timedwait*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

The **restrict** keyword is added to the *sem_getvalue*( ) prototype for alignment with the ISO/IEC 9899: 1999 standard.

NAME

sem_init — initialize an unnamed semaphore (**REALTIME**)

SYNOPSIS

SEM

```
#include <semaphore.h>

int sem_init(sem_t *sem, int pshared, unsigned value);
```

DESCRIPTION

The *sem_init*( ) function shall initialize the unnamed semaphore referred to by *sem*. The value of the initialized semaphore shall be *value*. Following a successful call to *sem_init*( ), the semaphore may be used in subsequent calls to *sem_wait*( ), *sem_trywait*( ), *sem_post*( ), and *sem_destroy*( ). This semaphore shall remain usable until the semaphore is destroyed.

If the *pshared* argument has a non-zero value, then the semaphore is shared between processes; in this case, any process that can access the semaphore *sem* can use *sem* for performing *sem_wait*( ), *sem_trywait*( ), *sem_post*( ), and *sem_destroy*( ) operations.

Only *sem* itself may be used for performing synchronization. The result of referring to copies of *sem* in calls to *sem_wait*( ), *sem_trywait*( ), *sem_post*( ), and *sem_destroy*( ), is undefined.

If the *pshared* argument is zero, then the semaphore is shared between threads of the process; any thread in this process can use *sem* for performing *sem_wait*( ), *sem_trywait*( ), *sem_post*( ), and *sem_destroy*( ) operations. The use of the semaphore by threads other than those created in the same process is undefined.

Attempting to initialize an already initialized semaphore results in undefined behavior.

RETURN VALUE

Upon successful completion, the *sem_init*( ) function shall initialize the semaphore in *sem*. Otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *sem_init*( ) function shall fail if:

[EINVAL]	The *value* argument exceeds {SEM_VALUE_MAX}.
[ENOSPC]	A resource required to initialize the semaphore has been exhausted, or the limit on semaphores ({SEM_NSEMS_MAX}) has been reached.
[EPERM]	The process lacks the appropriate privileges to initialize the semaphore.

EXAMPLES

None.

APPLICATION USAGE

The *sem_init*( ) function is part of the Semaphores option and need not be available on all implementations.

RATIONALE

Although this volume of IEEE Std 1003.1-200x fails to specify a successful return value, it is likely that a later version may require the implementation to return a value of zero if the call to *sem_init*( ) is successful.

FUTURE DIRECTIONS

None.

SEE ALSO

sem_destroy( ), *sem_post*( ), *sem_timedwait*( ), *sem_trywait*( ), *sem_wait*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<semaphore.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *sem_init*( ) function is marked as part of the Semaphores option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Semaphores option.

The *sem_timedwait*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

NAME

sem_open — initialize and open a named semaphore (**REALTIME**)

SYNOPSIS

SEM
```
#include <semaphore.h>

sem_t *sem_open(const char *name, int oflag, ...);
```

DESCRIPTION

The *sem_open*( ) function shall establish a connection between a named semaphore and a process. Following a call to *sem_open*( ) with semaphore name *name*, the process may reference the semaphore associated with *name* using the address returned from the call. This semaphore may be used in subsequent calls to *sem_wait*( ), *sem_trywait*( ), *sem_post*( ), and *sem_close*( ). The semaphore remains usable by this process until the semaphore is closed by a successful call to *sem_close*( ), *_exit*( ), or one of the *exec* functions.

The *oflag* argument controls whether the semaphore is created or merely accessed by the call to *sem_open*( ). The following flag bits may be set in *oflag*:

O_CREAT	This flag is used to create a semaphore if it does not already exist. If O_CREAT is set and the semaphore already exists, then O_CREAT has no effect, except as noted under O_EXCL. Otherwise, *sem_open*( ) creates a named semaphore. The O_CREAT flag requires a third and a fourth argument: *mode*, which is of type **mode_t**, and *value*, which is of type **unsigned**. The semaphore is created with an initial value of *value*. Valid initial values for semaphores are less than or equal to {SEM_VALUE_MAX}. The user ID of the semaphore is set to the effective user ID of the process; the group ID of the semaphore is set to a system default group ID or to the effective group ID of the process. The permission bits of the semaphore are set to the value of the *mode* argument except those set in the file mode creation mask of the process. When bits in *mode* other than the file permission bits are specified, the effect is unspecified. After the semaphore named *name* has been created by *sem_open*( ) with the O_CREAT flag, other processes can connect to the semaphore by calling *sem_open*( ) with the same value of *name*.
O_EXCL	If O_EXCL and O_CREAT are set, *sem_open*( ) fails if the semaphore *name* exists. The check for the existence of the semaphore and the creation of the semaphore if it does not exist are atomic with respect to other processes executing *sem_open*( ) with O_EXCL and O_CREAT set. If O_EXCL is set and O_CREAT is not set, the effect is undefined. If flags other than O_CREAT and O_EXCL are specified in the *oflag* parameter, the effect is unspecified.

The *name* argument points to a string naming a semaphore object. It is unspecified whether the name appears in the file system and is visible to functions that take pathnames as arguments. The *name* argument conforms to the construction rules for a pathname. If *name* begins with the slash character, then processes calling *sem_open*( ) with the same value of *name* shall refer to the same semaphore object, as long as that name has not been removed. If *name* does not begin with the slash character, the effect is implementation-defined. The interpretation of slash characters other than the leading slash character in *name* is implementation-defined.

If a process makes multiple successful calls to *sem_open*( ) with the same value for *name*, the same semaphore address shall be returned for each such successful call, provided that there have been no calls to *sem_unlink*( ) for this semaphore.

References to copies of the semaphore produce undefined results.

RETURN VALUE

Upon successful completion, the *sem_open*( ) function shall return the address of the semaphore. Otherwise, it shall return a value of SEM_FAILED and set *errno* to indicate the error. The symbol SEM_FAILED is defined in the **<semaphore.h>** header. No successful return from *sem_open*( ) shall return the value SEM_FAILED.

ERRORS

If any of the following conditions occur, the *sem_open*( ) function shall return SEM_FAILED and set *errno* to the corresponding value:

[EACCES]	The named semaphore exists and the permissions specified by *oflag* are denied, or the named semaphore does not exist and permission to create the named semaphore is denied.
[EEXIST]	O_CREAT and O_EXCL are set and the named semaphore already exists.
[EINTR]	The *sem_open*( ) operation was interrupted by a signal.
[EINVAL]	The *sem_open*( ) operation is not supported for the given name, or O_CREAT was specified in *oflag* and *value* was greater than {SEM_VALUE_MAX}.
[EMFILE]	Too many semaphore descriptors or file descriptors are currently in use by this process.
[ENAMETOOLONG]	The length of the *name* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENFILE]	Too many semaphores are currently open in the system.
[ENOENT]	O_CREAT is not set and the named semaphore does not exist.
[ENOSPC]	There is insufficient space for the creation of the new named semaphore.

EXAMPLES

None.

APPLICATION USAGE

The *sem_open*( ) function is part of the Semaphores option and need not be available on all implementations.

RATIONALE

An earlier version of this volume of IEEE Std 1003.1-200x required an error return value of −1 with the type **sem_t *** for the *sem_open*( ) function, which is not guaranteed to be portable across implementations. The revised text provides the symbolic error code SEM_FAILED to eliminate the type conflict.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *sem_open*( ) function is marked as part of the Semaphores option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Semaphores option.

The *sem_timedwait*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

NAME

sem_post — unlock a semaphore (**REALTIME**)

SYNOPSIS

SEM
```
#include <semaphore.h>

int sem_post(sem_t *sem);
```

DESCRIPTION

The *sem_post*( ) function shall unlock the semaphore referenced by *sem* by performing a semaphore unlock operation on that semaphore.

If the semaphore value resulting from this operation is positive, then no threads were blocked waiting for the semaphore to become unlocked; the semaphore value is simply incremented.

If the value of the semaphore resulting from this operation is zero, then one of the threads blocked waiting for the semaphore shall be allowed to return successfully from its call to *sem_wait*( ). PS If the Process Scheduling option is supported, the thread to be unblocked shall be chosen in a manner appropriate to the scheduling policies and parameters in effect for the blocked threads. In the case of the schedulers SCHED_FIFO and SCHED_RR, the highest priority waiting thread shall be unblocked, and if there is more than one highest priority thread blocked waiting for the semaphore, then the highest priority thread that has been waiting the longest shall be unblocked. If the Process Scheduling option is not defined, the choice of a thread to unblock is unspecified.

SS If the Process Sporadic Server option is supported, and the scheduling policy is SCHED_SPORADIC, the semantics are as per SCHED_FIFO above.

The *sem_post*( ) function shall be reentrant with respect to signals and may be invoked from a signal-catching function.

RETURN VALUE

If successful, the *sem_post*( ) function shall return zero; otherwise, the function shall return −1 and set *errno* to indicate the error.

ERRORS

The *sem_post*( ) function shall fail if:

[EINVAL]	The *sem* argument does not refer to a valid semaphore.

EXAMPLES

None.

APPLICATION USAGE

The *sem_post*( ) function is part of the Semaphores option and need not be available on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *sem_post*( ) function is marked as part of the Semaphores option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Semaphores option.

The *sem_timedwait*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

SCHED_SPORADIC is added to the list of scheduling policies for which the thread that is to be unblocked is specified for alignment with IEEE Std 1003.1d-1999.

NAME

sem_timedwait — lock a semaphore (**ADVANCED REALTIME**)

SYNOPSIS

SEM TMO

```
#include <semaphore.h>
#include <time.h>

int sem_timedwait(sem_t *restrict sem,
    const struct timespec *restrict abs_timeout);

```

DESCRIPTION

The *sem_timedwait*( ) function shall lock the semaphore referenced by *sem* as in the *sem_wait*( ) function. However, if the semaphore cannot be locked without waiting for another process or thread to unlock the semaphore by performing a *sem_post*( ) function, this wait shall be terminated when the specified timeout expires.

The timeout shall expire when the absolute time specified by *abs_timeout* passes, as measured by the clock on which timeouts are based (that is, when the value of that clock equals or exceeds *abs_timeout*), or if the absolute time specified by *abs_timeout* has already been passed at the time of the call.

TMR If the Timers option is supported, the timeout shall be based on the CLOCK_REALTIME clock. If the Timers option is not supported, the timeout shall be based on the system clock as returned by the *time*( ) function. The resolution of the timeout shall be the resolution of the clock on which it is based. The **timespec** data type is defined as a structure in the **<time.h>** header. |

Under no circumstance shall the function fail with a timeout if the semaphore can be locked immediately. The validity of the *abs_timeout* need not be checked if the semaphore can be locked immediately.

RETURN VALUE

The *sem_timedwait*( ) function shall return zero if the calling process successfully performed the semaphore lock operation on the semaphore designated by *sem*. If the call was unsuccessful, the state of the semaphore shall be unchanged, and the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *sem_timedwait*( ) function shall fail if:

[EINVAL]	The *sem* argument does not refer to a valid semaphore.
[EINVAL]	The process or thread would have blocked, and the *abs_timeout* parameter specified a nanoseconds field value less than zero or greater than or equal to 1 000 million.
[ETIMEDOUT]	The semaphore could not be locked before the specified timeout expired.

The *sem_timedwait*( ) function may fail if:

[EDEADLK]	A deadlock condition was detected.
[EINTR]	A signal interrupted this function.

EXAMPLES

None.

APPLICATION USAGE

Applications using these functions may be subject to priority inversion, as discussed in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.285, Priority Inversion.

The *sem_timedwait*( ) function is part of the Semaphores and Timeouts options and need not be provided on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

sem_post( ), *sem_trywait*( ), *sem_wait*( ), *semctl*( ), *semget*( ), *semop*( ), *time*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<semaphore.h>**, **<time.h>**

CHANGE HISTORY

First released in Issue 6. Derived from IEEE Std 1003.1d-1999.

NAME

sem_trywait, sem_wait — lock a semaphore (**REALTIME**)

SYNOPSIS

SEM

```
#include <semaphore.h>

int sem_trywait(sem_t *sem);
int sem_wait(sem_t *sem);
```

DESCRIPTION

The *sem_trywait*( ) function shall lock the semaphore referenced by *sem* only if the semaphore is currently not locked; that is, if the semaphore value is currently positive. Otherwise, shall does not lock the semaphore.

The *sem_wait*( ) function shall lock the semaphore referenced by *sem* by performing a semaphore lock operation on that semaphore. If the semaphore value is currently zero, then the calling thread shall not return from the call to *sem_wait*( ) until it either locks the semaphore or the call is interrupted by a signal.

Upon successful return, the state of the semaphore shall be locked and shall remain locked until the *sem_post*( ) function is executed and returns successfully.

The *sem_wait*( ) function is interruptible by the delivery of a signal.

RETURN VALUE

The *sem_trywait*( ) and *sem_wait*( ) functions shall return zero if the calling process successfully performed the semaphore lock operation on the semaphore designated by *sem*. If the call was unsuccessful, the state of the semaphore shall be unchanged, and the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *sem_trywait*( ) and *sem_wait*( ) functions shall fail if:

[EAGAIN]	The semaphore was already locked, so it cannot be immediately locked by the *sem_trywait*( ) operation (*sem_trywait*( ) only).
[EINVAL]	The *sem* argument does not refer to a valid semaphore.

The *sem_trywait*( ) and *sem_wait*( ) functions may fail if:

[EDEADLK]	A deadlock condition was detected.
[EINTR]	A signal interrupted this function.

EXAMPLES

None.

APPLICATION USAGE

Applications using these functions may be subject to priority inversion, as discussed in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.285, Priority Inversion.

The *sem_trywait*( ) and *sem_wait*( ) functions are part of the Semaphores option and need not be provided on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *sem_trywait*( ) and *sem_wait*( ) functions are marked as part of the Semaphores option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Semaphores option.

The *sem_timedwait*( ) function is added to the SEE ALSO section for alignment with IEEE Std 1003.1d-1999.

NAME

sem_unlink — remove a named semaphore (**REALTIME**)

SYNOPSIS

SEM

```
#include <semaphore.h>

int sem_unlink(const char *name);
```

DESCRIPTION

The *sem_unlink*( ) function shall remove the semaphore named by the string *name*. If the semaphore named by *name* is currently referenced by other processes, then *sem_unlink*( ) shall have no effect on the state of the semaphore. If one or more processes have the semaphore open when *sem_unlink*( ) is called, destruction of the semaphore is postponed until all references to the semaphore have been destroyed by calls to *sem_close*( ), *_exit*( ), or *exec*. Calls to *sem_open*( ) to recreate or reconnect to the semaphore refer to a new semaphore after *sem_unlink*( ) is called. The *sem_unlink*( ) call shall not block until all references have been destroyed; it shall return immediately. |

RETURN VALUE

Upon successful completion, the *sem_unlink*( ) function shall return a value of 0. Otherwise, the semaphore shall not be changed and the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *sem_unlink*( ) function shall fail if:

[EACCES]	Permission is denied to unlink the named semaphore.
[ENAMETOOLONG]	The length of the *name* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}. |
[ENOENT]	The named semaphore does not exist.

EXAMPLES

None.

APPLICATION USAGE

The *sem_unlink*( ) function is part of the Semaphores option and need not be available on all implementations.

RATIONALE

None.

FUTURE DIRECTIONS

NAME

sem_wait — lock a semaphore (**REALTIME**)

SYNOPSIS

SEM

```
#include <semaphore.h>

int sem_wait(sem_t *sem);
```

DESCRIPTION

Refer to *sem_trywait*( ).

NAME

semctl — XSI semaphore control operations

SYNOPSIS

XSI

```
#include <sys/sem.h>

int semctl(int semid, int semnum, int cmd, ...);
```

DESCRIPTION

The *semctl*( ) function operates on XSI semaphores (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.15, Semaphore). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *semctl*( ) function provides a variety of semaphore control operations as specified by *cmd*. The fourth argument is optional and depends upon the operation requested. If required, it is of type **union semun**, which the application shall explicitly declare:

```
union semun {
    int val;
    struct semid_ds *buf;
    unsigned short  *array;
} arg;
```

The following semaphore control operations as specified by *cmd* are executed with respect to the semaphore specified by *semid* and *semnum*. The level of permission required for each operation is shown with each command; see Section 2.7 (on page 489). The symbolic names for the values of *cmd* are defined in the **<sys/sem.h>** header:

GETVAL	Return the value of *semval*; see **<sys/sem.h>**. Requires read permission.
SETVAL	Set the value of *semval* to *arg.val*, where *arg* is the value of the fourth argument to *semctl*( ). When this command is successfully executed, the *semadj* value corresponding to the specified semaphore in all processes is cleared. Requires alter permission; see Section 2.7 (on page 489).
GETPID	Return the value of *sempid*. Requires read permission.
GETNCNT	Return the value of *semncnt*. Requires read permission.
GETZCNT	Return the value of *semzcnt*. Requires read permission.

The following values of *cmd* operate on each *semval* in the set of semaphores:

GETALL	Return the value of *semval* for each semaphore in the semaphore set and place into the array pointed to by *arg.array*, where *arg* is the fourth argument to *semctl*( ). Requires read permission.
SETALL	Set the value of *semval* for each semaphore in the semaphore set according to the array pointed to by *arg.array*, where *arg* is the fourth argument to *semctl*( ). When this command is successfully executed, the *semadj* values corresponding to each specified semaphore in all processes are cleared. Requires alter permission.

The following values of *cmd* are also available:

IPC_STAT	Place the current value of each member of the **semid_ds** data structure associated with *semid* into the structure pointed to by *arg.buf*, where *arg* is the fourth argument to *semctl*( ). The contents of this structure are defined in

	<sys/sem.h>. Requires read permission.

IPC_SET	Set the value of the following members of the **semid_ds** data structure associated with *semid* to the corresponding value found in the structure pointed to by *arg.buf*, where *arg* is the fourth argument to *semctl*( ):
	`sem_perm.uid`
	`sem_perm.gid`
	`sem_perm.mode`
	The mode bits specified in Section 2.7.1 (on page 490) are copied into the corresponding bits of the *sem_perm.mode* associated with *semid*. The stored values of any other bits are unspecified.
	This command can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of *sem_perm.cuid* or *sem_perm.uid* in the **semid_ds** data structure associated with *semid*.

IPC_RMID	Remove the semaphore identifier specified by *semid* from the system and destroy the set of semaphores and **semid_ds** data structure associated with it. This command can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of *sem_perm.cuid* or *sem_perm.uid* in the **semid_ds** data structure associated with *semid*.

RETURN VALUE

If successful, the value returned by *semctl*( ) depends on *cmd* as follows:

GETVAL	The value of *semval*.
GETPID	The value of *sempid*.
GETNCNT	The value of *semncnt*.
GETZCNT	The value of *semzcnt*.
All others	0.

Otherwise, *semctl*( ) shall return −1 and set *errno* to indicate the error.

ERRORS

The *semctl*( ) function shall fail if:

[EACCES]	Operation permission is denied to the calling process; see Section 2.7 (on page 489).
[EINVAL]	The value of *semid* is not a valid semaphore identifier, or the value of *semnum* is less than 0 or greater than or equal to *sem_nsems*, or the value of *cmd* is not a valid command.
[EPERM]	The argument *cmd* is equal to IPC_RMID or IPC_SET and the effective user ID of the calling process is not equal to that of a process with appropriate privileges and it is not equal to the value of *sem_perm.cuid* or *sem_perm.uid* in the data structure associated with *semid*.
[ERANGE]	The argument *cmd* is equal to SETVAL or SETALL and the value to which *semval* is to be set is greater than the system-imposed maximum.

EXAMPLES

None.

APPLICATION USAGE

The fourth parameter in the SYNOPSIS section is now specified as `"..."` in order to avoid a clash with the ISO C standard when referring to the union *semun* (as defined in Issue 3) and for backward compatibility.

The POSIX Realtime Extension defines alternative interfaces for interprocess communication. Application developers who need to use IPC should design their applications so that modules using the IPC routines described in Section 2.7 (on page 489) can be easily modified to use the alternative interfaces.

Issue 5

The note about use of POSIX Realtime Extension IPC routines has been moved from FUTURE DIRECTIONS to the APPLICATION USAGE section.

NAME

semget — get set of XSI semaphores

SYNOPSIS

XSI

```
#include <sys/sem.h>

int semget(key_t key, int nsems, int semflg);
```

DESCRIPTION

The *semget*( ) function operates on XSI semaphores (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.15, Semaphore). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *semget*( ) function shall return the semaphore identifier associated with *key*.

A semaphore identifier with its associated **semid_ds** data structure and its associated set of *nsems* semaphores (see **<sys/sem.h>**) is created for *key* if one of the following is true:

- The argument *key* is equal to IPC_PRIVATE.
- The argument *key* does not already have a semaphore identifier associated with it and (*semflg* &IPC_CREAT) is non-zero.

Upon creation, the **semid_ds** data structure associated with the new semaphore identifier is initialized as follows:

- In the operation permissions structure *sem_perm.cuid*, *sem_perm.uid*, *sem_perm.cgid*, and *sem_perm.gid* shall be set equal to the effective user ID and effective group ID, respectively, of the calling process.
- The low-order 9 bits of *sem_perm.mode* shall be set equal to the low-order 9 bits of *semflg*.
- The variable *sem_nsems* shall be set equal to the value of *nsems*.
- The variable *sem_otime* shall be set equal to 0 and *sem_ctime* shall be set equal to the current time.
- The data structure associated with each semaphore in the set shall not be initialized. The *semctl*( ) function with the command SETVAL or SETALL can be used to initialize each semaphore.

RETURN VALUE

Upon successful completion, *semget*( ) shall return a non-negative integer, namely a semaphore identifier; otherwise, it shall return –1 and set *errno* to indicate the error.

ERRORS

The *semget*( ) function shall fail if:

[EACCES]	A semaphore identifier exists for *key*, but operation permission as specified by the low-order 9 bits of *semflg* would not be granted; see Section 2.7 (on page 489).
[EEXIST]	A semaphore identifier exists for the argument *key* but ((*semflg* &IPC_CREAT) &&(*semflg* &IPC_EXCL)) is non-zero.
[EINVAL]	The value of *nsems* is either less than or equal to 0 or greater than the system-imposed limit, or a semaphore identifier exists for the argument *key*, but the number of semaphores in the set associated with it is less than *nsems* and *nsems* is not equal to 0.

[ENOENT]	A semaphore identifier does not exist for the argument *key* and (*semflg* &IPC_CREAT) is equal to 0.
[ENOSPC]	A semaphore identifier is to be created but the system-imposed limit on the maximum number of allowed semaphores system-wide would be exceeded.

EXAMPLES

Creating a Semaphore Identifier

The following example gets a unique semaphore key using the *ftok*( ) function, then gets a semaphore ID associated with that key using the *semget*( ) function (the first call also tests to make sure the semaphore exists). If the semaphore does not exist, the program creates it, as shown by the second call to *semget*( ). In creating the semaphore for the queuing process, the program attempts to create one semaphore with read/write permission for all. It also uses the IPC_EXCL flag, which forces *semget*( ) to fail if the semaphore already exists.

After creating the semaphore, the program uses a call to *semop*( ) to initialize it to the values in the *sbuf* array. The number of processes that can execute concurrently without queuing is initially set to 2. The final call to *semget*( ) creates a semaphore identifier that can be used later in the program.

```
#include <sys/types.h>
#include <stdio.h>
#include <sys/ipc.h>
#include <sys/sem.h>
#include <sys/stat.h>
#include <errno.h>
#include <unistd.h>
#include <stdlib.h>
#include <pwd.h>
#include <fcntl.h>
#include <limits.h>
...
key_t semkey;
int semid, pfd, fv;
struct sembuf sbuf;
char *lgn;
char filename[PATH_MAX+1];
struct stat outstat;
struct passwd *pw;
...
/* Get unique key for semaphore. */
if ((semkey = ftok("/tmp", 'a')) == (key_t) -1) {
    perror("IPC error: ftok"); exit(1);
}

/* Get semaphore ID associated with this key. */
if ((semid = semget(semkey, 0, 0)) == -1) {

    /* Semaphore does not exist - Create. */
    if ((semid = semget(semkey, 1, IPC_CREAT | IPC_EXCL | S_IRUSR |
        S_IWUSR | S_IRGRP | S_IWGRP | S_IROTH | S_IWOTH)) != -1)
    {
        /* Initialize the semaphore. */
        sbuf.sem_num = 0;
```

```
                sbuf.sem_op = 2;  /* This is the number of runs without queuing. */
                sbuf.sem_flg = 0;
                if (semop(semid, &sbuf, 1) == -1) {
                    perror("IPC error: semop"); exit(1);
                }
            }
            else if (errno == EEXIST) {
                if ((semid = semget(semkey, 0, 0)) == -1) {
                    perror("IPC error 1: semget"); exit(1);
                }
            }
            else {
                perror("IPC error 2: semget"); exit(1);
            }
        }
        ...
```

APPLICATION USAGE

The POSIX Realtime Extension defines alternative interfaces for interprocess communication. Application developers who need to use IPC should design their applications so that modules using the IPC routines described in Section 2.7 (on page 489) can be easily modified to use the alternative interfaces.

NAME

semop — XSI semaphore operations

SYNOPSIS

XSI

```
#include <sys/sem.h>

int semop(int semid, struct sembuf *sops, size_t nsops);
```

DESCRIPTION

The *semop*( ) function operates on XSI semaphores (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.15, Semaphore). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *semop*( ) function shall perform atomically a user-defined array of semaphore operations on the set of semaphores associated with the semaphore identifier specified by the argument *semid*.

The argument *sops* is a pointer to a user-defined array of semaphore operation structures. The implementation shall not modify elements of this array unless the application uses implementation-defined extensions.

The argument *nsops* is the number of such structures in the array.

Each structure, **sembuf**, includes the following members:

Member Type	Member Name	Description
short	*sem_num*	Semaphore number.
short	*sem_op*	Semaphore operation.
short	*sem_flg*	Operation flags.

Each semaphore operation specified by *sem_op* is performed on the corresponding semaphore specified by *semid* and *sem_num*.

The variable *sem_op* specifies one of three semaphore operations:

1. If *sem_op* is a negative integer and the calling process has alter permission, one of the following shall occur:
   - If *semval*(see **<sys/sem.h>**) is greater than or equal to the absolute value of *sem_op*, the absolute value of *sem_op* is subtracted from *semval*. Also, if (*sem_flg* &SEM_UNDO) is non-zero, the absolute value of *sem_op* shall be added to the calling process' *semadj* value for the specified semaphore.
   - If *semval* is less than the absolute value of *sem_op* and (*sem_flg* &IPC_NOWAIT) is non-zero, *semop*( ) shall return immediately.
   - If *semval* is less than the absolute value of *sem_op* and (*sem_flg* &IPC_NOWAIT) is 0, *semop*( ) shall increment the *semncnt* associated with the specified semaphore and suspend execution of the calling thread until one of the following conditions occurs:
     - — The value of *semval* becomes greater than or equal to the absolute value of *sem_op*. When this occurs, the value of *semncnt* associated with the specified semaphore shall be decremented, the absolute value of *sem_op* shall be subtracted from *semval* and, if (*sem_flg* &SEM_UNDO) is non-zero, the absolute value of *sem_op* shall be added to the calling process' *semadj* value for the specified semaphore.
     - — The *semid* for which the calling thread is awaiting action is removed from the system. When this occurs, *errno* shall be set equal to [EIDRM] and −1 shall be

returned.

- — The calling thread receives a signal that is to be caught. When this occurs, the value of *semncnt* associated with the specified semaphore shall be decremented, and the calling thread shall resume execution in the manner prescribed in *sigaction*( ).

2. If *sem_op* is a positive integer and the calling process has alter permission, the value of *sem_op* shall be added to *semval* and, if (*sem_flg* &SEM_UNDO) is non-zero, the value of *sem_op* shall be subtracted from the calling process' *semadj* value for the specified semaphore.

3. If *sem_op* is 0 and the calling process has read permission, one of the following shall occur:

   - If *semval* is 0, *semop*( ) shall return immediately.
   - If *semval* is non-zero and (*sem_flg* &IPC_NOWAIT) is non-zero, *semop*( ) shall return immediately.
   - If *semval* is non-zero and (*sem_flg* &IPC_NOWAIT) is 0, *semop*( ) shall increment the *semzcnt* associated with the specified semaphore and suspend execution of the calling thread until one of the following occurs:
     - — The value of *semval* becomes 0, at which time the value of *semzcnt* associated with the specified semaphore shall be decremented.
     - — The *semid* for which the calling thread is awaiting action is removed from the system. When this occurs, *errno* shall be set equal to [EIDRM] and −1 shall be returned.
     - — The calling thread receives a signal that is to be caught. When this occurs, the value of *semzcnt* associated with the specified semaphore shall be decremented, and the calling thread shall resume execution in the manner prescribed in *sigaction*( ).

Upon successful completion, the value of *sempid* for each semaphore specified in the array pointed to by *sops* shall be set equal to the process ID of the calling process.

RETURN VALUE

Upon successful completion, *semop*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *semop*( ) function shall fail if:

[E2BIG]	The value of *nsops* is greater than the system-imposed maximum.
[EACCES]	Operation permission is denied to the calling process; see Section 2.7 (on page 489).
[EAGAIN]	The operation would result in suspension of the calling process but (*sem_flg* &IPC_NOWAIT) is non-zero.
[EFBIG]	The value of *sem_num* is less than 0 or greater than or equal to the number of semaphores in the set associated with *semid*.
[EIDRM]	The semaphore identifier *semid* is removed from the system.
[EINTR]	The *semop*( ) function was interrupted by a signal.
[EINVAL]	The value of *semid* is not a valid semaphore identifier, or the number of individual semaphores for which the calling process requests a SEM_UNDO would exceed the system-imposed limit.

[ENOSPC]	The limit on the number of individual processes requesting a SEM_UNDO would be exceeded.
[ERANGE]	An operation would cause a *semval* to overflow the system-imposed limit, or an operation would cause a *semadj* value to overflow the system-imposed limit.

EXAMPLES

Setting Values in Semaphores

The following example sets the values of the two semaphores associated with the *semid* identifier to the values contained in the *sb* array.

```
#include <sys/sem.h>
...
int semid;
struct sembuf sb[2];
int nsops = 2;
int result;

/* Adjust value of semaphore in the semaphore array semid. */
sb[0].sem_num = 0;
sb[0].sem_op = -1;
sb[0].sem_flg = SEM_UNDO | IPC_NOWAIT;
sb[1].sem_num = 1;
sb[1].sem_op =  1;
sb[1].sem_flg = 0;

result = semop(semid, sb, nsops);
```

Creating a Semaphore Identifier

The following example gets a unique semaphore key using the *ftok*( ) function, then gets a semaphore ID associated with that key using the *semget*( ) function (the first call also tests to make sure the semaphore exists). If the semaphore does not exist, the program creates it, as shown by the second call to *semget*( ). In creating the semaphore for the queuing process, the program attempts to create one semaphore with read/write permission for all. It also uses the IPC_EXCL flag, which forces *semget*( ) to fail if the semaphore already exists.

After creating the semaphore, the program uses a call to *semop*( ) to initialize it to the values in the *sbuf* array. The number of processes that can execute concurrently without queuing is initially set to 2. The final call to *semget*( ) creates a semaphore identifier that can be used later in the program.

The final call to *semop*( ) acquires the semaphore and waits until it is free; the SEM_UNDO option releases the semaphore when the process exits, waiting until there are less than two processes running concurrently.

```
#include <sys/types.h>
#include <stdio.h>
#include <sys/ipc.h>
#include <sys/sem.h>
#include <sys/stat.h>
#include <errno.h>
#include <unistd.h>
#include <stdlib.h>
```

```
#include <pwd.h>
#include <fcntl.h>
#include <limits.h>
...
key_t semkey;
int semid, pfd, fv;
struct sembuf sbuf;
char *lgn;
char filename[PATH_MAX+1];
struct stat outstat;
struct passwd *pw;
...
/* Get unique key for semaphore. */
if ((semkey = ftok("/tmp", 'a')) == (key_t) -1) {
    perror("IPC error: ftok"); exit(1);
}

/* Get semaphore ID associated with this key. */
if ((semid = semget(semkey, 0, 0)) == -1) {

    /* Semaphore does not exist - Create. */
    if ((semid = semget(semkey, 1, IPC_CREAT | IPC_EXCL | S_IRUSR |
        S_IWUSR | S_IRGRP | S_IWGRP | S_IROTH | S_IWOTH)) != -1)
    {
        /* Initialize the semaphore. */
        sbuf.sem_num = 0;
        sbuf.sem_op = 2;  /* This is the number of runs without queuing. */
        sbuf.sem_flg = 0;
        if (semop(semid, &sbuf, 1) == -1) {
            perror("IPC error: semop"); exit(1);
        }
    }
    else if (errno == EEXIST) {
        if ((semid = semget(semkey, 0, 0)) == -1) {
            perror("IPC error 1: semget"); exit(1);
        }
    }
    else {
        perror("IPC error 2: semget"); exit(1);
    }
}
...
sbuf.sem_num = 0;
sbuf.sem_op = -1;
sbuf.sem_flg = SEM_UNDO;
if (semop(semid, &sbuf, 1) == -1) {
    perror("IPC Error: semop"); exit(1);
}
```

APPLICATION USAGE

The POSIX Realtime Extension defines alternative interfaces for interprocess communication. The note about use of POSIX Realtime Extension IPC routines has been moved from FUTURE DIRECTIONS to a new APPLICATION USAGE section.

NAME

send — send a message on a socket

SYNOPSIS

```
#include <sys/socket.h>

ssize_t send(int socket, const void *buffer, size_t length, int flags);
```

DESCRIPTION

The *send*( ) function shall initiate transmission of a message from the specified socket to its peer. The *send*( ) function shall send a message only when the socket is connected (including when the peer of a connectionless socket has been set via *connect*( )).

The *send*( ) functions takes the following arguments:

socket	Specifies the socket file descriptor.
buffer	Points to the buffer containing the message to send.
length	Specifies the length of the message in bytes.
flags	Specifies the type of message transmission. Values of this argument are formed by logically OR'ing zero or more of the following flags:

MSG_EOR	Terminates a record (if supported by the protocol).
MSG_OOB	Sends out-of-band data on sockets that support out-of-band communications. The significance and semantics of out-of-band data are protocol-specific.

The length of the message to be sent is specified by the *length* argument. If the message is too long to pass through the underlying protocol, *send*( ) shall fail and no data shall be transmitted.

Successful completion of a call to *send*( ) does not guarantee delivery of the message. A return value of −1 indicates only locally-detected errors.

If space is not available at the sending socket to hold the message to be transmitted, and the socket file descriptor does not have O_NONBLOCK set, *send*( ) shall block until space is available. If space is not available at the sending socket to hold the message to be transmitted, and the socket file descriptor does have O_NONBLOCK set, *send*( ) shall fail. The *select*( ) and *poll*( ) functions can be used to determine when it is possible to send more data.

The socket in use may require the process to have appropriate privileges to use the *send*( ) function.

RETURN VALUE

Upon successful completion, *send*( ) shall return the number of bytes sent. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *send*( ) function shall fail if:

[EAGAIN] or [EWOULDBLOCK]	The socket's file descriptor is marked O_NONBLOCK and the requested operation would block.
[EBADF]	The *socket* argument is not a valid file descriptor.
[ECONNRESET]	A connection was forcibly closed by a peer.
[EDESTADDRREQ]	The socket is not connection-mode and no peer address is set.

[EINTR]	A signal interrupted *send*( ) before any data was transmitted.
[EMSGSIZE]	The message is too large be sent all at once, as the socket requires.
[ENOTCONN]	The socket is not connected or otherwise has not had the peer pre-specified.
[ENOTSOCK]	The *socket* argument does not refer to a socket.
[EOPNOTSUPP]	The *socket* argument is associated with a socket that does not support one or more of the values set in *flags*.
[EPIPE]	The socket is shut down for writing, or the socket is connection-mode and is no longer connected. In the latter case, and if the socket is of type SOCK_STREAM, the SIGPIPE signal is generated to the calling thread.

The *send*( ) function may fail if:

[EACCES]	The calling process does not have the appropriate privileges.
[EIO]	An I/O error occurred while reading from or writing to the file system.
[ENETDOWN]	The local network interface used to reach the destination is down.
[ENETUNREACH]	No route to the network is present.
[ENOBUFS]	Insufficient resources were available in the system to perform the operation.

EXAMPLES

None.

APPLICATION USAGE

The *send*( ) function is equivalent to *sendto*( ) with a null pointer *dest_len* argument, and to *write*( ) if no flags are used. |

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

sendmsg — send a message on a socket using a message structure

SYNOPSIS

```
#include <sys/socket.h>

ssize_t sendmsg(int socket, const struct msghdr *message, int flags);
```

DESCRIPTION

The *sendmsg*( ) function shall send a message through a connection-mode or connectionless-mode socket. If the socket is connectionless-mode, the message shall be sent to the address specified by **msghdr**. If the socket is connection-mode, the destination address in **msghdr** shall be ignored.

The *sendmsg*( ) function takes the following arguments:

socket	Specifies the socket file descriptor.
message	Points to a **msghdr** structure, containing both the destination address and the buffers for the outgoing message. The length and format of the address depend on the address family of the socket. The *msg_flags* member is ignored.
flags	Specifies the type of message transmission. The application may specify 0 or the following flag:

MSG_EOR	Terminates a record (if supported by the protocol).
MSG_OOB	Sends out-of-band data on sockets that support out-of-bound data. The significance and semantics of out-of-band data are protocol-specific.

The *msg_iov* and *msg_iovlen* fields of *message* specify zero or more buffers containing the data to be sent. *msg_iov* points to an array of **iovec** structures; *msg_iovlen* shall be set to the dimension of this array. In each **iovec** structure, the *iov_base* field specifies a storage area and the *iov_len* field gives its size in bytes. Some of these sizes can be zero. The data from each storage area indicated by *msg_iov* is sent in turn.

Successful completion of a call to *sendmsg*( ) does not guarantee delivery of the message. A return value of −1 indicates only locally-detected errors.

If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does not have O_NONBLOCK set, *sendmsg*( ) function shall block until space is available. If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does have O_NONBLOCK set, *sendmsg*( ) function shall fail.

If the socket protocol supports broadcast and the specified address is a broadcast address for the socket protocol, *sendmsg*( ) shall fail if the SO_BROADCAST option is not set for the socket.

The socket in use may require the process to have appropriate privileges to use the *sendmsg*( ) function.

RETURN VALUE

Upon successful completion, *sendmsg*( ) shall return the number of bytes sent. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *sendmsg*( ) function shall fail if:

[EAGAIN] or [EWOULDBLOCK]

The socket's file descriptor is marked O_NONBLOCK and the requested operation would block.

[EAFNOSUPPORT]	Addresses in the specified address family cannot be used with this socket.
[EBADF]	The *socket* argument is not a valid file descriptor.
[ECONNRESET]	A connection was forcibly closed by a peer.
[EINTR]	A signal interrupted *sendmsg*( ) before any data was transmitted.
[EINVAL]	The sum of the *iov_len* values overflows an **ssize_t**.
[EMSGSIZE]	The message is too large to be sent all at once (as the socket requires), or the *msg_iovlen* member of the **msghdr** structure pointed to by *message* is less than or equal to 0 or is greater than {IOV_MAX}.
[ENOTCONN]	The socket is connection-mode but is not connected.
[ENOTSOCK]	The *socket* argument does not refer a socket.
[EOPNOTSUPP]	The *socket* argument is associated with a socket that does not support one or more of the values set in *flags*.
[EPIPE]	The socket is shut down for writing, or the socket is connection-mode and is no longer connected. In the latter case, and if the socket is of type SOCK_STREAM, the SIGPIPE signal is generated to the calling thread.

If the address family of the socket is AF_UNIX, then *sendmsg*( ) shall fail if:

[EIO]	An I/O error occurred while reading from or writing to the file system.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the pathname in the socket address.
[ENAMETOOLONG]	A component of a pathname exceeded {NAME_MAX} characters, or an entire pathname exceeded {PATH_MAX} characters.
[ENOENT]	A component of the pathname does not name an existing file or the path name is an empty string.
[ENOTDIR]	A component of the path prefix of the pathname in the socket address is not a directory.

The *sendmsg*( ) function may fail if:

[EACCES]	Search permission is denied for a component of the path prefix; or write access to the named socket is denied.
[EDESTADDRREQ]	The socket is not connection-mode and does not have its peer address set, and no destination address was specified.
[EHOSTUNREACH]	The destination host cannot be reached (probably because the host is down or a remote router cannot reach it).
[EIO]	An I/O error occurred while reading from or writing to the file system.
[EISCONN]	A destination address was specified and the socket is already connected.
[ENETDOWN]	The local network interface used to reach the destination is down.

[ENETUNREACH]
No route to the network is present.

[ENOBUFS] Insufficient resources were available in the system to perform the operation.

[ENOMEM] Insufficient memory was available to fulfill the request.

If the address family of the socket is AF_UNIX, then *sendmsg*( ) may fail if:

[ELOOP] More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the pathname in the socket address. |

[ENAMETOOLONG]
Pathname resolution of a symbolic link produced an intermediate result whose length exceeds {PATH_MAX}. |

EXAMPLES

Done.

APPLICATION USAGE

The *select*( ) and *poll*( ) functions can be used to determine when it is possible to send more data.

RATIONALE

None.

FUTURE DIRECTIONS

None.

getsockopt( ), *poll*( ), *recv*( ), *recvfrom*( ), *recvmsg*( ), *select*( ), *send*( ), *sendto*( ), *setsockopt*( ), *shutdown*( ), *socket*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/socket.h>**

CHANGE HISTORY

First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.

NAME

sendto — send a message on a socket

SYNOPSIS

```
#include <sys/socket.h>

ssize_t sendto(int socket, const void *message, size_t length,
    int flags, const struct sockaddr *dest_addr,
    socklen_t dest_len);
```

DESCRIPTION

The *sendto*( ) function shall send a message through a connection-mode or connectionless-mode socket. If the socket is connectionless-mode, the message shall be sent to the address specified by *dest_addr*. If the socket is connection-mode, *dest_addr* shall be ignored.

The *sendto*( ) function takes the following arguments:

socket	Specifies the socket file descriptor.
message	Points to a buffer containing the message to be sent.
length	Specifies the size of the message in bytes.
flags	Specifies the type of message transmission. Values of this argument are formed by logically OR'ing zero or more of the following flags: MSG_EOR Terminates a record (if supported by the protocol). MSG_OOB Sends out-of-band data on sockets that support out-of-band data. The significance and semantics of out-of-band data are protocol-specific.
dest_addr	Points to a **sockaddr** structure containing the destination address. The length and format of the address depend on the address family of the socket.
dest_len	Specifies the length of the **sockaddr** structure pointed to by the *dest_addr* argument.

If the socket protocol supports broadcast and the specified address is a broadcast address for the socket protocol, *sendto*( ) shall fail if the SO_BROADCAST option is not set for the socket.

The *dest_addr* argument specifies the address of the target. The *length* argument specifies the length of the message.

Successful completion of a call to *sendto*( ) does not guarantee delivery of the message. A return value of –1 indicates only locally-detected errors.

If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does not have O_NONBLOCK set, *sendto*( ) shall block until space is available. If space is not available at the sending socket to hold the message to be transmitted and the socket file descriptor does have O_NONBLOCK set, *sendto*( ) shall fail.

The socket in use may require the process to have appropriate privileges to use the *sendto*( ) function.

RETURN VALUE

Upon successful completion, *sendto*( ) shall return the number of bytes sent. Otherwise, –1 shall be returned and *errno* set to indicate the error.

ERRORS

The *sendto*( ) function shall fail if:

[EAFNOSUPPORT]	Addresses in the specified address family cannot be used with this socket.
[EAGAIN] or [EWOULDBLOCK]	The socket's file descriptor is marked O_NONBLOCK and the requested operation would block.
[EBADF]	The *socket* argument is not a valid file descriptor.
[ECONNRESET]	A connection was forcibly closed by a peer.
[EINTR]	A signal interrupted *sendto*( ) before any data was transmitted.
[EMSGSIZE]	The message is too large to be sent all at once, as the socket requires.
[ENOTCONN]	The socket is connection-mode but is not connected.
[ENOTSOCK]	The *socket* argument does not refer to a socket.
[EOPNOTSUPP]	The *socket* argument is associated with a socket that does not support one or more of the values set in *flags*.
[EPIPE]	The socket is shut down for writing, or the socket is connection-mode and is no longer connected. In the latter case, and if the socket is of type SOCK_STREAM, the SIGPIPE signal is generated to the calling thread.

If the address family of the socket is AF_UNIX, then *sendto*( ) shall fail if:

[EIO]	An I/O error occurred while reading from or writing to the file system.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the pathname in the socket address.
[ENAMETOOLONG]	A component of a pathname exceeded {NAME_MAX} characters, or an entire pathname exceeded {PATH_MAX} characters.
[ENOENT]	A component of the pathname does not name an existing file or the pathname is an empty string.
[ENOTDIR]	A component of the path prefix of the pathname in the socket address is not a directory.

The *sendto*( ) function may fail if:

[EACCES]	Search permission is denied for a component of the path prefix; or write access to the named socket is denied.
[EDESTADDRREQ]	The socket is not connection-mode and does not have its peer address set, and no destination address was specified.
[EHOSTUNREACH]	The destination host cannot be reached (probably because the host is down or a remote router cannot reach it).
[EINVAL]	The *dest_len* argument is not a valid length for the address family.
[EIO]	An I/O error occurred while reading from or writing to the file system.

[EISCONN]	A destination address was specified and the socket is already connected. This error may or may not be returned for connection mode sockets.
[ENETDOWN]	The local network interface used to reach the destination is down.
[ENETUNREACH]	No route to the network is present.
[ENOBUFS]	Insufficient resources were available in the system to perform the operation.
[ENOMEM]	Insufficient memory was available to fulfill the request.

If the address family of the socket is AF_UNIX, then *sendto*( ) may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the pathname in the socket address.
[ENAMETOOLONG]	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds {PATH_MAX}.

EXAMPLES

None.

APPLICATION USAGE

The *select*( ) and *poll*( ) functions can be used to determine when it is possible to send more data.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

getsockopt( ), *poll*( ), *recv*( ), *recvfrom*( ), *recvmsg*( ), *select*( ), *send*( ), *sendmsg*( ), *setsockopt*( ), *shutdown*( ), *socket*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/socket.h>**

CHANGE HISTORY

First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.

NAME

setbuf — assign buffering to a stream

SYNOPSIS

```
#include <stdio.h>

void setbuf(FILE *restrict stream, char *restrict buf);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

Except that it returns no value, the function call:

```
setbuf(stream, buf)
```

shall be equivalent to:

```
setvbuf(stream, buf, _IOFBF, BUFSIZ)
```

if *buf* is not a null pointer, or to:

```
setvbuf(stream, buf, _IONBF, BUFSIZ)
```

if *buf* is a null pointer.

RETURN VALUE

The *setbuf*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

A common source of error is allocating buffer space as an ‘‘automatic’’ variable in a code block, and then failing to close the stream in the same block.

With *setbuf*( ), allocating a buffer of BUFSIZ bytes does not necessarily imply that all of BUFSIZ bytes are used for the buffer area.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

fopen( ), *setvbuf*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdio.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The prototype for *setbuf*( ) is updated for alignment with the ISO / IEC 9899: 1999 standard.

NAME

setcontext — set current user context

SYNOPSIS

XSI

```
#include <ucontext.h>

int setcontext(const ucontext_t *ucp);
```

DESCRIPTION

Refer to *getcontext*( ).

NAME

setegid — set effective group ID

SYNOPSIS

```
#include <unistd.h>

int setegid(gid_t gid);
```

DESCRIPTION

If *gid* is equal to the real group ID or the saved set-group-ID, or if the process has appropriate privileges, *setegid*( ) shall set the effective group ID of the calling process to *gid*; the real group ID, saved set-group-ID, and any supplementary group IDs shall remain unchanged.

The *setegid*( ) function shall not affect the supplementary group list in any way.

RETURN VALUE

Upon successful completion, 0 shall be returned; otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *setegid*( ) function shall fail if:

[EINVAL]	The value of the *gid* argument is invalid and is not supported by the implementation.
[EPERM]	The process does not have appropriate privileges and *gid* does not match the real group ID or the saved set-group-ID.

EXAMPLES

None.

APPLICATION USAGE

None.

CHANGE HISTORY

First released in Issue 6. Derived from the IEEE P1003.1a draft standard.

NAME

setenv — add or change environment variable

SYNOPSIS

CX
```
#include <stdlib.h>

int setenv(const char *envname, const char *envval, int overwrite);
```

DESCRIPTION

The *setenv*( ) function shall update or add a variable in the environment of the calling process. The *envname* argument points to a string containing the name of an environment variable to be added or altered. The environment variable shall be set to the value to which *envval* points. The function shall fail if *envname* points to a string which contains an '=' character. If the environment variable named by *envname* already exists and the value of *overwrite* is non-zero, the function shall return success and the environment shall be updated. If the environment variable named by *envname* already exists and the value of *overwrite* is zero, the function shall return success and the environment shall remain unchanged.

If the application modifies *environ* or the pointers to which it points, the behavior of *setenv*( ) is undefined. The *setenv*( ) function shall update the list of pointers to which *environ* points.

The strings described by *envname* and *envval* are copied by this function.

The *setenv*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

Upon successful completion, zero shall be returned. Otherwise, −1 shall be returned, *errno* set to indicate the error, and the environment shall be unchanged.

ERRORS

The *setenv*( ) function shall fail if:

[EINVAL]	The *name* argument is a null pointer, points to an empty string, or points to a string containing an '=' character.
[ENOMEM]	Insufficient memory was available to add a variable or its value to the environment.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Unanticipated results may occur if *setenv*( ) changes the external variable *environ*. In particular, if the optional *envp* argument to *main*( ) is present, it is not changed, and thus may point to an obsolete copy of the environment (as may any other copy of *environ*). However, other than the aforementioned restriction, the developers of IEEE Std 1003.1-200x intended that the traditional method of walking through the environment by way of the *environ* pointer must be supported.

It was decided that *setenv*( ) should be required by this revision because it addresses a piece of missing functionality, and does not impose a significant burden on the implementor.

There was considerable debate as to whether the System V *putenv*( ) function or the BSD *setenv*( ) function should be required as a mandatory function. The *setenv*( ) function was chosen because it permitted the implementation of *unsetenv*( ) function to delete environmental variables, without specifying an additional interface. The *putenv*( ) function is available as an XSI extension.

The standard developers considered requiring that *setenv*( ) indicate an error when a call to it would result in exceeding {ARG_MAX}. The requirement was rejected since the condition might be temporary, with the application eventually reducing the environment size. The ultimate success or failure depends on the size at the time of a call to *exec*, which returns an indication of this error condition.

FUTURE DIRECTIONS

None.

NAME

seteuid — set effective user ID

SYNOPSIS

```
#include <unistd.h>

int seteuid(uid_t uid);
```

DESCRIPTION

If *uid* is equal to the real user ID or the saved set-user-ID, or if the process has appropriate privileges, *seteuid*( ) shall set the effective user ID of the calling process to *uid*; the real user ID and saved set-user-ID shall remain unchanged.

The *seteuid*( ) function shall not affect the supplementary group list in any way.

RETURN VALUE

Upon successful completion, 0 shall be returned; otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *seteuid*( ) function shall fail if:

[EINVAL]	The value of the *uid* argument is invalid and is not supported by the implementation.
[EPERM]	The process does not have appropriate privileges and *uid* does not match the real group ID or the saved set-group-ID.

NAME

setgid — set-group-ID

SYNOPSIS

```
#include <unistd.h>

int setgid(gid_t gid);
```

DESCRIPTION

If the process has appropriate privileges, *setgid*( ) shall set the real group ID, effective group ID, and the saved set-group-ID of the calling process to *gid*.

If the process does not have appropriate privileges, but *gid* is equal to the real group ID or the saved set-group-ID, *setgid*( ) shall set the effective group ID to *gid*; the real group ID and saved set-group-ID shall remain unchanged.

The *setgid*( ) function shall not affect the supplementary group list in any way.

Any supplementary group IDs of the calling process shall remain unchanged.

RETURN VALUE

Upon successful completion, 0 is returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *setgid*( ) function shall fail if:

[EINVAL]	The value of the *gid* argument is invalid and is not supported by the implementation.
[EPERM]	The process does not have appropriate privileges and *gid* does not match the real group ID or the saved set-group-ID.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

- Functionality associated with _POSIX_SAVED_IDS is now mandated. This is a FIPS requirement.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The effects of *setgid*( ) in processes without appropriate privileges are changed
- A requirement that the supplementary group list is not affected is added.

NAME

setgrent — reset group database to first entry

SYNOPSIS

XSI

```
#include <grp.h>

void setgrent(void);
```

DESCRIPTION

Refer to *endgrent*( ).

NAME

sethostent — network host database functions

SYNOPSIS

```
#include <netdb.h>

void sethostent(int stayopen);
```

DESCRIPTION

Refer to *endhostent*( ).

NAME

setitimer — set value of interval timer

SYNOPSIS

XSI

```
#include <sys/time.h>

int setitimer(int which, const struct itimerval *restrict value,
    struct itimerval *restrict ovalue);
```

DESCRIPTION

Refer to *getitimer*( ).

NAME

setjmp — set jump point for a non-local goto

SYNOPSIS

```
#include <setjmp.h>

int setjmp(jmp_buf env);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

A call to *setjmp*( ), shall save the calling environment in its *env* argument for later use by *longjmp*( ).

It is unspecified whether *setjmp*( ) is a macro or a function. If a macro definition is suppressed in order to access an actual function, or a program defines an external identifier with the name *setjmp*, the behavior is undefined.

An application shall ensure that an invocation of *setjmp*( ) appears in one of the following contexts only:

- The entire controlling expression of a selection or iteration statement
- One operand of a relational or equality operator with the other operand an integral constant expression, with the resulting expression being the entire controlling expression of a selection or iteration statement
- The operand of a unary `'!'` operator with the resulting expression being the entire controlling expression of a selection or iteration
- The entire expression of an expression statement (possibly cast to **void**)

If the invocation appears in any other context, the behavior is undefined.

RETURN VALUE

If the return is from a direct invocation, *setjmp*( ) shall return 0. If the return is from a call to *longjmp*( ), *setjmp*( ) shall return a non-zero value.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

In general, *sigsetjmp*( ) is more useful in dealing with errors and interrupts encountered in a low-level subroutine of a program.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

longjmp( ), *sigsetjmp*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<setjmp.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

setkey — set encoding key (**CRYPT**)

SYNOPSIS

XSI
```
#include <stdlib.h>

void setkey(const char *key);
```

DESCRIPTION

The *setkey*( ) function provides access to an implementation-defined encoding algorithm. The argument of *setkey*( ) is an array of length 64 bytes containing only the bytes with numerical value of 0 and 1. If this string is divided into groups of 8, the low-order bit in each group is ignored; this gives a 56-bit key which is used by the algorithm. This is the key that shall be used with the algorithm to encode a string *block* passed to *encrypt*( ).

The *setkey*( ) function shall not change the setting of *errno* if successful. An application wishing to check for error situations should set *errno* to 0 before calling *setkey*( ). If *errno* is non-zero on return, an error has occurred.

The *setkey*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

No values are returned.

ERRORS

The *setkey*( ) function shall fail if:

[ENOSYS]	The functionality is not supported on this implementation.

EXAMPLES

None.

APPLICATION USAGE

Decoding need not be implemented in all environments. This is related to government restrictions in some countries on encryption and decryption routines. Historical practice has been to ship a different version of the encryption library without the decryption feature in the routines supplied. Thus the exported version of *encrypt*( ) does encoding but not decoding.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

crypt( ), *encrypt*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdlib.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

NAME

setlocale — set program locale

SYNOPSIS

```
#include <locale.h>

char *setlocale(int category, const char *locale);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *setlocale*( ) function selects the appropriate piece of the program's locale, as specified by the *category* and *locale* arguments, and may be used to change or query the program's entire locale or portions thereof. The value *LC_ALL* for *category* names the program's entire locale; other values for *category* name only a part of the program's locale:

	LC_COLLATE	Affects the behavior of regular expressions and the collation functions.
	LC_CTYPE	Affects the behavior of regular expressions, character classification, character conversion functions, and wide-character functions.
CX	*LC_MESSAGES*	Affects what strings are expected by commands and utilities as affirmative or negative responses.
XSI		It also affects what strings are given by commands and utilities as affirmative or negative responses, and the content of messages.
	LC_MONETARY	Affects the behavior of functions that handle monetary values.
	LC_NUMERIC	Affects the behavior of functions that handle numeric values.
	LC_TIME	Affects the behavior of the time conversion functions.

The *locale* argument is a pointer to a character string containing the required setting of *category*. The contents of this string are implementation-defined. In addition, the following preset values of *locale* are defined for all settings of *category*:

CX	"POSIX"	Specifies the minimal environment for C-language translation called POSIX locale. If *setlocale*( ) is not invoked, the POSIX locale is the default at entry to *main*( ).
	"C"	Equivalent to `"POSIX"`.
CX	" "	Specifies an implementation-defined native environment. This corresponds to the value of the associated environment variables, *LC_** and *LANG*; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale and the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.
	A null pointer	Used to direct *setlocale*( ) to query the current internationalized environment and return the name of the *locale*( ).

THR The locale state is common to all threads within a process.

RETURN VALUE

Upon successful completion, *setlocale*( ) shall return the string associated with the specified category for the new locale. Otherwise, *setlocale*( ) shall return a null pointer and the program's locale is not changed.

A null pointer for *locale* causes *setlocale*( ) to return a pointer to the string associated with the *category* for the program's current locale. The program's locale shall not be changed.

The string returned by *setlocale*( ) is such that a subsequent call with that string and its associated *category* shall restore that part of the program's locale. The application shall not modify the string returned which may be overwritten by a subsequent call to *setlocale*( ).

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The following code illustrates how a program can initialize the international environment for one language, while selectively modifying the program's locale such that regular expressions and string operations can be applied to text recorded in a different language:

```
setlocale(LC_ALL, "De");
setlocale(LC_COLLATE, "Fr@dict");
```

Internationalized programs must call *setlocale*( ) to initiate a specific language operation. This can be done by calling *setlocale*( ) as follows:

```
setlocale(LC_ALL, "");
```

Changing the setting of *LC_MESSAGES* has no effect on catalogs that have already been opened by calls to *catopen*( ).

RATIONALE

The ISO C standard defines a collection of functions to support internationalization. One of the most significant aspects of these functions is a facility to set and query the *international environment*. The international environment is a repository of information that affects the behavior of certain functionality, namely:

1. Character handling
2. Collating
3. Date / time formatting
4. Numeric editing
5. Monetary formatting
6. Messaging

The *setlocale*( ) function provides the application developer with the ability to set all or portions, called *categories*, of the international environment. These categories correspond to the areas of functionality, mentioned above. The syntax for *setlocale*( ) is as follows:

```
char *setlocale(int category, const char *locale);
```

where *category* is the name of one of following categories, namely:

LC_COLLATE
LC_CTYPE
LC_MESSAGES
LC_MONETARY
LC_NUMERIC
LC_TIME

In addition, a special value called *LC_ALL* directs *setlocale*( ) to set all categories.

There are two primary uses of *setlocale*( ):

1. Querying the international environment to find out what it is set to
2. Setting the international environment, or *locale*, to a specific value

The behavior of *setlocale*( ) in these two areas is described below. Since it is difficult to describe the behavior in words, examples are used to illustrate the behavior of specific uses.

To query the international environment, *setlocale*( ) is invoked with a specific category and the NULL pointer as the locale. The NULL pointer is a special directive to *setlocale*( ) that tells it to query rather than set the international environment. The following syntax is used to query the name of the international environment:

```
setlocale({LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_MONETARY, \
    LC_NUMERIC, LC_TIME},(char *) NULL);
```

The *setlocale*( ) function shall return the string corresponding to the current international environment. This value may be used by a subsequent call to *setlocale*( ) to reset the international environment to this value. However, it should be noted that the return value from *setlocale*( ) may be a pointer to a static area within the function and is not guaranteed to remain unchanged (that is, it may be modified by a subsequent call to *setlocale*( )). Therefore, if the purpose of calling *setlocale*( ) is to save the value of the current international environment so it can be changed and reset later, the return value should be copied to an array of **char** in the calling program.

There are three ways to set the international environment with *setlocale*( ):

setlocale(*category*, *string*)
This usage sets a specific *category* in the international environment to a specific value corresponding to the value of the *string*. A specific example is provided below:

```
setlocale(LC_ALL, "fr_FR.ISO-8859-1");
```

In this example, all categories of the international environment are set to the locale corresponding to the string `"fr_FR.ISO-8859-1"`, or to the French language as spoken in France using the ISO / IEC 8859-1: 1998 standard codeset.

If the string does not correspond to a valid locale, *setlocale*( ) shall return a NULL pointer and the international environment is not changed. Otherwise, *setlocale*( ) shall return the name of the locale just set.

setlocale(*category*, "C")
The ISO C standard states that one locale must exist on all conforming implementations. The name of the locale is C and corresponds to a minimal international environment needed to support the C programming language.

setlocale(*category*, "")
This sets a specific category to an implementation-defined default. This corresponds to the value of the environment variables.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

Extensions beyond the ISO C standard are now marked.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

setlogmask — set log priority mask

SYNOPSIS

XSI

```
#include <syslog.h>

int setlogmask(int maskpri);
```

DESCRIPTION

Refer to *closelog*( ).

NAME

setnetent — network database function

SYNOPSIS

```
#include <netdb.h>

void setnetent(int stayopen);
```

DESCRIPTION

Refer to *endnetent*( ).

NAME

setpgid — set process group ID for job control

SYNOPSIS

```
#include <unistd.h>

int setpgid(pid_t pid, pid_t pgid);
```

DESCRIPTION

The *setpgid*( ) function shall either join an existing process group or create a new process group within the session of the calling process. The process group ID of a session leader shall not change. Upon successful completion, the process group ID of the process with a process ID that matches *pid* shall be set to *pgid*. As a special case, if *pid* is 0, the process ID of the calling process shall be used. Also, if *pgid* is 0, the process group ID of the indicated process shall be used. |

RETURN VALUE

Upon successful completion, *setpgid*( ) shall return 0; otherwise, −1 shall be returned and *errno* shall be set to indicate the error.

ERRORS

The *setpgid*( ) function shall fail if:

[EACCES]	The value of the *pid* argument matches the process ID of a child process of the calling process and the child process has successfully executed one of the *exec* functions.
[EINVAL]	The value of the *pgid* argument is less than 0, or is not a value supported by the implementation.
[EPERM]	The process indicated by the *pid* argument is a session leader.
[EPERM]	The value of the *pid* argument matches the process ID of a child process of the calling process and the child process is not in the same session as the calling process.
[EPERM]	The value of the *pgid* argument is valid but does not match the process ID of the process indicated by the *pid* argument and there is no process with a process group ID that matches the value of the *pgid* argument in the same session as the calling process.
[ESRCH]	The value of the *pid* argument does not match the process ID of the calling process or of a child process of the calling process.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The *setpgid*( ) function shall group processes together for the purpose of signaling, placement in foreground or background, and other job control actions. |

The *setpgid*( ) function is similar to the *setpgrp*( ) function of 4.2 BSD, except that 4.2 BSD allowed the specified new process group to assume any value. This presents certain security problems and is more flexible than necessary to support job control.

To provide tighter security, *setpgid*( ) only allows the calling process to join a process group already in use inside its session or create a new process group whose process group ID was equal to its process ID.

When a job control shell spawns a new job, the processes in the job must be placed into a new process group via *setpgid*( ). There are two timing constraints involved in this action:

1. The new process must be placed in the new process group before the appropriate program is launched via one of the *exec* functions.
2. The new process must be placed in the new process group before the shell can correctly send signals to the new process group.

To address these constraints, the following actions are performed. The new processes call *setpgid*( ) to alter their own process groups after *fork*( ) but before *exec*. This satisfies the first constraint. Under 4.3 BSD, the second constraint is satisfied by the synchronization property of *vfork*( ); that is, the shell is suspended until the child has completed the *exec*, thus ensuring that the child has completed the *setpgid*( ). A new version of *fork*( ) with this same synchronization property was considered, but it was decided instead to merely allow the parent shell process to adjust the process group of its child processes via *setpgid*( ). Both timing constraints are now satisfied by having both the parent shell and the child attempt to adjust the process group of the child process; it does not matter which succeeds first.

Since it would be confusing to an application to have its process group change after it began executing (that is, after *exec*), and because the child process would already have adjusted its process group before this, the [EACCES] error was added to disallow this. |

One non-obvious use of *setpgid*( ) is to allow a job control shell to return itself to its original process group (the one in effect when the job control shell was executed). A job control shell does this before returning control back to its parent when it is terminating or suspending itself as a way of restoring its job control ‘‘state’’ back to what its parent would expect. (Note that the original process group of the job control shell typically matches the process group of its parent, but this is not necessarily always the case.)

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- The *setpgid*( ) function is mandatory since _POSIX_JOB_CONTROL is required to be defined in this issue. This is a FIPS requirement.

NAME

setpgrp — set process group ID

SYNOPSIS

XSI
```
#include <unistd.h>

pid_t setpgrp(void);
```

DESCRIPTION

If the calling process is not already a session leader, *setpgrp*( ) sets the process group ID of the calling process to the process ID of the calling process. If *setpgrp*( ) creates a new session, then the new session has no controlling terminal.

The *setpgrp*( ) function has no effect when the calling process is a session leader.

RETURN VALUE

Upon completion, *setpgrp*( ) shall return the process group ID.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X / OPEN UNIX extension to BASE.

NAME

setpriority — set the nice value

SYNOPSIS

XSI

```
#include <sys/resource.h>

int setpriority(int which, id_t who, int nice);
```

DESCRIPTION

Refer to *getpriority*( ).

NAME

setprotoent — network protocol database functions

SYNOPSIS

```
#include <netdb.h>

void setprotoent(int stayopen);
```

DESCRIPTION

Refer to *endprotoent*( ).

NAME

setpwent — user database function

SYNOPSIS

XSI

```
#include <pwd.h>

void setpwent(void);
```

DESCRIPTION

Refer to *endpwent*( ).

NAME

setregid — set real and effective group IDs

SYNOPSIS

XSI

```
#include <unistd.h>

int setregid(gid_t rgid, gid_t egid);
```

DESCRIPTION

The *setregid*( ) function shall set the real and effective group IDs of the calling process.

If *rgid* is –1, the real group ID shall not be changed; if *egid* is –1, the effective group ID shall not be changed.

The real and effective group IDs may be set to different values in the same call.

Only a process with appropriate privileges can set the real group ID and the effective group ID to any valid value.

A non-privileged process can set either the real group ID to the saved set-group-ID from one of the *exec* family of functions, or the effective group ID to the saved set-group-ID or the real group ID.

Any supplementary group IDs of the calling process remain unchanged.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, –1 shall be returned and *errno* set to indicate the error, and neither of the group IDs are changed.

ERRORS

The *setregid*( ) function shall fail if:

[EINVAL]	The value of the *rgid* or *egid* argument is invalid or out-of-range.
[EPERM]	The process does not have appropriate privileges and a change other than changing the real group ID to the saved set-group-ID, or changing the effective group ID to the real group ID or the saved set-group-ID, was requested.

EXAMPLES

None.

APPLICATION USAGE

If a set-group-ID process sets its effective group ID to its real group ID, it can still set its effective group ID back to the saved set-group-ID.

RATIONALE

None.

FUTURE DIRECTIONS

None.

exec, *getegid*( ), *geteuid*( ), *getgid*( ), *getuid*( ), *setegid*( ), *seteuid*( ), *setgid*( ), *setreuid*( ), *setuid*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<unistd.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

The DESCRIPTION is updated to indicate that the saved set-group-ID can be set by any of the *exec* family of functions, not just *execev*( ).

NAME

setreuid — set real and effective user IDs

SYNOPSIS

XSI

```
#include <unistd.h>

int setreuid(uid_t ruid, uid_t euid);
```

DESCRIPTION

The *setreuid*( ) function shall set the real and effective user IDs of the current process to the values specified by the *ruid* and *euid* arguments. If *ruid* or *euid* is −1, the corresponding effective or real user ID of the current process shall be left unchanged. |

A process with appropriate privileges can set either ID to any value. An unprivileged process can only set the effective user ID if the *euid* argument is equal to either the real, effective, or saved user ID of the process.

It is unspecified whether a process without appropriate privileges is permitted to change the real user ID to match the current real, effective, or saved set-user-ID of the process.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *setreuid*( ) function shall fail if:

[EINVAL]	The value of the *ruid* or *euid* argument is invalid or out-of-range.
[EPERM]	The current process does not have appropriate privileges, and either an attempt was made to change the effective user ID to a value other than the real user ID or the saved set-user-ID or an attempt was made to change the real user ID to a value not permitted by the implementation.

EXAMPLES

Setting the Effective User ID to the Real User ID

The following example sets the effective user ID of the calling process to the real user ID, so that files created later will be owned by the current user.

```
#include <unistd.h>
#include <sys/types.h>
...
setreuid(getuid(), getuid());
...
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

NAME

setrlimit — control maximum resource consumption

SYNOPSIS

XSI

```
#include <sys/resource.h>

int setrlimit(int resource, const struct rlimit *rlp);

```

DESCRIPTION

Refer to *getrlimit*( ).

NAME

setservent — network services database functions

SYNOPSIS

```
#include <netdb.h>

void setservent(int stayopen);
```

DESCRIPTION

Refer to *endservent*( ).

NAME

setsid — create session and set process group ID

SYNOPSIS

```
#include <unistd.h>

pid_t setsid(void);
```

DESCRIPTION

The *setsid*( ) function shall create a new session, if the calling process is not a process group leader. Upon return the calling process shall be the session leader of this new session, shall be the process group leader of a new process group, and shall have no controlling terminal. The process group ID of the calling process shall be set equal to the process ID of the calling process. The calling process shall be the only process in the new process group and the only process in the new session.

RETURN VALUE

Upon successful completion, *setsid*( ) shall return the value of the new process group ID of the calling process. Otherwise, it shall return (**pid_t**)–1 and set *errno* to indicate the error.

ERRORS

The *setsid*( ) function shall fail if:

[EPERM]	The calling process is already a process group leader, or the process group ID of a process other than the calling process matches the process ID of the calling process.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The *setsid*( ) function is similar to the *setpgrp*( ) function of System V. System V, without job control, groups processes into process groups and creates new process groups via *setpgrp*( ); only one process group may be part of a login session.

Job control allows multiple process groups within a login session. In order to limit job control actions so that they can only affect processes in the same login session, this volume of IEEE Std 1003.1-200x adds the concept of a session that is created via *setsid*( ). The *setsid*( ) function also creates the initial process group contained in the session. Additional process groups can be created via the *setpgid*( ) function. A System V process group would correspond to a POSIX System Interfaces session containing a single POSIX process group. Note that this function requires that the calling process not be a process group leader. The usual way to ensure this is true is to create a new process with *fork*( ) and have it call *setsid*( ). The *fork*( ) function guarantees that the process ID of the new process does not match any existing process group ID.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

NAME

setsockopt — set the socket options

SYNOPSIS

```
#include <sys/socket.h>

int setsockopt(int socket, int level, int option_name,
    const void *option_value, socklen_t option_len);
```

DESCRIPTION

The *setsockopt*( ) function shall set the option specified by the *option_name* argument, at the protocol level specified by the *level* argument, to the value pointed to by the *option_value* argument for the socket associated with the file descriptor specified by the *socket* argument.

The *level* argument specifies the protocol level at which the option resides. To set options at the socket level, specify the *level* argument as SOL_SOCKET. To set options at other levels, supply the appropriate *level* identifier for the protocol controlling the option. For example, to indicate that an option is interpreted by the TCP (Transport Control Protocol), set *level* to IPPROTO_TCP as defined in the **<netinet/in.h>** header.

The *option_name* argument specifies a single option to set. The *option_name* argument and any specified options are passed uninterpreted to the appropriate protocol module for interpretations. The **<sys/socket.h>** header defines the socket-level options. The options are as follows:

SO_DEBUG	Turns on recording of debugging information. This option enables or disables debugging in the underlying protocol modules. This option takes an **int** value. This is a Boolean option.
SO_BROADCAST	Permits sending of broadcast messages, if this is supported by the protocol. This option takes an **int** value. This is a Boolean option.
SO_REUSEADDR	Specifies that the rules used in validating addresses supplied to *bind*( ) should allow reuse of local addresses, if this is supported by the protocol. This option takes an **int** value. This is a Boolean option.
SO_KEEPALIVE	Keeps connections active by enabling the periodic transmission of messages, if this is supported by the protocol. This option takes an **int** value. If the connected socket fails to respond to these messages, the connection is broken and threads writing to that socket are notified with a SIGPIPE signal. This is a Boolean option.
SO_LINGER	Lingers on a *close*( ) if data is present. This option controls the action taken when unsent messages queue on a socket and *close*( ) is performed. If SO_LINGER is set, the system shall block the process during *close*( ) until it can transmit the data or until the time expires. If SO_LINGER is not specified, and *close*( ) is issued, the system handles the call in a way that allows the process to continue as quickly as possible. This option takes a **linger** structure, as defined in the **<sys/socket.h>** header, to specify the state of the option and linger interval.
SO_OOBINLINE	Leaves received out-of-band data (data marked urgent) inline. This option takes an **int** value. This is a Boolean option.

SO_SNDBUF	Sets send buffer size. This option takes an **int** value.
SO_RCVBUF	Sets receive buffer size. This option takes an **int** value.
SO_DONTROUTE	Requests that outgoing messages bypass the standard routing facilities. The destination shall be on a directly-connected network, and messages are directed to the appropriate network interface according to the destination address. The effect, if any, of this option depends on what protocol is in use. This option takes an **int** value. This is a Boolean option.
SO_RCVLOWAT	Sets the minimum number of bytes to process for socket input operations. The default value for SO_RCVLOWAT is 1. If SO_RCVLOWAT is set to a larger value, blocking receive calls normally wait until they have received the smaller of the low water mark value or the requested amount. (They may return less than the low water mark if an error occurs, a signal is caught, or the type of data next in the receive queue is different from that returned; for example, out-of-band data.) This option takes an **int** value. Note that not all implementations allow this option to be set.
SO_RCVTIMEO	Sets the timeout value that specifies the maximum amount of time an input function waits until it completes. It accepts a **timeval** structure with the number of seconds and microseconds specifying the limit on how long to wait for an input operation to complete. If a receive operation has blocked for this much time without receiving additional data, it shall return with a partial count or *errno* set to [EAGAIN] or [EWOULDBLOCK] if no data is received. The default for this option is zero, which indicates that a receive operation shall not time out. This option takes a **timeval** structure. Note that not all implementations allow this option to be set.
SO_SNDLOWAT	Sets the minimum number of bytes to process for socket output operations. Non-blocking output operations shall process no data if flow control does not allow the smaller of the send low water mark value or the entire request to be processed. This option takes an **int** value. Note that not all implementations allow this option to be set.
SO_SNDTIMEO	Sets the timeout value specifying the amount of time that an output function blocks because flow control prevents data from being sent. If a send operation has blocked for this time, it shall return with a partial count or with *errno* set to [EAGAIN] or [EWOULDBLOCK] if no data is sent. The default for this option is zero, which indicates that a send operation shall not time out. This option stores a **timeval** structure. Note that not all implementations allow this option to be set.

For Boolean options, 0 indicates that the option is disabled and 1 indicates that the option is enabled.

Options at other protocol levels vary in format and name.

RETURN VALUE

Upon successful completion, *setsockopt*( ) shall return 0. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *setsockopt*( ) function shall fail if:

[EBADF]	The *socket* argument is not a valid file descriptor.

[EDOM]	The send and receive timeout values are too big to fit into the timeout fields in the socket structure.
[EINVAL]	The specified option is invalid at the specified socket level or the socket has been shut down.
[EISCONN]	The socket is already connected, and a specified option cannot be set while the socket is connected.
[ENOPROTOOPT]	The option is not supported by the protocol.
[ENOTSOCK]	The *socket* argument does not refer to a socket.

The *setsockopt*( ) function may fail if:

[ENOMEM]	There was insufficient memory available for the operation to complete.
[ENOBUFS]	Insufficient resources are available in the system to complete the call.

EXAMPLES

None.

APPLICATION USAGE

The *setsockopt*( ) function provides an application program with the means to control socket behavior. An application program can use *setsockopt*( ) to allocate buffer space, control timeouts, or permit socket data broadcasts. The **<sys/socket.h>** header defines the socket-level options available to *setsockopt*( ).

Options may exist at multiple protocol levels. The SO_ options are always present at the uppermost socket level.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Derived from the XNS, Issue 5.2 specification.

NAME

setstate — switch pseudo-random number generator state arrays

SYNOPSIS

XSI

```
#include <stdlib.h>

char *setstate(const char *state);
```

DESCRIPTION

Refer to *initstate*( ).

NAME

setuid — set user ID

SYNOPSIS

```
#include <unistd.h>

int setuid(uid_t uid);
```

DESCRIPTION

If the process has appropriate privileges, *setuid*( ) shall set the real user ID, effective user ID, and the saved set-user-ID of the calling process to *uid*.

If the process does not have appropriate privileges, but *uid* is equal to the real user ID or the saved set-user-ID, *setuid*( ) shall set the effective user ID to *uid*; the real user ID and saved set-user-ID shall remain unchanged.

The *setuid*( ) function shall not affect the supplementary group list in any way.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *setuid*( ) function shall fail, return −1, and set *errno* to the corresponding value if one or more of the following are true:

[EINVAL]	The value of the *uid* argument is invalid and not supported by the implementation.
[EPERM]	The process does not have appropriate privileges and *uid* does not match the real user ID or the saved set-user-ID.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The various behaviors of the *setuid*( ) and *setgid*( ) functions when called by non-privileged processes reflect the behavior of different historical implementations. For portability, it is recommended that new non-privileged applications use the *seteuid*( ) and *setegid*( ) functions instead.

The saved set-user-ID capability allows a program to regain the effective user ID established at the last *exec* call. Similarly, the saved set-group-ID capability allows a program to regain the effective group ID established at the last *exec* call. These capabilities are derived from System V. Without them, a program might have to run as superuser in order to perform the same functions, because superuser can write on the user's files. This is a problem because such a program can write on any user's files, and so must be carefully written to emulate the permissions of the calling process properly. In System V, these capabilities have traditionally been implemented only via the *setuid*( ) and *setgid*( ) functions for non-privileged processes. The fact that the behavior of those functions was different for privileged processes made them difficult to use. The POSIX.1-1990 standard defined the *setuid*( ) function to behave differently for privileged and unprivileged users. When the caller had the appropriate privilege, the function set the calling process' real user ID, effective user ID, and saved set-user ID on implementations that supported it. When the caller did not have the appropriate privilege, the function set only the effective user ID, subject to permission checks. The former use is generally needed for utilities like *login* and *su*, which are not conforming applications and thus outside the scope of IEEE Std 1003.1-200x. These utilities wish to change the user ID irrevocably to a new value, generally that of an unprivileged user. The latter use is needed for conforming applications that are installed with the set-user-ID bit and need to perform operations using the real user ID.

IEEE Std 1003.1-200x augments the latter functionality with a mandatory feature named _POSIX_SAVED_IDS. This feature permits a set-user-ID application to switch its effective user ID back and forth between the values of its *exec*-time real user ID and effective user ID. Unfortunately, the POSIX.1-1990 standard did not permit a conforming application using this feature to work properly when it happened to be executed with the (implementation-defined) appropriate privilege. Furthermore, the application did not even have a means to tell whether it had this privilege. Since the saved set-user-ID feature is quite desirable for applications, as evidenced by the fact that NIST required it in FIPS 151-2, it has been mandated by IEEE Std 1003.1-200x. However, there are implementors who have been reluctant to support it given the limitation described above.

The 4.3BSD system handles the problem by supporting separate functions: *setuid*( ) (which always sets both the real and effective user IDs, like *setuid*( ) in IEEE Std 1003.1-200x for privileged users), and *seteuid*( ) (which always sets just the effective user ID, like *setuid*( ) in IEEE Std 1003.1-200x for non-privileged users). This separation of functionality into distinct functions seems desirable. 4.3BSD does not support the saved set-user-ID feature. It supports similar functionality of switching the effective user ID back and forth via *setreuid*( ), which permits reversing the real and effective user IDs. This model seems less desirable than the saved set-user-ID because the real user ID changes as a side effect. The current 4.4BSD includes saved effective IDs and uses them for *seteuid*( ) and *setegid*( ) as described above. The *setreuid*( ) and *setregid*( ) functions will be deprecated or removed.

The solution here is:

- Require that all implementations support the functionality of the saved set-user-ID, which is set by the *exec* functions and by privileged calls to *setuid*( ).
- Add the *seteuid*( ) and *setegid*( ) functions as portable alternatives to *setuid*( ) and *setgid*( ) for non-privileged and privileged processes.

Historical systems have provided two mechanisms for a set-user-ID process to change its effective user ID to be the same as its real user ID in such a way that it could return to the original effective user ID: the use of the *setuid*( ) function in the presence of a saved set-user-ID, or the use of the BSD *setreuid*( ) function, which was able to swap the real and effective user IDs. The changes included in IEEE Std 1003.1-200x provide a new mechanism using *seteuid*( ) in conjunction with a saved set-user-ID. Thus, all implementations with the new *seteuid*( ) mechanism will have a saved set-user-ID for each process, and most of the behavior controlled by _POSIX_SAVED_IDS has been changed to agree with the case where the option was defined. The *kill*( ) function is an exception. Implementors of the new *seteuid*( ) mechanism will generally be required to maintain compatibility with the older mechanisms previously supported by their systems. However, compatibility with this use of *setreuid*( ) and with the _POSIX_SAVED_IDS behavior of *kill*( ) is unfortunately complicated. If an implementation with a saved set-user-ID allows a process to use *setreuid*( ) to swap its real and effective user IDs, but were to leave the saved set-user-ID unmodified, the process would then have an effective user ID equal to the original real user ID, and both real and saved set-user-ID would be equal to the original effective user ID. In that state, the real user would be unable to kill the process, even though the effective user ID of the process matches that of the real user, if the *kill*( ) behavior of _POSIX_SAVED_IDS was used. This is obviously not acceptable. The alternative choice, which is used in at least one implementation, is to change the saved set-user-ID to the effective user ID during most calls to *setreuid*( ). The standard developers considered that alternative to be less correct than the retention of the old behavior of *kill*( ) in such systems. Current conforming applications shall accommodate either behavior from *kill*( ), and there appears to be no strong reason for *kill*( ) to check the saved set-user-ID rather than the effective user ID.

FUTURE DIRECTIONS

None.

SEE ALSO

exec, *getegid*( ), *geteuid*( ), *getgid*( ), *getuid*( ), *setegid*( ), *seteuid*( ), *setgid*( ), *setregid*( ), *setreuid*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/types.h>**, **<unistd.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- The functionality associated with _POSIX_SAVED_IDS is now mandatory. This is a FIPS requirement.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The effects of *setuid*( ) in processes without appropriate privileges are changed.
- A requirement that the supplementary group list is not affected is added.

NAME

setutxent — reset user accounting database to first entry

SYNOPSIS

XSI

```
#include <utmpx.h>

void setutxent(void);
```

DESCRIPTION

Refer to *endutxent*( ).

NAME

setvbuf — assign buffering to a stream

SYNOPSIS

```
#include <stdio.h>

int setvbuf(FILE *restrict stream, char *restrict buf, int type,
    size_t size);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *setvbuf*( ) function may be used after the stream pointed to by *stream* is associated with an open file but before any other operation (other than an unsuccessful call to *setvbuf*( )) is performed on the stream. The argument *type* determines how *stream* shall be buffered, as follows:

- {_IOFBF} shall cause input/output to be fully buffered.
- {_IOLBF} shall cause input/output to be line buffered.
- {_IONBF} shall cause input/output to be unbuffered.

If *buf* is not a null pointer, the array it points to may be used instead of a buffer allocated by *setvbuf*( ) and the argument *size* specifies the size of the array; otherwise, *size* may determine the size of a buffer allocated by the *setvbuf*( ) function. The contents of the array at any time are unspecified. |

For information about streams, see Section 2.5 (on page 484).

RETURN VALUE

Upon successful completion, *setvbuf*( ) shall return 0. Otherwise, it shall return a non-zero value CX if an invalid value is given for *type* or if the request cannot be honored, and may set *errno* to indicate the error.

ERRORS

The *setvbuf*( ) function may fail if:

CX [EBADF] The file descriptor underlying *stream* is not valid.

EXAMPLES

None.

APPLICATION USAGE

A common source of error is allocating buffer space as an ‘‘automatic’’ variable in a code block, and then failing to close the stream in the same block.

With *setvbuf*( ), allocating a buffer of *size* bytes does not necessarily imply that all of *size* bytes are used for the buffer area.

Applications should note that many implementations only provide line buffering on input from terminal devices.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

fopen( ), *setbuf*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdio.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

Extensions beyond the ISO C standard are now marked.

The *setvbuf*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

shm_open — open a shared memory object (**REALTIME**)

SYNOPSIS

SHM

```
#include <sys/mman.h>

int shm_open(const char *name, int oflag, mode_t mode);

```

DESCRIPTION

The *shm_open*( ) function shall establish a connection between a shared memory object and a file descriptor. It shall create an open file description that refers to the shared memory object and a file descriptor that refers to that open file description. The file descriptor is used by other functions to refer to that shared memory object. The *name* argument points to a string naming a shared memory object. It is unspecified whether the name appears in the file system and is visible to other functions that take pathnames as arguments. The *name* argument conforms to the construction rules for a pathname. If *name* begins with the slash character, then processes calling *shm_open*( ) with the same value of *name* refer to the same shared memory object, as long as that name has not been removed. If *name* does not begin with the slash character, the effect is implementation-defined. The interpretation of slash characters other than the leading slash character in *name* is implementation-defined.

If successful, *shm_open*( ) shall return a file descriptor for the shared memory object that is the lowest numbered file descriptor not currently open for that process. The open file description is new, and therefore the file descriptor does not share it with any other processes. It is unspecified whether the file offset is set. The FD_CLOEXEC file descriptor flag associated with the new file descriptor is set.

The file status flags and file access modes of the open file description are according to the value of *oflag*. The *oflag* argument is the bitwise-inclusive OR of the following flags defined in the **<fcntl.h>** header. Applications specify exactly one of the first two values (access modes) below in the value of *oflag*:

O_RDONLY	Open for read access only.
O_RDWR	Open for read or write access.

Any combination of the remaining flags may be specified in the value of *oflag*:

O_CREAT	If the shared memory object exists, this flag has no effect, except as noted under O_EXCL below. Otherwise, the shared memory object is created; the user ID of the shared memory object shall be set to the effective user ID of the process; the group ID of the shared memory object is set to a system default group ID or to the effective group ID of the process. The permission bits of the shared memory object shall be set to the value of the *mode* argument except those set in the file mode creation mask of the process. When bits in *mode* other than the file permission bits are set, the effect is unspecified. The *mode* argument does not affect whether the shared memory object is opened for reading, for writing, or for both. The shared memory object has a size of zero.
O_EXCL	If O_EXCL and O_CREAT are set, *shm_open*( ) fails if the shared memory object exists. The check for the existence of the shared memory object and the creation of the object if it does not exist is atomic with respect to other processes executing *shm_open*( ) naming the same shared memory object with O_EXCL and O_CREAT set. If O_EXCL is set and O_CREAT is not set, the result is undefined.

O_TRUNC	If the shared memory object exists, and it is successfully opened O_RDWR, the object shall be truncated to zero length and the mode and owner shall be unchanged by this function call. The result of using O_TRUNC with O_RDONLY is undefined.

When a shared memory object is created, the state of the shared memory object, including all data associated with the shared memory object, persists until the shared memory object is unlinked and all other references are gone. It is unspecified whether the name and shared memory object state remain valid after a system reboot.

RETURN VALUE

Upon successful completion, the *shm_open*( ) function shall return a non-negative integer representing the lowest numbered unused file descriptor. Otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *shm_open*( ) function shall fail if:

[EACCES]	The shared memory object exists and the permissions specified by *oflag* are denied, or the shared memory object does not exist and permission to create the shared memory object is denied, or O_TRUNC is specified and write permission is denied.
[EEXIST]	O_CREAT and O_EXCL are set and the named shared memory object already exists.
[EINTR]	The *shm_open*( ) operation was interrupted by a signal.
[EINVAL]	The *shm_open*( ) operation is not supported for the given name.
[EMFILE]	Too many file descriptors are currently in use by this process.
[ENAMETOOLONG]	The length of the *name* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}. |
[ENFILE]	Too many shared memory objects are currently open in the system.
[ENOENT]	O_CREAT is not set and the named shared memory object does not exist.
[ENOSPC]	There is insufficient space for the creation of the new shared memory object.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

When the Memory Mapped Files option is supported, the normal *open*( ) call is used to obtain a descriptor to a file to be mapped according to existing practice with *mmap*( ). When the Shared Memory Objects option is supported, the *shm_open*( ) function shall obtain a descriptor to the shared memory object to be mapped. |

There is ample precedent for having a file descriptor represent several types of objects. In the POSIX.1-1990 standard, a file descriptor can represent a file, a pipe, a FIFO, a tty, or a directory. Many implementations simply have an operations vector, which is indexed by the file descriptor type and does very different operations. Note that in some cases the file descriptor passed to generic operations on file descriptors are returned by *open*( ) or *creat*( ) and in some cases returned by alternate functions, such as *pipe*( ). The latter technique is used by *shm_open*( ).

Note that such shared memory objects can actually be implemented as mapped files. In both cases, the size can be set after the open using *ftruncate*( ). The *shm_open*( ) function itself does not create a shared object of a specified size because this would duplicate an extant function that set the size of an object referenced by a file descriptor.

On implementations where memory objects are implemented using the existing file system, the *shm_open*( ) function may be implemented using a macro that invokes *open*( ), and the *shm_unlink*( ) function may be implemented using a macro that invokes *unlink*( ).

For implementations without a permanent file system, the definition of the name of the memory objects is allowed not to survive a system reboot. Note that this allows systems with a permanent file system to implement memory objects as data structures internal to the implementation as well.

On implementations that choose to implement memory objects using memory directly, a *shm_open*( ) followed by a *ftruncate*( ) and *close*( ) can be used to preallocate a shared memory area and to set the size of that preallocation. This may be necessary for systems without virtual memory hardware support in order to ensure that the memory is contiguous.

The set of valid open flags to *shm_open*( ) was restricted to O_RDONLY, O_RDWR, O_CREAT, and O_TRUNC because these could be easily implemented on most memory mapping systems. This volume of IEEE Std 1003.1-200x is silent on the results if the implementation cannot supply the requested file access because of implementation-defined reasons, including hardware ones.

The error conditions [EACCES] and [ENOTSUP] are provided to inform the application that the implementation cannot complete a request.

[EACCES] indicates for implementation-defined reasons, probably hardware-related, that the implementation cannot comply with a requested mode because it conflicts with another requested mode. An example might be that an application desires to open a memory object two times, mapping different areas with different access modes. If the implementation cannot map a single area into a process space in two places, which would be required if different access modes were required for the two areas, then the implementation may inform the application at the time of the second open.

[ENOTSUP] indicates for implementation-defined reasons, probably hardware-related, that the implementation cannot comply with a requested mode at all. An example would be that the hardware of the implementation cannot support write-only shared memory areas.

On all implementations, it may be desirable to restrict the location of the memory objects to specific file systems for performance (such as a RAM disk) or implementation-defined reasons (shared memory supported directly only on certain file systems). The *shm_open*( ) function may be used to enforce these restrictions. There are a number of methods available to the application to determine an appropriate name of the file or the location of an appropriate directory. One way is from the environment via *getenv*( ). Another would be from a configuration file.

This volume of IEEE Std 1003.1-200x specifies that memory objects have initial contents of zero when created. This is consistent with current behavior for both files and newly allocated memory. For those implementations that use physical memory, it would be possible that such implementations could simply use available memory and give it to the process uninitialized. This, however, is not consistent with standard behavior for the uninitialized data area, the stack, and of course, files. Finally, it is highly desirable to set the allocated memory to zero for security reasons. Thus, initializing memory objects to zero is required.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *shm_open*( ) function is marked as part of the Shared Memory Objects option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Shared Memory Objects option.

NAME

shm_unlink — remove a shared memory object (**REALTIME**)

SYNOPSIS

SHM
```
#include <sys/mman.h>

int shm_unlink(const char *name);
```

DESCRIPTION

The *shm_unlink*( ) function shall remove the name of the shared memory object named by the string pointed to by *name*.

If one or more references to the shared memory object exist when the object is unlinked, the name shall be removed before *shm_unlink*( ) returns, but the removal of the memory object contents shall be postponed until all open and map references to the shared memory object have been removed.

Even if the object continues to exist after the last *shm_unlink*( ), reuse of the name shall subsequently cause *shm_open*( ) to behave as if no shared memory object of this name exists (that is, *shm_open*( ) will fail if O_CREAT is not set, or will create a new shared memory object if O_CREAT is set).

RETURN VALUE

Upon successful completion, a value of zero shall be returned. Otherwise, a value of −1 shall be returned and *errno* set to indicate the error. If −1 is returned, the named shared memory object shall not be changed by this function call.

ERRORS

The *shm_unlink*( ) function shall fail if:

[EACCES]	Permission is denied to unlink the named shared memory object.
[ENAMETOOLONG]	The length of the *name* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	The named shared memory object does not exist.

EXAMPLES

None.

APPLICATION USAGE

Names of memory objects that were allocated with *open*( ) are deleted with *unlink*( ) in the usual fashion. Names of memory objects that were allocated with *shm_open*( ) are deleted with *shm_unlink*( ). Note that the actual memory object is not destroyed until the last close and unmap on it have occurred if it was already in use.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *shm_unlink*( ) function is marked as part of the Shared Memory Objects option.

In the DESCRIPTION, text is added to clarify that reusing the same name after a *shm_unlink*( ) will not attach to the old shared memory object.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Shared Memory Objects option.

NAME

shmat — XSI shared memory attach operation

SYNOPSIS

XSI
```
#include <sys/shm.h>

void *shmat(int shmid, const void *shmaddr, int shmflg);
```

DESCRIPTION

The *shmat*( ) function operates on XSI shared memory (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.340, Shared Memory Object). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *shmat*( ) function attaches the shared memory segment associated with the shared memory identifier specified by *shmid* to the address space of the calling process. The segment is attached at the address specified by one of the following criteria:

- If *shmaddr* is a null pointer, the segment is attached at the first available address as selected by the system.
- If *shmaddr* is not a null pointer and (*shmflg* &SHM_RND) is non-zero, the segment is attached at the address given by (*shmaddr* −((*uintptr_t*)*shmaddr* %SHMLBA)). The character '%' is the C-language remainder operator.
- If *shmaddr* is not a null pointer and (*shmflg* &SHM_RND) is 0, the segment is attached at the address given by *shmaddr*.
- The segment is attached for reading if (*shmflg* &SHM_RDONLY) is non-zero and the calling process has read permission; otherwise, if it is 0 and the calling process has read and write permission, the segment is attached for reading and writing.

RETURN VALUE

Upon successful completion, *shmat*( ) shall increment the value of *shm_nattch* in the data structure associated with the shared memory ID of the attached shared memory segment and return the segment's start address.

Otherwise, the shared memory segment shall not be attached, *shmat*( ) shall return −1, and *errno* shall be set to indicate the error.

ERRORS

The *shmat*( ) function shall fail if:

[EACCES]	Operation permission is denied to the calling process; see Section 2.7 (on page 489).
[EINVAL]	The value of *shmid* is not a valid shared memory identifier, the *shmaddr* is not a null pointer, and the value of (*shmaddr* −((*uintptr_t*)*shmaddr* %SHMLBA)) is an illegal address for attaching shared memory; or the *shmaddr* is not a null pointer, (*shmflg* &SHM_RND) is 0, and the value of *shmaddr* is an illegal address for attaching shared memory.
[EMFILE]	The number of shared memory segments attached to the calling process would exceed the system-imposed limit.
[ENOMEM]	The available data space is not large enough to accommodate the shared memory segment.

EXAMPLES

None.

APPLICATION USAGE

The POSIX Realtime Extension defines alternative interfaces for interprocess communication. Application developers who need to use IPC should design their applications so that modules using the IPC routines described in Section 2.7 (on page 489) can be easily modified to use the alternative interfaces.

NAME

shmctl — XSI shared memory control operations

SYNOPSIS

XSI

```
#include <sys/shm.h>

int shmctl(int shmid, int cmd, struct shmid_ds *buf);
```

DESCRIPTION

The *shmctl*( ) function operates on XSI shared memory (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.340, Shared Memory Object). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *shmctl*( ) function provides a variety of shared memory control operations as specified by *cmd*. The following values for *cmd* are available:

IPC_STAT Place the current value of each member of the **shmid_ds** data structure associated with *shmid* into the structure pointed to by *buf*. The contents of the structure are defined in **<sys/shm.h>**.

IPC_SET Set the value of the following members of the **shmid_ds** data structure associated with *shmid* to the corresponding value found in the structure pointed to by *buf*:

`shm_perm.uid`
`shm_perm.gid`
`shm_perm.mode` Low-order nine bits.

IPC_SET can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of *shm_perm.cuid* or *shm_perm.uid* in the **shmid_ds** data structure associated with *shmid*.

IPC_RMID Remove the shared memory identifier specified by *shmid* from the system and destroy the shared memory segment and **shmid_ds** data structure associated with it. IPC_RMID can only be executed by a process that has an effective user ID equal to either that of a process with appropriate privileges or to the value of *shm_perm.cuid* or *shm_perm.uid* in the **shmid_ds** data structure associated with *shmid*.

RETURN VALUE

Upon successful completion, *shmctl*( ) shall return 0; otherwise, it shall return –1 and set *errno* to indicate the error.

ERRORS

The *shmctl*( ) function shall fail if:

[EACCES] The argument *cmd* is equal to IPC_STAT and the calling process does not have read permission; see Section 2.7 (on page 489).

[EINVAL] The value of *shmid* is not a valid shared memory identifier, or the value of *cmd* is not a valid command.

[EPERM] The argument *cmd* is equal to IPC_RMID or IPC_SET and the effective user ID of the calling process is not equal to that of a process with appropriate privileges and it is not equal to the value of *shm_perm.cuid* or *shm_perm.uid* in the data structure associated with *shmid*.

The *shmctl*( ) function may fail if:

[EOVERFLOW] The *cmd* argument is IPC_STAT and the *gid* or *uid* value is too large to be stored in the structure pointed to by the *buf* argument.

EXAMPLES

None.

APPLICATION USAGE

The POSIX Realtime Extension defines alternative interfaces for interprocess communication. Application developers who need to use IPC should design their applications so that modules using the IPC routines described in Section 2.7 (on page 489) can be easily modified to use the alternative interfaces.

NAME

shmdt — XSI shared memory detach operation

SYNOPSIS

XSI

```
#include <sys/shm.h>

int shmdt(const void *shmaddr);
```

DESCRIPTION

The *shmdt*( ) function operates on XSI shared memory (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.340, Shared Memory Object). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *shmdt*( ) function detaches the shared memory segment located at the address specified by *shmaddr* from the address space of the calling process.

RETURN VALUE

Upon successful completion, *shmdt*( ) shall decrement the value of *shm_nattch* in the data structure associated with the shared memory ID of the attached shared memory segment and return 0.

Otherwise, the shared memory segment shall not be detached, *shmdt*( ) shall return –1, and *errno* shall be set to indicate the error.

ERRORS

The *shmdt*( ) function shall fail if:

[EINVAL] The value of *shmaddr* is not the data segment start address of a shared memory segment.

EXAMPLES

None.

APPLICATION USAGE

The POSIX Realtime Extension defines alternative interfaces for interprocess communication. Application developers who need to use IPC should design their applications so that modules using the IPC routines described in Section 2.7 (on page 489) can be easily modified to use the alternative interfaces.

NAME

shmget — get XSI shared memory segment

SYNOPSIS

XSI

```
#include <sys/shm.h>

int shmget(key_t key, size_t size, int shmflg);
```

DESCRIPTION

The *shmget*( ) function operates on XSI shared memory (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.340, Shared Memory Object). It is unspecified whether this function interoperates with the realtime interprocess communication facilities defined in Section 2.8 (on page 491).

The *shmget*( ) function shall return the shared memory identifier associated with *key*.

A shared memory identifier, associated data structure, and shared memory segment of at least *size* bytes (see **<sys/shm.h>**) are created for *key* if one of the following is true:

- The argument *key* is equal to IPC_PRIVATE.
- The argument *key* does not already have a shared memory identifier associated with it and (*shmflg* &IPC_CREAT) is non-zero.

Upon creation, the data structure associated with the new shared memory identifier shall be initialized as follows:

- The values of *shm_perm.cuid*, *shm_perm.uid*, *shm_perm.cgid*, and *shm_perm.gid* are set equal to the effective user ID and effective group ID, respectively, of the calling process.
- The low-order nine bits of *shm_perm.mode* are set equal to the low-order nine bits of *shmflg*. The value of *shm_segsz* is set equal to the value of *size*.
- The values of *shm_lpid*, *shm_nattch*, *shm_atime*, and *shm_dtime* are set equal to 0.
- The value of *shm_ctime* is set equal to the current time.

When the shared memory segment is created, it shall be initialized with all zero values.

RETURN VALUE

Upon successful completion, *shmget*( ) shall return a non-negative integer, namely a shared memory identifier; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *shmget*( ) function shall fail if:

[EACCES]	A shared memory identifier exists for *key* but operation permission as specified by the low-order nine bits of *shmflg* would not be granted; see Section 2.7 (on page 489).
[EEXIST]	A shared memory identifier exists for the argument *key* but (*shmflg* &IPC_CREAT) &&(*shmflg* &IPC_EXCL) is non-zero.
[EINVAL]	A shared memory segment is to be created and the value of size is less than the system-imposed minimum or greater than the system-imposed maximum.
[EINVAL]	No shared memory segment is to be created and a shared memory segment exists for *key* but the size of the segment associated with it is less than *size* and *size* is not 0.

[ENOENT] A shared memory identifier does not exist for the argument *key* and (*shmflg* &IPC_CREAT) is 0.

[ENOMEM] A shared memory identifier and associated shared memory segment shall be created, but the amount of available physical memory is not sufficient to fill the request.

[ENOSPC] A shared memory identifier is to be created, but the system-imposed limit on the maximum number of allowed shared memory identifiers system-wide would be exceeded.

EXAMPLES

None.

APPLICATION USAGE

The POSIX Realtime Extension defines alternative interfaces for interprocess communication. Application developers who need to use IPC should design their applications so that modules using the IPC routines described in Section 2.7 (on page 489) can be easily modified to use the alternative interfaces.

NAME

shutdown — shut down socket send and receive operations

SYNOPSIS

```
#include <sys/socket.h>

int shutdown(int socket, int how);
```

DESCRIPTION

The *shutdown*( ) function shall cause all or part of a full-duplex connection on the socket associated with the file descriptor *socket* to be shut down.

The *shutdown*( ) function takes the following arguments:

socket	Specifies the file descriptor of the socket.
how	Specifies the type of shutdown. The values are as follows:

SHUT_RD	Disables further receive operations.
SHUT_WR	Disables further send operations.
SHUT_RDWR	Disables further send and receive operations.

The *shutdown*( ) function disables subsequent send and/or receive operations on a socket, depending on the value of the *how* argument.

RETURN VALUE

Upon successful completion, *shutdown*( ) shall return 0; otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *shutdown*( ) function shall fail if:

[EBADF]	The *socket* argument is not a valid file descriptor.
[EINVAL]	The *how* argument is invalid.
[ENOTCONN]	The socket is not connected.
[ENOTSOCK]	The *socket* argument does not refer to a socket.

The *shutdown*( ) function may fail if:

[ENOBUFS]	Insufficient resources were available in the system to perform the operation.

NAME

sigaction — examine and change signal action

SYNOPSIS

CX

```
#include <signal.h>

int sigaction(int sig, const struct sigaction *restrict act,
    struct sigaction *restrict oact);
```

DESCRIPTION

The *sigaction*( ) function allows the calling process to examine and/or specify the action to be associated with a specific signal. The argument *sig* specifies the signal; acceptable values are defined in **<signal.h>**.

The structure **sigaction**, used to describe an action to be taken, is defined in the **<signal.h>** header to include at least the following members:

Member Type	Member Name	Description
void(*) (int)	*sa_handler*	SIG_DFL, SIG_IGN, or pointer to a function.
sigset_t	*sa_mask*	Additional set of signals to be blocked during execution of signal-catching function.
int	*sa_flags*	Special flags to affect behavior of signal.
void(*) (int, siginfo_t *, void *)	*sa_sigaction*	Signal-catching function.

The storage occupied by *sa_handler* and *sa_sigaction* may overlap, and a conforming application shall not use both simultaneously.

If the argument *act* is not a null pointer, it points to a structure specifying the action to be associated with the specified signal. If the argument *oact* is not a null pointer, the action previously associated with the signal is stored in the location pointed to by the argument *oact*. If the argument *act* is a null pointer, signal handling is unchanged; thus, the call can be used to enquire about the current handling of a given signal. The SIGKILL and SIGSTOP signals shall not be added to the signal mask using this mechanism; this restriction shall be enforced by the system without causing an error to be indicated.

XSI|RTS

If the SA_SIGINFO flag (see below) is cleared in the *sa_flags* field of the **sigaction** structure, the *sa_handler* field identifies the action to be associated with the specified signal. If the SA_SIGINFO flag is set in the *sa_flags* field, and the implementation supports the Realtime Signals Extension option or the X/Open System Interfaces Extension option, the *sa_sigaction* field specifies a signal-catching function. If the SA_SIGINFO bit is cleared and the *sa_handler* field specifies a signal-catching function, or if the SA_SIGINFO bit is set, the *sa_mask* field identifies a set of signals that shall be added to the signal mask of the thread before the signal-catching function is invoked. If the *sa_handler* field specifies a signal-catching function, the *sa_mask* field identifies a set of signals that shall be added to the process' signal mask before the signal-catching function is invoked.

The *sa_flags* field can be used to modify the behavior of the specified signal.

The following flags, defined in the **<signal.h>** header, can be set in *sa_flags*:

XSI

SA_NOCLDSTOP Do not generate SIGCHLD when children stop or stopped children continue.

If *sig* is SIGCHLD and the SA_NOCLDSTOP flag is not set in *sa_flags*, and the implementation supports the SIGCHLD signal, then a SIGCHLD signal shall be generated for the calling process whenever any of its child processes stop and a SIGCHLD signal may be generated for the calling process whnever any of its stopped child processes are continued. If *sig* is SIGCHLD and the SA_NOCLDSTOP flag is set in *sa_flags*, then the implementation shall not generate a SIGCHLD signal in this way.

SA_ONSTACK If set and an alternate signal stack has been declared with *sigaltstack*( ) or *sigstack*( ), the signal shall be delivered to the calling process on that stack. Otherwise, the signal shall be delivered on the current stack.

SA_RESETHAND If set, the disposition of the signal shall be reset to SIG_DFL and the SA_SIGINFO flag shall be cleared on entry to the signal handler.

Note: SIGILL and SIGTRAP cannot be automatically reset when delivered; the system silently enforces this restriction.

Otherwise, the disposition of the signal shall not be modified on entry to the signal handler.

In addition, if this flag is set, *sigaction*( ) behaves as if the SA_NODEFER flag were also set.

SA_RESTART This flag affects the behavior of interruptible functions; that is, those specified to fail with *errno* set to [EINTR]. If set, and a function specified as interruptible is interrupted by this signal, the function shall restart and shall not fail with [EINTR] unless otherwise specified. If the flag is not set, interruptible functions interrupted by this signal shall fail with *errno* set to [EINTR].

SA_SIGINFO If cleared and the signal is caught, the signal-catching function shall be entered as:

```
void func(int signo);
```

where *signo* is the only argument to the signal catching function. In this case, the application shall use the *sa_handler* member to describe the signal catching function and the application shall not modify the *sa_sigaction* member.

If SA_SIGINFO is set and the signal is caught, the signal-catching function shall be entered as:

```
void func(int signo, siginfo_t *info, void *context);
```

where two additional arguments are passed to the signal catching function. The second argument shall point to an object of type **siginfo_t** explaining the reason why the signal was generated; the third argument can be cast to a pointer to an object of type **ucontext_t** to refer to the receiving process' context that was interrupted when the signal was delivered. In this case, the application shall use the *sa_sigaction* member to describe the signal catching function and the application shall not modify the *sa_handler* member.

The *si_signo* member contains the system-generated signal number.

The *si_errno* member may contain implementation-defined additional error information; if non-zero, it contains an error number identifying the condition that caused the signal to be generated.

The *si_code* member contains a code identifying the cause of the signal.

If the value of *si_code* is less than or equal to 0, then the signal was generated by a process and *si_pid* and *si_uid*, respectively, indicate the process ID and the real user ID of the sender. The **<signal.h>** header description contains information about the signal specific contents of the elements of the **siginfo_t** type.

SA_NOCLDWAIT

If set, and *sig* equals SIGCHLD, child processes of the calling processes shall not be transformed into zombie processes when they terminate. If the calling process subsequently waits for its children, and the process has no unwaited-for children that were transformed into zombie processes, it shall block until all of its children terminate, and *wait*( ), *waitid*( ), and *waitpid*( ) shall fail and set *errno* to [ECHILD]. Otherwise, terminating child processes shall be transformed into zombie processes, unless SIGCHLD is set to SIG_IGN.

SA_NODEFER

If set and *sig* is caught, *sig* shall not be added to the process' signal mask on entry to the signal handler unless it is included in *sa_mask*. Otherwise, *sig* shall always be added to the process' signal mask on entry to the signal handler.

When a signal is caught by a signal-catching function installed by *sigaction*( ), a new signal mask is calculated and installed for the duration of the signal-catching function (or until a call to either *sigprocmask*( ) or *sigsuspend*( ) is made). This mask is formed by taking the union of the current signal mask and the value of the *sa_mask* for the signal being delivered unless SA_NODEFER or SA_RESETHAND is set, and then including the signal being delivered. If and when the user's signal handler returns normally, the original signal mask is restored.

Once an action is installed for a specific signal, it shall remain installed until another action is explicitly requested (by another call to *sigaction*( )), until the SA_RESETHAND flag causes resetting of the handler, or until one of the *exec* functions is called.

If the previous action for *sig* had been established by *signal*( ), the values of the fields returned in the structure pointed to by *oact* are unspecified, and in particular *oact*->*sa_handler* is not necessarily the same value passed to *signal*( ). However, if a pointer to the same structure or a copy thereof is passed to a subsequent call to *sigaction*( ) via the *act* argument, handling of the signal shall be as if the original call to *signal*( ) were repeated.

If *sigaction*( ) fails, no new signal handler is installed.

It is unspecified whether an attempt to set the action for a signal that cannot be caught or ignored to SIG_DFL is ignored or causes an error to be returned with *errno* set to [EINVAL].

If SA_SIGINFO is not set in *sa_flags*, then the disposition of subsequent occurrences of *sig* when it is already pending is implementation-defined; the signal-catching function shall be invoked with a single argument. If the implementation supports the Realtime Signals Extension option, and if SA_SIGINFO is set in *sa_flags*, then subsequent occurrences of *sig* generated by *sigqueue*( ) or as a result of any signal-generating function that supports the specification of an application-defined value (when *sig* is already pending) shall be queued in FIFO order until delivered or accepted; the signal-catching function shall be invoked with three arguments. The application specified value is passed to the signal-catching function as the *si_value* member of the **siginfo_t** structure.

The result of the use of *sigaction*( ) and a *sigwait*( ) function concurrently within a process on the same signal is unspecified.

RETURN VALUE

Upon successful completion, *sigaction*( ) shall return 0; otherwise, −1 shall be returned, *errno* shall be set to indicate the error, and no new signal-catching function shall be installed.

ERRORS

The *sigaction*( ) function shall fail if:

[EINVAL]	The *sig* argument is not a valid signal number or an attempt is made to catch a signal that cannot be caught or ignore a signal that cannot be ignored.
[ENOTSUP]	The SA_SIGINFO bit flag is set in the *sa_flags* field of the **sigaction** structure, and the implementation does not support either the Realtime Signals Extension option, or the X/Open System Interfaces Extension option.

The *sigaction*( ) function may fail if:

[EINVAL]	An attempt was made to set the action to SIG_DFL for a signal that cannot be caught or ignored (or both).

EXAMPLES

None.

APPLICATION USAGE

The *sigaction*( ) function supersedes the *signal*( ) function, and should be used in preference. In particular, *sigaction*( ) and *signal*( ) should not be used in the same process to control the same signal. The behavior of reentrant functions, as defined in the DESCRIPTION, is as specified by this volume of IEEE Std 1003.1-200x, regardless of invocation from a signal-catching function. This is the only intended meaning of the statement that reentrant functions may be used in signal-catching functions without restrictions. Applications must still consider all effects of such functions on such things as data structures, files, and process state. In particular, application writers need to consider the restrictions on interactions when interrupting *sleep*( ) and interactions among multiple handles for a file description. The fact that any specific function is listed as reentrant does not necessarily mean that invocation of that function from a signal-catching function is recommended.

In order to prevent errors arising from interrupting non-reentrant function calls, applications should protect calls to these functions either by blocking the appropriate signals or through the use of some programmatic semaphore (see *semget*( ), *sem_init*( ), *sem_open*( ), and so on). Note in particular that even the ‘‘safe’’ functions may modify *errno*; the signal-catching function, if not executing as an independent thread, may want to save and restore its value. Naturally, the same principles apply to the reentrancy of application routines and asynchronous data access. Note that *longjmp*( ) and *siglongjmp*( ) are not in the list of reentrant functions. This is because the code executing after *longjmp*( ) and *siglongjmp*( ) can call any unsafe functions with the same danger as calling those unsafe functions directly from the signal handler. Applications that use *longjmp*( ) and *siglongjmp*( ) from within signal handlers require rigorous protection in order to be portable. Many of the other functions that are excluded from the list are traditionally implemented using either *malloc*( ) or *free*( ) functions or the standard I/O library, both of which traditionally use data structures in a non-reentrant manner. Since any combination of different functions using a common data structure can cause reentrancy problems, this volume of IEEE Std 1003.1-200x does not define the behavior when any unsafe function is called in a signal handler that interrupts an unsafe function.

If the signal occurs other than as the result of calling *abort*( ), *kill*( ), or *raise*( ), the behavior is undefined if the signal handler calls any function in the standard library other than one of the functions listed in the table above or refers to any object with static storage duration other than by assigning a value to a static storage duration variable of type **volatile sig_atomic_t**. Furthermore, if such a call fails, the value of *errno* is unspecified.

Usually, the signal is executed on the stack that was in effect before the signal was delivered. An alternate stack may be specified to receive a subset of the signals being caught.

When the signal handler returns, the receiving process resumes execution at the point it was interrupted unless the signal handler makes other arrangements. If *longjmp*( ) or *_longjmp*( ) is used to leave the signal handler, then the signal mask must be explicitly restored by the process.

This volume of IEEE Std 1003.1-200x defines the third argument of a signal handling function when SA_SIGINFO is set as a **void *** instead of a **ucontext_t ***, but without requiring type checking. New applications should explicitly cast the third argument of the signal handling function to **ucontext_t ***.

The BSD optional four argument signal handling function is not supported by this volume of IEEE Std 1003.1-200x. The BSD declaration would be:

```
void handler(int sig, int code, struct sigcontext *scp,
    char *addr);
```

where *sig* is the signal number, *code* is additional information on certain signals, *scp* is a pointer to the sigcontext structure, and *addr* is additional address information. Much the same information is available in the objects pointed to by the second argument of the signal handler specified when SA_SIGINFO is set.

RATIONALE

Although this volume of IEEE Std 1003.1-200x requires that signals that cannot be ignored shall not be added to the signal mask when a signal-catching function is entered, there is no explicit requirement that subsequent calls to *sigaction*( ) reflect this in the information returned in the *oact* argument. In other words, if SIGKILL is included in the *sa_mask* field of *act*, it is unspecified whether or not a subsequent call to *sigaction*( ) returns with SIGKILL included in the *sa_mask* field of *oact*.

The SA_NOCLDSTOP flag, when supplied in the *act*->*sa_flags* parameter, allows overloading SIGCHLD with the System V semantics that each SIGCLD signal indicates a single terminated child. Most conforming applications that catch SIGCHLD are expected to install signal-catching functions that repeatedly call the *waitpid*( ) function with the WNOHANG flag set, acting on each child for which status is returned, until *waitpid*( ) returns zero. If stopped children are not of interest, the use of the SA_NOCLDSTOP flag can prevent the overhead from invoking the signal-catching routine when they stop.

Some historical implementations also define other mechanisms for stopping processes, such as the *ptrace*( ) function. These implementations usually do not generate a SIGCHLD signal when processes stop due to this mechanism; however, that is beyond the scope of this volume of IEEE Std 1003.1-200x.

This volume of IEEE Std 1003.1-200x requires that calls to *sigaction*( ) that supply a NULL *act* argument succeed, even in the case of signals that cannot be caught or ignored (that is, SIGKILL or SIGSTOP). The System V *signal*( ) and BSD *sigvec*( ) functions return [EINVAL] in these cases and, in this respect, their behavior varies from *sigaction*( ).

This volume of IEEE Std 1003.1-200x requires that *sigaction*( ) properly save and restore a signal action set up by the ISO C standard *signal*( ) function. However, there is no guarantee that the reverse is true, nor could there be given the greater amount of information conveyed by the **sigaction** structure. Because of this, applications should avoid using both functions for the same signal in the same process. Since this cannot always be avoided in case of general-purpose library routines, they should always be implemented with *sigaction*( ).

It was intended that the *signal*( ) function should be implementable as a library routine using *sigaction*( ).

The POSIX Realtime Extension extends the *sigaction*( ) function as specified by the POSIX.1-1990 standard to allow the application to request on a per-signal basis via an additional signal action flag that the extra parameters, including the application-defined signal value, if any, be passed to the signal-catching function.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and POSIX Threads Extension.

In the DESCRIPTION, the second argument to *func* when SA_SIGINFO is set is no longer permitted to be NULL, and the description of permitted **siginfo_t** contents is expanded by reference to **<signal.h>**.

Since the X/OPEN UNIX Extension functionality is now folded into the BASE, the [ENOTSUP] error is deleted.

Issue 6

The Open Group Corrigendum U028/7 is applied. In the paragraph entitled ‘‘Signal Effects on Other Functions’’, a reference to *sigpending*( ) is added.

In the DESCRIPTION, the text ‘‘Signal Generation and Delivery’’, ‘‘Signal Actions’’, and ‘‘Signal Effects on Other Functions’’ are moved to a separate section of this volume of IEEE Std 1003.1-200x.

Text describing functionality from the Realtime Signals option is marked.

The following changes are made for alignment with the ISO POSIX-1: 1996 standard:

- The [ENOTSUP] error condition is added.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The **restrict** keyword is added to the *sigaction*( ) prototype for alignment with the ISO/IEC 9899: 1999 standard.

References to the *wait3*( ) function are removed.

The SYNOPSIS is marked CX since the presence of this function in the **<signal.h>** header is an extension over the ISO C standard.

NAME

sigaddset — add a signal to a signal set

SYNOPSIS

CX
```
#include <signal.h>

int sigaddset(sigset_t *set, int signo);
```

DESCRIPTION

The *sigaddset*( ) function adds the individual signal specified by the *signo* to the signal set pointed to by *set*.

Applications shall call either *sigemptyset*( ) or *sigfillset*( ) at least once for each object of type **sigset_t** prior to any other use of that object. If such an object is not initialized in this way, but is nonetheless supplied as an argument to any of *pthread_sigmask*( ), *sigaction*( ), *sigaddset*( ), *sigdelset*( ), *sigismember*( ), *sigpending*( ), *sigprocmask*( ), *sigsuspend*( ), *sigtimedwait*( ), *sigwait*( ), or *sigwaitinfo*( ), the results are undefined.

RETURN VALUE

Upon successful completion, *sigaddset*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *sigaddset*( ) function may fail if:

[EINVAL]	The value of the *signo* argument is an invalid or unsupported signal number.

EXAMPLES

None.

APPLICATION USAGE

None.

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 5

The last paragraph of the DESCRIPTION was included as an APPLICATION USAGE note in previous issues.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The SYNOPSIS is marked CX since the presence of this function in the **<signal.h>** header is an extension over the ISO C standard.

NAME

sigaltstack — set and get signal alternate stack context

SYNOPSIS

XSI

```
#include <signal.h>

int sigaltstack(const stack_t *restrict ss, stack_t *restrict oss);
```

DESCRIPTION

The *sigaltstack*( ) function allows a process to define and examine the state of an alternate stack for signal handlers. Signals that have been explicitly declared to execute on the alternate stack shall be delivered on the alternate stack.

If *ss* is not a null pointer, it points to a **stack_t** structure that specifies the alternate signal stack that shall take effect upon return from *sigaltstack*( ). The *ss_flags* member specifies the new stack state. If it is set to SS_DISABLE, the stack is disabled and *ss_sp* and *ss_size* are ignored. Otherwise, the stack shall be enabled, and the *ss_sp* and *ss_size* members specify the new address and size of the stack.

The range of addresses starting at *ss_sp* up to but not including *ss_sp*+*ss_size*, is available to the implementation for use as the stack. This function makes no assumptions regarding which end is the stack base and in which direction the stack grows as items are pushed.

If *oss* is not a null pointer, on successful completion it shall point to a **stack_t** structure that specifies the alternate signal stack that was in effect prior to the call to *sigaltstack*( ). The *ss_sp* and *ss_size* members specify the address and size of that stack. The *ss_flags* member specifies the stack's state, and may contain one of the following values:

SS_ONSTACK	The process is currently executing on the alternate signal stack. Attempts to modify the alternate signal stack while the process is executing on it fail. This flag shall not be modified by processes.
SS_DISABLE	The alternate signal stack is currently disabled.

The value SIGSTKSZ is a system default specifying the number of bytes that would be used to cover the usual case when manually allocating an alternate stack area. The value MINSIGSTKSZ is defined to be the minimum stack size for a signal handler. In computing an alternate stack size, a program should add that amount to its stack requirements to allow for the system implementation overhead. The constants SS_ONSTACK, SS_DISABLE, SIGSTKSZ, and MINSIGSTKSZ are defined in **<signal.h>**.

After a successful call to one of the *exec* functions, there are no alternate signal stacks in the new process image.

In some implementations, a signal (whether or not indicated to execute on the alternate stack) shall always execute on the alternate stack if it is delivered while another signal is being caught using the alternate stack.

Use of this function by library threads that are not bound to kernel-scheduled entities results in undefined behavior.

RETURN VALUE

Upon successful completion, *sigaltstack*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *sigaltstack*( ) function shall fail if:

[EINVAL]	The *ss* argument is not a null pointer, and the *ss_flags* member pointed to by *ss* contains flags other than SS_DISABLE.
[ENOMEM]	The size of the alternate stack area is less than MINSIGSTKSZ.
[EPERM]	An attempt was made to modify an active stack.

EXAMPLES

Allocating Memory for an Alternate Stack

The following example illustrates a method for allocating memory for an alternate stack.

```
#include <signal.h>
...
if ((sigstk.ss_sp = malloc(SIGSTKSZ)) == NULL)
    /* Error return. */
sigstk.ss_size = SIGSTKSZ;
sigstk.ss_flags = 0;
if (sigaltstack(&sigstk,(stack_t *)0) < 0)
    perror("sigaltstack");
```

APPLICATION USAGE

On some implementations, stack space is automatically extended as needed. On those implementations, automatic extension is typically not available for an alternate stack. If the stack overflows, the behavior is undefined.

RATIONALE

None.

FUTURE DIRECTIONS

None.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The **restrict** keyword is added to the *sigaltstack*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

sigdelset — delete a signal from a signal set

SYNOPSIS

CX
```
#include <signal.h>

int sigdelset(sigset_t *set, int signo);
```

DESCRIPTION

The *sigdelset*( ) function deletes the individual signal specified by *signo* from the signal set pointed to by *set*.

Applications should call either *sigemptyset*( ) or *sigfillset*( ) at least once for each object of type **sigset_t** prior to any other use of that object. If such an object is not initialized in this way, but is nonetheless supplied as an argument to any of *pthread_sigmask*( ), *sigaction*( ), *sigaddset*( ), *sigdelset*( ), *sigismember*( ), *sigpending*( ), *sigprocmask*( ), *sigsuspend*( ), *sigtimedwait*( ), *sigwait*( ), or *sigwaitinfo*( ), the results are undefined.

RETURN VALUE

Upon successful completion, *sigdelset*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *sigdelset*( ) function may fail if:

[EINVAL]	The *signo* argument is not a valid signal number, or is an unsupported signal number.

NAME

sigemptyset — initialize and empty a signal set

SYNOPSIS

CX

```
#include <signal.h>

int sigemptyset(sigset_t *set);
```

DESCRIPTION

The *sigemptyset*( ) function initializes the signal set pointed to by *set*, such that all signals defined in IEEE Std 1003.1-200x are excluded.

RETURN VALUE

Upon successful completion, *sigemptyset*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The implementation of the *sigemptyset*( ) (or *sigfillset*( )) function could quite trivially clear (or set) all the bits in the signal set. Alternatively, it would be reasonable to initialize part of the structure, such as a version field, to permit binary-compatibility between releases where the size of the set varies. For such reasons, either *sigemptyset*( ) or *sigfillset*( ) must be called prior to any other use of the signal set, even if such use is read-only (for example, as an argument to *sigpending*( )). This function is not intended for dynamic allocation.

The *sigfillset*( ) and *sigemptyset*( ) functions require that the resulting signal set include (or exclude) all the signals defined in this volume of IEEE Std 1003.1-200x. Although it is outside the scope of this volume of IEEE Std 1003.1-200x to place this requirement on signals that are implemented as extensions, it is recommended that implementation-defined signals also be affected by these functions. However, there may be a good reason for a particular signal not to be affected. For example, blocking or ignoring an implementation-defined signal may have undesirable side effects, whereas the default action for that signal is harmless. In such a case, it would be preferable for such a signal to be excluded from the signal set returned by *sigfillset*( ).

In early proposals there was no distinction between invalid and unsupported signals (the names of optional signals that were not supported by an implementation were not defined by that implementation). The [EINVAL] error was thus specified as a required error for invalid signals. With that distinction, it is not necessary to require implementations of these functions to determine whether an optional signal is actually supported, as that could have a significant performance impact for little value. The error could have been required for invalid signals and optional for unsupported signals, but this seemed unnecessarily complex. Thus, the error is optional in both cases.

FUTURE DIRECTIONS

None.

NAME

sigfillset — initialize and fill a signal set

SYNOPSIS

CX
```
#include <signal.h>

int sigfillset(sigset_t *set);
```

DESCRIPTION

The *sigfillset*( ) function shall initialize the signal set pointed to by *set*, such that all signals defined in this volume of IEEE Std 1003.1-200x are included.

RETURN VALUE

Upon successful completion, *sigfillset*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

No errors are defined.

Issue 6

The SYNOPSIS is marked CX since the presence of this function in the **<signal.h>** header is an extension over the ISO C standard.

NAME

sighold, sigignore, sigpause, sigrelse, sigset — signal management

SYNOPSIS

XSI

```
#include <signal.h>

int sighold(int sig);
int sigignore(int sig);
int sigpause(int sig);
int sigrelse(int sig);
void (*sigset(int sig, void (*disp)(int)))(int);

```

DESCRIPTION

Use of any of these functions is unspecified in a multi-threaded process.

The *sighold*( ), *sigignore*( ), *sigpause*( ), *sigrelse*( ), and *sigset*( ) functions provide simplified signal management.

The *sigset*( ) function shall modify signal dispositions. The *sig* argument specifies the signal, which may be any signal except SIGKILL and SIGSTOP. The *disp* argument specifies the signal's disposition, which may be SIG_DFL, SIG_IGN, or the address of a signal handler. If *sigset*( ) is used, and *disp* is the address of a signal handler, the system shall add *sig* to the calling process' signal mask before executing the signal handler; when the signal handler returns, the system shall restore the calling process' signal mask to its state prior to the delivery of the signal. In addition, if *sigset*( ) is used, and *disp* is equal to SIG_HOLD, *sig* shall be added to the calling process' signal mask and *sig*'s disposition shall remain unchanged. If *sigset*( ) is used, and *disp* is not equal to SIG_HOLD, *sig* shall be removed from the calling process' signal mask.

The *sighold*( ) function shall add *sig* to the calling process' signal mask.

The *sigrelse*( ) function shall remove *sig* from the calling process' signal mask.

The *sigignore*( ) function shall set the disposition of *sig* to SIG_IGN.

The *sigpause*( ) function shall remove *sig* from the calling process' signal mask and suspend the calling process until a signal is received. The *sigpause*( ) function shall restore the process' signal mask to its original state before returning.

If the action for the SIGCHLD signal is set to SIG_IGN, child processes of the calling processes shall not be transformed into zombie processes when they terminate. If the calling process subsequently waits for its children, and the process has no unwaited-for children that were transformed into zombie processes, it shall block until all of its children terminate, and *wait*( ), *waitid*( ), and *waitpid*( ) shall fail and set *errno* to [ECHILD].

RETURN VALUE

Upon successful completion, *sigset*( ) shall return SIG_HOLD if the signal had been blocked and the signal's previous disposition if it had not been blocked. Otherwise, SIG_ERR shall be returned and *errno* set to indicate the error.

The *sigpause*( ) function shall suspend execution of the thread until a signal is received, whereupon it shall return −1 and set *errno* to [EINTR].

For all other functions, upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

These functions shall fail if:

[EINVAL] The *sig* argument is an illegal signal number.

The *sigset*( ) and *sigignore*( ) functions shall fail if:

[EINVAL] An attempt is made to catch a signal that cannot be caught, or to ignore a signal that cannot be ignored.

EXAMPLES

None.

APPLICATION USAGE

The *sigaction*( ) function provides a more comprehensive and reliable mechanism for controlling signals; new applications should use *sigaction*( ) rather than *sigset*( ).

The *sighold*( ) function, in conjunction with *sigrelse*( ) or *sigpause*( ), may be used to establish critical regions of code that require the delivery of a signal to be temporarily deferred.

The *sigsuspend*( ) function should be used in preference to *sigpause*( ) for broader portability.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.4 (on page 478), *exec*, *pause*( ), *sigaction*( ), *signal*( ), *sigsuspend*( ), *waitid*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<signal.h>**

CHANGE HISTORY

First released in Issue 4 Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

The DESCRIPTION is updated to indicate that the *sigpause*( ) function restores the process' signal mask to its original state before returning.

The RETURN VALUE section is updated to indicate that the *sigpause*( ) function suspends execution of the process until a signal is received, whereupon it returns –1 and sets *errno* to [EINTR].

Issue 6

The DESCRIPTION is updated to avoid use of the term ''must'' for application requirements.

References to the *wait3*( ) function are removed.

The XSI functions are split out into their own reference page.

NAME

sigignore — signal management

SYNOPSIS

XSI

```
#include <signal.h>

int sigignore(int sig);
```

DESCRIPTION

Refer to *sighold*( ).

NAME

siginterrupt — allow signals to interrupt functions

SYNOPSIS

XSI

```
#include <signal.h>

int siginterrupt(int sig, int flag);
```

DESCRIPTION

The *siginterrupt*( ) function shall change the restart behavior when a function is interrupted by the specified signal. The function *siginterrupt*(*sig*, *flag*) has an effect as if implemented as: |

```
siginterrupt(int sig, int flag) {
    int ret;
    struct sigaction act;

    (void) sigaction(sig, NULL, &act);
    if (flag)
        act.sa_flags &= ˜SA_RESTART;
    else
        act.sa_flags |= SA_RESTART;
    ret = sigaction(sig, &act, NULL);
    return ret;
}
```

RETURN VALUE

Upon successful completion, *siginterrupt*( ) shall return 0; otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *siginterrupt*( ) function shall fail if:

[EINVAL]	The *sig* argument is not a valid signal number.

EXAMPLES

None.

APPLICATION USAGE

The *siginterrupt*( ) function supports programs written to historical system interfaces. A conforming application, when being written or rewritten, should use *sigaction*( ) with the SA_RESTART flag instead of *siginterrupt*( ). |

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

sigismember — test for a signal in a signal set

SYNOPSIS

CX

```
#include <signal.h>

int sigismember(const sigset_t *set, int signo);
```

DESCRIPTION

The *sigismember*( ) function shall test whether the signal specified by *signo* is a member of the set pointed to by *set*.

Applications should call either *sigemptyset*( ) or *sigfillset*( ) at least once for each object of type **sigset_t** prior to any other use of that object. If such an object is not initialized in this way, but is nonetheless supplied as an argument to any of *pthread_sigmask*( ), *sigaction*( ), *sigaddset*( ), *sigdelset*( ), *sigismember*( ), *sigpending*( ), *sigprocmask*( ), *sigsuspend*( ), *sigtimedwait*( ), *sigwait*( ), or *sigwaitinfo*( ), the results are undefined.

RETURN VALUE

Upon successful completion, *sigismember*( ) shall return 1 if the specified signal is a member of the specified set, or 0 if it is not. Otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *sigismember*( ) function may fail if:

[EINVAL] The *signo* argument is not a valid signal number, or is an unsupported signal number.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 5

The last paragraph of the DESCRIPTION was included as an APPLICATION USAGE note in previous issues.

Issue 6

The SYNOPSIS is marked CX since the presence of this function in the **<signal.h>** header is an extension over the ISO C standard.

NAME

siglongjmp — non-local goto with signal handling

SYNOPSIS

CX
```
#include <setjmp.h>

void siglongjmp(sigjmp_buf env, int val);
```

DESCRIPTION

The *siglongjmp*( ) function shall be equivalent to the *longjmp*( ) function, except as follows:

- References to *setjmp*( ) shall be equivalent to *sigsetjmp*( ).
- The *siglongjmp*( ) function shall restore the saved signal mask if and only if the *env* argument was initialized by a call to *sigsetjmp*( ) with a non-zero *savemask* argument.

RETURN VALUE

After *siglongjmp*( ) is completed, program execution shall continue as if the corresponding invocation of *sigsetjmp*( ) had just returned the value specified by *val*. The *siglongjmp*( ) function shall not cause *sigsetjmp*( ) to return 0; if *val* is 0, *sigsetjmp*( ) shall return the value 1.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The distinction between *setjmp*( ) or *longjmp*( ) and *sigsetjmp*( ) or *siglongjmp*( ) is only significant for programs which use *sigaction*( ), *sigprocmask*( ), or *sigsuspend*( ).

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the ISO POSIX-1 standard.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

The DESCRIPTION is rewritten in terms of *longjmp*( ).

The SYNOPSIS is marked CX since the presence of this function in the **<setjmp.h>** header is an extension over the ISO C standard.

NAME

signal — signal management

SYNOPSIS

```
#include <signal.h>

void (*signal(int sig, void (*func)(int)))(int);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

CX Use of this function is unspecified in a multi-threaded process.

The *signal*( ) function chooses one of three ways in which receipt of the signal number *sig* is to be subsequently handled. If the value of *func* is SIG_DFL, default handling for that signal shall occur. If the value of *func* is SIG_IGN, the signal shall be ignored. Otherwise, the application shall ensure that *func* points to a function to be called when that signal occurs. An invocation of such a function because of a signal, or (recursively) of any further functions called by that invocation (other than functions in the standard library), is called a ‘‘signal handler’’.

When a signal occurs, and *func* points to a function, it is implementation-defined whether the equivalent of a:

```
signal(sig, SIG_DFL);
```

is executed or the implementation prevents some implementation-defined set of signals (at least including *sig*) from occurring until the current signal handling has completed. (If the value of *sig* is SIGILL, the implementation may alternatively define that no action is taken.) Next the equivalent of:

```
(*func)(sig);
```

is executed. If and when the function returns, if the value of *sig* was SIGFPE, SIGILL, or SIGSEGV or any other implementation-defined value corresponding to a computational exception, the behavior is undefined. Otherwise, the program shall resume execution at the point it was interrupted. CX If the signal occurs as the result of calling the *abort*( ), *raise*( ), *kill*( ), *pthread_kill*( ), or *sigqueue*( ) function, the signal handler shall not call the *raise*( ) function. |

CX If the signal occurs other than as the result of calling *abort*( ), *raise*( ), *kill*( ), *pthread_kill*( ), or *sigqueue*( ), the behavior is undefined if the signal handler refers to any object with static storage duration other than by assigning a value to an object declared as volatile **sig_atomic_t**, or if the signal handler calls any function in the standard library other than one of the functions listed in Section 2.4 (on page 478). Furthermore, if such a call fails, the value of *errno* is unspecified. |

At program start-up, the equivalent of:

```
signal(sig, SIG_IGN);
```

is executed for some signals, and the equivalent of:

```
signal(sig, SIG_DFL);
```

CX is executed for all other signals (see *exec*).

RETURN VALUE

If the request can be honored, *signal*( ) shall return the value of *func* for the most recent call to *signal*( ) for the specified signal *sig*. Otherwise, SIG_ERR shall be returned and a positive value shall be stored in *errno*.

ERRORS

The *signal*( ) function shall fail if:

CX [EINVAL] The *sig* argument is not a valid signal number or an attempt is made to catch a signal that cannot be caught or ignore a signal that cannot be ignored.

The *signal*( ) function may fail if:

CX [EINVAL] An attempt was made to set the action to SIG_DFL for a signal that cannot be caught or ignored (or both).

EXAMPLES

None.

APPLICATION USAGE

The *sigaction*( ) function provides a more comprehensive and reliable mechanism for controlling signals; new applications should use *sigaction*( ) rather than *signal*( ).

RATIONALE

None.

FUTURE DIRECTIONS

None.

Section 2.4 (on page 478), *exec*, *pause*( ), *sigaction*( ), *sigsuspend*( ), *waitid*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<signal.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

The DESCRIPTION is updated to indicate that the *sigpause*( ) function restores the process' signal mask to its original state before returning.

The RETURN VALUE section is updated to indicate that the *sigpause*( ) function suspends execution of the process until a signal is received, whereupon it returns –1 and sets *errno* to [EINTR].

Issue 6

Extensions beyond the ISO C standard are now marked.

The DESCRIPTION is updated to avoid use of the term ''must'' for application requirements.

The DESCRIPTION is updated for alignment with the ISO/IEC 9899:1999 standard.

References to the *wait3*( ) function are removed.

The *sighold*( ), *sigignore*( ), *sigrelse*( ), and *sigset*( ) functions are split out onto their own reference page.

NAME

signbit — test sign

SYNOPSIS

```
#include <math.h>

int signbit(real-floating x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *signbit*( ) macro shall determine whether the sign of its argument value is negative. NaNs, zeros, and infinities have a sign bit.

RETURN VALUE

The *signbit*( ) macro shall return a non-zero value if and only if the sign of its argument value is negative.

ERRORS

No errors are defined.

NAME

sigpause — remove a signal from the signal mask and suspend the thread

SYNOPSIS

XSI
```
#include <signal.h>

int sigpause(int sig);
```

DESCRIPTION

Refer to *sighold*( ).

NAME

sigpending — examine pending signals

SYNOPSIS

CX

```
#include <signal.h>

int sigpending(sigset_t *set);
```

DESCRIPTION

The *sigpending*( ) function shall store, in the location referenced by the *set* argument, the set of signals that are blocked from delivery to the calling thread and that are pending on the process or the calling thread.

RETURN VALUE

Upon successful completion, *sigpending*( ) shall return 0; otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

No errors are defined.

CHANGE HISTORY

First released in Issue 3.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

The SYNOPSIS is marked CX since the presence of this function in the **<signal.h>** header is an extension over the ISO C standard.

NAME

sigprocmask — examine and change blocked signals

SYNOPSIS

CX
```
#include <signal.h>

int sigprocmask(int how, const sigset_t *restrict set,
    sigset_t *restrict oset);
```

DESCRIPTION

Refer to *pthread_sigmask*( ).

NAME

sigqueue — queue a signal to a process (**REALTIME**)

SYNOPSIS

RTS

```
#include <signal.h>

int sigqueue(pid_t pid, int signo, const union sigval value);
```

DESCRIPTION

The *sigqueue*( ) function shall cause the signal specified by *signo* to be sent with the value specified by *value* to the process specified by *pid*. If *signo* is zero (the null signal), error checking is performed but no signal is actually sent. The null signal can be used to check the validity of *pid*.

The conditions required for a process to have permission to queue a signal to another process are the same as for the *kill*( ) function.

The *sigqueue*( ) function shall return immediately. If SA_SIGINFO is set for *signo* and if the resources were available to queue the signal, the signal shall be queued and sent to the receiving process. If SA_SIGINFO is not set for *signo*, then *signo* shall be sent at least once to the receiving process; it is unspecified whether *value* shall be sent to the receiving process as a result of this call.

If the value of *pid* causes *signo* to be generated for the sending process, and if *signo* is not blocked for the calling thread and if no other thread has *signo* unblocked or is waiting in a *sigwait*( ) function for *signo*, either *signo* or at least the pending, unblocked signal shall be delivered to the calling thread before the *sigqueue*( ) function returns. Should any multiple pending signals in the range SIGRTMIN to SIGRTMAX be selected for delivery, it shall be the lowest numbered one. The selection order between realtime and non-realtime signals, or between multiple pending non-realtime signals, is unspecified.

RETURN VALUE

Upon successful completion, the specified signal shall have been queued, and the *sigqueue*( ) function shall return a value of zero. Otherwise, the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *sigqueue*( ) function shall fail if:

[EAGAIN]	No resources available to queue the signal. The process has already queued SIGQUEUE_MAX signals that are still pending at the receiver(s), or a system-wide resource limit has been exceeded.
[EINVAL]	The value of the *signo* argument is an invalid or unsupported signal number.
[EPERM]	The process does not have the appropriate privilege to send the signal to the receiving process.
[ESRCH]	The process *pid* does not exist.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The *sigqueue*( ) function allows an application to queue a realtime signal to itself or to another process, specifying the application-defined value. This is common practice in realtime applications on existing realtime systems. It was felt that specifying another function in the *sig*... name space already carved out for signals was preferable to extending the interface to *kill*( ).

Such a function became necessary when the put/get event function of the message queues was removed. It should be noted that the *sigqueue*( ) function implies reduced performance in a security-conscious implementation as the access permissions between the sender and receiver have to be checked on each send when the *pid* is resolved into a target process. Such access checks were necessary only at message queue open in the previous interface.

The standard developers required that *sigqueue*( ) have the same semantics with respect to the null signal as *kill*( ), and that the same permission checking be used. But because of the difficulty of implementing the ‘‘broadcast’’ semantic of *kill*( ) (for example, to process groups) and the interaction with resource allocation, this semantic was not adopted. The *sigqueue*( ) function queues a signal to a single process specified by the *pid* argument.

The *sigqueue*( ) function can fail if the system has insufficient resources to queue the signal. An explicit limit on the number of queued signals that a process could send was introduced. While the limit is ‘‘per-sender’’, this volume of IEEE Std 1003.1-200x does not specify that the resources be part of the state of the sender. This would require either that the sender be maintained after exit until all signals that it had sent to other processes were handled or that all such signals that had not yet been acted upon be removed from the queue(s) of the receivers. This volume of IEEE Std 1003.1-200x does not preclude this behavior, but an implementation that allocated queuing resources from a system-wide pool (with per-sender limits) and that leaves queued signals pending after the sender exits is also permitted.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.8.1 (on page 491), the Base Definitions volume of IEEE Std 1003.1-200x, **<signal.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Issue 6

The *sigqueue*( ) function is marked as part of the Realtime Signals Extension option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Realtime Signals Extension option.

NAME

sigrelse — remove a signal from signal mask or modify signal disposition

SYNOPSIS

XSI

```
#include <signal.h>

int sigrelse(int sig);
```

DESCRIPTION

Refer to *sighold*( ).

NAME

sigset — signal management

SYNOPSIS

```
#include <signal.h>
```

XSI
```
void (*sigset(int sig, void (*disp)(int)))(int);
```

DESCRIPTION

Refer to *sighold*( ).

NAME

sigsetjmp — set jump point for a non-local goto

SYNOPSIS

CX
```
#include <setjmp.h>

int sigsetjmp(sigjmp_buf env, int savemask);
```

DESCRIPTION

The *sigsetjmp*( ) function shall be equivalent to the *setjmp*( ) function, except as follows:

- References to *setjmp*( ) are equivalent to *sigsetjmp*( ).
- References to *longjmp*( ) are equivalent to *siglongjmp*( ).
- If the value of the *savemask* argument is not 0, *sigsetjmp*( ) shall also save the current signal mask of the calling thread as part of the calling environment.

RETURN VALUE

If the return is from a successful direct invocation, *sigsetjmp*( ) shall return 0. If the return is from a call to *siglongjmp*( ), *sigsetjmp*( ) shall return a non-zero value.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The distinction between *setjmp*( )/*longjmp*( ) and *sigsetjmp*( )/*siglongjmp*( ) is only significant for programs which use *sigaction*( ), *sigprocmask*( ), or *sigsuspend*( ).

Note that since this function is defined in terms of *setjmp*( ), if *savemask* is zero, it is unspecified whether the signal mask is saved.

RATIONALE

The ISO C standard specifies various restrictions on the usage of the *setjmp*( ) macro in order to permit implementors to recognize the name in the compiler and not implement an actual function. These same restrictions apply to the *sigsetjmp*( ) macro.

There are processors that cannot easily support these calls, but this was not considered a sufficient reason to exclude them.

4.2 BSD, 4.3 BSD, and XSI-conformant systems provide functions named *_setjmp*( ) and *_longjmp*( ) that, together with *setjmp*( ) and *longjmp*( ), provide the same functionality as *sigsetjmp*( ) and *siglongjmp*( ). On those systems, *setjmp*( ) and *longjmp*( ) save and restore signal masks, while *_setjmp*( ) and *_longjmp*( ) do not. On System V, Release 3 and in corresponding issues of the SVID, *setjmp*( ) and *longjmp*( ) are explicitly defined not to save and restore signal masks. In order to permit existing practice in both cases, the relation of *setjmp*( ) and *longjmp*( ) to signal masks is not specified, and a new set of functions is defined instead.

The *longjmp*( ) and *siglongjmp*( ) functions operate as in the previous issue provided the matching *setjmp*( ) or *sigsetjmp*( ) has been performed in the same thread. Non-local jumps into contexts saved by other threads would be at best a questionable practice and were not considered worthy of standardization.

FUTURE DIRECTIONS

None.

siglongjmp( ), *signal*( ), *sigprocmask*( ), *sigsuspend*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<setjmp.h>**

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

The DESCRIPTION is reworded in terms of *setjmp*( ).

The SYNOPSIS is marked CX since the presence of this function in the **<setjmp.h>** header is an extension over the ISO C standard.

NAME

sigsuspend — wait for a signal

SYNOPSIS

CX
```
#include <signal.h>

int sigsuspend(const sigset_t *sigmask);
```

DESCRIPTION

The *sigsuspend*( ) function shall replace the current signal mask of the calling thread with the set of signals pointed to by *sigmask* and then suspend the thread until delivery of a signal whose action is either to execute a signal-catching function or to terminate the process. This shall not cause any other signals that may have been pending on the process to become pending on the thread.

If the action is to terminate the process then *sigsuspend*( ) shall never return. If the action is to execute a signal-catching function, then *sigsuspend*( ) shall return after the signal-catching function returns, with the signal mask restored to the set that existed prior to the *sigsuspend*( ) call.

It is not possible to block signals that cannot be ignored. This is enforced by the system without causing an error to be indicated.

RETURN VALUE

Since *sigsuspend*( ) suspends thread execution indefinitely, there is no successful completion return value. If a return occurs, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *sigsuspend*( ) function shall fail if:

[EINTR] A signal is caught by the calling process and control is returned from the signal-catching function.

EXAMPLES

None.

APPLICATION USAGE

Normally, at the beginning of a critical code section, a specified set of signals is blocked using the *sigprocmask*( ) function. When the thread has completed the critical section and needs to wait for the previously blocked signal(s), it pauses by calling *sigsuspend*( ) with the mask that was returned by the *sigprocmask*( ) call.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

The text in the RETURN VALUE section has been changed from ‘‘suspends process execution’’ to ‘‘suspends thread execution’’. This reflects IEEE PASC Interpretation 1003.1c #40.

Text in the APPLICATION USAGE section has been replaced.

The SYNOPSIS is marked CX since the presence of this function in the **<signal.h>** header is an extension over the ISO C standard.

NAME

sigtimedwait, sigwaitinfo — wait for queued signals (**REALTIME**)

SYNOPSIS

RTS

```
#include <signal.h>

int sigtimedwait(const sigset_t *restrict set,
    siginfo_t *restrict info,
    const struct timespec *restrict timeout);
int sigwaitinfo(const sigset_t *restrict set,
    siginfo_t *restrict info);
```

DESCRIPTION

The *sigtimedwait*( ) function shall be equivalent to *sigwaitinfo*( ) except that if none of the signals specified by *set* are pending, *sigtimedwait*( ) shall wait for the time interval specified in the **timespec** structure referenced by *timeout*. If the **timespec** structure pointed to by *timeout* is zero-valued and if none of the signals specified by *set* are pending, then *sigtimedwait*( ) shall return immediately with an error. If *timeout* is the NULL pointer, the behavior is unspecified. MON If the Monotonic Clock option is supported, the CLOCK_MONOTONIC clock shall be used to measure the time interval specified by the *timeout* argument.

The *sigwaitinfo*( ) function selects the pending signal from the set specified by *set*. Should any of multiple pending signals in the range SIGRTMIN to SIGRTMAX be selected, it shall be the lowest numbered one. The selection order between realtime and non-realtime signals, or between multiple pending non-realtime signals, is unspecified. If no signal in *set* is pending at the time of the call, the calling thread shall be suspended until one or more signals in *set* become pending or until it is interrupted by an unblocked, caught signal.

The *sigwaitinfo*( ) function shall be equivalent to the *sigwait*( ) function if the *info* argument is NULL. If the *info* argument is non-NULL, the *sigwaitinfo*( ) function shall be equivalent to *sigwait*( ), except that the selected signal number shall be stored in the *si_signo* member, and the cause of the signal shall be stored in the *si_code* member. If any value is queued to the selected signal, the first such queued value shall be dequeued and, if the *info* argument is non-NULL, the value shall be stored in the *si_value* member of *info*. The system resource used to queue the signal shall be released and returned to the system for other use. If no value is queued, the content of the *si_value* member is undefined. If no further signals are queued for the selected signal, the pending indication for that signal shall be reset.

RETURN VALUE

Upon successful completion (that is, one of the signals specified by *set* is pending or is generated) *sigwaitinfo*( ) and *sigtimedwait*( ) shall return the selected signal number. Otherwise, the function shall return a value of –1 and set *errno* to indicate the error.

ERRORS

The *sigtimedwait*( ) function shall fail if:

[EAGAIN] No signal specified by *set* was generated within the specified timeout period.

The *sigtimedwait*( ) and *sigwaitinfo*( ) functions may fail if:

[EINTR] The wait was interrupted by an unblocked, caught signal. It shall be documented in system documentation whether this error causes these functions to fail.

The *sigtimedwait*( ) function may also fail if:

[EINVAL] The *timeout* argument specified a *tv_nsec* value less than zero or greater than or equal to 1 000 million.

An implementation only checks for this error if no signal is pending in *set* and it is necessary to wait.

EXAMPLES

None.

APPLICATION USAGE

The *sigtimedwait*( ) function times out and returns an [EAGAIN] error. Application writers should note that this is inconsistent with other functions such as *pthread_cond_timedwait*( ) that return [ETIMEDOUT].

RATIONALE

Existing programming practice on realtime systems uses the ability to pause waiting for a selected set of events and handle the first event that occurs in-line instead of in a signal-handling function. This allows applications to be written in an event-directed style similar to a state machine. This style of programming is useful for largescale transaction processing in which the overall throughput of an application and the ability to clearly track states are more important than the ability to minimize the response time of individual event handling.

It is possible to construct a signal-waiting macro function out of the realtime signal function mechanism defined in this volume of IEEE Std 1003.1-200x. However, such a macro has to include the definition of a generalized handler for all signals to be waited on. A significant portion of the overhead of handler processing can be avoided if the signal-waiting function is provided by the kernel. This volume of IEEE Std 1003.1-200x therefore provides two signal-waiting functions—one that waits indefinitely and one with a timeout—as part of the overall realtime signal function specification.

The specification of a function with a timeout allows an application to be written that can be broken out of a wait after a set period of time if no event has occurred. It was argued that setting a timer event before the wait and recognizing the timer event in the wait would also implement the same functionality, but at a lower performance level. Because of the performance degradation associated with the user-level specification of a timer event and the subsequent cancelation of that timer event after the wait completes for a valid event, and the complexity associated with handling potential race conditions associated with the user-level method, the separate function has been included.

Note that the semantics of the *sigwaitinfo*( ) function are nearly identical to that of the *sigwait*( ) function defined by this volume of IEEE Std 1003.1-200x. The only difference is that *sigwaitinfo*( ) returns the queued signal value in the *value* argument. The return of the queued value is required so that applications can differentiate between multiple events queued to the same signal number.

The two distinct functions are being maintained because some implementations may choose to implement the POSIX Threads Extension functions and not implement the queued signals extensions. Note, though, that *sigwaitinfo*( ) does not return the queued value if the *value* argument is NULL, so the POSIX Threads Extension *sigwait*( ) function can be implemented as a macro on *sigwaitinfo*( ).

The *sigtimedwait*( ) function was separated from the *sigwaitinfo*( ) function to address concerns regarding the overloading of the *timeout* pointer to indicate indefinite wait (no timeout), timed wait, and immediate return, and concerns regarding consistency with other functions where the conditional and timed waits were separate functions from the pure blocking function. The semantics of *sigtimedwait*( ) are specified such that *sigwaitinfo*( ) could be implemented as a macro with a NULL pointer for *timeout*.

The *sigwait* functions provide a synchronous mechanism for threads to wait for asynchronously generated signals. One important question was how many threads that are suspended in a call to a *sigwait*( ) function for a signal should return from the call when the signal is sent. Four choices were considered:

1. Return an error for multiple simultaneous calls to *sigwait* functions for the same signal.
2. One or more threads return.
3. All waiting threads return.
4. Exactly one thread returns.

Prohibiting multiple calls to *sigwait*( ) for the same signal was felt to be overly restrictive. The ''one or more'' behavior made implementation of conforming packages easy at the expense of forcing POSIX threads clients to protect against multiple simultaneous calls to *sigwait*( ) in application code in order to achieve predictable behavior. There was concern that the ''all waiting threads'' behavior would result in ''signal broadcast storms'', consuming excessive CPU resources by replicating the signals in the general case. Furthermore, no convincing examples could be presented that delivery to all was either simpler or more powerful than delivery to one.

Thus, the consensus was that exactly one thread that was suspended in a call to a *sigwait* function for a signal should return when that signal occurs. This is not an onerous restriction as:

- A multi-way signal wait can be built from the single-way wait.
- Signals should only be handled by application-level code, as library routines cannot guess what the application wants to do with signals generated for the entire process.
- Applications can thus arrange for a single thread to wait for any given signal and call any needed routines upon its arrival.

In an application that is using signals for interprocess communication, signal processing is typically done in one place. Alternatively, if the signal is being caught so that process cleanup can be done, the signal handler thread can call separate process cleanup routines for each portion of the application. Since the application main line started each portion of the application, it is at the right abstraction level to tell each portion of the application to clean up.

Certainly, there exist programming styles where it is logical to consider waiting for a single signal in multiple threads. A simple *sigwait_multiple*( ) routine can be constructed to achieve this goal. A possible implementation would be to have each *sigwait_multiple*( ) caller registered as having expressed interest in a set of signals. The caller then waits on a thread-specific condition variable. A single server thread calls a *sigwait*( ) function on the union of all registered signals. When the *sigwait*( ) function returns, the appropriate state is set and condition variables are broadcast. New *sigwait_multiple*( ) callers may cause the pending *sigwait*( ) call to be canceled and reissued in order to update the set of signals being waited for.

FUTURE DIRECTIONS

None.

Issue 6

These functions are marked as part of the Realtime Signals Extension option.

The Open Group Corrigendum U035/3 is applied. The SYNOPSIS of the *sigwaitinfo*( ) function has been corrected so that the second argument is of type **siginfo_t ***.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Realtime Signals Extension option.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that the CLOCK_MONOTONIC clock, if supported, is used to measure timeout intervals.

The **restrict** keyword is added to the *sigtimedwait*( ) and *sigwaitinfo*( ) prototypes for alignment with the ISO/IEC 9899:1999 standard.

NAME

sigwait — wait for queued signals

SYNOPSIS

CX

```
#include <signal.h>

int sigwait(const sigset_t *restrict set, int *restrict sig);
```

DESCRIPTION

The *sigwait*( ) function shall select a pending signal from *set*, atomically clear it from the system's set of pending signals, and return that signal number in the location referenced by *sig*. If prior to the call to *sigwait*( ) there are multiple pending instances of a single signal number, it is implementation-defined whether upon successful return there are any remaining pending signals for that signal number. RTS If the implementation supports queued signals and there are multiple signals queued for the signal number selected, the first such queued signal shall cause a return from *sigwait*( ) and the remainder shall remain queued. If no signal in *set* is pending at the time of the call, the thread shall be suspended until one or more becomes pending. The signals defined by *set* shall have been blocked at the time of the call to *sigwait*( ); otherwise, the behavior is undefined. The effect of *sigwait*( ) on the signal actions for the signals in *set* is unspecified.

If more than one thread is using *sigwait*( ) to wait for the same signal, no more than one of these threads shall return from *sigwait*( ) with the signal number. Which thread returns from *sigwait*( ) if more than a single thread is waiting is unspecified.

RTS Should any of the multiple pending signals in the range SIGRTMIN to SIGRTMAX be selected, it shall be the lowest numbered one. The selection order between realtime and non-realtime signals, or between multiple pending non-realtime signals, is unspecified.

RETURN VALUE

Upon successful completion, *sigwait*( ) shall store the signal number of the received signal at the location referenced by *sig* and return zero. Otherwise, an error number shall be returned to indicate the error.

ERRORS

The *sigwait*( ) function may fail if:

[EINVAL]	The *set* argument contains an invalid or unsupported signal number.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

To provide a convenient way for a thread to wait for a signal, this volume of IEEE Std 1003.1-200x provides the *sigwait*( ) function. For most cases where a thread has to wait for a signal, the *sigwait*( ) function should be quite convenient, efficient, and adequate.

However, requests were made for a lower-level primitive than *sigwait*( ) and for semaphores that could be used by threads. After some consideration, threads were allowed to use semaphores and *sem_post*( ) was defined to be async-signal and async-cancel-safe.

In summary, when it is necessary for code run in response to an asynchronous signal to notify a thread, *sigwait*( ) should be used to handle the signal. Alternatively, if the implementation provides semaphores, they also can be used, either following *sigwait*( ) or from within a signal handling routine previously registered with *sigaction*( ).

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Issue 6

The RATIONALE section is added.

The **restrict** keyword is added to the *sigwait*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

sigwaitinfo — wait for queued signals (**REALTIME**)

SYNOPSIS

RTS

```
#include <signal.h>

int sigwaitinfo(const sigset_t *restrict set, siginfo_t *restrict info);
```

DESCRIPTION

Refer to *sigtimedwait*( ).

NAME

sin, sinf, sinl — sine function

SYNOPSIS

```
#include <math.h>

double sin(double x);
float sinf(float x);
long double sinl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the sine of their argument *x*, measured in radians.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the sine of *x*.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0, *x* shall be returned.

If *x* is subnormal, a range error may occur and *x* should be returned.

If *x* is ±Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

ERRORS

These functions shall fail if:

MX Domain Error The *x* argument is ±Inf.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

These functions may fail if:

MX Range Error The value of *x* is subnormal

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

Taking the Sine of a 45-Degree Angle

```
#include <math.h>
...
double radians = 45.0 * M_PI / 180;
double result;
...
result = sin(radians);
```

APPLICATION USAGE

These functions may lose accuracy when their argument is near a multiple of π or is far from 0.0.

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The last two paragraphs of the DESCRIPTION were included as APPLICATION USAGE notes in previous issues.

Issue 6

The *sinf*( ) and *sinl*( ) functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

IEC 60559:1989 standard floating-point extensions over the ISO/IEC 9899:1999 standard are marked.

NAME

sinf — sine function

SYNOPSIS

```
#include <math.h>

float sinf(float x);
```

DESCRIPTION

Refer to *sin*( ).

NAME

sinh, sinhf, sinhl — hyperbolic sine function

SYNOPSIS

```
#include <math.h>

double sinh(double x);
float sinhf(float x);
long double sinhl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the hyperbolic sine of their argument *x*.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the hyperbolic sine of *x*.

If the result would cause an overflow, a range error shall occur and ±HUGE_VAL, ±HUGE_VALF, and ±HUGE_VALL (with the same sign as *x*) shall be returned as appropriate for the type of the function.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0, or ±Inf, *x* shall be returned.

If *x* is subnormal, a range error may occur and *x* should be returned.

ERRORS

These functions shall fail if:

Range Error The result would cause an overflow.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

These functions may fail if:

MX Range Error The value *x* is subnormal.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

NAME

sinl — sine function

SYNOPSIS

```
#include <math.h>

long double sinl(long double x);
```

DESCRIPTION

Refer to *sin*( ).

NAME

sleep — suspend execution for an interval of time

SYNOPSIS

```
#include <unistd.h>

unsigned sleep(unsigned seconds);
```

DESCRIPTION

The *sleep*( ) function shall cause the calling thread to be suspended from execution until either the number of realtime seconds specified by the argument *seconds* has elapsed or a signal is delivered to the calling thread and its action is to invoke a signal-catching function or to terminate the process. The suspension time may be longer than requested due to the scheduling of other activity by the system.

If a SIGALRM signal is generated for the calling process during execution of *sleep*( ) and if the SIGALRM signal is being ignored or blocked from delivery, it is unspecified whether *sleep*( ) returns when the SIGALRM signal is scheduled. If the signal is being blocked, it is also unspecified whether it remains pending after *sleep*( ) returns or it is discarded.

If a SIGALRM signal is generated for the calling process during execution of *sleep*( ), except as a result of a prior call to *alarm*( ), and if the SIGALRM signal is not being ignored or blocked from delivery, it is unspecified whether that signal has any effect other than causing *sleep*( ) to return.

If a signal-catching function interrupts *sleep*( ) and examines or changes either the time a SIGALRM is scheduled to be generated, the action associated with the SIGALRM signal, or whether the SIGALRM signal is blocked from delivery, the results are unspecified.

If a signal-catching function interrupts *sleep*( ) and calls *siglongjmp*( ) or *longjmp*( ) to restore an environment saved prior to the *sleep*( ) call, the action associated with the SIGALRM signal and the time at which a SIGALRM signal is scheduled to be generated are unspecified. It is also unspecified whether the SIGALRM signal is blocked, unless the process' signal mask is restored as part of the environment.

XSI Interactions between *sleep*( ) and any of *setitimer*( ), *ualarm*( ), or *usleep*( ) are unspecified.

RETURN VALUE

If *sleep*( ) returns because the requested time has elapsed, the value returned shall be 0. If *sleep*( ) returns due to delivery of a signal, the return value shall be the ‘‘unslept’’ amount (the requested time minus the time actually slept) in seconds.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

There are two general approaches to the implementation of the *sleep*( ) function. One is to use the *alarm*( ) function to schedule a SIGALRM signal and then suspend the process waiting for that signal. The other is to implement an independent facility. This volume of IEEE Std 1003.1-200x permits either approach.

In order to comply with the requirement that no primitive shall change a process attribute unless explicitly described by this volume of IEEE Std 1003.1-200x, an implementation using SIGALRM must carefully take into account any SIGALRM signal scheduled by previous *alarm*( ) calls, the action previously established for SIGALRM, and whether SIGALRM was blocked. If a SIGALRM has been scheduled before the *sleep*( ) would ordinarily complete, the *sleep*( ) must be shortened to that time and a SIGALRM generated (possibly simulated by direct invocation of the signal-catching function) before *sleep*( ) returns. If a SIGALRM has been scheduled after the *sleep*( ) would ordinarily complete, it must be rescheduled for the same time before *sleep*( ) returns. The action and blocking for SIGALRM must be saved and restored.

Historical implementations often implement the SIGALRM-based version using *alarm*( ) and *pause*( ). One such implementation is prone to infinite hangups, as described in *pause*( ). Another such implementation uses the C-language *setjmp*( ) and *longjmp*( ) functions to avoid that window. That implementation introduces a different problem: when the SIGALRM signal interrupts a signal-catching function installed by the user to catch a different signal, the *longjmp*( ) aborts that signal-catching function. An implementation based on *sigprocmask*( ), *alarm*( ), and *sigsuspend*( ) can avoid these problems.

Despite all reasonable care, there are several very subtle, but detectable and unavoidable, differences between the two types of implementations. These are the cases mentioned in this volume of IEEE Std 1003.1-200x where some other activity relating to SIGALRM takes place, and the results are stated to be unspecified. All of these cases are sufficiently unusual as not to be of concern to most applications.

See also the discussion of the term *realtime* in *alarm*( ).

Since *sleep*( ) can be implemented using *alarm*( ), the discussion about alarms occurring early under *alarm*( ) applies to *sleep*( ) as well. |

Application writers should note that the type of the argument *seconds* and the return value of *sleep*( ) is **unsigned**. That means that a Strictly Conforming POSIX System Interfaces Application cannot pass a value greater than the minimum guaranteed value for {UINT_MAX}, which the ISO C standard sets as 65 535, and any application passing a larger value is restricting its portability. A different type was considered, but historical implementations, including those with a 16-bit **int** type, consistently use either **unsigned** or **int**.

Scheduling delays may cause the process to return from the *sleep*( ) function significantly after the requested time. In such cases, the return value should be set to zero, since the formula (requested time minus the time actually spent) yields a negative number and *sleep*( ) returns an **unsigned**.

FUTURE DIRECTIONS

NAME

snprintf — print formatted output

SYNOPSIS

```
#include <stdio.h>

int snprintf(char *restrict s, size_t n,
    const char *restrict format, ...);
```

DESCRIPTION

Refer to *fprintf*( ).

NAME

socket — create an endpoint for communication

SYNOPSIS

```
#include <sys/socket.h>

int socket(int domain, int type, int protocol);
```

DESCRIPTION

The *socket*( ) function shall create an unbound socket in a communications domain, and return a file descriptor that can be used in later function calls that operate on sockets.

The *socket*( ) function takes the following arguments:

domain	Specifies the communications domain in which a socket is to be created.
type	Specifies the type of socket to be created.
protocol	Specifies a particular protocol to be used with the socket. Specifying a *protocol* of 0 causes *socket*( ) to use an unspecified default protocol appropriate for the requested socket type.

The *domain* argument specifies the address family used in the communications domain. The address families supported by the system are implementation-defined.

Symbolic constants that can be used for the domain argument are defined in the **<sys/socket.h>** header.

The *type* argument specifies the socket type, which determines the semantics of communication over the socket. The following socket types are defined; implementations may specify additional socket types:

SOCK_STREAM	Provides sequenced, reliable, bidirectional, connection-mode byte streams, and may provide a transmission mechanism for out-of-band data.
SOCK_DGRAM	Provides datagrams, which are connectionless-mode, unreliable messages of fixed maximum length.
SOCK_SEQPACKET	Provides sequenced, reliable, bidirectional, connection-mode transmission path for records. A record can be sent using one or more output operations and received using one or more input operations, but a single operation never transfers part of more than one record. Record boundaries are visible to the receiver via the MSG_EOR flag.

If the *protocol* argument is non-zero, it shall specify a protocol that is supported by the address family. If the *protocol* argument is zero, the default protocol for this address family and type shall be used. The protocols supported by the system are implementation-defined.

The process may need to have appropriate privileges to use the *socket*( ) function or to create some sockets.

RETURN VALUE

Upon successful completion, *socket*( ) shall return a non-negative integer, the socket file descriptor. Otherwise, a value of −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *socket*( ) function shall fail if:

[EAFNOSUPPORT]
The implementation does not support the specified address family.

[EMFILE]	No more file descriptors are available for this process.
[ENFILE]	No more file descriptors are available for the system.
[EPROTONOSUPPORT]	The protocol is not supported by the address family, or the protocol is not supported by the implementation.
[EPROTOTYPE]	The socket type is not supported by the protocol.

The *socket*( ) function may fail if:

[EACCES]	The process does not have appropriate privileges.
[ENOBUFS]	Insufficient resources were available in the system to perform the operation.
[ENOMEM]	Insufficient memory was available to fulfill the request.

EXAMPLES

None.

APPLICATION USAGE

The documentation for specific address families specifies which protocols each address family supports. The documentation for specific protocols specifies which socket types each protocol supports.

The application can determine whether an address family is supported by trying to create a socket with *domain* set to the protocol in question.

NAME

socketpair — create a pair of connected sockets

SYNOPSIS

```
#include <sys/socket.h>

int socketpair(int domain, int type, int protocol,
    int socket_vector[2]);
```

DESCRIPTION

The *socketpair*( ) function shall create an unbound pair of connected sockets in a specified *domain*, of a specified *type*, under the protocol optionally specified by the *protocol* argument. The two sockets shall be identical. The file descriptors used in referencing the created sockets shall be returned in *socket_vector*[0] and *socket_vector*[1].

The *socketpair*( ) function takes the following arguments:

domain	Specifies the communications domain in which the sockets are to be created.
type	Specifies the type of sockets to be created.
protocol	Specifies a particular protocol to be used with the sockets. Specifying a *protocol* of 0 causes *socketpair*( ) to use an unspecified default protocol appropriate for the requested socket type.
socket_vector	Specifies a 2-integer array to hold the file descriptors of the created socket pair.

The *type* argument specifies the socket type, which determines the semantics of communications over the socket. The following socket types are defined; implementations may specify additional socket types:

SOCK_STREAM	Provides sequenced, reliable, bidirectional, connection-mode byte streams, and may provide a transmission mechanism for out-of-band data.
SOCK_DGRAM	Provides datagrams, which are connectionless-mode, unreliable messages of fixed maximum length.
SOCK_SEQPACKET	Provides sequenced, reliable, bidirectional, connection-mode transmission paths for records. A record can be sent using one or more output operations and received using one or more input operations, but a single operation never transfers part of more than one record. Record boundaries are visible to the receiver via the MSG_EOR flag.

If the *protocol* argument is non-zero, it shall specify a protocol that is supported by the address family. If the *protocol* argument is zero, the default protocol for this address family and type shall be used. The protocols supported by the system are implementation-defined.

The process may need to have appropriate privileges to use the *socketpair*( ) function or to create some sockets.

RETURN VALUE

Upon successful completion, this function shall return 0; otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *socketpair*( ) function shall fail if:

[EAFNOSUPPORT]
The implementation does not support the specified address family.

[EMFILE]	No more file descriptors are available for this process.
[ENFILE]	No more file descriptors are available for the system.
[EOPNOTSUPP]	The specified protocol does not permit creation of socket pairs.
[EPROTONOSUPPORT]	The protocol is not supported by the address family, or the protocol is not supported by the implementation.
[EPROTOTYPE]	The socket type is not supported by the protocol.

The *socketpair*( ) function may fail if:

[EACCES]	The process does not have appropriate privileges.
[ENOBUFS]	Insufficient resources were available in the system to perform the operation.
[ENOMEM]	Insufficient memory was available to fulfill the request.

EXAMPLES

None.

APPLICATION USAGE

The documentation for specific address families specifies which protocols each address family supports. The documentation for specific protocols specifies which socket types each protocol supports.

The *socketpair*( ) function is used primarily with UNIX domain sockets and need not be supported for other domains.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

sqrt, sqrtf, sqrtl — square root function

SYNOPSIS

```
#include <math.h>

double sqrt(double x);
float sqrtf(float x);
long double sqrtl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the square root of their argument x, $\sqrt{x}$.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the square root of x.

MX For finite values of $x < -0$, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

MX If x is NaN, a NaN shall be returned.

If x is ±0, or +Inf, x shall be returned.

If x is –Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

ERRORS

These functions shall fail if:

MX Domain Error The finite value of x is < -0, or x is –Inf.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

EXAMPLES

Taking the Square Root of 9.0

```
#include <math.h>
...
double x = 9.0;
double result;
...
result = sqrt(x);
```

NAME

stat — get file status

SYNOPSIS

```
#include <sys/stat.h>

int stat(const char *restrict path, struct stat *restrict buf);
```

DESCRIPTION

The *stat*( ) function shall obtain information about the named file and write it to the area pointed to by the *buf* argument. The *path* argument points to a pathname naming a file. Read, write, or execute permission of the named file is not required. An implementation that provides additional or alternate file access control mechanisms may, under implementation-defined conditions, cause *stat*( ) to fail. In particular, the system may deny the existence of the file specified by *path*.

If the named file is a symbolic link, the *stat*( ) function shall continue pathname resolution using the contents of the symbolic link, and shall return information pertaining to the resulting file if the file exists.

The *buf* argument is a pointer to a **stat** structure, as defined in the **<sys/stat.h>** header, into which information is placed concerning the file.

The *stat*( ) function shall update any time-related fields (as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.7, File Times Update), before writing into the **stat** structure.

The structure members *st_mode*, *st_ino*, *st_dev*, *st_uid*, *st_gid*, *st_atime*, *st_ctime*, and *st_mtime* shall have meaningful values for all file types defined in this volume of IEEE Std 1003.1-200x. The value of the member *st_nlink* shall be set to the number of links to the file.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *stat*( ) function shall fail if:

[EACCES]	Search permission is denied for a component of the path prefix.
[EIO]	An error occurred while reading from the file system.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of *path* does not name an existing file or *path* is an empty string.
[ENOTDIR]	A component of the path prefix is not a directory.
[EOVERFLOW]	The file size in bytes or the number of blocks allocated to the file or the file serial number cannot be represented correctly in the structure pointed to by *buf*.

The *stat*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.

[ENAMETOOLONG]
As a result of encountering a symbolic link in resolution of the *path* argument, the length of the substituted pathname string exceeded {PATH_MAX}.

[EOVERFLOW] A value to be stored would overflow one of the members of the **stat** structure.

EXAMPLES

Obtaining File Status Information

The following example shows how to obtain file status information for a file named **/home/cnd/mod1**. The structure variable *buffer* is defined for the **stat** structure.

```
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>

struct stat buffer;
int         status;
...
status = stat("/home/cnd/mod1", &buffer);
```

Getting Directory Information

The following example fragment gets status information for each entry in a directory. The call to the *stat*( ) function stores file information in the **stat** structure pointed to by *statbuf*. The lines that follow the *stat*( ) call format the fields in the **stat** structure for presentation to the user of the program.

```
#include <sys/types.h>
#include <sys/stat.h>
#include <dirent.h>
#include <pwd.h>
#include <grp.h>
#include <time.h>
#include <locale.h>
#include <langinfo.h>
#include <stdio.h>
#include <stdint.h>

struct dirent  *dp;
struct stat     statbuf;
struct passwd  *pwd;
struct group   *grp;
struct tm      *tm;
char            datestring[256];
...
/* Loop through directory entries */
while ((dp = readdir(dir)) != NULL) {

    /* Get entry's information. */
    if (stat(dp->d_name, &statbuf) == -1)
        continue;

    /* Print out type, permissions, and number of links. */
    printf("%10.10s", sperm (statbuf.st_mode));
    printf("%4d", statbuf.st_nlink);
```

```
        /* Print out owners name if it is found using getpwuid(). */
        if ((pwd = getpwuid(statbuf.st_uid)) != NULL)
            printf(" %-8.8s", pwd->pw_name);
        else
            printf(" %-8d", statbuf.st_uid);

        /* Print out group name if it’s found using getgrgid(). */
        if ((grp = getgrgid(statbuf.st_gid)) != NULL)
            printf(" %-8.8s", grp->gr_name);
        else
            printf(" %-8d", statbuf.st_gid);

        /* Print size of file. */
        printf(" %9jd", (intmax_t)statbuf.st_size);

        tm = localtime(&statbuf.st_mtime);

        /* Get localized date string. */
        strftime(datestring, sizeof(datestring), nl_langinfo(D_T_FMT), tm);

        printf(" %s %s\n", datestring, dp->d_name);
    }
```

APPLICATION USAGE

None.

RATIONALE

The intent of the paragraph describing ‘‘additional or alternate file access control mechanisms’’ is to allow a secure implementation where a process with a label that does not dominate the file’s label cannot perform a *stat*( ) function. This is not related to read permission; a process with a label that dominates the file’s label does not need read permission. An implementation that supports write-up operations could fail *fstat*( ) function calls even though it has a valid file descriptor open for writing.

FUTURE DIRECTIONS

None.

SEE ALSO

fstat( ), *lstat*( ), *readlink*( ), *symlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/stat.h>**, **<sys/types.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

Large File Summit extensions are added.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification: |

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- The [EIO] mandatory error condition is added.

- The [ELOOP] mandatory error condition is added.
- The [EOVERFLOW] mandatory error condition is added. This change is to support large files.
- The [ENAMETOOLONG] and the second [EOVERFLOW] optional error conditions are added.

The following changes were made to align with the IEEE P1003.1a draft standard:

- Details are added regarding the treatment of symbolic links.
- The [ELOOP] optional error condition is added.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The **restrict** keyword is added to the *stat*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

statvfs — get file system information

SYNOPSIS

XSI

```
#include <sys/statvfs.h>

int statvfs(const char *restrict path, struct statvfs *restrict buf);
```

DESCRIPTION

Refer to *fstatvfs*( ).

NAME

stderr, stdin, stdout — standard I/O streams

SYNOPSIS

```
#include <stdio.h>

extern FILE *stderr, *stdin, *stdout;
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

A file with associated buffering is called a *stream* and is declared to be a pointer to a defined type **FILE**. The *fopen*( ) function shall create certain descriptive data for a stream and return a pointer to designate the stream in all further transactions. Normally, there are three open streams with constant pointers declared in the **<stdio.h>** header and associated with the standard open files.

At program start-up, three streams shall be predefined and need not be opened explicitly: *standard input* (for reading conventional input), *standard output* (for writing conventional output), and *standard error* (for writing diagnostic output). When opened, the standard error stream is not fully buffered; the standard input and standard output streams are fully buffered if and only if the stream can be determined not to refer to an interactive device.

CX The following symbolic values in **<unistd.h>** define the file descriptors that shall be associated with the C-language *stdin*, *stdout*, and *stderr* when the application is started:

STDIN_FILENO	Standard input value, *stdin*. Its value is 0.
STDOUT_FILENO	Standard output value, *stdout*. Its value is 1.
STDERR_FILENO	Standard error value, *stderr*. Its value is 2.

The *stderr* stream is expected to be open for reading and writing.

RETURN VALUE

None.

ERRORS

CHANGE HISTORY

First released in Issue 1.

Issue 6

Extensions beyond the ISO C standard are now marked.

A note that *stderr* is expected to be open for reading and writing is added to the DESCRIPTION.

NAME

strcasecmp, strncasecmp — case-insensitive string comparisons

SYNOPSIS

XSI
```
#include <strings.h>

int strcasecmp(const char *s1, const char *s2);
int strncasecmp(const char *s1, const char *s2, size_t n);
```

DESCRIPTION

The *strcasecmp*( ) function shall compare, while ignoring differences in case, the string pointed to by *s1* to the string pointed to by *s2*. The *strncasecmp*( ) function shall compare, while ignoring differences in case, not more than *n* bytes from the string pointed to by *s1* to the string pointed to by *s2*.

In the POSIX locale, *strcasecmp*( ) and *strncasecmp*( ) shall behave as if the strings had been converted to lowercase and then a byte comparison performed. The results are unspecified in other locales. |

RETURN VALUE

Upon completion, *strcasecmp*( ) shall return an integer greater than, equal to, or less than 0, if the string pointed to by *s1* is, ignoring case, greater than, equal to, or less than the string pointed to by *s2*, respectively.

Upon successful completion, *strncasecmp*( ) shall return an integer greater than, equal to, or less than 0, if the possibly null-terminated array pointed to by *s1* is, ignoring case, greater than, equal to, or less than the possibly null-terminated array pointed to by *s2*, respectively.

ERRORS

No errors are defined.

NAME

strcat — concatenate two strings

SYNOPSIS

```
#include <string.h>

char *strcat(char *restrict s1, const char *restrict s2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strcat*( ) function shall append a copy of the string pointed to by *s2* (including the terminating null byte) to the end of the string pointed to by *s1*. The initial byte of *s2* overwrites the null byte at the end of *s1*. If copying takes place between objects that overlap, the behavior is undefined.

RETURN VALUE

The *strcat*( ) function shall return *s1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

This issue is aligned with the ISO C standard; this does not affect compatibility with XPG3 applications. Reliable error detection by this function was never guaranteed.

Issue 6

The *strcat*( ) prototype is updated for alignment with the ISO / IEC 9899: 1999 standard.

NAME

strchr — string scanning operation

SYNOPSIS

```
#include <string.h>

char *strchr(const char *s, int c);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

CX The *strchr*( ) function shall locate the first occurrence of *c* (converted to an **unsigned char**) in the string pointed to by *s*. The terminating null byte is considered to be part of the string.

RETURN VALUE

Upon completion, *strchr*( ) shall return a pointer to the byte, or a null pointer if the byte was not found.

ERRORS

No errors are defined.

NAME

strcmp — compare two strings

SYNOPSIS

```
#include <string.h>

int strcmp(const char *s1, const char *s2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strcmp*( ) function shall compare the string pointed to by *s1* to the string pointed to by *s2*.

The sign of a non-zero return value shall be determined by the sign of the difference between the values of the first pair of bytes (both interpreted as type **unsigned char**) that differ in the strings being compared.

RETURN VALUE

Upon completion, *strcmp*( ) shall return an integer greater than, equal to, or less than 0, if the string pointed to by *s1* is greater than, equal to, or less than the string pointed to by *s2*, respectively.

ERRORS

No errors are defined.

EXAMPLES

Checking a Password Entry

The following example compares the information read from standard input to the value of the name of the user entry. If the *strcmp*( ) function returns 0 (indicating a match), a further check will be made to see if the user entered the proper old password. The *crypt*( ) function shall encrypt the old password entered by the user, using the value of the encrypted password in the **passwd** structure as the salt. If this value matches the value of the encrypted **passwd** in the structure, the entered password *oldpasswd* is the correct user's password. Finally, the program encrypts the new password so that it can store the information in the **passwd** structure.

```
#include <string.h>
#include <unistd.h>
#include <stdio.h>
...
int valid_change;
struct passwd *p;
char user[100];
char oldpasswd[100];
char newpasswd[100];
char savepasswd[100];
...
if (strcmp(p->pw_name, user) == 0) {
    if (strcmp(p->pw_passwd, crypt(oldpasswd, p->pw_passwd)) == 0) {
        strcpy(savepasswd, crypt(newpasswd, user));
        p->pw_passwd = savepasswd;
        valid_change = 1;
    }
    else {
```

```
                fprintf(stderr, "Old password is not valid\n");
            }
        }
        ...
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

Issue 6

Extensions beyond the ISO C standard are now marked.

NAME

strcoll — string comparison using collating information

SYNOPSIS

```
#include <string.h>

int strcoll(const char *s1, const char *s2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strcoll*( ) function shall compare the string pointed to by *s1* to the string pointed to by *s2*, both interpreted as appropriate to the *LC_COLLATE* category of the current locale.

CX The *strcoll*( ) function shall not change the setting of *errno* if successful.

Since no return value is reserved to indicate an error, an application wishing to check for error situations should set *errno* to 0, then call *strcoll*( ), then check *errno*. |

RETURN VALUE

Upon successful completion, *strcoll*( ) shall return an integer greater than, equal to, or less than 0, according to whether the string pointed to by *s1* is greater than, equal to, or less than the string pointed to by *s2* when both are interpreted as appropriate to the current locale. CX On error, *strcoll*( ) may set *errno*, but no return value is reserved to indicate an error.

ERRORS

The *strcoll*( ) function may fail if:

CX [EINVAL] The *s1* or *s2* arguments contain characters outside the domain of the collating sequence.

EXAMPLES

Comparing Nodes

The following example uses an application-defined function, *node_compare*( ), to compare two nodes based on an alphabetical ordering of the *string* field.

```
#include <string.h>
...
struct node { /* These are stored in the table. */
    char *string;
    int length;
};
...
int node_compare(const void *node1, const void *node2)
{
    return strcoll(((const struct node *)node1)->string,
        ((const struct node *)node2)->string);
}
...
```

APPLICATION USAGE

The *strxfrm*( ) and *strcmp*( ) functions should be used for sorting large lists.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

strcmp( ), *strxfrm*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<string.h>**

CHANGE HISTORY

First released in Issue 3.

Issue 5

The DESCRIPTION is updated to indicate that *errno* does not be changed if the function is successful.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The [EINVAL] optional error condition is added.

An example is added.

NAME

strcpy — copy a string

SYNOPSIS

```
#include <string.h>

char *strcpy(char *restrict s1, const char *restrict s2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strcpy*( ) function shall copy the string pointed to by *s2* (including the terminating null byte) into the array pointed to by *s1*. If copying takes place between objects that overlap, the behavior is undefined.

RETURN VALUE

The *strcpy*( ) function shall return *s1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

Initializing a String

The following example copies the string `"----------"` into the *permstring* variable.

```
#include <string.h>
...
static char permstring[11];
...
strcpy(permstring, "----------");
...
```

Storing a Key and Data

The following example allocates space for a key using *malloc*( ) then uses *strcpy*( ) to place the key there. Then it allocates space for data using *malloc*( ), and uses *strcpy*( ) to place data there. (The user-defined function *dbfree*( ) frees memory previously allocated to an array of type **struct element ***.)

```
#include <string.h>
#include <stdlib.h>
#include <stdio.h>
...
/* Structure used to read data and store it. */
struct element {
    char *key;
    char *data;
};

struct element *tbl, *curtbl;
char *key, *data;
int count;
...
void dbfree(struct element *, int);
```

```
        ...
        if ((curtbl->key = malloc(strlen(key) + 1)) == NULL) {
            perror("malloc"); dbfree(tbl, count); return NULL;
        }
        strcpy(curtbl->key, key);

        if ((curtbl->data = malloc(strlen(data) + 1)) == NULL) {
            perror("malloc"); free(curtbl->key); dbfree(tbl, count); return NULL;
        }
        strcpy(curtbl->data, data);
        ...
```

APPLICATION USAGE

Character movement is performed differently in different implementations. Thus, overlapping moves may yield surprises.

This issue is aligned with the ISO C standard; this does not affect compatibility with XPG3 applications. Reliable error detection by this function was never guaranteed.

RATIONALE

None.

FUTURE DIRECTIONS

None.

The *strcpy*( ) prototype is updated for alignment with the ISO / IEC 9899: 1999 standard.

NAME

strcspn — get length of a complementary substring

SYNOPSIS

```
#include <string.h>

size_t strcspn(const char *s1, const char *s2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strcspn*( ) function shall compute the length (in bytes) of the maximum initial segment of the string pointed to by *s1* which consists entirely of bytes *not* from the string pointed to by *s2*. |

RETURN VALUE

The *strcspn*( ) function shall return the length of the computed segment of the string pointed to by *s1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

strspn( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<string.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The RETURN VALUE section is updated to indicated that *strcspn*( ) returns the length of *s1*, and not *s1* itself as was previously stated.

Issue 6

The Open Group Corrigendum U030/1 is applied. The text of the RETURN VALUE section is updated to indicate that the computed segment length is returned, not the *s1* length.

NAME

strdup — duplicate a string

SYNOPSIS

XSI

```
#include <string.h>

char *strdup(const char *s1);
```

DESCRIPTION

The *strdup*( ) function shall return a pointer to a new string, which is a duplicate of the string pointed to by *s1*. The returned pointer can be passed to *free*( ). A null pointer is returned if the new string cannot be created.

RETURN VALUE

The *strdup*( ) function shall return a pointer to a new string on success. Otherwise, it shall return a null pointer and set *errno* to indicate the error.

ERRORS

The *strdup*( ) function may fail if:

[ENOMEM] Storage space available is insufficient.

EXAMPLES

NAME

strerror, strerror_r — get error message string

SYNOPSIS

```
#include <string.h>

char *strerror(int errnum);
int strerror_r(int errnum, char *strerrbuf, size_t buflen);
```

DESCRIPTION

For *strerror*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strerror*( ) function shall map the error number in *errnum* to a locale-dependent error message string and shall return a pointer to it. Typically, the values for *errnum* come from *errno*, but *strerror*( ) shall map any value of type **int** to a message.

The string pointed to shall not be modified by the application, but may be overwritten by a subsequent call to *strerror*( ) or *perror*( ).

The contents of the error message strings returned by *strerror*( ) should be determined by the setting of the *LC_MESSAGES* category in the current locale.

The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *strerror*( ).

The *strerror*( ) function shall not change the setting of *errno* if successful.

Since no return value is reserved to indicate an error, an application wishing to check for error situations should set *errno* to 0, then call *strerror*( ), then check *errno*. |

The *strerror*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

The *strerror_r*( ) function shall map the error number in *errnum* to a locale-dependent error message string and shall return the string in the buffer pointed to by *strerrbuf*, with length *buflen*.

RETURN VALUE

Upon successful completion, *strerror*( ) shall return a pointer to the generated message string. On error *errno* may be set, but no return value is reserved to indicate an error.

Upon successful completion, *strerror_r*( ) shall return 0. Otherwise, an error number shall be returned to indicate the error.

ERRORS

These functions may fail if:

[EINVAL]	The value of *errnum* is not a valid error number.

The *strerror_r*( ) function may fail if:

[ERANGE]	Insufficient storage was supplied via *strerrbuf* and *buflen* to contain the generated message string.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

perror( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<string.h>**

CHANGE HISTORY

First released in Issue 3.

Issue 5

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

A note indicating that this function need not be reentrant is added to the DESCRIPTION.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE section, the fact that *errno* may be set is added.
- The [EINVAL] optional error condition is added.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The *strerror_r*( ) function is added in response to IEEE PASC Interpretation 1003.1c #39.

The *strerror_r*( ) function is marked as part of the Thread-Safe Functions option.

NAME

strfmon — convert monetary value to a string

SYNOPSIS

XSI
```
#include <monetary.h>

ssize_t strfmon(char *restrict s, size_t maxsize,
    const char *restrict format, ...);
```

DESCRIPTION

The *strfmon*( ) function shall place characters into the array pointed to by *s* as controlled by the string pointed to by *format*. No more than *maxsize* bytes are placed into the array.

The format is a character string, beginning and ending in its initial state, if any, that contains two types of objects: *plain characters*, which are simply copied to the output stream, and *conversion specifications*, each of which shall result in the fetching of zero or more arguments which are converted and formatted. The results are undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are simply ignored.

The application shall ensure that a conversion specification consists of the following sequence:

- A '%' character
- Optional flags
- Optional field width
- Optional left precision
- Optional right precision
- A required conversion specifier character that determines the conversion to be performed

Flags

One or more of the following optional flags can be specified to control the conversion:

=*f*	An '=' followed by a single character *f* which is used as the numeric fill character. In order to work with precision or width counts, the fill character shall be a single byte character; if not, the behavior is undefined. The default numeric fill character is the <space>. This flag does not affect field width filling which always uses the <space>. This flag is ignored unless a left precision (see below) is specified.
^	Do not format the currency amount with grouping characters. The default is to insert the grouping characters if defined for the current locale.
+ or (	Specify the style of representing positive and negative currency amounts. Only one of '+' or '(' may be specified. If '+' is specified, the locale's equivalent of '+' and '−' are used (for example, in the U.S., the empty string if positive and '−' if negative). If '(' is specified, negative amounts are enclosed within parentheses. If neither flag is specified, the '+' style is used.
!	Suppress the currency symbol from the output conversion.
−	Specify the alignment. If this flag is present the result of the conversion is left-justified (padded to the right) rather than right-justified. This flag shall be ignored unless a field width (see below) is specified.

Field Width

w A decimal digit string *w* specifying a minimum field width in bytes in which the result of the conversion is right-justified (or left-justified if the flag `'−'` is specified). The default is 0.

Left Precision

#*n* A `'#'` followed by a decimal digit string *n* specifying a maximum number of digits expected to be formatted to the left of the radix character. This option can be used to keep the formatted output from multiple calls to the *strfmon*( ) function aligned in the same columns. It can also be used to fill unused positions with a special character as in `"$***123.45"`. This option causes an amount to be formatted as if it has the number of digits specified by *n*. If more than *n* digit positions are required, this conversion specification is ignored. Digit positions in excess of those actually required are filled with the numeric fill character (see the =*f* flag above).

If grouping has not been suppressed with the `'^'` flag, and it is defined for the current locale, grouping separators are inserted before the fill characters (if any) are added. Grouping separators are not applied to fill characters even if the fill character is a digit.

To ensure alignment, any characters appearing before or after the number in the formatted output such as currency or sign symbols are padded as necessary with <space>s to make their positive and negative formats an equal length.

Right Precision

.*p* A period followed by a decimal digit string *p* specifying the number of digits after the radix character. If the value of the right precision *p* is 0, no radix character appears. If a right precision is not included, a default specified by the current locale is used. The amount being formatted is rounded to the specified number of digits prior to formatting.

Conversion Specifier Characters

The conversion specifier characters and their meanings are:

`i` The **double** argument is formatted according to the locale's international currency format (for example, in the U.S.: USD 1,234.56). If the argument is ±Inf or NaN, the result of the conversion is unspecified.

`n` The **double** argument is formatted according to the locale's national currency format (for example, in the U.S.: $1,234.56). If the argument is ±Inf or NaN, the result of the conversion is unspecified.

`%` Convert to a `'%'`; no argument is converted. The entire conversion specification shall be %%.

Locale Information

The *LC_MONETARY* category of the program's locale affects the behavior of this function including the monetary radix character (which may be different from the numeric radix character affected by the *LC_NUMERIC* category), the grouping separator, the currency symbols, and formats. The international currency symbol should be conformant with the ISO 4217: 1995 standard.

If the value of *maxsize* is greater than {SSIZE_MAX}, the result is implementation-defined.

RETURN VALUE

If the total number of resulting bytes including the terminating null byte is not more than *maxsize*, *strfmon*( ) shall return the number of bytes placed into the array pointed to by *s*, not including the terminating null byte. Otherwise, –1 shall be returned, the contents of the array are unspecified, and *errno* shall be set to indicate the error.

ERRORS

The *strfmon*( ) function shall fail if:

[E2BIG]	Conversion stopped due to lack of space in the buffer.

EXAMPLES

Given a locale for the U.S. and the values 123.45, –123.45, and 3456.781:

Conversion Specification	Output	Comments

`%n`	`$123.45`
	`-$123.45`
	`$3,456.78`
		Default formatting.

`%11n`	`$123.45`
	`-$123.45`
	`$3,456.78`
		Right align within an 11 character field.

`%#5n`	`$    123.45`
	`-$    123.45`
	`$ 3,456.78`
		Aligned columns for values up to 99,999.

`%=*#5n`	`$***123.45`
	`-$***123.45`
	`$*3,456.78`
		Specify a fill character.

`%=0#5n`	`$000123.45`
	`-$000123.45`
	`$03,456.78`
		Fill characters do not use grouping even if the fill character is a digit.

`%^#5n`	`$  123.45`
	`-$  123.45`
	`$ 3456.78`
		Disable the grouping separator.

`%^#5.0n`	`$  123`
	`-$  123`
	`$ 3457`
		Round off to whole units.

`%^#5.4n`	`$  123.4500`
	`-$  123.4500`
	`$ 3456.7810`
		Increase the precision.

`%(#5n`	`$    123.45`
	`($    123.45)`
	`$ 3,456.78`
		Use an alternative pos/neg style.

`%(!#5n`	`123.45`
	`(    123.45)`
	`3,456.78`
		Disable the currency symbol.

`%-14#5.4n`	`$  123.4500`
	`-$  123.4500`
	`$3,456.7810`
		Left-justify the output.

`%14#5.4n`	`$  123.4500`
	`-$  123.4500`
	`$3,456.7810`
		Corresponding right-justified output.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

Lowercase conversion characters are reserved for future standards use and uppercase for implementation-defined use.

SEE ALSO

CHANGE HISTORY

First released in Issue 4.

Issue 5

Moved from ENHANCED I18N to BASE.

The [ENOSYS] error is removed.

A sentence is added to the DESCRIPTION warning about values of *maxsize* that are greater than {SSIZE_MAX}.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The **restrict** keyword is added to the *strfmon*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

strftime — convert date and time to a string

SYNOPSIS

```
#include <time.h>

size_t strftime(char *restrict s, size_t maxsize,
    const char *restrict format, const struct tm *restrict timeptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strftime*( ) function shall place bytes into the array pointed to by *s* as controlled by the string pointed to by *format*. The format is a character string, beginning and ending in its initial shift state, if any. The *format* string consists of zero or more conversion specifications and ordinary characters. A conversion specification consists of a `'%'` character, possibly followed by an `E` or `O` modifier, and a terminating conversion specifier character that determines the conversion specification's behavior. All ordinary characters (including the terminating null byte) are copied unchanged into the array. If copying takes place between objects that overlap, the behavior is undefined. No more than *maxsize* bytes are placed into the array. Each conversion specifier is replaced by appropriate characters as described in the following list. The appropriate characters are determined using the *LC_TIME* category of the current locale and by the values of zero or more members of the broken-down time structure pointed to by *timeptr*, as specified in brackets in the description. If any of the specified values are outside the normal range, the characters stored are unspecified.

CX Local timezone information is used as though *strftime*( ) called *tzset*( ).

The following conversion specifications are supported:

`%a`	Replaced by the locale's abbreviated weekday name. [*tm_wday*]
`%A`	Replaced by the locale's full weekday name. [*tm_wday*]
`%b`	Replaced by the locale's abbreviated month name. [*tm_mon*]
`%B`	Replaced by the locale's full month name. [*tm_mon*]
`%c`	Replaced by the locale's appropriate date and time representation. (See the Base Definitions volume of IEEE Std 1003.1-200x, **<time.h>**.)
`%C`	Replaced by the year divided by 100 and truncated to an integer, as a decimal number [00,99]. [*tm_year*]
`%d`	Replaced by the day of the month as a decimal number [01,31]. [*tm_mday*]
`%D`	Equivalent to `%m/%d/%y`. [*tm_mon*, *tm_mday*, *tm_year*]
`%e`	Replaced by the day of the month as a decimal number [1,31]; a single digit is preceded by a space. [*tm_mday*]
`%F`	Equivalent to `%Y-%m-%d` (the ISO 8601:2000 standard date format). [*tm_year*, *tm_mon*, *tm_mday*]
`%g`	Replaced by the last 2 digits of the week-based year (see below) as a decimal number [00,99]. [*tm_year*, *tm_wday*, *tm_yday*]
`%G`	Replaced by the week-based year (see below) as a decimal number (for example, 1977). [*tm_year*, *tm_wday*, *tm_yday*]

	`%h`	Equivalent to `%b`. [*tm_mon*]
	`%H`	Replaced by the hour (24-hour clock) as a decimal number [00,23]. [*tm_hour*]
	`%I`	Replaced by the hour (12-hour clock) as a decimal number [01,12]. [*tm_hour*]
	`%j`	Replaced by the day of the year as a decimal number [001,366]. [*tm_yday*]
	`%m`	Replaced by the month as a decimal number [01,12]. [*tm_mon*]
	`%M`	Replaced by the minute as a decimal number [00,59]. [*tm_min*]
	`%n`	Replaced by a <newline>.
	`%p`	Replaced by the locale's equivalent of either a.m. or p.m. [*tm_hour*]
CX	`%r`	Replaced by the time in a.m. and p.m. notation; in the POSIX locale this shall be equivalent to `%I:%M:%S %p`. [*tm_hour*, *tm_min*, *tm_sec*]
	`%R`	Replaced by the time in 24 hour notation (`%H:%M`). [*tm_hour*, *tm_min*]
	`%S`	Replaced by the second as a decimal number [00,60]. [*tm_sec*]
	`%t`	Replaced by a <tab>.
	`%T`	Replaced by the time (`%H:%M:%S`). [*tm_hour*, *tm_min*, *tm_sec*]
	`%u`	Replaced by the weekday as a decimal number [1,7], with 1 representing Monday. [*tm_wday*]
	`%U`	Replaced by the week number of the year as a decimal number [00,53]. The frist Sunday of January is the first day of week 1; days in the new year before this are in week 0. [*tm_year*, *tm_wday*, *tm_yday*]
	`%V`	Replaced by the week number of the year (Monday as the first day of the week) as a decimal number [01,53]. If the week containing 1 January has four or more days in the new year, then it is considered week 1. Otherwise, it is the last week of the previous year, and the next week is week 1. Both January 4th and the first Thursday of January are always in week 1. [*tm_year*, *tm_wday*, *tm_yday*]
	`%w`	Replaced by the weekday as a decimal number [0,6], with 0 representing Sunday. [*tm_wday*]
	`%W`	Replaced by the week number of the year as a decimal number [00,53]. The first Monday of January is the first day of week 1; days in the new year before this are in week 0. [*tm_year*, *tm_wday*, *tm_yday*]
	`%x`	Replaced by the locale's appropriate date representation. (See the Base Definitions volume of IEEE Std 1003.1-200x, **<time.h>**.)
	`%X`	Replaced by the locale's appropriate time representation. (See the Base Definitions volume of IEEE Std 1003.1-200x, **<time.h>**.)
	`%y`	Replaced by the last two digits of the year as a decimal number [00,99]. [*tm_year*]
	`%Y`	Replaced by the year as a decimal number (for example, 1997). [*tm_year*]
CX	`%z`	Replaced by the offset from UTC in the ISO 8601:2000 standard format (`+hhmm` or `−hhmm`), or by no characters if no timezone is determinable. For example, `"−0430"` means 4 hours 30 minutes behind UTC (west of Greenwich). If *tm_isdst* is zero, the standard time offset is used. If *tm_isdst* is greater than zero, the daylight savings time offset is used. If *tm_isdst* is negative, no characters are returned. [*tm_isdst*]

`%Z`	Replaced by the timezone name or abbreviation, or by no bytes if no timezone information exists. [*tm_isdst*]
`%%`	Replaced by `%`.

If a conversion specification does not correspond to any of the above, the behavior is undefined.

Modified Conversion Specifiers

Some conversion specifiers can be modified by the `E` or `O` modifier characters to indicate that an alternative format or specification should be used rather than the one normally used by the unmodified conversion specifier. If the alternative format or specification does not exist for the current locale, (see ERA in the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3.5, LC_TIME) the behavior shall be as if the unmodified conversion specification were used.

`%Ec`	Replaced by the locale's alternative appropriate date and time representation.
`%EC`	Replaced by the name of the base year (period) in the locale's alternative representation.
`%Ex`	Replaced by the locale's alternative date representation.
`%EX`	Replaced by the locale's alternative time representation.
`%Ey`	Replaced by the offset from `%EC` (year only) in the locale's alternative representation.
`%EY`	Replaced by the full alternative year representation.
`%Od`	Replaced by the day of the month, using the locale's alternative numeric symbols, filled as needed with leading zeros if there is any alternative symbol for zero; otherwise, with leading spaces.
`%Oe`	Replaced by the day of the month, using the locale's alternative numeric symbols, filled as needed with leading spaces.
`%OH`	Replaced by the hour (24-hour clock) using the locale's alternative numeric symbols.
`%OI`	Replaced by the hour (12-hour clock) using the locale's alternative numeric symbols.
`%Om`	Replaced by the month using the locale's alternative numeric symbols.
`%OM`	Replaced by the minutes using the locale's alternative numeric symbols.
`%OS`	Replaced by the seconds using the locale's alternative numeric symbols.
`%Ou`	Replaced by the weekday as a number in the locale's alternative representation (Monday=1).
`%OU`	Replaced by the week number of the year (Sunday as the first day of the week, rules corresponding to `%U`) using the locale's alternative numeric symbols.
`%OV`	Replaced by the week number of the year (Monday as the first day of the week, rules corresponding to `%V`) using the locale's alternative numeric symbols.
`%Ow`	Replaced by the number of the weekday (Sunday=0) using the locale's alternative numeric symbols.
`%OW`	Replaced by the week number of the year (Monday as the first day of the week) using the locale's alternative numeric symbols.
`%Oy`	Replaced by the year (offset from `%C`) using the locale's alternative numeric symbols.

`%g`, `%G`, and `%V` give values according to the ISO 8601:2000 standard week-based year. In this system, weeks begin on a Monday and week 1 of the year is the week that includes January 4th, which is also the week that includes the first Thursday of the year, and is also the first week that contains at least four days in the year. If the first Monday of January is the 2nd, 3rd, or 4th, the preceding days are part of the last week of the preceding year; thus, for Saturday 2nd January 1999, `%G` is replaced by 1998 and `%V` is replaced by 53. If December 29th, 30th, or 31st is a Monday, it and any following days are part of week 1 of the following year. Thus, for Tuesday 30th December 1997, `%G` is replaced by 1998 and `%V` is replaced by 01.

If a conversion specifier is not one of the above, the behavior is undefined. |

RETURN VALUE

If the total number of resulting bytes including the terminating null byte is not more than *maxsize*, *strftime*( ) shall return the number of bytes placed into the array pointed to by *s*, not including the terminating null byte. Otherwise, 0 shall be returned and the contents of the array are unspecified. |

ERRORS

No errors are defined.

EXAMPLES

Getting a Localized Date String

The following example first sets the locale to the user's default. The locale information will be used in the *nl_langinfo*( ) and *strftime*( ) functions. The *nl_langinfo*( ) function returns the localized date string which specifies how the date is laid out. The *strftime*( ) function takes this information and, using the **tm** structure for values, places the date and time information into *datestring*.

```
#include <time.h>
#include <locale.h>
#include <langinfo.h>
...
struct tm *tm;
char datestring[256];
...
setlocale (LC_ALL, "");
...
strftime (datestring, sizeof(datestring), nl_langinfo (D_T_FMT), tm);
...
```

APPLICATION USAGE

The range of values for `%S` is [00,60] rather than [00,59] to allow for the occasional leap second.

Some of the conversion specifications are duplicates of others. They are included for compatibility with *nl_cxtime*( ) and *nl_ascxtime*( ), which were published in Issue 2. |

Applications should use `%Y` (4-digit years) in preference to `%y` (2-digit years).

In the C locale, the `E` and `O` modifiers are ignored and the replacement strings for the following specifiers are:

`%a`	The first three characters of `%A`.
`%A`	One of Sunday, Monday, . . ., Saturday.
`%b`	The first three characters of `%B`.
`%B`	One of January, February, . . ., December.
`%c`	Equivalent to `%a %b %e %T %Y`.

`%p`	One of AM or PM.
`%r`	Equivalent to `%I:%M:%S %p`.
`%x`	Equivalent to `%m/%d/%y`.
`%X`	Equivalent to `%T`.
`%Z`	Implementation-defined.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

asctime( ), *clock*( ), *ctime*( ), *difftime*( ), *getdate*( ), *gmtime*( ), *localtime*( ), *mktime*( ), *strptime*( ), *time*( ), *tzset*( ), *utime*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<time.h>**

CHANGE HISTORY

First released in Issue 3.

Issue 5

The description of `%OV` is changed to be consistent with `%V` and defines Monday as the first day of the week.

The description of `%Oy` is clarified.

Issue 6

Extensions beyond the ISO C standard are now marked.

The Open Group Corrigendum U033/8 is applied. The `%V` conversion specifier is changed from ''Otherwise, it is week 53 of the previous year, and the next week is week 1'' to ''Otherwise, it is the last week of the previous year, and the next week is week 1''.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The `%C`, `%D`, `%e`, `%h`, `%n`, `%r`, `%R`, `%t`, and `%T` conversion specifiers are added.
- The modified conversion specifiers are added for consistency with the ISO POSIX-2 standard *date* utility.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

- The *strftime*( ) prototype is updated.
- The DESCRIPTION is extensively revised.
- The `%z` conversion specifier is added.

A new example is added.

NAME

strlen — get string length

SYNOPSIS

```
#include <string.h>

size_t strlen(const char *s);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strlen*( ) function shall compute the number of bytes in the string to which *s* points, not including the terminating null byte.

RETURN VALUE

The *strlen*( ) function shall return the length of *s*; no return value shall be reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

Getting String Lengths

The following example sets the maximum length of *key* and *data* by using *strlen*( ) to get the lengths of those strings.

```
#include <string.h>
...
struct element {
    char *key;
    char *data;
};
...
char *key, *data;
int len;

*keylength = *datalength = 0;
...
if ((len = strlen(key)) > *keylength)
    *keylength = len;
if ((len = strlen(data)) > *datalength)
    *datalength = len;
...
```

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

The Base Definitions volume of IEEE Std 1003.1-200x, **<string.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The RETURN VALUE section is updated to indicate that *strlen*( ) returns the length of *s*, and not *s* itself as was previously stated.

NAME

strncasecmp — case-insensitive string comparison

SYNOPSIS

XSI

```
#include <strings.h>

int strncasecmp(const char *s1, const char *s2, size_t n);
```

DESCRIPTION

Refer to *strcasecmp*( ).

NAME

strncat — concatenate a string with part of another

SYNOPSIS

```
#include <string.h>

char *strncat(char *restrict s1, const char *restrict s2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strncat*( ) function shall append not more than *n* bytes (a null byte and bytes that follow it are not appended) from the array pointed to by *s2* to the end of the string pointed to by *s1*. The initial byte of *s2* overwrites the null byte at the end of *s1*. A terminating null byte is always appended to the result. If copying takes place between objects that overlap, the behavior is undefined.

RETURN VALUE

The *strncat*( ) function shall return *s1*; no return value shall be reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The *strncat*( ) prototype is updated for alignment with the ISO / IEC 9899: 1999 standard.

NAME

strncmp — compare part of two strings

SYNOPSIS

```
#include <string.h>

int strncmp(const char *s1, const char *s2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strncmp*( ) function shall compare not more than *n* bytes (bytes that follow a null byte are not compared) from the array pointed to by *s1* to the array pointed to by *s2*.

The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes (both interpreted as type **unsigned char**) that differ in the strings being compared.

RETURN VALUE

Upon successful completion, *strncmp*( ) shall return an integer greater than, equal to, or less than 0, if the possibly null-terminated array pointed to by *s1* is greater than, equal to, or less than the possibly null-terminated array pointed to by *s2* respectively.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

NAME

strncpy — copy part of a string

SYNOPSIS

```
#include <string.h>

char *strncpy(char *restrict s1, const char *restrict s2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strncpy*( ) function shall copy not more than *n* bytes (bytes that follow a null byte are not copied) from the array pointed to by *s2* to the array pointed to by *s1*. If copying takes place between objects that overlap, the behavior is undefined.

If the array pointed to by *s2* is a string that is shorter than *n* bytes, null bytes shall be appended to the copy in the array pointed to by *s1*, until *n* bytes in all are written.

RETURN VALUE

The *strncpy*( ) function shall return *s1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

Character movement is performed differently in different implementations. Thus, overlapping moves may yield surprises.

If there is no null byte in the first *n* bytes of the array pointed to by *s2*, the result is not null-terminated.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

strpbrk — scan string for byte

SYNOPSIS

```
#include <string.h>

char *strpbrk(const char *s1, const char *s2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strpbrk*( ) function shall locate the first occurrence in the string pointed to by *s1* of any byte from the string pointed to by *s2*.

RETURN VALUE

Upon successful completion, *strpbrk*( ) shall return a pointer to the byte or a null pointer if no byte from *s2* occurs in *s1*.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

NAME

strptime — date and time conversion

SYNOPSIS

XSI
```
#include <time.h>

char *strptime(const char *restrict buf, const char *restrict format,
    struct tm *restrict tm);
```

DESCRIPTION

The *strptime*( ) function shall convert the character string pointed to by *buf* to values which are stored in the **tm** structure pointed to by *tm*, using the format specified by *format*.

The *format* is composed of zero or more directives. Each directive is composed of one of the following: one or more white-space characters (as specified by *isspace*( )); an ordinary character (neither `'%'` nor a white-space character); or a conversion specification. Each conversion specification is composed of a `'%'` character followed by a conversion character which specifies the replacement required. The application shall ensure that there is white-space or other non-alphanumeric characters between any two conversion specifications. The following conversion specifications are supported:

`%a`	The day of the week, using the locale's weekday names; either the abbreviated or full name may be specified.
`%A`	Equivalent to `%a`.
`%b`	The month, using the locale's month names; either the abbreviated or full name may be specified.
`%B`	Equivalent to `%b`.
`%c`	Replaced by the locale's appropriate date and time representation.
`%C`	The century number [0,99]; leading zeros are permitted but not required.
`%d`	The day of the month [1,31]; leading zeros are permitted but not required.
`%D`	The date as `%m/%d/%y`.
`%e`	Equivalent to `%d`.
`%h`	Equivalent to `%b`.
`%H`	The hour (24-hour clock) [0,23]; leading zeros are permitted but not required.
`%I`	The hour (12-hour clock) [1,12]; leading zeros are permitted but not required.
`%j`	The day number of the year [1,366]; leading zeros are permitted but not required.
`%m`	The month number [1,12]; leading zeros are permitted but not required.
`%M`	The minute [0,59]; leading zeros are permitted but not required.
`%n`	Any white space.
`%p`	The locale's equivalent of a.m or p.m.
`%r`	12-hour clock time using the AM / PM notation if **t_fmt_ampm** is not an empty string in the LC_TIME portion of the current locale; in the POSIX locale, this shall be equivalent to `%I:%M:%S %p`.
`%R`	The time as `%H:%M`.

`%S`	The seconds [0,60]; leading zeros are permitted but not required.
`%t`	Any white space.
`%T`	The time as `%H:%M:%S`.
`%U`	The week number of the year (Sunday as the first day of the week) as a decimal number [00,53]; leading zeros are permitted but not required.
`%w`	The weekday as a decimal number [0,6], with 0 representing Sunday; leading zeros are permitted but not required.
`%W`	The week number of the year (Monday as the first day of the week) as a decimal number [00,53]; leading zeros are permitted but not required.
`%x`	The date, using the locale's date format.
`%X`	The time, using the locale's time format.
`%y`	The year within century. When a century is not otherwise specified, values in the range [69,99] shall refer to years 1969 to 1999 inclusive, and values in the range [00,68] shall refer to years 2000 to 2068 inclusive; leading zeros shall be permitted but shall not be required. **Note:** It is expected that in a future version of IEEE Std 1003.1-200x the default century inferred from a 2-digit year will change. (This would apply to all commands accepting a 2-digit year as input.)
`%Y`	The year, including the century (for example, 1988).
`%%`	Replaced by `%`.

Modified Conversion Specifiers

Some conversion specifiers can be modified by the `E` and `O` modifier characters to indicate that an alternative format or specification should be used rather than the one normally used by the unmodified conversion specifier. If the alternative format or specification does not exist in the current locale, the behavior shall be as if the unmodified conversion specification were used.

`%Ec`	The locale's alternative appropriate date and time representation.
`%EC`	The name of the base year (period) in the locale's alternative representation.
`%Ex`	The locale's alternative date representation.
`%EX`	The locale's alternative time representation.
`%Ey`	The offset from `%EC` (year only) in the locale's alternative representation.
`%EY`	The full alternative year representation.
`%Od`	The day of the month using the locale's alternative numeric symbols; leading zeros are permitted but not required.
`%Oe`	Equivalent to `%Od`.
`%OH`	The hour (24-hour clock) using the locale's alternative numeric symbols.
`%OI`	The hour (12-hour clock) using the locale's alternative numeric symbols.
`%Om`	The month using the locale's alternative numeric symbols.
`%OM`	The minutes using the locale's alternative numeric symbols.

`%OS`	The seconds using the locale's alternative numeric symbols.
`%OU`	The week number of the year (Sunday as the first day of the week) using the locale's alternative numeric symbols.
`%Ow`	The number of the weekday (Sunday=0) using the locale's alternative numeric symbols.
`%OW`	The week number of the year (Monday as the first day of the week) using the locale's alternative numeric symbols.
`%Oy`	The year (offset from `%C`) using the locale's alternative numeric symbols.

A conversion specification composed of white-space characters is executed by scanning input up to the first character that is not white-space (which remains unscanned), or until no more characters can be scanned.

A conversion specification that is an ordinary character is executed by scanning the next character from the buffer. If the character scanned from the buffer differs from the one comprising the directive, the directive fails, and the differing and subsequent characters remain unscanned.

A series of conversion specifications composed of `%n`, `%t`, white-space characters, or any combination is executed by scanning up to the first character that is not white space (which remains unscanned), or until no more characters can be scanned.

Any other conversion specification is executed by scanning characters until a character matching the next directive is scanned, or until no more characters can be scanned. These characters, except the one matching the next directive, are then compared to the locale values associated with the conversion specifier. If a match is found, values for the appropriate **tm** structure members are set to values corresponding to the locale information. Case is ignored when matching items in *buf* such as month or weekday names. If no match is found, *strptime*( ) fails and no more characters are scanned.

RETURN VALUE

Upon successful completion, *strptime*( ) shall return a pointer to the character following the last character parsed. Otherwise, a null pointer shall be returned.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

Several ''equivalent to'' formats and the special processing of white-space characters are provided in order to ease the use of identical *format* strings for *strftime*( ) and *strptime*( ). |

Applications should use `%Y` (4-digit years) in preference to `%y` (2-digit years).

It is unspecified whether multiple calls to *strptime*( ) using the same **tm** structure will update the current contents of the structure or overwrite all contents of the structure. Conforming applications should make a single call to *strptime*( ) with a format and all data needed to completely specify the date and time being converted. |

RATIONALE

None.

FUTURE DIRECTIONS

The *strptime*( ) function is expected to be mandatory in the next version of this volume of IEEE Std 1003.1-200x.

SEE ALSO

scanf( ), *strftime*( ), *time*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<time.h>**

CHANGE HISTORY

First released in Issue 4.

Issue 5

Moved from ENHANCED I18N to BASE.

The [ENOSYS] error is removed.

The exact meaning of the `%y` and `%Oy` specifiers are clarified in the DESCRIPTION.

Issue 6

The Open Group Corrigendum U033/5 is applied. The `%r` specifier description is reworded.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The **restrict** keyword is added to the *strptime*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

The Open Group Corrigendum U047/2 is applied.

The DESCRIPTION is updated to use the terms ‘‘conversion specifier’’ and ‘‘conversion specification’’ for consistency with *strftime*( ).

NAME

strrchr — string scanning operation

SYNOPSIS

```
#include <string.h>

char *strrchr(const char *s, int c);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

CX The *strrchr*( ) function shall locate the last occurrence of *c* (converted to an **unsigned char**) in the string pointed to by *s*. The terminating null byte is considered to be part of the string.

RETURN VALUE

Upon successful completion, *strrchr*( ) shall return a pointer to the byte or a null pointer if *c* does not occur in the string.

ERRORS

No errors are defined.

EXAMPLES

Finding the Base Name of a File

The following example uses *strrchr*( ) to get a pointer to the base name of a file. The *strrchr*( ) function searches backwards through the name of the file to find the last '/' character in *name*. This pointer (plus one) will point to the base name of the file.

```
#include <string.h>
...
const char *name;
char *basename;
...
basename = strrchr(name, '/') + 1;
...
```

APPLICATION USAGE

None.

RATIONALE

NAME

strspn — get length of a substring

SYNOPSIS

```
#include <string.h>

size_t strspn(const char *s1, const char *s2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strspn*( ) function shall compute the length (in bytes) of the maximum initial segment of the string pointed to by *s1* which consists entirely of bytes from the string pointed to by *s2*. |

RETURN VALUE

The *strspn*( ) function shall return the length of *s1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The RETURN VALUE section is updated to indicate that *strspn*( ) returns the length of *s*, and not *s* itself as was previously stated.

NAME

strstr — find a substring

SYNOPSIS

```
#include <string.h>

char *strstr(const char *s1, const char *s2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strstr*( ) function shall locate the first occurrence in the string pointed to by *s1* of the sequence of bytes (excluding the terminating null byte) in the string pointed to by *s2*.

RETURN VALUE

Upon successful completion, *strstr*( ) shall return a pointer to the located string or a null pointer if the string is not found.

If *s2* points to a string with zero length, the function shall return *s1*.

ERRORS

No errors are defined.

NAME

strtod, strtof, strtold — convert string to a double-precision number

SYNOPSIS

```
#include <stdlib.h>

double strtod(const char *restrict nptr, char **restrict endptr);
float strtof(const char *restrict nptr, char **restrict endptr);
long double strtold(const char *restrict nptr, char **restrict endptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall convert the initial portion of the string pointed to by *nptr* to **double**, **float**, and **long double** representation, respectively. First, they decompose the input string into three parts:

1. An initial, possibly empty, sequence of white-space characters (as specified by *isspace*( ))
2. A subject sequence interpreted as a floating-point constant or representing infinity or NaN
3. A final string of one or more unrecognized characters, including the terminating null byte of the input string

Then they shall attempt to convert the subject sequence to a floating-point number, and return the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent part
- A 0x or 0X, then a non-empty sequence of hexadecimal digits optionally containing a radix character, then an optional binary exponent part
- One of INF or INFINITY, ignoring case
- One of NAN or NAN(*n-char-sequence*$_{opt}$), ignoring case in the NAN part, where:

```
n-char-sequence:
    digit
    nondigit
    n-char-sequence digit
    n-char-sequence nondigit
```

The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is not of the expected form.

If the subject sequence has the expected form for a floating-point number, the sequence of characters starting with the first digit or the decimal-point character (whichever occurs first) shall be interpreted as a floating constant of the C language, except that the radix character shall be used in place of a period, and that if neither an exponent part nor a radix character appears in a decimal floating-point number, or if a binary exponent part does not appear in a hexadecimal floating-point number, an exponent part of the appropriate type with value zero is assumed to follow the last digit in the string. If the subject sequence begins with a minus sign, the sequence shall be interpreted as negated. A character sequence INF or INFINITY shall be interpreted as an infinity, if representable in the return type, else as if it were a floating constant that is too large for the range of the return type. A character sequence NAN or NAN(*n-char-sequence*$_{opt}$) shall be interpreted as a quiet NaN, if supported in the return type, else as if it were a subject sequence part that does not have the expected form; the meaning of the *n*-char sequences is implementation-defined. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

If the subject sequence has the hexadecimal form and FLT_RADIX is a power of 2, the value resulting from the conversion is correctly rounded.

CX The radix character is defined in the program's locale (category *LC_NUMERIC*). In the POSIX locale, or in a locale where the radix character is not defined, the radix character shall default to a period (`'.'`).

CX In other than the C or POSIX locales, other implementation-defined subject sequences may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion shall be performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX The *strtod*( ) function shall not change the setting of *errno* if successful.

Since 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set *errno* to 0, then call *strtod*( ), *strtof*( ), or *strtold*( ), then check *errno*.

RETURN VALUE

Upon successful completion, these functions shall return the converted value. If no conversion could be performed, 0 shall be returned, and *errno* may be set to [EINVAL].

If the correct value is outside the range of representable values, HUGE_VAL, HUGE_VALF, or HUGE_VALL shall be returned (according to the sign of the value), and *errno* shall be set to [ERANGE].

If the correct value would cause an underflow, a value whose magnitude is no greater than the smallest normalized positive number in the return type shall be returned and *errno* set to [ERANGE].

ERRORS

These functions shall fail if:

CX [ERANGE] The value to be returned would cause overflow or underflow.

These functions may fail if:

CX [EINVAL] No conversion could be performed.

EXAMPLES

None.

APPLICATION USAGE

If the subject sequence has the hexadecimal form and FLT_RADIX is not a power of 2, adn the result is not exactly representable, the result should be one of the two numbers in the appropriate internal format that are adjacent to the hexadecimal floating source value, with the extra stipulation that the error should have a correct sign for the current rounding direction.

If the subject sequence has the decimal form and at most DECIMAL_DIG (defined in **<float.h>**) significant digits, the result should be correctly rounded. If the subject sequence *D* has the decimal form and more than DECIMAL_DIG significant digits, consider the two bounding, adjacent decimal strings *L* and *U*, both having DECIMAL_DIG significant digits, such that the values of L, D, and U satisfy $L <= D <= U$. The result should be one of the (equal or adjacent) values that would be obtained by correctly rounding L and U according to the current rounding direction, with the extra stipulation that the error with respect to D should have a correct sign for the current rounding direction.

The changes to *strtod*( ) introduced by the ISO / IEC 9899: 1999 standard can alter the behavior of well-formed applications complying with the ISO / IEC 9899: 1990 standard and thus earlier versions of IEEE Std 1003.1-200x. One such example would be:

```
int
what_kind_of_number (char *s)
{
    char *endp;
    double d;
    long l;

    d = strtod(s, &endp);
    if (s != endp && *endp == '\0')
        printf("It's a float with value %g\n", d);
    else
    {
        l = strtol(s, &endp, 0);
        if (s != endp && *endp == '\0')
            printf("It's an integer with value %ld\n", 1);
        else
            return 1;
    }
    return 0;
}
```

If the function is called with:

```
what_kind_of_number ("0x10")
```

an ISO / IEC 9899: 1990 standard-compliant library will result in the function printing:

```
It's an integer with value 16
```

With the ISO / IEC 9899: 1999 standard, the result is:

```
It's a float with value 16
```

The change in behavior is due to the inclusion of floating-point numbers in hexadecimal notation without requiring that either a decimal point or the binary exponent be present.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The following changes are made for alignment with the ISO / IEC 9899: 1999 standard:

- The *strtod*( ) function is updated.
- The *strtof*( ) and *strtold*( ) functions are added.
- The DESCRIPTION is extensively revised.

ISO / IEC 9899: 1999 standard, Technical Corrigendum No. 1 is incorporated. |

NAME

strtof — convert string to a double-precision number

SYNOPSIS

```
#include <stdlib.h>

float strtof(const char *restrict nptr, char **restrict endptr);
```

DESCRIPTION

Refer to *strtod*( ).

NAME

strtoimax, strtoumax — convert string to integer type

SYNOPSIS

```
#include <inttypes.h>

intmax_t strtoimax(const char *restrict nptr, char **restrict endptr,
    int base);
uintmax_t strtoumax(const char *restrict nptr, char **restrict endptr,
    int base);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall be equivalent to the *strtol*( ), *strtoll*( ), *strtoul*( ), and *strtoull*( ) functions, except that the initial portion of the string shall be converted to **intmax_t** and **uintmax_t** representation, respectively.

RETURN VALUE

These functions shall return the converted value, if any.

If no conversion could be performed, zero shall be returned.

If the correct value is outside the range of representable values, {INTMAX_MAX}, {INTMAX_MIN}, or {UINTMAX_MAX} shall be returned (according to the return type and sign of the value, if any), and *errno* shall be set to [ERANGE].

ERRORS

These functions shall fail if:

[ERANGE]	The value to be returned is not representable.

These functions may fail if:

[EINVAL]	The value of *base* is not supported.

NAME

strtok, strtok_r — split string into tokens

SYNOPSIS

```
#include <string.h>

char *strtok(char *restrict s1, const char *restrict s2);
char *strtok_r(char *restrict s, const char *restrict sep,
    char **restrict lasts);
```

TSF

DESCRIPTION

CX For *strtok*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

A sequence of calls to *strtok*( ) breaks the string pointed to by *s1* into a sequence of tokens, each of which is delimited by a byte from the string pointed to by *s2*. The first call in the sequence has *s1* as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by *s2* may be different from call to call.

The first call in the sequence searches the string pointed to by *s1* for the first byte that is *not* contained in the current separator string pointed to by *s2*. If no such byte is found, then there are no tokens in the string pointed to by *s1* and *strtok*( ) shall return a null pointer. If such a byte is found, it is the start of the first token.

The *strtok*( ) function then searches from there for a byte that *is* contained in the current separator string. If no such byte is found, the current token extends to the end of the string pointed to by *s1*, and subsequent searches for a token shall return a null pointer. If such a byte is found, it is overwritten by a null byte, which terminates the current token. The *strtok*( ) function saves a pointer to the following byte, from which the next search for a token shall start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *strtok*( ).

CX The *strtok*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

TSF The *strtok_r*( ) function considers the null-terminated string *s* as a sequence of zero or more text tokens separated by spans of one or more characters from the separator string *sep*. The argument *lasts* points to a user-provided pointer which points to stored information necessary for *strtok_r*( ) to continue scanning the same string.

In the first call to *strtok_r*( ), *s* points to a null-terminated string, *sep* to a null-terminated string of separator characters, and the value pointed to by *lasts* is ignored. The *strtok_r*( ) function shall return a pointer to the first character of the first token, write a null character into *s* immediately following the returned token, and update the pointer to which *lasts* points.

In subsequent calls, *s* is a NULL pointer and *lasts* shall be unchanged from the previous call so that subsequent calls shall move through the string *s*, returning successive tokens until no tokens remain. The separator string *sep* may be different from call to call. When no token remains in *s*, a NULL pointer shall be returned.

RETURN VALUE

Upon successful completion, *strtok*( ) shall return a pointer to the first byte of a token. Otherwise, if there is no token, *strtok*( ) shall return a null pointer.

TSF The *strtok_r*( ) function shall return a pointer to the token found, or a NULL pointer when no token is found.

ERRORS

No errors are defined.

EXAMPLES

Searching for Word Separators

The following example searches for tokens separated by space characters.

```
#include <string.h>
...
char *token;
char *line = "LINE TO BE SEPARATED";
char *search = " ";

/* Token will point to "LINE". */
token = strtok(line, search);

/* Token will point to "TO". */
token = strtok(NULL, search);
```

Breaking a Line

The following example uses *strtok*( ) to break a line into two character strings separated by any combination of <space>s, <tab>s, or <newline>s.

```
#include <string.h>
...
struct element {
    char *key;
    char *data;
};
...
char line[LINE_MAX];
char *key, *data;
...
key = strtok(line, " \n");
data = strtok(NULL, " \n");
...
```

APPLICATION USAGE

The *strtok_r*( ) function is thread-safe and stores its state in a user-supplied buffer instead of possibly using a static data area that may be overwritten by an unrelated call from another thread.

RATIONALE

The *strtok*( ) function searches for a separator string within a larger string. It returns a pointer to the last substring between separator strings. This function uses static storage to keep track of the current string position between calls. The new function, *strtok_r*( ), takes an additional argument, *lasts*, to keep track of the current position in the string.

FUTURE DIRECTIONS

None.

SEE ALSO

The Base Definitions volume of IEEE Std 1003.1-200x, **<string.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The *strtok_r*( ) function is included for alignment with the POSIX Threads Extension.

A note indicating that the *strtok*( ) function need not be reentrant is added to the DESCRIPTION.

Issue 6

Extensions beyond the ISO C standard are now marked.

The *strtok_r*( ) function is marked as part of the Thread-Safe Functions option.

In the DESCRIPTION, the note about reentrancy is expanded to cover thread-safety.

The APPLICATION USAGE section is updated to include a note on the thread-safe function and its avoidance of possibly using a static data area.

The **restrict** keyword is added to the *strtok*( ) and *strtok_r*( ) prototypes for alignment with the ISO/IEC 9899:1999 standard.

NAME

strtol, strtoll — convert string to a long integer

SYNOPSIS

```
#include <stdlib.h>

long strtol(const char *restrict str, char **restrict endptr, int base);
long long strtoll(const char *restrict str, char **restrict endptr,
    int base)
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall convert the initial portion of the string pointed to by *str* to a type **long** and **long long** representation, respectively. First, they decompose the input string into three parts:

1. An initial, possibly empty, sequence of white-space characters (as specified by *isspace*( ))
2. A subject sequence interpreted as an integer represented in some radix determined by the value of *base*
3. A final string of one or more unrecognized characters, including the terminating null byte of the input string.

Then they shall attempt to convert the subject sequence to an integer, and return the result. |

If the value of *base* is 0, the expected form of the subject sequence is that of a decimal constant, octal constant, or hexadecimal constant, any of which may be preceded by a `'+'` or `'−'` sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix `'0'` optionally followed by a sequence of the digits `'0'` to `'7'` only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters `'a'` (or `'A'`) to `'f'` (or `'F'`) with values 10 to 15 respectively.

If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by *base*, optionally preceded by a `'+'` or `'−'` sign. The letters from `'a'` (or `'A'`) to `'z'` (or `'Z'`) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of *base* are permitted. If the value of *base* is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character that is of the expected form. The subject sequence shall | contain no characters if the input string is empty or consists entirely of white-space characters, | or if the first non-white-space character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of *base* is 0, the sequence of | characters starting with the first digit shall be interpreted as an integer constant. If the subject | sequence has the expected form and the value of *base* is between 2 and 36, it shall be used as the | base for conversion, ascribing to each letter its value as given above. If the subject sequence | begins with a minus sign, the value resulting from the conversion shall be negated. A pointer to | the final string shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null | pointer.

CX In other than the C or POSIX locales, other implementation-defined subject sequences may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX The *strtol*( ) function shall not change the setting of *errno* if successful.

Since 0, {LONG_MIN} or {LLONG_MIN}, and {LONG_MAX} or {LLONG_MAX} are returned on error and are also valid returns on success, an application wishing to check for error situations should set *errno* to 0, then call *strtol*( ) or *strtoll*( ), then check *errno*.

RETURN VALUE

Upon successful completion, these functions shall return the converted value, if any. If no conversion could be performed, 0 shall be returned CX and *errno* may be set to [EINVAL].

If the correct value is outside the range of representable values, {LONG_MIN}, {LONG_MAX}, {LLONG_MIN} or {LLONG_MAX} shall be returned (according to the sign of the value), and *errno* set to [ERANGE].

ERRORS

These functions shall fail if:

[ERANGE] The value to be returned is not representable.

These functions may fail if:

CX [EINVAL] The value of *base* is not supported.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The following changes are made for alignment with the ISO / IEC 9899: 1999 standard:

- The *strtol*( ) prototype is updated.
- The *strtoll*( ) function is added.

NAME

strtold — convert string to a double-precision number

SYNOPSIS

```
#include <stdlib.h>

long double strtold(const char *restrict nptr, char **restrict endptr);
```

DESCRIPTION

Refer to *strtod*( ).

NAME

strtoll — convert string to a long integer

SYNOPSIS

```
#include <stdlib.h>

long long strtoll(const char *restrict str, char **restrict endptr,
    int base);
```

DESCRIPTION

Refer to *strtol*( ).

NAME

strtoul, strtoull — convert string to an unsigned long

SYNOPSIS

```
#include <stdlib.h>

unsigned long strtoul(const char *restrict str,
    char **restrict endptr, int base);
unsigned long long strtoull(const char *restrict str,
    char **restrict endptr, int base);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall convert the initial portion of the string pointed to by *str* to a type **unsigned long** and **unsigned long long** representation, respectively. First, they decompose the input string into three parts:

1. An initial, possibly empty, sequence of white-space characters (as specified by *isspace*( ))
2. A subject sequence interpreted as an integer represented in some radix determined by the value of *base*
3. A final string of one or more unrecognized characters, including the terminating null byte of the input string

Then they shall attempt to convert the subject sequence to an unsigned integer, and return the result.

If the value of *base* is 0, the expected form of the subject sequence is that of a decimal constant, octal constant, or hexadecimal constant, any of which may be preceded by a `'+'` or `'−'` sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix `'0'` optionally followed by a sequence of the digits `'0'` to `'7'` only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters `'a'` (or `'A'`) to `'f'` (or `'F'`) with values 10 to 15 respectively.

If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by *base*, optionally preceded by a `'+'` or `'−'` sign. The letters from `'a'` (or `'A'`) to `'z'` (or `'Z'`) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of *base* are permitted. If the value of *base* is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character that is of the expected form. The subject sequence shall contain no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and the value of *base* is 0, the sequence of characters starting with the first digit shall be interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it shall be used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion shall be negated. A pointer to the final string shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX In other than the C or POSIX locales, other implementation-defined subject sequences may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion shall be performed; the value of *str* shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer. |

CX The *strtoul*( ) function shall not change the setting of *errno* if successful.

Since 0, {ULONG_MAX}, and {ULLONG_MAX} are returned on error and are also valid returns on success, an application wishing to check for error situations should set *errno* to 0, then call *strtoul*( ) or *strtoull*( ), then check *errno*. |

RETURN VALUE

Upon successful completion, these functions shall return the converted value, if any. If no conversion could be performed, 0 shall be returned CX and *errno* may be set to [EINVAL]. If the correct value is outside the range of representable values, {ULONG_MAX} or {ULLONG_MAX} shall be returned and *errno* set to [ERANGE].

ERRORS

These functions shall fail if:

CX [EINVAL]	The value of *base* is not supported.
[ERANGE]	The value to be returned is not representable.

These functions may fail if:

CX [EINVAL]	No conversion could be performed.

CHANGE HISTORY

First released in Issue 4. Derived from the ANSI C standard.

Issue 5

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The [EINVAL] error condition is added for when the value of *base* is not supported.

  In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

- The *strtoul*( ) prototype is updated.
- The *strtoull*( ) function is added.

NAME

strtoumax — convert string to integer type

SYNOPSIS

```
#include <inttypes.h>

uintmax_t strtoumax(const char *restrict nptr, char **restrict endptr,
    int base);
```

DESCRIPTION

Refer to *strtoimax*( ).

NAME

strxfrm — string transformation

SYNOPSIS

```
#include <string.h>

size_t strxfrm(char *restrict s1, const char *restrict s2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *strxfrm*( ) function shall transform the string pointed to by *s2* and place the resulting string into the array pointed to by *s1*. The transformation is such that if *strcmp*( ) is applied to two transformed strings, it shall return a value greater than, equal to, or less than 0, corresponding to the result of *strcoll*( ) applied to the same two original strings. No more than *n* bytes are placed into the resulting array pointed to by *s1*, including the terminating null byte. If *n* is 0, *s1* is permitted to be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.

CX The *strxfrm*( ) function shall not change the setting of *errno* if successful.

Since no return value is reserved to indicate an error, an application wishing to check for error situations should set *errno* to 0, then call *strxfrm*( ), then check *errno*. |

RETURN VALUE

Upon successful completion, *strxfrm*( ) shall return the length of the transformed string (not including the terminating null byte). If the value returned is *n* or more, the contents of the array pointed to by *s1* are unspecified. |

CX On error, *strxfrm*( ) may set *errno* but no return value is reserved to indicate an error.

ERRORS

The *strxfrm*( ) function may fail if:

CX [EINVAL] The string pointed to by the *s2* argument contains characters outside the domain of the collating sequence.

EXAMPLES

None.

APPLICATION USAGE

The transformation function is such that two transformed strings can be ordered by *strcmp*( ) as appropriate to collating sequence information in the program's locale (category *LC_COLLATE*).

The fact that when *n* is 0 *s1* is permitted to be a null pointer is useful to determine the size of the *s1* array prior to making the transformation.

Entry included for alignment with the ISO C standard.

Issue 5

The DESCRIPTION is updated to indicate that *errno* does not changed if the function is successful.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The *strxfrm*( ) prototype is updated for alignment with the ISO / IEC 9899: 1999 standard.

NAME

swab — swap bytes

SYNOPSIS

XSI

```
#include <unistd.h>

void swab(const void *restrict src, void *restrict dest,
    ssize_t nbytes);
```

DESCRIPTION

The *swab*( ) function shall copy *nbytes* bytes, which are pointed to by *src*, to the object pointed to by *dest*, exchanging adjacent bytes. The *nbytes* argument should be even. If *nbytes* is odd, *swab*( ) copies and exchanges *nbytes*−1 bytes and the disposition of the last byte is unspecified. If copying takes place between objects that overlap, the behavior is undefined. If *nbytes* is negative, *swab*( ) does nothing.

RETURN VALUE

None.

ERRORS

No errors are defined.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

The **restrict** keyword is added to the *swab*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

swapcontext — swap user context

SYNOPSIS

XSI

```
#include <ucontext.h>

int swapcontext(ucontext_t *restrict oucp,
    const ucontext_t *restrict ucp);
```

DESCRIPTION

Refer to *makecontext*( ).

NAME

swprintf — print formatted wide-character output

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

int swprintf(wchar_t *ws, size_t n, const wchar_t *format, ...);
```

DESCRIPTION

Refer to *fwprintf*( ).

NAME

swscanf — convert formatted wide-character input

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

int swscanf(const wchar_t *restrict ws,
    const wchar_t *restrict format, ... );
```

DESCRIPTION

Refer to *fwscanf*( ).

NAME

symlink — make symbolic link to a file

SYNOPSIS

```
#include <unistd.h>

int symlink(const char *path1, const char *path2);
```

DESCRIPTION

The *symlink*( ) function shall create a symbolic link called *path2* that contains the string pointed to by *path1* (*path2* is the name of the symbolic link created, *path1* is the string contained in the symbolic link).

The string pointed to by *path1* shall be treated only as a character string and shall not be validated as a pathname.

If the *symlink*( ) function fails for any reason other than [EIO], any file named by *path2* shall be unaffected.

RETURN VALUE

Upon successful completion, *symlink*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *symlink*( ) function shall fail if:

[EACCES]	Write permission is denied in the directory where the symbolic link is being created, or search permission is denied for a component of the path prefix of *path2*.
[EEXIST]	The *path2* argument names an existing file or symbolic link.
[EIO]	An I/O error occurs while reading from or writing to the file system.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path2* argument.
[ENAMETOOLONG]	The length of the *path2* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX} or the length of the *path1* argument is longer than {SYMLINK_MAX}.
[ENOENT]	A component of *path2* does not name an existing file or *path2* is an empty string.
[ENOSPC]	The directory in which the entry for the new symbolic link is being placed cannot be extended because no space is left on the file system containing the directory, or the new symbolic link cannot be created because no space is left on the file system which shall contain the link, or the file system is out of file-allocation resources.
[ENOTDIR]	A component of the path prefix of *path2* is not a directory.
[EROFS]	The new symbolic link would reside on a read-only file system.

The *symlink*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path2* argument.
[ENAMETOOLONG]	As a result of encountering a symbolic link in resolution of the *path2*

argument, the length of the substituted pathname string exceeded {PATH_MAX} bytes (including the terminating null byte), or the length of the string pointed to by *path1* exceeded {SYMLINK_MAX}.

EXAMPLES

None.

APPLICATION USAGE

Like a hard link, a symbolic link allows a file to have multiple logical names. The presence of a hard link guarantees the existence of a file, even after the original name has been removed. A symbolic link provides no such assurance; in fact, the file named by the *path1* argument need not exist when the link is created. A symbolic link can cross file system boundaries.

Normal permission checks are made on each component of the symbolic link pathname during its resolution.

RATIONALE

Since IEEE Std 1003.1-200x does not require any association of file times with symbolic links, there is no requirement that file times be updated by *symlink*( ).

FUTURE DIRECTIONS

None.

Issue 6

The following changes were made to align with the IEEE P1003.1a draft standard:

- The DESCRIPTION text is updated.
- The [ELOOP] optional error condition is added.

NAME

sync — schedule file system updates

SYNOPSIS

XSI

```
#include <unistd.h>

void sync(void);
```

DESCRIPTION

The *sync*( ) function shall cause all information in memory that updates file systems to be scheduled for writing out to all file systems.

The writing, although scheduled, is not necessarily complete upon return from *sync*( ).

RETURN VALUE

The *sync*( ) function shall not return a value.

ERRORS

No errors are defined.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

NAME

sysconf — get configurable system variables

SYNOPSIS

```
#include <unistd.h>

long sysconf(int name);
```

DESCRIPTION

The *sysconf*( ) function provides a method for the application to determine the current value of a configurable system limit or option (*variable*). Support for some system variables is dependent on implementation options (as indicated by the margin codes in the following table). Where an implementation option is not supported, the variable need not be supported.

The *name* argument represents the system variable to be queried. The following table lists the minimal set of system variables from **<limits.h>** or **<unistd.h>** that can be returned by *sysconf*( ), and the symbolic constants, defined in **<unistd.h>** that are the corresponding values used for *name*. Support for some configuration variables is dependent on implementation options (see shading and margin codes in the table below). Where an implementation option is not supported, the variable need not be supported.

RETURN VALUE

If *name* is an invalid value, *sysconf*( ) shall return −1 and set *errno* to indicate the error. If the variable corresponding to *name* has no limit, *sysconf*( ) shall return −1 without changing the value of *errno*. Note that indefinite limits do not imply infinite limits; see **<limits.h>**.

Otherwise, *sysconf*( ) shall return the current variable value on the system. The value returned shall not be more restrictive than the corresponding value described to the application when it was compiled with the implementation's **<limits.h>** or **<unistd.h>**. The value shall not change during the lifetime of the calling process.

ERRORS

The *sysconf*( ) function shall fail if:

[EINVAL] The value of the *name* argument is invalid.

EXAMPLES

None.

APPLICATION USAGE

As −1 is a permissible return value in a successful situation, an application wishing to check for error situations should set *errno* to 0, then call *sysconf*( ), and, if it returns −1, check to see if *errno* is non-zero.

If the value of *sysconf*(_SC_2_VERSION) is not equal to the value of the _POSIX2_VERSION symbolic constant, the utilities available via *system*( ) or *popen*( ) might not behave as described in the Shell and Utilities volume of IEEE Std 1003.1-200x. This would mean that the application is not running in an environment that conforms to the Shell and Utilities volume of IEEE Std 1003.1-200x. Some applications might be able to deal with this, others might not. However, the functions defined in this volume of IEEE Std 1003.1-200x continue to operate as specified, even if: *sysconf*(_SC_2_VERSION) reports that the utilities no longer perform as specified.

RATIONALE

This functionality was added in response to requirements of application developers and of system vendors who deal with many international system configurations. It is closely related to *pathconf*( ) and *fpathconf*( ).

Although a conforming application can run on all systems by never demanding more resources than the minimum values published in this volume of IEEE Std 1003.1-200x, it is useful for that application to be able to use the actual value for the quantity of a resource available on any given system. To do this, the application makes use of the value of a symbolic constant in **<limits.h>** or **<unistd.h>**.

However, once compiled, the application must still be able to cope if the amount of resource available is increased. To that end, an application may need a means of determining the quantity of a resource, or the presence of an option, at execution time.

Two examples are offered:

1. Applications may wish to act differently on systems with or without job control. Applications vendors who wish to distribute only a single binary package to all instances of a computer architecture would be forced to assume job control is never available if it were to rely solely on the **<unistd.h>** value published in this volume of IEEE Std 1003.1-200x.
2. International applications vendors occasionally require knowledge of the number of clock ticks per second. Without these facilities, they would be required to either distribute their applications partially in source form or to have 50Hz and 60Hz versions for the various countries in which they operate.

It is the knowledge that many applications are actually distributed widely in executable form that leads to this facility. If limited to the most restrictive values in the headers, such applications would have to be prepared to accept the most limited environments offered by the smallest microcomputers. Although this is entirely portable, there was a consensus that they should be able to take advantage of the facilities offered by large systems, without the restrictions associated with source and object distributions.

During the discussions of this feature, it was pointed out that it is almost always possible for an application to discern what a value might be at runtime by suitably testing the various functions themselves. And, in any event, it could always be written to adequately deal with error returns from the various functions. In the end, it was felt that this imposed an unreasonable level of complication and sophistication on the application writer.

This runtime facility is not meant to provide ever-changing values that applications have to check multiple times. The values are seen as changing no more frequently than once per system initialization, such as by a system administrator or operator with an automatic configuration program. This volume of IEEE Std 1003.1-200x specifies that they shall not change within the lifetime of the process.

Some values apply to the system overall and others vary at the file system or directory level. The latter are described in *pathconf*( ).

Note that all values returned must be expressible as integers. String values were considered, but the additional flexibility of this approach was rejected due to its added complexity of implementation and use.

Some values, such as {PATH_MAX}, are sometimes so large that they must not be used to, say, allocate arrays. The *sysconf*( ) function returns a negative value to show that this symbolic constant is not even defined in this case.

Similar to *pathconf*( ), this permits the implementation not to have a limit. When one resource is infinite, returning an error indicating that some other resource limit has been reached is conforming behavior.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

The _XBS_ variables and name values are added to the table of system variables in the DESCRIPTION. These are all marked EX.

Issue 6

The symbol CLK_TCK is obsolescent and removed. It is replaced with the phrase ‘‘clock ticks per second’’.

The symbol {PASS_MAX} is removed.

The following changes were made to align with the IEEE P1003.1a draft standard:

- Table entries added for the following variables: _SC_REGEXP, _SC_SHELL, _SC_REGEX_VERSION, _SC_SYMLOOP_MAX.

The following *sysconf*( ) variables and their associated names are added for alignment with IEEE Std 1003.1d-1999:

_POSIX_ADVISORY_INFO
_POSIX_CPUTIME
_POSIX_SPAWN
_POSIX_SPORADIC_SERVER
_POSIX_THREAD_CPUTIME
_POSIX_THREAD_SPORADIC_SERVER
_POSIX_TIMEOUTS

The following changes are made to the DESCRIPTION for alignment with IEEE Std 1003.1j-2000:

- A statement expressing the dependency of support for some system variables on implementation options is added.

- The following system variables are added:

_POSIX_BARRIERS
_POSIX_CLOCK_SELECTION
_POSIX_MONOTONIC_CLOCK
_POSIX_READER_WRITER_LOCKS
_POSIX_SPIN_LOCKS
_POSIX_TYPED_MEMORY_OBJECTS

The following system variables are added for alignment with IEEE Std 1003.2d-1994:

_POSIX2_PBS
_POSIX2_PBS_ACCOUNTING
_POSIX2_PBS_LOCATE
_POSIX2_PBS_MESSAGE
_POSIX2_PBS_TRACK

The following *sysconf*( ) variables and their associated names are added for alignment with IEEE Std 1003.1q-2000:

_POSIX_TRACE
_POSIX_TRACE_EVENT_FILTER
_POSIX_TRACE_INHERIT
_POSIX_TRACE_LOG

The macros associated with the *c89* programming models are marked LEGACY, and new equivalent macros associated with *c99* are introduced.

NAME

syslog — log a message

SYNOPSIS

XSI

```
#include <syslog.h>

void syslog(int priority, const char *message, ... /* argument */);
```

DESCRIPTION

Refer to *closelog*( ).

NAME

system — issue a command

SYNOPSIS

```
#include <stdlib.h>

int system(const char *command);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

If *command* is a null pointer, the *system*( ) function shall determine whether the host environment has a command processor. If *command* is not a null pointer, the *system*( ) function shall pass the string pointed to by *command* to that command processor to be executed in an implementation-defined manner; this might then cause the program calling *system*( ) to behave in a non-conforming manner or to terminate.

CX The environment of the executed command shall be as if a child process were created using *fork*( ), and the child process invoked the *sh* utility using *execl*( ) as follows:

```
execl(<shell path>, "sh", "-c", command, (char *)0);
```

where <*shell path*> is an unspecified pathname for the *sh* utility.

The *system*( ) function shall ignore the SIGINT and SIGQUIT signals, and shall block the SIGCHLD signal, while waiting for the command to terminate. If this might cause the application to miss a signal that would have killed it, then the application should examine the return value from *system*( ) and take whatever action is appropriate to the application if the command terminated due to receipt of a signal.

The *system*( ) function shall not affect the termination status of any child of the calling processes other than the process or processes it itself creates.

The *system*( ) function shall not return until the child process has terminated.

RETURN VALUE

If *command* is a null pointer, *system*( ) shall return non-zero to indicate that a command processor is available, or zero if none is available. CX The *system*( ) function shall always return non-zero when *command* is NULL.

CX If *command* is not a null pointer, *system*( ) shall return the termination status of the command language interpreter in the format specified by *waitpid*( ). The termination status shall be as defined for the *sh* utility; otherwise, the termination status is unspecified. If some error prevents the command language interpreter from executing after the child process is created, the return value from *system*( ) shall be as if the command language interpreter had terminated using *exit*(127) or *_exit*(127). If a child process cannot be created, or if the termination status for the command language interpreter cannot be obtained, *system*( ) shall return −1 and set *errno* to indicate the error.

ERRORS

CX The *system*( ) function may set *errno* values as described by *fork*( ).

In addition, *system*( ) may fail if:

CX [ECHILD] The status of the child process created by *system*( ) is no longer available.

EXAMPLES

None.

APPLICATION USAGE

If the return value of *system*( ) is not –1, its value can be decoded through the use of the macros described in **<sys/wait.h>**. For convenience, these macros are also provided in **<stdlib.h>**.

Note that, while *system*( ) must ignore SIGINT and SIGQUIT and block SIGCHLD while waiting for the child to terminate, the handling of signals in the executed command is as specified by *fork*( ) and *exec*. For example, if SIGINT is being caught or is set to SIG_DFL when *system*( ) is called, then the child is started with SIGINT handling set to SIG_DFL.

Ignoring SIGINT and SIGQUIT in the parent process prevents coordination problems (two processes reading from the same terminal, for example) when the executed command ignores or catches one of the signals. It is also usually the correct action when the user has given a command to the application to be executed synchronously (as in the `'!'` command in many interactive applications). In either case, the signal should be delivered only to the child process, not to the application itself. There is one situation where ignoring the signals might have less than the desired effect. This is when the application uses *system*( ) to perform some task invisible to the user. If the user typed the interrupt character (`"^C"`, for example) while *system*( ) is being used in this way, one would expect the application to be killed, but only the executed command is killed. Applications that use *system*( ) in this way should carefully check the return status from *system*( ) to see if the executed command was successful, and should take appropriate action when the command fails.

Blocking SIGCHLD while waiting for the child to terminate prevents the application from catching the signal and obtaining status from *system*( )'s child process before *system*( ) can get the status itself.

The context in which the utility is ultimately executed may differ from that in which *system*( ) was called. For example, file descriptors that have the FD_CLOEXEC flag set are closed, and the process ID and parent process ID are different. Also, if the executed utility changes its environment variables or its current working directory, that change is not reflected in the caller's context.

There is no defined way for an application to find the specific path for the shell. However, *confstr*( ) can provide a value for *PATH* that is guaranteed to find the *sh* utility.

RATIONALE

The *system*( ) function should not be used by programs that have set user (or group) ID privileges. The *fork*( ) and *exec* family of functions (except *execlp*( ) and *execvp*( )), should be used instead. This prevents any unforeseen manipulation of the environment of the user that could cause execution of commands not anticipated by the calling program.

There are three levels of specification for the *system*( ) function. The ISO C standard gives the most basic. It requires that the function exists, and defines a way for an application to query whether a command language interpreter exists. It says nothing about the command language or the environment in which the command is interpreted.

IEEE Std 1003.1-200x places additional restrictions on *system*( ). It requires that if there is a command language interpreter, the environment must be as specified by *fork*( ) and *exec*. This ensures, for example, that close-on-*exec* works, that file locks are not inherited, and that the process ID is different. It also specifies the return value from *system*( ) when the command line can be run, thus giving the application some information about the command's completion statu.

Finally, IEEE Std 1003.1-200x requires the command to be interpreted as in the shell command language defined in the Shell and Utilities volume of IEEE Std 1003.1-200x.

Note that, *system*(NULL) is required to return non-zero, indicating that there is a command language interpreter. At first glance, this would seem to conflict with the ISO C standard which allows *system*(NULL) to return zero. There is no conflict, however. A system must have a command language interpreter, and is non-conforming if none is present. It is therefore permissible for the *system*( ) function on such a system to implement the behavior specified by the ISO C standard as long as it is understood that the implementation does not conform to IEEE Std 1003.1-200x if *system*(NULL) returns zero.

It was explicitly decided that when *command* is NULL, *system*( ) should not be required to check to make sure that the command language interpreter actually exists with the correct mode, that there are enough processes to execute it, and so on. The call *system*(NULL) could, theoretically, check for such problems as too many existing child processes, and return zero. However, it would be inappropriate to return zero due to such a (presumably) transient condition. If some condition exists that is not under the control of this application and that would cause any *system*( ) call to fail, that system has been rendered non-conforming.

Early drafts required, or allowed, *system*( ) to return with *errno* set to [EINTR] if it was interrupted with a signal. This error return was removed, and a requirement that *system*( ) not return until the child has terminated was added. This means that if a *waitpid*( ) call in *system*( ) exits with *errno* set to [EINTR], *system*( ) must re-issue the *waitpid*( ). This change was made for two reasons:

1. There is no way for an application to clean up if *system*( ) returns [EINTR], short of calling *wait*( ), and that could have the undesirable effect of returning the status of children other than the one started by *system*( ).

2. While it might require a change in some historical implementations, those implementations already have to be changed because they use *wait*( ) instead of *waitpid*( ).

Note that if the application is catching SIGCHLD signals, it will receive such a signal before a successful *system*( ) call returns.

To conform to IEEE Std 1003.1-200x, *system*( ) must use *waitpid*( ), or some similar function, instead of *wait*( ).

The following code sample illustrates how *system*( ) might be implemented on an implementation conforming to IEEE Std 1003.1-200x.

```
#include <signal.h>
int system(const char *cmd)
{
    int stat;
    pid_t pid;
    struct sigaction sa, savintr, savequit;
    sigset_t saveblock;
    if (cmd == NULL)
        return(1);
    sa.sa_handler = SIG_IGN;
    sigemptyset(&sa.sa_mask);
    sa.sa_flags = 0;
    sigemptyset(&savintr.sa_mask);
    sigemptyset(&savequit.sa_mask);
    sigaction(SIGINT, &sa, &savintr);
    sigaction(SIGQUIT, &sa, &savequit);
```

```
        sigaddset(&sa.sa_mask, SIGCHLD);
        sigprocmask(SIG_BLOCK, &sa.sa_mask, &saveblock);
        if ((pid = fork()) == 0) {
            sigaction(SIGINT, &savintr, (struct sigaction *)0);
            sigaction(SIGQUIT, &savequit, (struct sigaction *)0);
            sigprocmask(SIG_SETMASK, &saveblock, (sigset_t *)0);
            execl("/bin/sh", "sh", "-c", cmd, (char *)0);
            _exit(127);
        }
        if (pid == -1) {
            stat = -1; /* errno comes from fork() */
        } else {
            while (waitpid(pid, &stat, 0) == -1) {
                if (errno != EINTR){
                    stat = -1;
                    break;
                }
            }
        }
        sigaction(SIGINT, &savintr, (struct sigaction *)0);
        sigaction(SIGQUIT, &savequit, (struct sigaction *)0);
        sigprocmask(SIG_SETMASK, &saveblock, (sigset_t *)0);
        return(stat);
    }
```

Note that, while a particular implementation of *system*( ) (such as the one above) can assume a particular path for the shell, such a path is not necessarily valid on another system. The above example is not portable, and is not intended to be.

One reviewer suggested that an implementation of *system*( ) might want to use an environment variable such as *SHELL* to determine which command interpreter to use. The supposed implementation would use the default command interpreter if the one specified by the environment variable was not available. This would allow a user, when using an application that prompts for command lines to be processed using *system*( ), to specify a different command interpreter. Such an implementation is discouraged. If the alternate command interpreter did not follow the command line syntax specified in the Shell and Utilities volume of IEEE Std 1003.1-200x, then changing *SHELL* would render *system*( ) non-conforming. This would affect applications that expected the specified behavior from *system*( ), and since the Shell and Utilities volume of IEEE Std 1003.1-200x does not mention that *SHELL* affects *system*( ), the application would not know that it needed to unset *SHELL*.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID. |

Issue 6

The following changes were made to align with the IEEE P1003.1a draft standard:

- The DESCRIPTION is adjusted to reflect the behavior on systems that do not support the Shell option.

NAME

tan, tanf, tanl — tangent function

SYNOPSIS

```
#include <math.h>

double tan(double x);
float tanf(float x);
long double tanl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the tangent of their argument *x*, measured in radians.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the tangent of *x*.

If the correct value would cause underflow, and is not representable, a range error may occur, and MX either 0.0 (if supported), or an implementation-defined value shall be returned.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0, *x* shall be returned.

If *x* is subnormal, a range error may occur and *x* should be returned.

If *x* is ±Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If the correct value would cause underflow, and is representable, a range error may occur and the correct value shall be returned.

XSI If the correct value would cause overflow, a range error shall occur and *tan*( ), *tanf*( ), and *tanl*( ) shall return the value of the macro HUGE_VAL, HUGE_VALF, and HUGE_VALL, respectively.

ERRORS

These functions shall fail if:

MX	Domain Error	The value *x* is ±Inf.
		If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.
XSI	Range Error	The result overflows
		If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

These functions may fail if:

MX Range Error The result underflows, or the value *x* is subnormal.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

Taking the Tangent of a 45-Degree Angle

```
#include <math.h>
...
double radians = 45.0 * M_PI / 180;
double result;
...
result = tan (radians);
```

APPLICATION USAGE

There are no known floating-point representations such that for a normal argument, *tan*(x) is either overflow or underflow.

These functions may lose accuracy when their argument is near a multiple of $\pi/2$ or is far from 0.0.

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The last two paragraphs of the DESCRIPTION were included as APPLICATION USAGE notes in previous issues.

Issue 6

The *tanf*( ) and *tanl*( ) functions are added for alignment with the ISO/IEC 9899:1999 standard.

The DESCRIPTION, RETURN VALUE, ERRORS, and APPLICATION USAGE sections are revised to align with the ISO/IEC 9899:1999 standard.

IEC 60559:1989 standard floating-point extensions over the ISO/IEC 9899:1999 standard are marked.

NAME

tanf — tangent function

SYNOPSIS

```
#include <math.h>

float tanf(float x);
```

DESCRIPTION

Refer to *tan*( ).

NAME

tanh, tanhf, tanhl — hyperbolic tangent functions

SYNOPSIS

```
#include <math.h>

double tanh(double x);
float tanhf(float x);
long double tanhl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the hyperbolic tangent of their argument *x*.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the hyperbolic tangent of *x*.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0, *x* shall be returned.

If *x* is ±Inf, ±1 shall be returned.

If *x* is subnormal, a range error may occur and *x* should be returned.

ERRORS

These functions may fail if:

MX Range Error The value of *x* is subnormal.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

NAME

tanl — tangent function

SYNOPSIS

```
#include <math.h>

long double tanl(long double x);
```

DESCRIPTION

Refer to *tan*( ).

NAME

tcdrain — wait for transmission of output

SYNOPSIS

```
#include <termios.h>

int tcdrain(int fildes);
```

DESCRIPTION

The *tcdrain*( ) function shall block until all output written to the object referred to by *fildes* is transmitted. The *fildes* argument is an open file descriptor associated with a terminal.

Any attempts to use *tcdrain*( ) from a process which is a member of a background process group on a *fildes* associated with its controlling terminal, shall cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process shall be allowed to perform the operation, and no signal is sent.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *tcdrain*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid file descriptor.
[EINTR]	A signal interrupted *tcdrain*( ).
[ENOTTY]	The file associated with *fildes* is not a terminal.

The *tcdrain*( ) function may fail if:

[EIO]	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the final paragraph is no longer conditional on _POSIX_JOB_CONTROL. This is a FIPS requirement.

- The [EIO] error is added.

NAME

tcflow — suspend or restart the transmission or reception of data

SYNOPSIS

```
#include <termios.h>

int tcflow(int fildes, int action);
```

DESCRIPTION

The *tcflow*( ) function shall suspend or restart transmission or reception of data on the object referred to by *fildes*, depending on the value of *action*. The *fildes* argument is an open file descriptor associated with a terminal.

- If *action* is TCOOFF, output shall be suspended.
- If *action* is TCOON, suspended output shall be restarted.
- If *action* is TCIOFF, the system shall transmit a STOP character, which is intended to cause the terminal device to stop transmitting data to the system.
- If *action* is TCION, the system shall transmit a START character, which is intended to cause the terminal device to start transmitting data to the system.

The default on the opening of a terminal file is that neither its input nor its output are suspended.

Attempts to use *tcflow*( ) from a process which is a member of a background process group on a *fildes* associated with its controlling terminal, shall cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process shall be allowed to perform the operation, and no signal is sent.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *tcflow*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid file descriptor.
[EINVAL]	The *action* argument is not a supported value.
[ENOTTY]	The file associated with *fildes* is not a terminal.

The *tcflow*( ) function may fail if:

[EIO]	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The [EIO] error is added.

NAME

tcflush — flush non-transmitted output data, non-read input data, or both

SYNOPSIS

```
#include <termios.h>

int tcflush(int fildes, int queue_selector);
```

DESCRIPTION

Upon successful completion, *tcflush*( ) shall discard data written to the object referred to by *fildes* (an open file descriptor associated with a terminal) but not transmitted, or data received but not read, depending on the value of *queue_selector*:

- If *queue_selector* is TCIFLUSH, it shall flush data received but not read.
- If *queue_selector* is TCOFLUSH, it shall flush data written but not transmitted.
- If *queue_selector* is TCIOFLUSH, it shall flush both data received but not read and data written but not transmitted.

Attempts to use *tcflush*( ) from a process which is a member of a background process group on a *fildes* associated with its controlling terminal shall cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process shall be allowed to perform the operation, and no signal is sent.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *tcflush*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid file descriptor.
[EINVAL]	The *queue_selector* argument is not a supported value.
[ENOTTY]	The file associated with *fildes* is not a terminal.

The *tcflush*( ) function may fail if:

[EIO]	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

The Open Group Corrigendum U035/1 is applied. In the ERRORS and APPLICATION USAGE sections, references to *tcflow*( ) are replaced with *tcflush*( ).

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the final paragraph is no longer conditional on _POSIX_JOB_CONTROL. This is a FIPS requirement.
- The [EIO] error is added.

NAME

tcgetattr — get the parameters associated with the terminal

SYNOPSIS

```
#include <termios.h>

int tcgetattr(int fildes, struct termios *termios_p);
```

DESCRIPTION

The *tcgetattr*( ) function shall get the parameters associated with the terminal referred to by *fildes* and store them in the **termios** structure referenced by *termios_p*. The *fildes* argument is an open file descriptor associated with a terminal.

The *termios_p* argument is a pointer to a **termios** structure.

The *tcgetattr*( ) operation is allowed from any process.

If the terminal device supports different input and output baud rates, the baud rates stored in the **termios** structure returned by *tcgetattr*( ) shall reflect the actual baud rates, even if they are equal. If differing baud rates are not supported, the rate returned as the output baud rate shall be the actual baud rate. If the terminal device does not support split baud rates, the input baud rate stored in the **termios** structure shall be the output rate (as one of the symbolic values).

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *tcgetattr*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid file descriptor.
[ENOTTY]	The file associated with *fildes* is not a terminal.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Care must be taken when changing the terminal attributes. Applications should always do a *tcgetattr*( ), save the **termios** structure values returned, and then do a *tcsetattr*( ) changing only the necessary fields. The application should use the values saved from the *tcgetattr*( ) to reset the terminal state whenever it is done with the terminal. This is necessary because terminal attributes apply to the underlying port and not to each individual open instance; that is, all processes that have used the terminal see the latest attribute changes.

A program that uses these functions should be written to catch all signals and take other appropriate actions to ensure that when the program terminates, whether planned or not, the terminal device's state is restored to its original state.

Existing practice dealing with error returns when only part of a request can be honored is based on calls to the *ioctl*( ) function. In historical BSD and System V implementations, the corresponding *ioctl*( ) returns zero if the requested actions were semantically correct, even if some of the requested changes could not be made. Many existing applications assume this behavior and would no longer work correctly if the return value were changed from zero to −1 in this case.

Note that either specification has a problem. When zero is returned, it implies everything succeeded even if some of the changes were not made. When −1 is returned, it implies everything failed even though some of the changes were made.

Applications that need all of the requested changes made to work properly should follow *tcsetattr*( ) with a call to *tcgetattr*( ) and compare the appropriate field values.

FUTURE DIRECTIONS

None.

SEE ALSO

tcsetattr( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<termios.h>**, the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

In the DESCRIPTION, the rate returned as the input baud rate shall be the output rate. Previously, the number zero was also allowed but was obsolescent.

NAME

tcgetpgrp — get the foreground process group ID

SYNOPSIS

```
#include <unistd.h>

pid_t tcgetpgrp(int fildes);
```

DESCRIPTION

The *tcgetpgrp*( ) function shall return the value of the process group ID of the foreground process group associated with the terminal.

If there is no foreground process group, *tcgetpgrp*( ) shall return a value greater than 1 that does not match the process group ID of any existing process group.

The *tcgetpgrp*( ) function is allowed from a process that is a member of a background process group; however, the information may be subsequently changed by a process that is a member of a foreground process group.

RETURN VALUE

Upon successful completion, *tcgetpgrp*( ) shall return the value of the process group ID of the foreground process associated with the terminal. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *tcgetpgrp*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid file descriptor.
[ENOTTY]	The calling process does not have a controlling terminal, or the file is not the controlling terminal.

EXAMPLES

None.

APPLICATION USAGE

None.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

- In the DESCRIPTION, text previously conditional on support for _POSIX_JOB_CONTROL is now mandatory. This is a FIPS requirement.

NAME

tcgetsid — get process group ID for session leader for controlling terminal

SYNOPSIS

XSI

```
#include <termios.h>

pid_t tcgetsid(int fildes);
```

DESCRIPTION

The *tcgetsid*( ) function shall obtain the process group ID of the session for which the terminal specified by *fildes* is the controlling terminal.

RETURN VALUE

Upon successful completion, *tcgetsid*( ) shall return the process group ID associated with the terminal. Otherwise, a value of (**pid_t**)–1 shall be returned and *errno* set to indicate the error.

ERRORS

The *tcgetsid*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid file descriptor.
[ENOTTY]	The calling process does not have a controlling terminal, or the file is not the controlling terminal.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

The [EACCES] error has been removed from the list of mandatory errors, and the description of [ENOTTY] has been reworded.

NAME

tcsendbreak — send a ‘‘break’’ for a specific duration

SYNOPSIS

```
#include <termios.h>

int tcsendbreak(int fildes, int duration);
```

DESCRIPTION

If the terminal is using asynchronous serial data transmission, *tcsendbreak*( ) shall cause transmission of a continuous stream of zero-valued bits for a specific duration. If *duration* is 0, it shall cause transmission of zero-valued bits for at least 0,25 seconds, and not more than 0,5 seconds. If *duration* is not 0, it shall send zero-valued bits for an implementation-defined period of time.

The *fildes* argument is an open file descriptor associated with a terminal.

If the terminal is not using asynchronous serial data transmission, it is implementation-defined whether *tcsendbreak*( ) sends data to generate a break condition or returns without taking any action.

Attempts to use *tcsendbreak*( ) from a process which is a member of a background process group on a *fildes* associated with its controlling terminal shall cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process shall be allowed to perform the operation, and no signal is sent.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *tcsendbreak*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid file descriptor.
[ENOTTY]	The file associated with *fildes* is not a terminal.

The *tcsendbreak*( ) function may fail if:

[EIO]	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.

EXAMPLES

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, text previously conditional on _POSIX_JOB_CONTROL is now mandated. This is a FIPS requirement.
- The [EIO] error is added.

NAME

tcsetattr — set the parameters associated with the terminal

SYNOPSIS

```
#include <termios.h>

int tcsetattr(int fildes, int optional_actions,
    const struct termios *termios_p);
```

DESCRIPTION

The *tcsetattr*( ) function shall set the parameters associated with the terminal referred to by the open file descriptor *fildes* (an open file descriptor associated with a terminal) from the **termios** structure referenced by *termios_p* as follows:

- If *optional_actions* is TCSANOW, the change shall occur immediately.
- If *optional_actions* is TCSADRAIN, the change shall occur after all output written to *fildes* is transmitted. This function should be used when changing parameters that affect output.
- If *optional_actions* is TCSAFLUSH, the change shall occur after all output written to *fildes* is transmitted, and all input so far received but not read shall be discarded before the change is made.

If the output baud rate stored in the **termios** structure pointed to by *termios_p* is the zero baud rate, B0, the modem control lines shall no longer be asserted. Normally, this shall disconnect the line.

If the input baud rate stored in the **termios** structure pointed to by *termios_p* is 0, the input baud rate given to the hardware is the same as the output baud rate stored in the **termios** structure.

The *tcsetattr*( ) function shall return successfully if it was able to perform any of the requested actions, even if some of the requested actions could not be performed. It shall set all the attributes that the implementation supports as requested and leaves all the attributes not supported by the implementation unchanged. If no part of the request can be honored, it shall return −1 and set *errno* to [EINVAL]. If the input and output baud rates differ and are a combination that is not supported, neither baud rate shall be changed. A subsequent call to *tcgetattr*( ) shall return the actual state of the terminal device (reflecting both the changes made and not made in the previous *tcsetattr*( ) call). The *tcsetattr*( ) function shall not change the values found in the **termios** structure under any circumstances.

The effect of *tcsetattr*( ) is undefined if the value of the **termios** structure pointed to by *termios_p* was not derived from the result of a call to *tcgetattr*( ) on *fildes*; an application should modify only fields and flags defined by this volume of IEEE Std 1003.1-200x between the call to *tcgetattr*( ) and *tcsetattr*( ), leaving all other fields and flags unmodified.

No actions defined by this volume of IEEE Std 1003.1-200x, other than a call to *tcsetattr*( ) or a close of the last file descriptor in the system associated with this terminal device, shall cause any of the terminal attributes defined by this volume of IEEE Std 1003.1-200x to change.

If *tcsetattr*( ) is called from a process which is a member of a background process group on a *fildes* associated with its controlling terminal:

- If the calling process is blocking or ignoring SIGTTOU signals, the operation completes normally and no signal is sent.
- Otherwise, a SIGTTOU signal shall be sent to the process group.

RETURN VALUE

Upon successful completion, 0 shall be shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error. |

ERRORS

The *tcsetattr*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid file descriptor.
[EINTR]	A signal interrupted *tcsetattr*( ).
[EINVAL]	The *optional_actions* argument is not a supported value, or an attempt was made to change an attribute represented in the **termios** structure to an unsupported value.
[ENOTTY]	The file associated with *fildes* is not a terminal.

The *tcsetattr*( ) function may fail if:

[EIO]	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.

EXAMPLES

None.

APPLICATION USAGE

If trying to change baud rates, applications should call *tcsetattr*( ) then call *tcgetattr*( ) in order to determine what baud rates were actually selected.

RATIONALE

The *tcsetattr*( ) function can be interrupted in the following situations:

- It is interrupted while waiting for output to drain.
- It is called from a process in a background process group and SIGTTOU is caught.

See also the RATIONALE section in *tcgetattr*( ).

FUTURE DIRECTIONS

Using an input baud rate of 0 to set the input rate equal to the output rate may not necessarily be supported in a future version of this volume of IEEE Std 1003.1-200x.

In the DESCRIPTION, the text describing use of *tcsetattr*( ) from a process which is a member of a background process group is clarified.

NAME

tcsetpgrp — set the foreground process group ID

SYNOPSIS

```
#include <unistd.h>

int tcsetpgrp(int fildes, pid_t pgid_id);
```

DESCRIPTION

If the process has a controlling terminal, *tcsetpgrp*( ) shall set the foreground process group ID associated with the terminal to *pgid_id*. The application shall ensure that the file associated with *fildes* is the controlling terminal of the calling process and the controlling terminal is currently associated with the session of the calling process. The application shall ensure that the value of *pgid_id* matches a process group ID of a process in the same session as the calling process.

Attempts to use *tcsetpgrp*( ) from a process which is a member of a background process group on a *fildes* associated with its controlling terminal shall cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process shall be allowed to perform the operation, and no signal is sent. |

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *tcsetpgrp*( ) function shall fail if:

[EBADF]	The *fildes* argument is not a valid file descriptor.
[EINVAL]	This implementation does not support the value in the *pgid_id* argument.
[ENOTTY]	The calling process does not have a controlling terminal, or the file is not the controlling terminal, or the controlling terminal is no longer associated with the session of the calling process.
[EPERM]	The value of *pgid_id* is a value supported by the implementation, but does not match the process group ID of a process in the same session as the calling process.

EXAMPLES

None.

APPLICATION USAGE

None.

CHANGE HISTORY

First released in Issue 3.

Entry included for alignment with the POSIX.1-1988 standard.

Issue 6

In the SYNOPSIS, the inclusion of **<sys/types.h>** is no longer required.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- In the DESCRIPTION and ERRORS sections, text previously conditional on _POSIX_JOB_CONTROL is now mandated. This is a FIPS requirement.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The Open Group Corrigendum U047/4 is applied.

NAME

tdelete, tfind, tsearch, twalk — manage a binary search tree

SYNOPSIS

XSI

```
#include <search.h>

void *tdelete(const void *restrict key, void **restrict rootp,
    int(*compar)(const void *, const void *));
void *tfind(const void *key, void *const *rootp,
    int(*compar)(const void *, const void *));
void *tsearch(const void *key, void **rootp,
    int (*compar)(const void *, const void *));
void twalk(const void *root,
    void (*action)(const void *, VISIT, int));
```

DESCRIPTION

The *tdelete*( ), *tfind*( ), *tsearch*( ), and *twalk*( ) functions manipulate binary search trees. Comparisons are made with a user-supplied routine, the address of which is passed as the *compar* argument. This routine is called with two arguments, the pointers to the elements being compared. The application shall ensure that the user-supplied routine returns an integer less than, equal to, or greater than 0, according to whether the first argument is to be considered less than, equal to, or greater than the second argument. The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

The *tsearch*( ) function shall build and access the tree. The *key* argument is a pointer to an element to be accessed or stored. If there is a node in the tree whose element is equal to the value pointed to by *key*, a pointer to this found node shall be returned. Otherwise, the value pointed to by *key* shall be inserted (that is, a new node is created and the value of *key* is copied to this node), and a pointer to this node returned. Only pointers are copied, so the application shall ensure that the calling routine stores the data. The *rootp* argument points to a variable that points to the root node of the tree. A null pointer value for the variable pointed to by *rootp* denotes an empty tree; in this case, the variable shall be set to point to the node which shall be at the root of the new tree.

Like *tsearch*( ), *tfind*( ) shall search for a node in the tree, returning a pointer to it if found. However, if it is not found, *tfind*( ) shall return a null pointer. The arguments for *tfind*( ) are the same as for *tsearch*( ).

The *tdelete*( ) function shall delete a node from a binary search tree. The arguments are the same as for *tsearch*( ). The variable pointed to by *rootp* shall be changed if the deleted node was the root of the tree. The *tdelete*( ) function shall return a pointer to the parent of the deleted node, or a null pointer if the node is not found.

The *twalk*( ) function shall traverse a binary search tree. The *root* argument is a pointer to the root node of the tree to be traversed. (Any node in a tree may be used as the root for a walk below that node.) The argument *action* is the name of a routine to be invoked at each node. This routine is, in turn, called with three arguments. The first argument shall be the address of the node being visited. The structure pointed to by this argument is unspecified and shall not be modified by the application, but it shall be possible to cast a pointer-to-node into a pointer-to-pointer-to-element to access the element stored in the node. The second argument shall be a value from an enumeration data type:

```
typedef enum { preorder, postorder, endorder, leaf } VISIT;
```

(defined in **<search.h>**), depending on whether this is the first, second, or third time that the node is visited (during a depth-first, left-to-right traversal of the tree), or whether the node is a leaf. The third argument shall be the level of the node in the tree, with the root being level 0.

If the calling function alters the pointer to the root, the result is undefined.

RETURN VALUE

If the node is found, both *tsearch*( ) and *tfind*( ) shall return a pointer to it. If not, *tfind*( ) shall return a null pointer, and *tsearch*( ) shall return a pointer to the inserted item.

A null pointer shall be returned by *tsearch*( ) if there is not enough space available to create a new node.

A null pointer shall be returned by *tdelete*( ), *tfind*( ), and *tsearch*( ) if *rootp* is a null pointer on entry.

The *tdelete*( ) function shall return a pointer to the parent of the deleted node, or a null pointer if the node is not found.

The *twalk*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

The following code reads in strings and stores structures containing a pointer to each string and a count of its length. It then walks the tree, printing out the stored strings and their lengths in alphabetical order.

```
#include <search.h>
#include <string.h>
#include <stdio.h>

#define STRSZ    10000
#define NODSZ    500

struct node {      /* Pointers to these are stored in the tree. */
    char    *string;
    int     length;
};

char   string_space[STRSZ];  /* Space to store strings. */
struct node nodes[NODSZ];    /* Nodes to store. */
void  *root = NULL;          /* This points to the root. */

int main(int argc, char *argv[])
{
    char   *strptr = string_space;
    struct node    *nodeptr = nodes;
    void   print_node(const void *, VISIT, int);
    int    i = 0, node_compare(const void *, const void *);

    while (gets(strptr) != NULL && i++ < NODSZ)  {
        /* Set node. */
        nodeptr->string = strptr;
        nodeptr->length = strlen(strptr);
        /* Put node into the tree. */
        (void) tsearch((void *)nodeptr, (void **)&root,
            node_compare);
```

```
            /* Adjust pointers, so we do not overwrite tree. */
            strptr += nodeptr->length + 1;
            nodeptr++;
        }
        twalk(root, print_node);
        return 0;
    }
    /*
     *  This routine compares two nodes, based on an
     *  alphabetical ordering of the string field.
     */
    int
    node_compare(const void *node1, const void *node2)
    {
        return strcmp(((const struct node *) node1)->string,
            ((const struct node *) node2)->string);
    }
    /*
     *  This routine prints out a node, the second time
     *  twalk encounters it or if it is a leaf.
     */
    void
    print_node(const void *ptr, VISIT order, int level)
    {
        const struct node *p = *(const struct node **) ptr;
        if (order == postorder || order == leaf)  {
            (void) printf("string = %s,  length = %d\n",
                p->string, p->length);
        }
    }
```

APPLICATION USAGE

The *root* argument to *twalk*( ) is one level of indirection less than the *rootp* arguments to *tdelete*( ) and *tsearch*( ).

There are two nomenclatures used to refer to the order in which tree nodes are visited. The *tsearch*( ) function uses **preorder**, **postorder**, and **endorder** to refer respectively to visiting a node before any of its children, after its left child and before its right, and after both its children. The alternative nomenclature uses **preorder**, **inorder**, and **postorder** to refer to the same visits, which could result in some confusion over the meaning of **postorder**.

The **restrict** keyword is added to the *tdelete*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

telldir — current location of a named directory stream

SYNOPSIS

XSI
```
#include <dirent.h>

long telldir(DIR *dirp);
```

DESCRIPTION

The *telldir*( ) function shall obtain the current location associated with the directory stream specified by *dirp*.

If the most recent operation on the directory stream was a *seekdir*( ), the directory position returned from the *telldir*( ) shall be the same as that supplied as a *loc* argument for *seekdir*( ).

RETURN VALUE

Upon successful completion, *telldir*( ) shall return the current location of the specified directory stream.

ERRORS

No errors are defined.

EXAMPLES

NAME

tempnam — create a name for a temporary file

SYNOPSIS

XSI

```
#include <stdio.h>

char *tempnam(const char *dir, const char *pfx);
```

DESCRIPTION

The *tempnam*( ) function shall generate a pathname that may be used for a temporary file.

The *tempnam*( ) function allows the user to control the choice of a directory. The *dir* argument points to the name of the directory in which the file is to be created. If *dir* is a null pointer or points to a string which is not a name for an appropriate directory, the path prefix defined as P_tmpdir in the **<stdio.h>** header shall be used. If that directory is not accessible, an implementation-defined directory may be used.

Many applications prefer their temporary files to have certain initial letter sequences in their names. The *pfx* argument should be used for this. This argument may be a null pointer or point to a string of up to five bytes to be used as the beginning of the filename.

Some implementations of *tempnam*( ) may use *tmpnam*( ) internally. On such implementations, if called more than {TMP_MAX} times in a single process, the behavior is implementation-defined.

RETURN VALUE

Upon successful completion, *tempnam*( ) shall allocate space for a string, put the generated pathname in that space, and return a pointer to it. The pointer shall be suitable for use in a subsequent call to *free*( ). Otherwise, it shall return a null pointer and set *errno* to indicate the error.

ERRORS

The *tempnam*( ) function shall fail if:

[ENOMEM] Insufficient storage space is available.

EXAMPLES

Generating a Pathname

The following example generates a pathname for a temporary file in directory **/tmp**, with the prefix *file*. After the filename has been created, the call to *free*( ) deallocates the space used to store the filename.

```
#include <stdio.h>
#include <stdlib.h>
...
char *directory = "/tmp";
char *fileprefix = "file";
char *file;

file = tempnam(directory, fileprefix);
free(file);
```

APPLICATION USAGE

This function only creates pathnames. It is the application's responsibility to create and remove the files. Between the time a pathname is created and the file is opened, it is possible for some other process to create a file with the same name. Applications may find *tmpfile*( ) more useful.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

tfind — search binary search tree

SYNOPSIS

XSI

```
#include <search.h>

void *tfind(const void *key, void *const *rootp,
    int (*compar)(const void *, const void *));
```

DESCRIPTION

Refer to *tdelete*( ).

NAME

tgamma, tgammaf, tgammal — compute gamma( ) function

SYNOPSIS

```
#include <math.h>

double tgamma(double x);
float tgammaf(float x);
long double tgammal(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall compute the *gamma*( ) function of *x*.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return *Gamma*(*x*).

If *x* is a negative integer, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

If the correct value would cause overflow, a range error shall occur and *tgamma*( ), *tgammaf*( ), and *tgammal*( ) shall return the value of the macro HUGE_VAL, HUGE_VALF, or HUGE_VALL, respectively.

MX If *x* is NaN, a NaN shall be returned.

If *x* is +Inf, *x* shall be returned.

If *x* is ±0, a pole error shall occur, and *tgamma*( ), *tgammaf*( ), and *tgammal*( ) shall return ±HUGE_VAL, ±HUGE_VALF, and ±HUGE_VALL, respectively.

If *x* is –Inf, a domain error shall occur, and either a NaN (if supported), or an implementation-defined value shall be returned.

ERRORS

These functions shall fail if:

MX Domain Error — The value of *x* is a negative integer, or *x* is –Inf.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

MX Pole Error — The value of *x* is zero.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.

Range Error — The value overflows.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised. |

EXAMPLES

None.

APPLICATION USAGE

For IEEE Std 754-1985 **double**, overflow happens when $0 < x < 1/\text{DBL\_MAX}$, and $171.7 < x$. Overflow also happens near negative integers.

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

This function is named *tgamma*( ) in order to avoid conflicts with the historical *gamma*( ) and *lgamma*( ) functions.

FUTURE DIRECTIONS

It is possible that the error response for a negative integer argument may be changed to a pole error and a return value of ±Inf.

CHANGE HISTORY

First released in Issue 6. Derived from the ISO/IEC 9899:1999 standard.

NAME

time — get time

SYNOPSIS

```
#include <time.h>

time_t time(time_t *tloc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

CX The *time*( ) function shall return the value of time in seconds since the Epoch.

The *tloc* argument points to an area where the return value is also stored. If *tloc* is a null pointer, no value is stored.

RETURN VALUE

Upon successful completion, *time*( ) shall return the value of time. Otherwise, (**time_t**)–1 shall be returned.

ERRORS

No errors are defined.

EXAMPLES

Getting the Current Time

The following example uses the *time*( ) function to calculate the time elapsed, in seconds, since January 1, 1970 0:00 UTC, *localtime*( ) to convert that value to a broken-down time, and *asctime*( ) to convert the broken-down time values into a printable string.

```
#include <stdio.h>
#include <time.h>

main()
{
time_t result;

    result = time(NULL);
    printf("%s%ld secs since the Epoch\n",
        asctime(localtime(&result)),
            (long)result);
    return(0);
}
```

This example writes the current time to *stdout* in a form like this:

```
Wed Jun 26 10:32:15 1996
835810335 secs since the Epoch
```

Timing an Event

The following example gets the current time, prints it out in the user's format, and prints the number of minutes to an event being timed.

```
#include <time.h>
#include <stdio.h>
...
time_t now;
int minutes_to_event;
...
time(&now);
minutes_to_event = ...;
printf("The time is ");
puts(asctime(localtime(&now)));
printf("There are %d minutes to the event.\n",
    minutes_to_event);
...
```

APPLICATION USAGE

None.

RATIONALE

The *time*( ) function returns a value in seconds (type **time_t**) while *times*( ) returns a set of values in clock ticks (type **clock_t**). Some historical implementations, such as 4.3 BSD, have mechanisms capable of returning more precise times (see below). A generalized timing scheme to unify these various timing mechanisms has been proposed but not adopted.

Implementations in which **time_t** is a 32-bit signed integer (many historical implementations) fail in the year 2038. IEEE Std 1003.1-200x does not address this problem. However, the use of the **time_t** type is mandated in order to ease the eventual fix.

The use of the **<time.h>**, header instead of **<sys/types.h>**, allows compatibility with the ISO C standard.

Many historical implementations (including Version 7) and the 1984 /usr/group standard use **long** instead of **time_t**. This volume of IEEE Std 1003.1-200x uses the latter type in order to agree with the ISO C standard.

4.3 BSD includes *time*( ) only as an alternate function to the more flexible *gettimeofday*( ) function.

FUTURE DIRECTIONS

In a future version of this volume of IEEE Std 1003.1-200x, **time_t** is likely to be required to be capable of representing times far in the future. Whether this will be mandated as a 64-bit type or a requirement that a specific date in the future be representable (for example, 10000 AD) is not yet determined. Systems purchased after the approval of this volume of IEEE Std 1003.1-200x should be evaluated to determine whether their lifetime will extend past 2038.

NAME

timer_create — create a per-process timer (**REALTIME**)

SYNOPSIS

TMR

```
#include <signal.h>
#include <time.h>

int timer_create(clockid_t clockid, struct sigevent *restrict evp,
    timer_t *restrict timerid);
```

DESCRIPTION

The *timer_create*( ) function shall create a per-process timer using the specified clock, *clock_id*, as the timing base. The *timer_create*( ) function shall return, in the location referenced by *timerid*, a timer ID of type **timer_t** used to identify the timer in timer requests. This timer ID shall be unique within the calling process until the timer is deleted. The particular clock, *clock_id*, is defined in **<time.h>**. The timer whose ID is returned shall be in a disarmed state upon return from *timer_create*( ).

The *evp* argument, if non-NULL, points to a **sigevent** structure. This structure, allocated by the application, defines the asynchronous notification to occur as specified in Section 2.4.1 (on page 478) when the timer expires. If the *evp* argument is NULL, the effect is as if the *evp* argument pointed to a **sigevent** structure with the *sigev_notify* member having the value SIGEV_SIGNAL, the *sigev_signo* having a default signal number, and the *sigev_value* member having the value of the timer ID.

Each implementation shall define a set of clocks that can be used as timing bases for per-process timers. All implementations shall support a *clock_id* of CLOCK_REALTIME. MON If the Monotonic Clock option is supported, implementations shall support a *clock_id* of CLOCK_MONOTONIC.

Per-process timers shall not be inherited by a child process across a *fork*( ) and shall be disarmed and deleted by an *exec*.

CPT If _POSIX_CPUTIME is defined, implementations shall support *clock_id* values representing the CPU-time clock of the calling process.

TCT If _POSIX_THREAD_CPUTIME is defined, implementations shall support *clock_id* values representing the CPU-time clock of the calling thread.

CPT|TCT It is implementation-defined whether a *timer_create*( ) function will succeed if the value defined by *clock_id* corresponds to the CPU-time clock of a process or thread different from the process or thread invoking the function.

RETURN VALUE

If the call succeeds, *timer_create*( ) shall return zero and update the location referenced by *timerid* to a **timer_t**, which can be passed to the per-process timer calls. If an error occurs, the function shall return a value of –1 and set *errno* to indicate the error. The value of *timerid* is undefined if an error occurs.

ERRORS

The *timer_create*( ) function shall fail if:

[EAGAIN]	The system lacks sufficient signal queuing resources to honor the request.
[EAGAIN]	The calling process has already created all of the timers it is allowed by this implementation.
[EINVAL]	The specified clock ID is not defined.

CPT|TCT [ENOTSUP] The implementation does not support the creation of a timer attached to the CPU-time clock that is specified by *clock_id* and associated with a process or thread different from the process or thread invoking *timer_create*( ).

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Periodic Timer Overrun and Resource Allocation

The specified timer facilities may deliver realtime signals (that is, queued signals) on implementations that support this option. Since realtime applications cannot afford to lose notifications of asynchronous events, like timer expirations or asynchronous I/O completions, it must be possible to ensure that sufficient resources exist to deliver the signal when the event occurs. In general, this is not a difficulty because there is a one-to-one correspondence between a request and a subsequent signal generation. If the request cannot allocate the signal delivery resources, it can fail the call with an [EAGAIN] error.

Periodic timers are a special case. A single request can generate an unspecified number of signals. This is not a problem if the requesting process can service the signals as fast as they are generated, thus making the signal delivery resources available for delivery of subsequent periodic timer expiration signals. But, in general, this cannot be assured—processing of periodic timer signals may ‘‘overrun’’; that is, subsequent periodic timer expirations may occur before the currently pending signal has been delivered.

Also, for signals, according to the POSIX.1-1990 standard, if subsequent occurrences of a pending signal are generated, it is implementation-defined whether a signal is delivered for each occurrence. This is not adequate for some realtime applications. So a mechanism is required to allow applications to detect how many timer expirations were delayed without requiring an indefinite amount of system resources to store the delayed expirations.

The specified facilities provide for an overrun count. The overrun count is defined as the number of extra timer expirations that occurred between the time a timer expiration signal is generated and the time the signal is delivered. The signal-catching function, if it is concerned with overruns, can retrieve this count on entry. With this method, a periodic timer only needs one ‘‘signal queuing resource’’ that can be allocated at the time of the *timer_create*( ) function call.

A function is defined to retrieve the overrun count so that an application need not allocate static storage to contain the count, and an implementation need not update this storage asynchronously on timer expirations. But, for some high-frequency periodic applications, the overhead of an additional system call on each timer expiration may be prohibitive. The functions, as defined, permit an implementation to maintain the overrun count in user space, associated with the *timerid*. The *timer_getoverrun*( ) function can then be implemented as a macro that uses the *timerid* argument (which may just be a pointer to a user space structure containing the counter) to locate the overrun count with no system call overhead. Other implementations, less concerned with this class of applications, can avoid the asynchronous update of user space by maintaining the count in a system structure at the cost of the extra system call to obtain it.

Timer Expiration Signal Parameters

The Realtime Signals Extension option supports an application-specific datum that is delivered to the extended signal handler. This value is explicitly specified by the application, along with the signal number to be delivered, in a **sigevent** structure. The type of the application-defined value can be either an integer constant or a pointer. This explicit specification of the value, as opposed to always sending the timer ID, was selected based on existing practice.

It is common practice for realtime applications (on non-POSIX systems or realtime extended POSIX systems) to use the parameters of event handlers as the case label of a switch statement or as a pointer to an application-defined data structure. Since *timer_id*s are dynamically allocated by the *timer_create*( ) function, they can be used for neither of these functions without additional application overhead in the signal handler; for example, to search an array of saved timer IDs to associate the ID with a constant or application data structure. |

FUTURE DIRECTIONS

None.

SEE ALSO

clock_getres( ), *timer_delete*( ), *timer_getoverrun*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<time.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *timer_create*( ) function is marked as part of the Timers option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Timers option.

CPU-time clocks are added for alignment with IEEE Std 1003.1d-1999.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by adding the requirement for the CLOCK_MONOTONIC clock under the Monotonic Clock option.

The **restrict** keyword is added to the *timer_create*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

timer_delete — delete a per-process timer (**REALTIME**)

SYNOPSIS

TMR
```
#include <time.h>

int timer_delete(timer_t timerid);
```

DESCRIPTION

The *timer_delete*( ) function deletes the specified timer, *timerid*, previously created by the *timer_create*( ) function. If the timer is armed when *timer_delete*( ) is called, the behavior shall be as if the timer is automatically disarmed before removal. The disposition of pending signals for the deleted timer is unspecified.

RETURN VALUE

If successful, the *timer_delete*( ) function shall return a value of zero. Otherwise, the function shall return a value of −1 and set *errno* to indicate the error.

ERRORS

The *timer_delete*( ) function shall fail if:

[EINVAL]	The timer ID specified by *timerid* is not a valid timer ID.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

timer_create( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<time.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *timer_delete*( ) function is marked as part of the Timers option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Timers option.

NAME

timer_getoverrun, timer_gettime, timer_settime — per-process timers (**REALTIME**)

SYNOPSIS

TMR

```
#include <time.h>

int timer_getoverrun(timer_t timerid);
int timer_gettime(timer_t timerid, struct itimerspec *value);
int timer_settime(timer_t timerid, int flags,
    const struct itimerspec *restrict value,
    struct itimerspec *restrict ovalue);
```

DESCRIPTION

The *timer_gettime*( ) function shall store the amount of time until the specified timer, *timerid*, expires and the reload value of the timer into the space pointed to by the *value* argument. The *it_value* member of this structure shall contain the amount of time before the timer expires, or zero if the timer is disarmed. This value is returned as the interval until timer expiration, even if the timer was armed with absolute time. The *it_interval* member of *value* shall contain the reload value last set by *timer_settime*( ).

The *timer_settime*( ) function shall set the time until the next expiration of the timer specified by *timerid* from the *it_value* member of the *value* argument and arms the timer if the *it_value* member of *value* is non-zero. If the specified timer was already armed when *timer_settime*( ) is called, this call shall reset the time until next expiration to the *value* specified. If the *it_value* member of *value* is zero, the timer shall be disarmed. The effect of disarming or resetting a timer with pending expiration notifications is unspecified.

If the flag TIMER_ABSTIME is not set in the argument *flags*, *timer_settime*( ) shall behave as if the time until next expiration is set to be equal to the interval specified by the *it_value* member of *value*. That is, the timer shall expire in *it_value* nanoseconds from when the call is made. If the flag TIMER_ABSTIME is set in the argument *flags*, *timer_settime*( ) shall behave as if the time until next expiration is set to be equal to the difference between the absolute time specified by the *it_value* member of *value* and the current value of the clock associated with *timerid*. That is, the timer shall expire when the clock reaches the value specified by the *it_value* member of *value*. If the specified time has already passed, the function shall succeed and the expiration notification shall be made.

The reload value of the timer shall be set to the value specified by the *it_interval* member of *value*. When a timer is armed with a non-zero *it_interval*, a periodic (or repetitive) timer is specified.

Time values that are between two consecutive non-negative integer multiples of the resolution of the specified timer shall be rounded up to the larger multiple of the resolution. Quantization error shall not cause the timer to expire earlier than the rounded time value.

If the argument *ovalue* is not NULL, the function *timer_settime*( ) shall store, in the location referenced by *ovalue*, a value representing the previous amount of time before the timer would have expired, or zero if the timer was disarmed, together with the previous timer reload value. Timers shall not expire before their scheduled time.

Only a single signal shall be queued to the process for a given timer at any point in time. When a timer for which a signal is still pending expires, no signal shall be queued, and a timer overrun shall occur. RTS When a timer expiration signal is delivered to or accepted by a process, if the implementation supports the Realtime Signals Extension, the *timer_getoverrun*( ) function shall return the timer expiration overrun count for the specified timer. The overrun count returned contains the number of extra timer expirations that occurred between the time the signal was generated (queued) and when it was delivered or accepted, up to but not including an implementation-defined maximum of {DELAYTIMER_MAX}. If the number of such extra expirations is greater than or equal to {DELAYTIMER_MAX}, then the overrun count shall be set to {DELAYTIMER_MAX}. The value returned by *timer_getoverrun*( ) shall apply to the most recent expiration signal delivery or acceptance for the timer. If no expiration signal has been delivered for the timer, or if the Realtime Signals Extension is not supported, the return value of *timer_getoverrun*( ) is unspecified.

RETURN VALUE

If the *timer_getoverrun*( ) function succeeds, it shall return the timer expiration overrun count as explained above.

If the *timer_gettime*( ) or *timer_settime*( ) functions succeed, a value of 0 shall be returned.

If an error occurs for any of these functions, the value −1 shall be returned, and *errno* set to indicate the error.

ERRORS

The *timer_getoverrun*( ), *timer_gettime*( ), and *timer_settime*( ) functions shall if:

[EINVAL] The *timerid* argument does not correspond to an ID returned by *timer_create*( ) but not yet deleted by *timer_delete*( ).

The *timer_settime*( ) function shall fail if:

[EINVAL] A *value* structure specified a nanosecond value less than zero or greater than or equal to 1,000 million, and the *it_value* member of that structure did not specify zero seconds and nanoseconds.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Practical clocks tick at a finite rate, with rates of 100 Hertz and 1,000 Hertz being common. The inverse of this tick rate is the clock resolution, also called the clock granularity, which in either case is expressed as a time duration, being 10 milliseconds and 1 millisecond respectively for these common rates. The granularity of practical clocks implies that if one reads a given clock twice in rapid succession, one may get the same time value twice; and that timers must wait for the next clock tick after the theoretical expiration time, to ensure that a timer never returns too soon. Note also that the granularity of the clock may be significantly coarser than the resolution of the data format used to set and get time and interval values. Also note that some implementations may choose to adjust time and/or interval values to exactly match the ticks of the underlying clock.

This volume of IEEE Std 1003.1-200x defines functions that allow an application to determine the implementation-supported resolution for the clocks and requires an implementation to document the resolution supported for timers and *nanosleep*( ) if they differ from the supported clock resolution. This is more of a procurement issue than a runtime application issue.

FUTURE DIRECTIONS

None.

SEE ALSO

clock_getres( ), *timer_create*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<time.h>**

CHANGE HISTORY

First released in Issue 5. Included for alignment with the POSIX Realtime Extension.

Issue 6

The *timer_getoverrun*( ), *timer_gettime*( ), and *timer_settime*( ) functions are marked as part of the Timers option.

The [ENOSYS] error condition has been removed as stubs need not be provided if an implementation does not support the Timers option.

The [EINVAL] error condition is updated to include the following: ‘‘and the *it_value* member of that structure did not specify zero seconds and nanoseconds.’’ This change is for IEEE PASC Interpretation 1003.1 #89.

The DESCRIPTION for *timer_getoverrun*( ) is updated to clarify that ‘‘If no expiration signal has been delivered for the timer, or if the Realtime Signals Extension is not supported, the return value of *timer_getoverrun*( ) is unspecified’’.

The **restrict** keyword is added to the *timer_settime*( ) prototype for alignment with the ISO / IEC 9899: 1999 standard.

NAME

times — get process and waited-for child process times

SYNOPSIS

```
#include <sys/times.h>

clock_t times(struct tms *buffer);
```

DESCRIPTION

The *times*( ) function shall fill the **tms** structure pointed to by *buffer* with time-accounting information. The **tms** structure is defined in **<sys/times.h>**.

All times are measured in terms of the number of clock ticks used.

The times of a terminated child process shall be included in the *tms_cutime* and *tms_cstime* elements of the parent when *wait*( ) or *waitpid*( ) returns the process ID of this terminated child. If a child process has not waited for its children, their times shall not be included in its times.

- The *tms_utime* structure member is the CPU time charged for the execution of user instructions of the calling process.
- The *tms_stime* structure member is the CPU time charged for execution by the system on behalf of the calling process.
- The *tms_cutime* structure member is the sum of the *tms_utime* and *tms_cutime* times of the child processes.
- The *tms_cstime* structure member is the sum of the *tms_stime* and *tms_cstime* times of the child processes.

RETURN VALUE

Upon successful completion, *times*( ) shall return the elapsed real time, in clock ticks, since an arbitrary point in the past (for example, system start-up time). This point does not change from one invocation of *times*( ) within the process to another. The return value may overflow the possible range of type **clock_t**. If *times*( ) fails, (**clock_t**)−1 shall be returned and *errno* set to indicate the error.

ERRORS

No errors are defined.

EXAMPLES

Timing a Database Lookup

The following example defines two functions, *start_clock*( ) and *end_clock*( ), that are used to time a lookup. It also defines variables of type **clock_t** and **tms** to measure the duration of transactions. The *start_clock*( ) function saves the beginning times given by the *times*( ) function. The *end_clock*( ) function gets the ending times and prints the difference between the two times.

```
#include <sys/times.h>
#include <stdio.h>
...
void start_clock(void);
void end_clock(char *msg);
...
static clock_t st_time;
static clock_t en_time;
static struct tms st_cpu;
static struct tms en_cpu;
```

```
...
void
start_clock()
{
    st_time = times(&st_cpu);
}

void
end_clock(char *msg)
{
    en_time = times(&en_cpu);

    printf(msg);
    printf("Real Time: %ld, User Time %ld, System Time %ld\n",
        en_time - st_time,
        en_cpu.tms_utime - st_cpu.tms_utime,
        en_cpu.tms_stime - st_cpu.tms_stime);
}
```

APPLICATION USAGE

Applications should use *sysconf*(_SC_CLK_TCK) to determine the number of clock ticks per second as it may vary from system to system.

RATIONALE

The accuracy of the times reported is intentionally left unspecified to allow implementations flexibility in design, from uniprocessor to multi-processor networks.

The inclusion of times of child processes is recursive, so that a parent process may collect the total times of all of its descendants. But the times of a child are only added to those of its parent when its parent successfully waits on the child. Thus, it is not guaranteed that a parent process can always see the total times of all its descendants; see also the discussion of the term *realtime* in *alarm*( ).

If the type **clock_t** is defined to be a signed 32-bit integer, it overflows in somewhat more than a year if there are 60 clock ticks per second, or less than a year if there are 100. There are individual systems that run continuously for longer than that. This volume of IEEE Std 1003.1-200x permits an implementation to make the reference point for the returned value be the start-up time of the process, rather than system start-up time.

The term *charge* in this context has nothing to do with billing for services. The operating system accounts for time used in this way. That information must be correct, regardless of how that information is used.

FUTURE DIRECTIONS

None.

SEE ALSO

exec, *fork*( ), *sysconf*( ), *time*( ), *wait*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/times.h>**

CHANGE HISTORY

NAME

timezone — difference from UTC and local standard time

SYNOPSIS

XSI

```
#include <time.h>

extern long timezone;
```

DESCRIPTION

Refer to *tzset*( ).

NAME

tmpfile — create a temporary file

SYNOPSIS

```
#include <stdio.h>

FILE *tmpfile(void);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *tmpfile*( ) function shall create a temporary file and open a corresponding stream. The file shall be automatically deleted when all references to the file are closed. The file is opened as in *fopen*( ) for update (*w*+).

CX In some implementations, a permanent file may be left behind if the process calling *tmpfile*( ) is killed while it is processing a call to *tmpfile*( ).

An error message may be written to standard error if the stream cannot be opened.

RETURN VALUE

Upon successful completion, *tmpfile*( ) shall return a pointer to the stream of the file that is created. Otherwise, it shall return a null pointer CX and set *errno* to indicate the error.

ERRORS

The *tmpfile*( ) function shall fail if:

CX	[EINTR]	A signal was caught during *tmpfile*( ).
CX	[EMFILE]	{OPEN_MAX} file descriptors are currently open in the calling process.
CX	[ENFILE]	The maximum allowable number of files is currently open in the system.
CX	[ENOSPC]	The directory or file system which would contain the new file cannot be expanded.
CX	[EOVERFLOW]	The file is a regular file and the size of the file cannot be represented correctly in an object of type **off_t**.

The *tmpfile*( ) function may fail if:

CX	[EMFILE]	{FOPEN_MAX} streams are currently open in the calling process.
CX	[ENOMEM]	Insufficient storage space is available.

EXAMPLES

Creating a Temporary File

The following example creates a temporary file for update, and returns a pointer to a stream for the created file in the *fp* variable.

```
#include <stdio.h>
...
FILE *fp;

fp = tmpfile ();
```

APPLICATION USAGE

It should be possible to open at least {TMP_MAX} temporary files during the lifetime of the program (this limit may be shared with *tmpnam*( )) and there should be no limit on the number simultaneously open other than this limit and any limit on the number of open files ({FOPEN_MAX}).

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

fopen( ), *tmpnam*( ), *unlink*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<stdio.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

Large File Summit extensions are added.

The last two paragraphs of the DESCRIPTION were included as APPLICATION USAGE notes in previous issues.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the ERRORS section, the [EOVERFLOW] condition is added. This change is to support large files.
- The [EMFILE] optional error condition is added.

The APPLICATION USAGE section is added for alignment with the ISO/IEC 9899:1999 standard.

NAME

tmpnam — create a name for a temporary file

SYNOPSIS

```
#include <stdio.h>

char *tmpnam(char *s);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *tmpnam*( ) function shall generate a string that is a valid filename and that is not the same as the name of an existing file. The function is potentially capable of generating {TMP_MAX} different strings, but any or all of them may already be in use by existing files and thus not be suitable return values.

The *tmpnam*( ) function generates a different string each time it is called from the same process, up to {TMP_MAX} times. If it is called more than {TMP_MAX} times, the behavior is implementation-defined.

The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *tmpnam*( ).

CX If the application uses any of the functions guaranteed to be available if either _POSIX_THREAD_SAFE_FUNCTIONS or _POSIX_THREADS is defined, the application shall ensure that the *tmpnam*( ) function is called with a non-NULL parameter.

RETURN VALUE

Upon successful completion, *tmpnam*( ) shall return a pointer to a string. If no suitable string can be generated, the *tmpnam*( ) function shall return a null pointer.

If the argument *s* is a null pointer, *tmpnam*( ) shall leave its result in an internal static object and return a pointer to that object. Subsequent calls to *tmpnam*( ) may modify the same object. If the argument *s* is not a null pointer, it is presumed to point to an array of at least L_tmpnam **char**s; *tmpnam*( ) shall write its result in that array and shall return the argument as its value.

ERRORS

No errors are defined.

EXAMPLES

Generating a Filename

The following example generates a unique filename and stores it in the array pointed to by *ptr*.

```
#include <stdio.h>
...
char filename[L_tmpnam+1];
char *ptr;

ptr = tmpnam(filename);
```

APPLICATION USAGE

This function only creates filenames. It is the application's responsibility to create and remove the files.

Between the time a pathname is created and the file is opened, it is possible for some other process to create a file with the same name. Applications may find *tmpfile*( ) more useful. |

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

tolower — transliterate uppercase characters to lowercase

SYNOPSIS

```
#include <ctype.h>

int tolower(int c);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *tolower*( ) function has as a domain a type **int**, the value of which is representable as an **unsigned char** or the value of EOF. If the argument has any other value, the behavior is undefined. If the argument of *tolower*( ) represents an uppercase letter, and there exists a corresponding lowercase letter CX (as defined by character type information in the program locale category *LC_CTYPE*), the result shall be the corresponding lowercase letter. All other arguments in the domain are returned unchanged.

RETURN VALUE

Upon successful completion, *tolower*( ) shall return the lowercase letter corresponding to the argument passed; otherwise, it shall return the argument unchanged.

ERRORS

No errors are defined.

NAME

towctrans — wide-character transliteration

SYNOPSIS

```
#include <wctype.h>

wint_t towctrans(wint_t wc, wctrans_t desc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *towctrans*( ) function shall transliterate the wide-character code *wc* using the mapping described by *desc*. The current setting of the *LC_CTYPE* category should be the same as during the call to *wctrans*( ) that returned the value *desc*. CX If the value of *desc* is invalid (that is, not obtained by a call to *wctrans*( ) or *desc* is invalidated by a subsequent call to *setlocale*( ) that has affected category *LC_CTYPE*), the result is unspecified.

An application wishing to check for error situations should set *errno* to 0 before calling *towctrans*( ). If *errno* is non-zero on return, an error has occurred.

RETURN VALUE

If successful, the *towctrans*( ) function shall return the mapped value of *wc* using the mapping described by *desc*. Otherwise, it shall return *wc* unchanged.

ERRORS

The *towctrans*( ) function may fail if:

CX [EINVAL] *desc* contains an invalid transliteration descriptor.

EXAMPLES

None.

APPLICATION USAGE

The strings `"tolower"` and `"toupper"` are reserved for the standard mapping names. In the table below, the functions in the left column are equivalent to the functions in the right column.

```
towlower(wc)    towctrans(wc, wctrans("tolower"))
towupper(wc)    towctrans(wc, wctrans("toupper"))
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

Issue 6

Extensions beyond the ISO C standard are now marked.

NAME

towlower — transliterate uppercase wide-character code to lowercase

SYNOPSIS

```
#include <wctype.h>

wint_t towlower(wint_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *towlower*( ) function has as a domain a type **wint_t**, the value of which the application shall ensure is a character representable as a **wchar_t**, and a wide-character code corresponding to a valid character in the current locale or the value of WEOF. If the argument has any other value, the behavior is undefined. If the argument of *towlower*( ) represents an uppercase wide-character code, and there exists a corresponding lowercase wide-character code (as defined by character type information in the program locale category *LC_CTYPE*), the result shall be the corresponding lowercase wide-character code. All other arguments in the domain are returned unchanged.

RETURN VALUE

Upon successful completion, *towlower*( ) shall return the lowercase letter corresponding to the argument passed; otherwise, it shall return the argument unchanged.

ERRORS

No errors are defined.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The following change has been made in this issue for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E):

- The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

towupper — transliterate lowercase wide-character code to uppercase

SYNOPSIS

```
#include <wctype.h>

wint_t towupper(wint_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *towupper*( ) function has as a domain a type **wint_t**, the value of which the application shall ensure is a character representable as a **wchar_t**, and a wide-character code corresponding to a valid character in the current locale or the value of WEOF. If the argument has any other value, the behavior is undefined. If the argument of *towupper*( ) represents a lowercase wide-character code, and there exists a corresponding uppercase wide-character code (as defined by character type information in the program locale category *LC_CTYPE*), the result shall be the corresponding uppercase wide-character code. All other arguments in the domain are returned unchanged.

RETURN VALUE

Upon successful completion, *towupper*( ) shall return the uppercase letter corresponding to the argument passed. Otherwise, it shall return the argument unchanged.

- The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

trunc, truncf, truncl — round to truncated integer value

SYNOPSIS

```
#include <math.h>

double trunc(double x);
float truncf(float x);
long double truncl(long double x);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall round their argument to the integer value, in floating format, nearest to but no larger in magnitude than the argument.

RETURN VALUE

Upon successful completion, these functions shall return the truncated integer value.

MX If *x* is NaN, a NaN shall be returned.

If *x* is ±0, or ±Inf, *x* shall be returned.

ERRORS

No errors are defined.

EXAMPLES

NAME

truncate — truncate a file to a specified length

SYNOPSIS

XSI

```
#include <unistd.h>

int truncate(const char *path, off_t length);
```

DESCRIPTION

The *truncate*( ) function shall cause the regular file named by *path* to have a size which shall be equal to *length* bytes.

If the file previously was larger than *length*, the extra data is discarded. If the file was previously shorter than *length*, its size is increased, and the extended area appears as if it were zero-filled.

The application shall ensure that the process has write permission for the file.

If the request would cause the file size to exceed the soft file size limit for the process, the request shall fail and the implementation shall generate the SIGXFSZ signal for the process.

This function shall not modify the file offset for any open file descriptions associated with the file. Upon successful completion, if the file size is changed, this function shall mark for update the *st_ctime* and *st_mtime* fields of the file, and the S_ISUID and S_ISGID bits of the file mode may be cleared.

RETURN VALUE

Upon successful completion, *truncate*( ) shall return 0. Otherwise, –1 shall be returned, and *errno* set to indicate the error.

ERRORS

The *truncate*( ) function shall fail if:

[EINTR]	A signal was caught during execution.
[EINVAL]	The *length* argument was less than 0.
[EFBIG] or [EINVAL]	The *length* argument was greater than the maximum file size.
[EIO]	An I/O error occurred while reading from or writing to a file system.
[EACCES]	A component of the path prefix denies search permission, or write permission is denied on the file.
[EISDIR]	The named file is a directory.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of *path* does not name an existing file or *path* is an empty string.
[ENOTDIR]	A component of the path prefix of *path* is not a directory.
[EROFS]	The named file resides on a read-only file system.

The *truncate*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[ENAMETOOLONG]	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds {PATH_MAX}.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

open( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<unistd.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X / OPEN UNIX extension to BASE.

Large File Summit extensions are added.

Issue 6

This reference page is split out from the *ftruncate*( ) reference page.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.

NAME

truncf, truncl — round to truncated integer value

SYNOPSIS

```
#include <math.h>

float truncf(float x);
long double truncl(long double x);
```

DESCRIPTION

Refer to *trunc*( ).

NAME

tsearch — search a binary search tree

SYNOPSIS

XSI

```
#include <search.h>

void *tsearch(const void *key, void **rootp,
    int (*compar)(const void *, const void *));
```

DESCRIPTION

Refer to *tdelete*( ).

NAME

ttyname, ttyname_r — find pathname of a terminal

SYNOPSIS

```
#include <unistd.h>

char *ttyname(int fildes);
TSF int ttyname_r(int fildes, char *name, size_t namesize);
```

DESCRIPTION

The *ttyname*( ) function shall return a pointer to a string containing a null-terminated pathname of the terminal associated with file descriptor *fildes*. The return value may point to static data whose content is overwritten by each call.

The *ttyname*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

TSF The *ttyname_r*( ) function shall store the null-terminated pathname of the terminal associated with the file descriptor *fildes* in the character array referenced by *name*. The array is *namesize* characters long and should have space for the name and the terminating null character. The maximum length of the terminal name shall be {TTY_NAME_MAX}.

RETURN VALUE

Upon successful completion, *ttyname*( ) shall return a pointer to a string. Otherwise, a null pointer shall be returned and *errno* set to indicate the error.

TSF If successful, the *ttyname_r*( ) function shall return zero. Otherwise, an error number shall be returned to indicate the error.

ERRORS

The *ttyname*( ) function may fail if:

[EBADF]	The *fildes* argument is not a valid file descriptor.
[ENOTTY]	The *fildes* argument does not refer to a terminal.

The *ttyname_r*( ) function may fail if:

TSF	[EBADF]	The *fildes* argument is not a valid file descriptor.
TSF	[ENOTTY]	The *fildes* argument does not refer to a terminal.
TSF	[ERANGE]	The value of *namesize* is smaller than the length of the string to be returned including the terminating null character.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The term *terminal* is used instead of the historical term *terminal device* in order to avoid a reference to an undefined term.

The thread-safe version places the terminal name in a user-supplied buffer and returns a non-zero value if it fails. The non-thread-safe version may return the name in a static data area that may be overwritten by each call.

FUTURE DIRECTIONS

None.

SEE ALSO

The Base Definitions volume of IEEE Std 1003.1-200x, **<unistd.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The *ttyname_r*( ) function is included for alignment with the POSIX Threads Extension.

A note indicating that the *ttyname*( ) function need not be reentrant is added to the DESCRIPTION.

Issue 6

The *ttyname_r*( ) function is marked as part of the Thread-Safe Functions option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The statement that *errno* is set on error is added.
- The [EBADF] and [ENOTTY] optional error conditions are added.

NAME

twalk — traverse a binary search tree

SYNOPSIS

XSI

```
#include <search.h>

void twalk(const void *root,
    void (*action)(const void *, VISIT, int ));
```

DESCRIPTION

Refer to *tdelete*( ).

NAME

tzname — timezone strings

SYNOPSIS

CX
```
#include <time.h>

extern char *tzname[2];
```

DESCRIPTION

Refer to *tzset*( ).

NAME

daylight, timezone, tzname, tzset — set timezone conversion information

SYNOPSIS

```
#include <time.h>
```

XSI

```
extern int daylight;
extern long timezone;
```

CX

```
extern char *tzname[2];
void tzset(void);
```

DESCRIPTION

The *tzset*( ) function shall use the value of the environment variable *TZ* to set time conversion information used by *ctime*( ), *localtime*( ), *mktime*( ), and *strftime*( ). If *TZ* is absent from the environment, implementation-defined default timezone information shall be used.

The *tzset*( ) function shall set the external variable *tzname* as follows:

```
tzname[0] = "std";
tzname[1] = "dst";
```

where *std* and *dst* are as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

XSI The *tzset*( ) function also shall set the external variable *daylight* to 0 if Daylight Savings Time conversions should never be applied for the timezone in use; otherwise, non-zero. The external variable *timezone* shall be set to the difference, in seconds, between Coordinated Universal Time (UTC) and local standard time.

RETURN VALUE

The *tzset*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

Example TZ variables and their timezone differences are given in the table below:

TZ	*timezone*
EST5EDT	5*60*60
GMT0	0*60*60
JST-9	–9*60*60
MET-1MEST	–1*60*60
MST7MDT	7*60*60
PST8PDT	8*60*60

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

Issue 6

The example is corrected.

NAME

ualarm — set the interval timer

SYNOPSIS

OB XSI

```
#include <unistd.h>

useconds_t ualarm(useconds_t useconds, useconds_t interval);
```

DESCRIPTION

The *ualarm*( ) function shall cause the SIGALRM signal to be generated for the calling process after the number of realtime microseconds specified by the *useconds* argument has elapsed. When the *interval* argument is non-zero, repeated timeout notification occurs with a period in microseconds specified by the *interval* argument. If the notification signal, SIGALRM, is not caught or ignored, the calling process is terminated.

Implementations may place limitations on the granularity of timer values. For each interval timer, if the requested timer value requires a finer granularity than the implementation supports, the actual timer value shall be rounded up to the next supported value.

Interactions between *ualarm*( ) and any of the following are unspecified:

alarm( )
nanosleep( )
setitimer( )
timer_create( )
timer_delete( )
timer_getoverrun( )
timer_gettime( )
timer_settime( )
sleep( )

RETURN VALUE

The *ualarm*( ) function shall return the number of microseconds remaining from the previous *ualarm*( ) call. If no timeouts are pending or if *ualarm*( ) has not previously been called, *ualarm*( ) shall return 0.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

Applications are recommended to use *nanosleep*( ) if the Timers option is supported, or *setitimer*( ), *timer_create*( ), *timer_delete*( ), *timer_getoverrun*( ), *timer_gettime*( ), or *timer_settime*( ) instead of this function.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

alarm( ), *nanosleep*( ), *setitimer*( ), *sleep*( ), *timer_create*( ), *timer_delete*( ), *timer_getoverrun*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<unistd.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

This function is marked obsolescent.

NAME

ulimit — get and set process limits

SYNOPSIS

XSI
```
#include <ulimit.h>

long ulimit(int cmd, ...);
```

DESCRIPTION

The *ulimit*( ) function shall control process limits. The process limits that can be controlled by this function include the maximum size of a single file that can be written (this is equivalent to using *setrlimit*( ) with RLIMIT_FSIZE). The *cmd* values, defined in **<ulimit.h>** include: |

UL_GETFSIZE	Return the file size limit (RLIMIT_FSIZE) of the process. The limit shall be in units of 512-byte blocks and shall be inherited by child processes. Files of any size can be read. The return value shall be the integer part of the soft file size limit divided by 512. If the result cannot be represented as a **long**, the result is unspecified. |
UL_SETFSIZE	Set the file size limit for output operations of the process to the value of the second argument, taken as a **long**, multiplied by 512. If the result would overflow an **rlim_t**, the actual value set is unspecified. Any process may decrease its own limit, but only a process with appropriate privileges may increase the limit. The return value shall be the integer part of the new file size limit divided by 512.

The *ulimit*( ) function shall not change the setting of *errno* if successful.

As all return values are permissible in a successful situation, an application wishing to check for error situations should set *errno* to 0, then call *ulimit*( ), and, if it returns –1, check to see if *errno* is non-zero.

RETURN VALUE

Upon successful completion, *ulimit*( ) shall return the value of the requested limit. Otherwise, –1 shall be returned and *errno* set to indicate the error.

ERRORS

The *ulimit*( ) function shall fail and the limit shall be unchanged if:

[EINVAL]	The *cmd* argument is not valid.
[EPERM]	A process not having appropriate privileges attempts to increase its file size limit.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

getrlimit( ), *setrlimit*( ), *write*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<ulimit.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

In the description of UL_SETFSIZE, the text is corrected to refer to **rlim_t** rather than the spurious **rlimit_t**.

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

NAME

umask — set and get file mode creation mask

SYNOPSIS

```
#include <sys/stat.h>

mode_t umask(mode_t cmask);
```

DESCRIPTION

The *umask*( ) function shall set the process' file mode creation mask to *cmask* and return the previous value of the mask. Only the file permission bits of *cmask* (see **<sys/stat.h>**) are used; the meaning of the other bits is implementation-defined.

The process' file mode creation mask is used during *open*( ), *creat*( ), *mkdir*( ), and *mkfifo*( ) to turn off permission bits in the *mode* argument supplied. Bit positions that are set in *cmask* are cleared in the mode of the created file.

RETURN VALUE

The file permission bits in the value returned by *umask*( ) shall be the previous value of the file mode creation mask. The state of any other bits in that value is unspecified, except that a subsequent call to *umask*( ) with the returned value as *cmask* shall leave the state of the mask the same as its state before the first call, including any unspecified use of those bits.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Unsigned argument and return types for *umask*( ) were proposed. The return type and the argument were both changed to **mode_t**.

Historical implementations have made use of additional bits in *cmask* for their implementation-defined purposes. The addition of the text that the meaning of other bits of the field is implementation-defined permits these implementations to conform to this volume of IEEE Std 1003.1-200x.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed. |

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

NAME

uname — get name of current system

SYNOPSIS

```
#include <sys/utsname.h>

int uname(struct utsname *name);
```

DESCRIPTION

The *uname*( ) function shall store information identifying the current system in the structure pointed to by *name*.

The *uname*( ) function uses the **utsname** structure defined in **<sys/utsname.h>**.

The *uname*( ) function shall return a string naming the current system in the character array *sysname*. Similarly, *nodename* shall contain the name of this node within an implementation-defined communications network. The arrays *release* and *version* shall further identify the operating system. The array *machine* shall contain a name that identifies the hardware that the system is running on.

The format of each member is implementation-defined.

RETURN VALUE

Upon successful completion, a non-negative value shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The inclusion of the *nodename* member in this structure does not imply that it is sufficient information for interfacing to communications networks.

RATIONALE

The values of the structure members are not constrained to have any relation to the version of this volume of IEEE Std 1003.1-200x implemented in the operating system. An application should instead depend on _POSIX_VERSION and related constants defined in **<unistd.h>**.

This volume of IEEE Std 1003.1-200x does not define the sizes of the members of the structure and permits them to be of different sizes, although most implementations define them all to be the same size: eight bytes plus one byte for the string terminator. That size for *nodename* is not enough for use with many networks.

The *uname*( ) function originated in System III, System V, and related implementations, and it does not exist in Version 7 or 4.3 BSD. The values it returns are set at system compile time in those historical implementations.

4.3 BSD has *gethostname*( ) and *gethostid*( ), which return a symbolic name and a numeric value, respectively. There are related *sethostname*( ) and *sethostid*( ) functions that are used to set the values the other two functions return. The former functions are included in this specification, the latter are not.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

NAME

ungetc — push byte back into input stream

SYNOPSIS

```
#include <stdio.h>

int ungetc(int c, FILE *stream);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *ungetc*( ) function shall push the byte specified by *c* (converted to an **unsigned char**) back onto the input stream pointed to by *stream*. The pushed-back bytes shall be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call (with the stream pointed to by *stream*) to a file-positioning function (*fseek*( ), *fsetpos*( ), or *rewind*( )) shall discard any pushed-back bytes for the stream. The external storage corresponding to the stream shall be unchanged.

One byte of push-back shall be provided. If *ungetc*( ) is called too many times on the same stream without an intervening read or file-positioning operation on that stream, the operation may fail.

If the value of *c* equals that of the macro EOF, the operation shall fail and the input stream shall be left unchanged.

A successful call to *ungetc*( ) shall clear the end-of-file indicator for the stream. The value of the file-position indicator for the stream after reading or discarding all pushed-back bytes shall be the same as it was before the bytes were pushed back. The file-position indicator is decremented by each successful call to *ungetc*( ); if its value was 0 before a call, its value is unspecified after the call.

RETURN VALUE

Upon successful completion, *ungetc*( ) shall return the byte pushed back after conversion. Otherwise, it shall return EOF.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

NAME

ungetwc — push wide-character code back into input stream

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

wint_t ungetwc(wint_t wc, FILE *stream);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *ungetwc*( ) function shall push the character corresponding to the wide-character code specified by *wc* back onto the input stream pointed to by *stream*. The pushed-back characters shall be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call (with the stream pointed to by *stream*) to a file-positioning function (*fseek*( ), *fsetpos*( ), or *rewind*( )) discards any pushed-back characters for the stream. The external storage corresponding to the stream is unchanged.

At least one character of push-back shall be provided. If *ungetwc*( ) is called too many times on the same stream without an intervening read or file-positioning operation on that stream, the operation may fail. |

If the value of *wc* equals that of the macro WEOF, the operation shall fail and the input stream shall be left unchanged. |

A successful call to *ungetwc*( ) shall clear the end-of-file indicator for the stream. The value of the file-position indicator for the stream after reading or discarding all pushed-back characters shall be the same as it was before the characters were pushed back. The file-position indicator is decremented (by one or more) by each successful call to *ungetwc*( ); if its value was 0 before a call, its value is unspecified after the call. |

RETURN VALUE

Upon successful completion, *ungetwc*( ) shall return the wide-character code corresponding to the pushed-back character. Otherwise, it shall return WEOF.

ERRORS

The *ungetwc*( ) function may fail if:

CX [EILSEQ] An invalid character sequence is detected, or a wide-character code does not correspond to a valid character. |

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

The Optional Header (OH) marking is removed from **<stdio.h>**.

Issue 6

The [EILSEQ] optional error condition is marked CX.

NAME

unlink — remove a directory entry

SYNOPSIS

```
#include <unistd.h>

int unlink(const char *path);
```

DESCRIPTION

The *unlink*( ) function shall remove a link to a file. If *path* names a symbolic link, *unlink*( ) shall remove the symbolic link named by *path* and shall not affect any file or directory named by the contents of the symbolic link. Otherwise, *unlink*( ) shall remove the link named by the pathname pointed to by *path* and shall decrement the link count of the file referenced by the link.

When the file's link count becomes 0 and no process has the file open, the space occupied by the file shall be freed and the file shall no longer be accessible. If one or more processes have the file open when the last link is removed, the link shall be removed before *unlink*( ) returns, but the removal of the file contents shall be postponed until all references to the file are closed.

The *path* argument shall not name a directory unless the process has appropriate privileges and the implementation supports using *unlink*( ) on directories.

Upon successful completion, *unlink*( ) shall mark for update the *st_ctime* and *st_mtime* fields of the parent directory. Also, if the file's link count is not 0, the *st_ctime* field of the file shall be marked for update.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error. If −1 is returned, the named file shall not be changed.

ERRORS

The *unlink*( ) function shall fail and shall not unlink the file if:

[EACCES]	Search permission is denied for a component of the path prefix, or write permission is denied on the directory containing the directory entry to be removed.
[EBUSY]	The file named by the *path* argument cannot be unlinked because it is being used by the system or another process and the implementation considers this an error.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of *path* does not name an existing file or *path* is an empty string.
[ENOTDIR]	A component of the path prefix is not a directory.
[EPERM]	The file named by *path* is a directory, and either the calling process does not have appropriate privileges, or the implementation prohibits using *unlink*( ) on directories.
XSI [EPERM] or [EACCES]	The S_ISVTX flag is set on the directory containing the file referred to by the *path* argument and the caller is not the file owner, nor is the caller the directory owner, nor does the caller have appropriate privileges.

[EROFS]	The directory entry to be unlinked is part of a read-only file system.

The *unlink*( ) function may fail and not unlink the file if:

XSI [EBUSY]	The file named by *path* is a named STREAM.
[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[ENAMETOOLONG]	As a result of encountering a symbolic link in resolution of the *path* argument, the length of the substituted pathname string exceeded {PATH_MAX}.
[ETXTBSY]	The entry to be unlinked is the last directory entry to a pure procedure (shared text) file that is being executed.

EXAMPLES

Removing a Link to a File

The following example shows how to remove a link to a file named **/home/cnd/mod1** by removing the entry named **/modules/pass1**.

```
#include <unistd.h>

char *path = "/modules/pass1";
int   status;
...
status = unlink(path);
```

Checking for an Error

The following example fragment creates a temporary password lock file named **LOCKFILE**, which is defined as **/etc/ptmp**, and gets a file descriptor for it. If the file cannot be opened for writing, *unlink*( ) is used to remove the link between the file descriptor and **LOCKFILE**.

```
#include <sys/types.h>
#include <stdio.h>
#include <fcntl.h>
#include <errno.h>
#include <unistd.h>
#include <sys/stat.h>

#define LOCKFILE "/etc/ptmp"

int pfd;  /* Integer for file descriptor returned by open call. */
FILE *fpfd;  /* File pointer for use in putpwent(). */
...
/* Open password Lock file. If it exists, this is an error. */
if ((pfd = open(LOCKFILE, O_WRONLY| O_CREAT | O_EXCL, S_IRUSR
    | S_IWUSR | S_IRGRP | S_IROTH)) == -1)  {
    fprintf(stderr, "Cannot open /etc/ptmp. Try again later.\n");
    exit(1);
}

/* Lock file created, proceed with fdopen of lock file so that
   putpwent() can be used.
  */
if ((fpfd = fdopen(pfd, "w")) == NULL) {
```

```
    close(pfd);
    unlink(LOCKFILE);
    exit(1);
}
```

Replacing Files

The following example fragment uses *unlink*( ) to discard links to files, so that they can be replaced with new versions of the files. The first call remove the link to **LOCKFILE** if an error occurs. Successive calls remove the links to **SAVEFILE** and **PASSWDFILE** so that new links can be created, then removes the link to **LOCKFILE** when it is no longer needed.

```
#include <sys/types.h>
#include <stdio.h>
#include <fcntl.h>
#include <errno.h>
#include <unistd.h>
#include <sys/stat.h>

#define LOCKFILE "/etc/ptmp"
#define PASSWDFILE "/etc/passwd"
#define SAVEFILE "/etc/opasswd"
...
/* If no change was made, assume error and leave passwd unchanged. */
if (!valid_change) {
    fprintf(stderr, "Could not change password for user %s\n", user);
    unlink(LOCKFILE);
    exit(1);
}

/* Change permissions on new password file. */
chmod(LOCKFILE, S_IRUSR | S_IRGRP | S_IROTH);

/* Remove saved password file. */
unlink(SAVEFILE);

/* Save current password file. */
link(PASSWDFILE, SAVEFILE);

/* Remove current password file. */
unlink(PASSWDFILE);

/* Save new password file as current password file. */
link(LOCKFILE,PASSWDFILE);

/* Remove lock file. */
unlink(LOCKFILE);

exit(0);
```

APPLICATION USAGE

Applications should use *rmdir*( ) to remove a directory.

RATIONALE

Unlinking a directory is restricted to the superuser in many historical implementations for reasons given in *link*( ) (see also *rename*( )).

The meaning of [EBUSY] in historical implementations is ‘‘mount point busy’’. Since this volume of IEEE Std 1003.1-200x does not cover the system administration concepts of mounting and unmounting, the description of the error was changed to ‘‘resource busy’’. (This meaning is used by some device drivers when a second process tries to open an exclusive use device.) The wording is also intended to allow implementations to refuse to remove a directory if it is the root or current working directory of any process.

FUTURE DIRECTIONS

None.

SEE ALSO

close( ), *link*( ), *remove*( ), *rmdir*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<unistd.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The [EBUSY] error is added to the ‘‘may fail’’ part of the ERRORS section.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the effect is specified if *path* specifies a symbolic link.
- The [ELOOP] mandatory error condition is added.
- A second [ENAMETOOLONG] is added as an optional error condition.
- The [ETXTBSY] optional error condition is added.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The [ELOOP] optional error condition is added.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

unlockpt — unlock a pseudo-terminal master/slave pair

SYNOPSIS

XSI
```
#include <stdlib.h>

int unlockpt(int fildes);
```

DESCRIPTION

The *unlockpt*( ) function shall unlock the slave pseudo-terminal device associated with the master to which *fildes* refers.

Conforming applications shall ensure that they call *unlockpt*( ) before opening the slave side of a pseudo-terminal device. |

RETURN VALUE

Upon successful completion, *unlockpt*( ) shall return 0. Otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *unlockpt*( ) function may fail if:

[EBADF]	The *fildes* argument is not a file descriptor open for writing.
[EINVAL]	The *fildes* argument is not associated with a master pseudo-terminal device.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

unsetenv — remove environment variable

SYNOPSIS

CX

```
#include <stdlib.h>

int unsetenv(const char *name);
```

DESCRIPTION

The *unsetenv*( ) function shall remove an environment variable from the environment of the calling process. The *name* argument points to a string, which is the name of the variable to be removed. The named argument shall not contain an `'='` character. If the named variable does not exist in the current environment, the environment shall be unchanged and the function is considered to have completed successfully.

If the application modifies *environ* or the pointers to which it points, the behavior of *unsetenv*( ) is undefined. The *unsetenv*( ) function shall update the list of pointers to which *environ* points.

The *unsetenv*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

Upon successful completion, zero shall be returned. Otherwise, −1 shall be returned, *errno* set to indicate the error, and the environment shall be unchanged.

ERRORS

The *unsetenv*( ) function shall fail if:

[EINVAL]	The *name* argument is a null pointer, points to an empty string, or points to a string containing an `'='` character.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

Refer to the RATIONALE section in *setenv*( ).

CHANGE HISTORY

First released in Issue 6. Derived from the IEEE P1003.1a draft standard.

NAME

usleep — suspend execution for an interval

SYNOPSIS

OB XSI

```
#include <unistd.h>

int usleep(useconds_t useconds);
```

DESCRIPTION

The *usleep*( ) function shall cause the calling thread to be suspended from execution until either the number of realtime microseconds specified by the argument *useconds* has elapsed or a signal is delivered to the calling thread and its action is to invoke a signal-catching function or to terminate the process. The suspension time may be longer than requested due to the scheduling of other activity by the system.

The *useconds* argument shall be less than one million. If the value of *useconds* is 0, then the call has no effect. |

If a SIGALRM signal is generated for the calling process during execution of *usleep*( ) and if the SIGALRM signal is being ignored or blocked from delivery, it is unspecified whether *usleep*( ) returns when the SIGALRM signal is scheduled. If the signal is being blocked, it is also unspecified whether it remains pending after *usleep*( ) returns or it is discarded.

If a SIGALRM signal is generated for the calling process during execution of *usleep*( ), except as a result of a prior call to *alarm*( ), and if the SIGALRM signal is not being ignored or blocked from delivery, it is unspecified whether that signal has any effect other than causing *usleep*( ) to return.

If a signal-catching function interrupts *usleep*( ) and examines or changes either the time a SIGALRM is scheduled to be generated, the action associated with the SIGALRM signal, or whether the SIGALRM signal is blocked from delivery, the results are unspecified.

If a signal-catching function interrupts *usleep*( ) and calls *siglongjmp*( ) or *longjmp*( ) to restore an environment saved prior to the *usleep*( ) call, the action associated with the SIGALRM signal and the time at which a SIGALRM signal is scheduled to be generated are unspecified. It is also unspecified whether the SIGALRM signal is blocked, unless the process' signal mask is restored as part of the environment.

Implementations may place limitations on the granularity of timer values. For each interval timer, if the requested timer value requires a finer granularity than the implementation supports, the actual timer value shall be rounded up to the next supported value.

Interactions between *usleep*( ) and any of the following are unspecified:

nanosleep( )
setitimer( )
timer_create( )
timer_delete( )
timer_getoverrun( )
timer_gettime( )
timer_settime( )
ualarm( )
sleep( )

RETURN VALUE

Upon successful completion, *usleep*( ) shall return 0; otherwise, it shall return −1 and set *errno* to indicate the error.

ERRORS

The *usleep*( ) function may fail if:

[EINVAL]	The time interval specified one million or more microseconds.

EXAMPLES

None.

APPLICATION USAGE

Applications are recommended to use *nanosleep*( ) if the Timers option is supported, or *setitimer*( ), *timer_create*( ), *timer_delete*( ), *timer_getoverrun*( ), *timer_gettime*( ), or *timer_settime*( ) instead of this function.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

alarm( ), *getitimer*( ), *nanosleep*( ), *sigaction*( ), *sleep*( ), *timer_create*( ), *timer_delete*( ), *timer_getoverrun*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<unistd.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

The DESCRIPTION is changed to indicate that timers are now thread-based rather than process-based.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

This function is marked obsolescent.

NAME

utime — set file access and modification times

SYNOPSIS

```
#include <utime.h>

int utime(const char *path, const struct utimbuf *times);
```

DESCRIPTION

The *utime*( ) function shall set the access and modification times of the file named by the *path* argument.

If *times* is a null pointer, the access and modification times of the file shall be set to the current time. The effective user ID of the process shall match the owner of the file, or the process has write permission to the file or has appropriate privileges, to use *utime*( ) in this manner.

If *times* is not a null pointer, *times* shall be interpreted as a pointer to a **utimbuf** structure and the access and modification times shall be set to the values contained in the designated structure. Only a process with effective user ID equal to the user ID of the file or a process with appropriate privileges may use *utime*( ) this way.

The **utimbuf** structure is defined in the **<utime.h>** header. The times in the structure **utimbuf** are measured in seconds since the Epoch.

Upon successful completion, *utime*( ) shall mark the time of the last file status change, *st_ctime*, to be updated; see **<sys/stat.h>**.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* shall be set to indicate the error, and the file times shall not be affected.

ERRORS

The *utime*( ) function shall fail if:

[EACCES]	Search permission is denied by a component of the path prefix; or the *times* argument is a null pointer and the effective user ID of the process does not match the owner of the file, the process does not have write permission for the file, and the process does not have appropriate privileges.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of *path* does not name an existing file or *path* is an empty string.
[ENOTDIR]	A component of the path prefix is not a directory.
[EPERM]	The *times* argument is not a null pointer and the calling process' effective user ID does not match the owner of the file and the calling process does not have the appropriate privileges.
[EROFS]	The file system containing the file is read-only.

The *utime*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.

[ENAMETOOLONG]
As a result of encountering a symbolic link in resolution of the *path* argument, the length of the substituted pathname string exceeded {PATH_MAX}.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

The *actime* structure member must be present so that an application may set it, even though an implementation may ignore it and not change the access time on the file. If an application intends to leave one of the times of a file unchanged while changing the other, it should use *stat*( ) to retrieve the file's *st_atime* and *st_mtime* parameters, set *actime* and *modtime* in the buffer, and change one of them before making the *utime*( ) call.

FUTURE DIRECTIONS

None.

SEE ALSO

The Base Definitions volume of IEEE Std 1003.1-200x, **<sys/types.h>**, **<utime.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.
- The [ELOOP] mandatory error condition is added.
- A second [ENAMETOOLONG] is added as an optional error condition.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The [ELOOP] optional error condition is added.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

utimes — set file access and modification times (**LEGACY**)

SYNOPSIS

XSI

```
#include <sys/time.h>

int utimes(const char *path, const struct timeval times[2]);
```

DESCRIPTION

The *utimes*( ) function shall set the access and modification times of the file pointed to by the *path* argument to the value of the *times* argument. The *utimes*( ) function allows time specifications accurate to the microsecond.

For *utimes*( ), the *times* argument is an array of **timeval** structures. The first array member represents the date and time of last access, and the second member represents the date and time of last modification. The times in the **timeval** structure are measured in seconds and microseconds since the Epoch, although rounding toward the nearest second may occur.

If the *times* argument is a null pointer, the access and modification times of the file shall be set to the current time. The effective user ID of the process shall match the owner of the file, or has write access to the file or appropriate privileges to use this call in this manner. Upon completion, *utimes*( ) shall mark the time of the last file status change, *st_ctime*, for update.

RETURN VALUE

Upon successful completion, 0 shall be returned. Otherwise, −1 shall be returned and *errno* shall be set to indicate the error, and the file times shall not be affected.

ERRORS

The *utimes*( ) function shall fail if:

[EACCES]	Search permission is denied by a component of the path prefix; or the *times* argument is a null pointer and the effective user ID of the process does not match the owner of the file and write access is denied.
[ELOOP]	A loop exists in symbolic links encountered during resolution of the *path* argument.
[ENAMETOOLONG]	The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.
[ENOENT]	A component of *path* does not name an existing file or *path* is an empty string.
[ENOTDIR]	A component of the path prefix is not a directory.
[EPERM]	The *times* argument is not a null pointer and the calling process' effective user ID has write access to the file but does not match the owner of the file and the calling process does not have the appropriate privileges.
[EROFS]	The file system containing the file is read-only.

The *utimes*( ) function may fail if:

[ELOOP]	More than {SYMLOOP_MAX} symbolic links were encountered during resolution of the *path* argument.
[ENAMETOOLONG]	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds {PATH_MAX}.

EXAMPLES

None.

APPLICATION USAGE

For applications portability, the *utime*( ) function should be used to set file access and modification times instead of *utimes*( ).

RATIONALE

None.

FUTURE DIRECTIONS

This function may be withdrawn in a future version.

SEE ALSO

The Base Definitions volume of IEEE Std 1003.1-200x, **<sys/time.h>**

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

Issue 6

This function is marked LEGACY.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements. |

The wording of the mandatory [ELOOP] error condition is updated, and a second optional [ELOOP] error condition is added.

NAME

va_arg, va_copy, va_end, va_start — handle variable argument list

SYNOPSIS

```
#include <stdarg.h>

type va_arg(va_list ap, type);
void va_copy(va_list dest, va_list src);
void va_end(va_list ap);
void va_start(va_list ap, argN);
```

DESCRIPTION

Refer to the Base Definitions volume of IEEE Std 1003.1-200x, **<stdarg.h>**.

NAME

vfork — create new process; share virtual memory

SYNOPSIS

OB XSI

```
#include <unistd.h>

pid_t vfork(void);
```

DESCRIPTION

The *vfork*( ) function shall be equivalent to *fork*( ), except that the behavior is undefined if the process created by *vfork*( ) either modifies any data other than a variable of type **pid_t** used to store the return value from *vfork*( ), or returns from the function in which *vfork*( ) was called, or calls any other function before successfully calling *_exit*( ) or one of the *exec* family of functions.

RETURN VALUE

Upon successful completion, *vfork*( ) shall return 0 to the child process and return the process ID of the child process to the parent process. Otherwise, –1 shall be returned to the parent, no child process shall be created, and *errno* shall be set to indicate the error.

ERRORS

The *vfork*( ) function shall fail if:

[EAGAIN]	The system-wide limit on the total number of processes under execution would be exceeded, or the system-imposed limit on the total number of processes under execution by a single user would be exceeded.
[ENOMEM]	There is insufficient swap space for the new process.

EXAMPLES

None.

APPLICATION USAGE

Conforming applications are recommended not to depend on *vfork*( ), but to use *fork*( ) instead. The *vfork*( ) function may be withdrawn in a future version.

On some implementations, *vfork*( ) is equivalent to *fork*( ).

The *vfork*( ) function differs from *fork*( ) only in that the child process can share code and data with the calling process (parent process). This speeds cloning activity significantly at a risk to the integrity of the parent process if *vfork*( ) is misused.

The use of *vfork*( ) for any purpose except as a prelude to an immediate call to a function from the *exec* family, or to *_exit*( ), is not advised.

The *vfork*( ) function can be used to create new processes without fully copying the address space of the old process. If a forked process is simply going to call *exec*, the data space copied from the parent to the child by *fork*( ) is not used. This is particularly inefficient in a paged environment, making *vfork*( ) particularly useful. Depending upon the size of the parent's data space, *vfork*( ) can give a significant performance improvement over *fork*( ).

The *vfork*( ) function can normally be used just like *fork*( ). It does not work, however, to return while running in the child's context from the caller of *vfork*( ) since the eventual return from *vfork*( ) would then return to a no longer existent stack frame. Care should be taken, also, to call *_exit*( ) rather than *exit*( ) if *exec* cannot be used, since *exit*( ) flushes and closes standard I/O channels, thereby damaging the parent process' standard I/O data structures. (Even with *fork*( ), it is wrong to call *exit*( ), since buffered data would then be flushed twice.)

If signal handlers are invoked in the child process after *vfork*( ), they must follow the same rules as other code in the child process.

RATIONALE

None.

FUTURE DIRECTIONS

This function may be withdrawn in a future version.

Moved from X/OPEN UNIX extension to BASE.

Issue 6

Marked obsolescent.

NAME

vfprintf, vprintf, vsnprintf, vsprintf — format output of a stdarg argument list

SYNOPSIS

```
#include <stdarg.h>
#include <stdio.h>

int vfprintf(FILE *restrict stream, const char *restrict format,
    va_list ap);
int vprintf(const char *restrict format, va_list ap);
int vsnprintf(char *restrict s, size_t n, const char *restrict format,
    va_list ap);
int vsprintf(char *restrict s, const char *restrict format, va_list ap);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *vprintf*( ), *vfprintf*( ), *vsnprintf*( ), and *vsprintf*( ) functions shall be equivalent to *printf*( ), *fprintf*( ), *snprintf*( ), and *sprintf*( ) respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by **<stdarg.h>**.

These functions shall not invoke the *va_end* macro. As these functions invoke the *va_arg* macro, the value of *ap* after the return is unspecified.

RETURN VALUE

Refer to *fprintf*( ).

ERRORS

Refer to *fprintf*( ).

EXAMPLES

None.

APPLICATION USAGE

Applications using these functions should call *va_end*(*ap*) afterwards to clean up.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

wait, waitpid — wait for a child process to stop or terminate

SYNOPSIS

```
#include <sys/wait.h>

pid_t wait(int *stat_loc);
pid_t waitpid(pid_t pid, int *stat_loc, int options);
```

DESCRIPTION

The *wait*( ) and *waitpid*( ) functions shall obtain status information pertaining to one of the caller's child processes. Various options permit status information to be obtained for child processes that have terminated or stopped. If status information is available for two or more child processes, the order in which their status is reported is unspecified.

The *wait*( ) function shall suspend execution of the calling thread until status information for one of the terminated child processes of the calling process is available, or until delivery of a signal whose action is either to execute a signal-catching function or to terminate the process. If more than one thread is suspended in *wait*( ) or *waitpid*( ) awaiting termination of the same process, exactly one thread shall return the process status at the time of the target process termination. If status information is available prior to the call to *wait*( ), return shall be immediate.

The *waitpid*( ) function shall be equivalent to *wait*( ) if the *pid* argument is (**pid_t**)−1 and the *options* argument is 0. Otherwise, its behavior shall be modified by the values of the *pid* and *options* arguments.

The *pid* argument specifies a set of child processes for which *status* is requested. The *waitpid*( ) function shall only return the status of a child process from this set:

- If *pid* is equal to (**pid_t**)−1, *status* is requested for any child process. In this respect, *waitpid*( ) is then equivalent to *wait*( ).
- If *pid* is greater than 0, it specifies the process ID of a single child process for which *status* is requested.
- If *pid* is 0, *status* is requested for any child process whose process group ID is equal to that of the calling process.
- If *pid* is less than (**pid_t**)−1, *status* is requested for any child process whose process group ID is equal to the absolute value of *pid*.

The *options* argument is constructed from the bitwise-inclusive OR of zero or more of the following flags, defined in the **<sys/wait.h>** header:

XSI	WCONTINUED	The *waitpid*( ) function shall report the status of any continued child process specified by *pid* whose status has not been reported since it continued from a job control stop.
	WNOHANG	The *waitpid*( ) function shall not suspend execution of the calling thread if *status* is not immediately available for one of the child processes specified by *pid*.
	WUNTRACED	The status of any child processes specified by *pid* that are stopped, and whose status has not yet been reported since they stopped, shall also be reported to the requesting process.

XSI If the calling process has SA_NOCLDWAIT set or has SIGCHLD set to SIG_IGN, and the process has no unwaited-for children that were transformed into zombie processes, the calling thread shall block until all of the children of the process containing the calling thread terminate, and *wait*( ) and *waitpid*( ) shall fail and set *errno* to [ECHILD].

If *wait*( ) or *waitpid*( ) return because the status of a child process is available, these functions shall return a value equal to the process ID of the child process. In this case, if the value of the argument *stat_loc* is not a null pointer, information shall be stored in the location pointed to by *stat_loc*. The value stored at the location pointed to by *stat_loc* shall be 0 if and only if the status returned is from a terminated child process that terminated by one of the following means:

1. The process returned 0 from *main*( ).
2. The process called *_exit*( ) or *exit*( ) with a *status* argument of 0.
3. The process was terminated because the last thread in the process terminated.

Regardless of its value, this information may be interpreted using the following macros, which are defined in **<sys/wait.h>** and evaluate to integral expressions; the *stat_val* argument is the integer value pointed to by *stat_loc*.

WIFEXITED(*stat_val*)
Evaluates to a non-zero value if *status* was returned for a child process that terminated normally.

WEXITSTATUS(*stat_val*)
If the value of WIFEXITED(*stat_val*) is non-zero, this macro evaluates to the low-order 8 bits of the *status* argument that the child process passed to *_exit*( ) or *exit*( ), or the value the child process returned from *main*( ).

WIFSIGNALED(*stat_val*)
Evaluates to non-zero value if status was returned for a child process that terminated due to the receipt of a signal that was not caught (see **<signal.h>**).

WTERMSIG(*stat_val*)
If the value of WIFSIGNALED(*stat_val*) is non-zero, this macro evaluates to the number of the signal that caused the termination of the child process.

WIFSTOPPED(*stat_val*)
Evaluates to a non-zero value if status was returned for a child process that is currently stopped.

WSTOPSIG(*stat_val*)
If the value of WIFSTOPPED(*stat_val*) is non-zero, this macro evaluates to the number of the signal that caused the child process to stop.

XSI WIFCONTINUED(*stat_val*)
Evaluates to a non-zero value if status was returned for a child process that has continued from a job control stop.

SPN It is unspecified whether the *status* value returned by calls to *wait*( ) or *waitpid*( ) for processes created by *posix_spawn*( ) or *posix_spawnp*( ) can indicate a WIFSTOPPED(*stat_val*) before subsequent calls to *wait*( ) or *waitpid*( ) indicate WIFEXITED(*stat_val*) as the result of an error detected before the new process image starts executing.

It is unspecified whether the *status* value returned by calls to *wait*( ) or *waitpid*( ) for processes created by *posix_spawn*( ) or *posix_spawnp*( ) can indicate a WIFSIGNALED(*stat_val*) if a signal is sent to the parent's process group after *posix_spawn*( ) or *posix_spawnp*( ) is called.

If the information pointed to by *stat_loc* was stored by a call to *waitpid*( ) that specified the XSI WUNTRACED flag and did not specify the WCONTINUED flag, exactly one of the macros WIFEXITED(**stat_loc*), WIFSIGNALED(**stat_loc*), and WIFSTOPPED(**stat_loc*) shall evaluate to a non-zero value.

XSI If the information pointed to by *stat_loc* was stored by a call to *waitpid*( ) that specified the WUNTRACED and WCONTINUED flags, exactly one of the macros WIFEXITED(**stat_loc*), WIFSIGNALED(**stat_loc*), WIFSTOPPED(**stat_loc*), and WIFCONTINUED(**stat_loc*) shall evaluate to a non-zero value.

XSI If the information pointed to by *stat_loc* was stored by a call to *waitpid*( ) that did not specify the WUNTRACED or WCONTINUED flags, or by a call to the *wait*( ) function, exactly one of the macros WIFEXITED(**stat_loc*) and WIFSIGNALED(**stat_loc*) shall evaluate to a non-zero value.

XSI If the information pointed to by *stat_loc* was stored by a call to *waitpid*( ) that did not specify the WUNTRACED flag and specified the WCONTINUED flag, or by a call to the *wait*( ) function, exactly one of the macros WIFEXITED(**stat_loc*), WIFSIGNALED(**stat_loc*), and WIFCONTINUED(**stat_loc*) shall evaluate to a non-zero value.

If _POSIX_REALTIME_SIGNALS is defined, and the implementation queues the SIGCHLD signal, then if *wait*( ) or *waitpid*( ) returns because the status of a child process is available, any pending SIGCHLD signal associated with the process ID of the child process shall be discarded. Any other pending SIGCHLD signals shall remain pending.

Otherwise, if SIGCHLD is blocked, if *wait*( ) or *waitpid*( ) return because the status of a child process is available, any pending SIGCHLD signal shall be cleared unless the status of another child process is available.

For all other conditions, it is unspecified whether child *status* will be available when a SIGCHLD signal is delivered.

There may be additional implementation-defined circumstances under which *wait*( ) or *waitpid*( ) report *status*. This shall not occur unless the calling process or one of its child processes explicitly makes use of a non-standard extension. In these cases the interpretation of the reported *status* is implementation-defined.

XSI If a parent process terminates without waiting for all of its child processes to terminate, the remaining child processes shall be assigned a new parent process ID corresponding to an implementation-defined system process.

RETURN VALUE

If *wait*( ) or *waitpid*( ) returns because the status of a child process is available, these functions shall return a value equal to the process ID of the child process for which *status* is reported. If *wait*( ) or *waitpid*( ) returns due to the delivery of a signal to the calling process, −1 shall be returned and *errno* set to [EINTR]. If *waitpid*( ) was invoked with WNOHANG set in *options*, it has at least one child process specified by *pid* for which *status* is not available, and *status* is not available for any process specified by *pid*, 0 is returned. Otherwise, (**pid_t**)−1 shall be returned, and *errno* set to indicate the error.

ERRORS

The *wait*( ) function shall fail if:

[ECHILD]	The calling process has no existing unwaited-for child processes.
[EINTR]	The function was interrupted by a signal. The value of the location pointed to by *stat_loc* is undefined.

The *waitpid*( ) function shall fail if:

[ECHILD]	The process specified by *pid* does not exist or is not a child of the calling process, or the process group specified by *pid* does not exist or does not have any member process that is a child of the calling process.

[EINTR]	The function was interrupted by a signal. The value of the location pointed to by *stat_loc* is undefined.
[EINVAL]	The *options* argument is not valid.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

A call to the *wait*( ) or *waitpid*( ) function only returns *status* on an immediate child process of the calling process; that is, a child that was produced by a single *fork*( ) call (perhaps followed by an *exec* or other function calls) from the parent. If a child produces grandchildren by further use of *fork*( ), none of those grandchildren nor any of their descendants affect the behavior of a *wait*( ) from the original parent process. Nothing in this volume of IEEE Std 1003.1-200x prevents an implementation from providing extensions that permit a process to get *status* from a grandchild or any other process, but a process that does not use such extensions must be guaranteed to see *status* from only its direct children.

The *waitpid*( ) function is provided for three reasons:

1. To support job control
2. To permit a non-blocking version of the *wait*( ) function
3. To permit a library routine, such as *system*( ) or *pclose*( ), to wait for its children without interfering with other terminated children for which the process has not waited

The first two of these facilities are based on the *wait3*( ) function provided by 4.3 BSD. The function uses the *options* argument, which is equivalent to an argument to *wait3*( ). The WUNTRACED flag is used only in conjunction with job control on systems supporting job control. Its name comes from 4.3 BSD and refers to the fact that there are two types of stopped processes in that implementation: processes being traced via the *ptrace*( ) debugging facility and (untraced) processes stopped by job control signals. Since *ptrace*( ) is not part of this volume of IEEE Std 1003.1-200x, only the second type is relevant. The name WUNTRACED was retained because its usage is the same, even though the name is not intuitively meaningful in this context.

The third reason for the *waitpid*( ) function is to permit independent sections of a process to spawn and wait for children without interfering with each other. For example, the following problem occurs in developing a portable shell, or command interpreter:

```
stream = popen("/bin/true");
(void) system("sleep 100");
(void) pclose(stream);
```

On all historical implementations, the final *pclose*( ) fails to reap the *wait*( ) *status* of the *popen*( ).

The status values are retrieved by macros, rather than given as specific bit encodings as they are in most historical implementations (and thus expected by existing programs). This was necessary to eliminate a limitation on the number of signals an implementation can support that was inherent in the traditional encodings. This volume of IEEE Std 1003.1-200x does require that a *status* value of zero corresponds to a process calling *_exit*(0), as this is the most common encoding expected by existing programs. Some of the macro names were adopted from 4.3 BSD.

These macros syntactically operate on an arbitrary integer value. The behavior is undefined unless that value is one stored by a successful call to *wait*( ) or *waitpid*( ) in the location pointed to by the *stat_loc* argument. An early proposal attempted to make this clearer by specifying each argument as **stat_loc* rather than *stat_val*. However, that did not follow the conventions of other specifications in this volume of IEEE Std 1003.1-200x or traditional usage. It also could have implied that the argument to the macro must literally be **stat_loc*; in fact, that value can be stored or passed as an argument to other functions before being interpreted by these macros.

The extension that affects *wait*( ) and *waitpid*( ) and is common in historical implementations is the *ptrace*( ) function. It is called by a child process and causes that child to stop and return a *status* that appears identical to the *status* indicated by WIFSTOPPED. The *status* of *ptrace*( ) children is traditionally returned regardless of the WUNTRACED flag (or by the *wait*( ) function). Most applications do not need to concern themselves with such extensions because they have control over what extensions they or their children use. However, applications, such as command interpreters, that invoke arbitrary processes may see this behavior when those arbitrary processes misuse such extensions.

Implementations that support *core* file creation or other implementation-defined actions on termination of some processes traditionally provide a bit in the *status* returned by *wait*( ) to indicate that such actions have occurred.

Allowing the *wait*( ) family of functions to discard a pending SIGCHLD signal that is associated with a successfully waited-for child process puts them into the *sigwait*( ) and *sigwaitinfo*( ) category with respect to SIGCHLD.

This definition allows implementations to treat a pending SIGCHLD signal as accepted by the process in *wait*( ), with the same meaning of ‘‘accepted’’ as when that word is applied to the *sigwait*( ) family of functions.

Allowing the *wait*( ) family of functions to behave this way permits an implementation to be able to deal precisely with SIGCHLD signals.

In particular, an implementation that does accept (discard) the SIGCHLD signal can make the following guarantees regardless of the queuing depth of signals in general (the list of waitable children can hold the SIGCHLD queue):

1. If a SIGCHLD signal handler is established via *sigaction*( ) without the SA_RESETHAND flag, SIGCHLD signals can be accurately counted; that is, exactly one SIGCHLD signal will be delivered to or accepted by the process for every child process that terminates.

2. A single *wait*( ) issued from a SIGCHLD signal handler can be guaranteed to return immediately with status information for a child process.

3. When SA_SIGINFO is requested, the SIGCHLD signal handler can be guaranteed to receive a non-NULL pointer to a **siginfo_t** structure that describes a child process for which a wait via *waitpid*( ) or *waitid*( ) will not block or fail.

4. The *system*( ) function will not cause a processs SIGCHLD handler to be called as a result of the *fork*( )/*exec* executed within *system*( ) because *system*( ) will accept the SIGCHLD signal when it performs a *waitpid*( ) for its child process. This is a desirable behavior of *system*( ) so that it can be used in a library without causing side effects to the application linked with the library.

An implementation that does not permit the *wait*( ) family of functions to accept (discard) a pending SIGCHLD signal associated with a successfully waited-for child, cannot make the guarantees described above for the following reasons:

Guarantee #1

Although it might be assumed that reliable queuing of all SIGCHLD signals generated by the system can make this guarantee, the counter example is the case of a process that blocks SIGCHLD and performs an indefinite loop of *fork*( )/*wait*( ) operations. If the implementation supports queued signals, then eventually the system will run out of memory for the queue. The guarantee cannot be made because there must be some limit to the depth of queuing.

Guarantees #2 and #3

These cannot be guaranteed unless the *wait*( ) family of functions accepts the SIGCHLD signal. Otherwise, a *fork*( )/*wait*( ) executed while SIGCHLD is blocked (as in the *system*( ) function) will result in an invocation of the handler when SIGCHLD is unblocked, after the process has disappeared.

Guarantee #4

Although possible to make this guarantee, *system*( ) would have to set the SIGCHLD handler to SIG_DFL so that the SIGCHLD signal generated by its *fork*( ) would be discarded (the SIGCHLD default action is to be ignored), then restore it to its previous setting. This would have the undesirable side effect of discarding all SIGCHLD signals pending to the process.

FUTURE DIRECTIONS

None.

SEE ALSO

exec, *exit*( ), *fork*( ), *waitid*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<sys/types.h>**, **<sys/wait.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

In the SYNOPSIS, the optional include of the **<sys/types.h>** header is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The requirement to include **<sys/types.h>** has been removed. Although **<sys/types.h>** was required for conforming implementations of previous POSIX specifications, it was not required for UNIX applications.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The processing of the SIGCHLD signal and the [ECHILD] error is clarified.

The semantics of WIFSTOPPED(*stat_val*), WIFEXITED(*stat_val*), and WIFSIGNALED(*stat_val*) are defined with respect to *posix_spawn*( ) or *posix_spawnp*( ) for alignment with IEEE Std 1003.1d-1999.

The DESCRIPTION is updated for alignment with the ISO/IEC 9899:1999 standard.

waitid — wait for a child process to change state

SYNOPSIS

XSI

```
#include <sys/wait.h>

int waitid(idtype_t idtype, id_t id, siginfo_t *infop, int options);
```

DESCRIPTION

The *waitid*( ) function shall suspend the calling thread until one child of the process containing the calling thread changes state. It records the current state of a child in the structure pointed to by *infop*. If a child process changed state prior to the call to *waitid*( ), *waitid*( ) shall return immediately. If more than one thread is suspended in *wait*( ) or *waitpid*( ) waiting termination of the same process, exactly one thread shall return the process status at the time of the target process termination.

The *idtype* and *id* arguments are used to specify which children *waitid*( ) waits for.

If *idtype* is P_PID, *waitid*( ) shall wait for the child with a process ID equal to (**pid_t**)*id*.

If *idtype* is P_PGID, *waitid*( ) shall wait for any child with a process group ID equal to (**pid_t**)*id*.

If *idtype* is P_ALL, *waitid*( ) shall wait for any children and *id* is ignored.

The *options* argument is used to specify which state changes *waitid*( ) shall wait for. It is formed by OR'ing together one or more of the following flags:

WEXITED	Wait for processes that have exited.
WSTOPPED	Status shall be returned for any child that has stopped upon receipt of a signal.
WCONTINUED	Status shall be returned for any child that was stopped and has been continued.
WNOHANG	Return immediately if there are no children to wait for.
WNOWAIT	Keep the process whose status is returned in *infop* in a waitable state. This shall not affect the state of the process; the process may be waited for again after this call completes.

The application shall ensure that the *infop* argument points to a **siginfo_t** structure. If *waitid*( ) returns because a child process was found that satisfied the conditions indicated by the arguments *idtype* and *options*, then the structure pointed to by *infop* shall be filled in by the system with the status of the process. The *si_signo* member shall always be equal to SIGCHLD.

RETURN VALUE

If WNOHANG was specified and there are no children to wait for, 0 shall be returned. If *waitid*( ) returns due to the change of state of one of its children, 0 shall be returned. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

The *waitid*( ) function shall fail if:

[ECHILD]	The calling process has no existing unwaited-for child processes.
[EINTR]	The *waitid*( ) function was interrupted by a signal.
[EINVAL]	An invalid value was specified for *options*, or *idtype* and *id* specify an invalid set of processes.

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 5

Moved from X/OPEN UNIX extension to BASE.

The DESCRIPTION is updated for alignment with the POSIX Threads Extension.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

waitpid — wait for a child process to stop or terminate

SYNOPSIS

```
#include <sys/wait.h>

pid_t waitpid(pid_t pid, int *stat_loc, int options);
```

DESCRIPTION

Refer to *wait*( ).

NAME

wcrtomb — convert a wide-character code to a character (restartable)

SYNOPSIS

```
#include <stdio.h>

size_t wcrtomb(char *restrict s, wchar_t wc, mbstate_t *restrict ps);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

If *s* is a null pointer, the *wcrtomb*( ) function shall be equivalent to the call:

```
wcrtomb(buf, L'\0', ps)
```

where *buf* is an internal buffer.

If *s* is not a null pointer, the *wcrtomb*( ) function shall determine the number of bytes needed to represent the character that corresponds to the wide character given by *wc* (including any shift sequences), and store the resulting bytes in the array whose first element is pointed to by *s*. At most {MB_CUR_MAX} bytes are stored. If *wc* is a null wide character, a null byte shall be stored, preceded by any shift sequence needed to restore the initial shift state. The resulting state described shall be the initial conversion state.

If *ps* is a null pointer, the *wcrtomb*( ) function shall use its own internal **mbstate_t** object, which is initialized at program start-up to the initial conversion state. Otherwise, the **mbstate_t** object pointed to by *ps* shall be used to completely describe the current conversion state of the associated character sequence. The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *wcrtomb*( ).

CX If the application uses any of the _POSIX_THREAD_SAFE_FUNCTIONS or _POSIX_THREADS functions, the application shall ensure that the *wcrtomb*( ) function is called with a non-NULL *ps* argument.

The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale.

RETURN VALUE

The *wcrtomb*( ) function shall return the number of bytes stored in the array object (including any shift sequences). When *wc* is not a valid wide character, an encoding error shall occur. In this case, the function shall store the value of the macros [EILSEQ] in *errno* and shall return (**size_t**)−1; the conversion state shall be undefined.

ERRORS

The *wcrtomb*( ) function may fail if:

CX	[EINVAL]	*ps* points to an object that contains an invalid conversion state.
	[EILSEQ]	Invalid wide-character code is detected.

CHANGE HISTORY

First released in Issue 5. Included for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E).

Issue 6

In the DESCRIPTION, a note on using this function in a threaded application is added.

Extensions beyond the ISO C standard are now marked.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The *wcrtomb*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

wcscat — concatenate two wide-character strings

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcscat(wchar_t *restrict ws1, const wchar_t *restrict ws2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcscat*( ) function shall append a copy of the wide-character string pointed to by *ws2* (including the terminating null wide-character code) to the end of the wide-character string pointed to by *ws1*. The initial wide-character code of *ws2* shall overwrite the null wide-character code at the end of *ws1*. If copying takes place between objects that overlap, the behavior is undefined. |

RETURN VALUE

The *wcscat*( ) function shall return *ws1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

Issue 6

The Open Group Corrigendum U040/2 is applied. In the RETURN VALUE section, *s1* is changed to *ws1*.

The *wcscat*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

wcschr — wide-character string scanning operation

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcschr(const wchar_t *ws, wchar_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcschr*( ) function shall locate the first occurrence of *wc* in the wide-character string pointed to by *ws*. The application shall ensure that the value of *wc* is a character representable as a type **wchar_t** and a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string.

RETURN VALUE

Upon completion, *wcschr*( ) shall return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.

ERRORS

No errors are defined.

NAME

wcscmp — compare two wide-character strings

SYNOPSIS

```
#include <wchar.h>

int wcscmp(const wchar_t *ws1, const wchar_t *ws2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcscmp*( ) function shall compare the wide-character string pointed to by *ws1* to the wide-character string pointed to by *ws2*.

The sign of a non-zero return value shall be determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. |

RETURN VALUE

Upon completion, *wcscmp*( ) shall return an integer greater than, equal to, or less than 0, if the wide-character string pointed to by *ws1* is greater than, equal to, or less than the wide-character string pointed to by *ws2*, respectively.

ERRORS

No errors are defined.

EXAMPLES

None.

NAME

wcscoll — wide-character string comparison using collating information

SYNOPSIS

```
#include <wchar.h>

int wcscoll(const wchar_t *ws1, const wchar_t *ws2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcscoll*( ) function shall compare the wide-character string pointed to by *ws1* to the wide-character string pointed to by *ws2*, both interpreted as appropriate to the *LC_COLLATE* category of the current locale.

CX The *wcscoll*( ) function shall not change the setting of *errno* if successful.

An application wishing to check for error situations should set *errno* to 0 before calling *wcscoll*( ). If *errno* is non-zero on return, an error has occurred.

RETURN VALUE

Upon successful completion, *wcscoll*( ) shall return an integer greater than, equal to, or less than 0, according to whether the wide-character string pointed to by *ws1* is greater than, equal to, or less than the wide-character string pointed to by *ws2*, when both are interpreted as appropriate to the current locale. CX On error, *wcscoll*( ) shall set *errno*, but no return value is reserved to indicate an error.

ERRORS

The *wcscoll*( ) function may fail if:

CX [EINVAL] The *ws1* or *ws2* arguments contain wide-character codes outside the domain of the collating sequence.

EXAMPLES

None.

APPLICATION USAGE

The *wcsxfrm*( ) and *wcscmp*( ) functions should be used for sorting large lists.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

wcscmp( ), *wcsxfrm*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<wchar.h>**

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

Moved from ENHANCED I18N to BASE and the [ENOSYS] error is removed.

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

NAME

wcscpy — copy a wide-character string

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcscpy(wchar_t *restrict ws1, const wchar_t *restrict ws2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcscpy*( ) function shall copy the wide-character string pointed to by *ws2* (including the terminating null wide-character code) into the array pointed to by *ws1*. If copying takes place between objects that overlap, the behavior is undefined.

RETURN VALUE

The *wcscpy*( ) function shall return *ws1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

NAME

wcscspn — get length of a complementary wide substring

SYNOPSIS

```
#include <wchar.h>

size_t wcscspn(const wchar_t *ws1, const wchar_t *ws2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcscspn*( ) function shall compute the length (in wide characters) of the maximum initial segment of the wide-character string pointed to by *ws1* which consists entirely of wide-character codes *not* from the wide-character string pointed to by *ws2*. |

RETURN VALUE

The *wcscspn*( ) function shall return the length of the initial substring of *ws1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

Issue 5

The RETURN VALUE section is updated to indicate that *wcscspn*( ) returns the length of *ws1*, rather than *ws1* itself.

NAME

wcsftime — convert date and time to a wide-character string

SYNOPSIS

```
#include <wchar.h>

size_t wcsftime(wchar_t *restrict wcs, size_t maxsize,
    const wchar_t *restrict format, const struct tm *restrict timeptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcsftime*( ) function shall be equivalent to the *strftime*( ) function, except that:

- The argument *wcs* points to the initial element of an array of wide characters into which the generated output is to be placed.
- The argument *maxsize* indicates the maximum number of wide characters to be placed in the output array.
- The argument *format* is a wide-character string and the conversion specifications are replaced by corresponding sequences of wide characters.
- The return value indicates the number of wide characters placed in the output array.

If copying takes place between objects that overlap, the behavior is undefined.

RETURN VALUE

If the total number of resulting wide-character codes including the terminating null wide-character code is no more than *maxsize*, *wcsftime*( ) shall return the number of wide-character codes placed into the array pointed to by *wcs*, not including the terminating null wide-character code. Otherwise, zero is returned and the contents of the array are unspecified.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

Moved from ENHANCED I18N to BASE and the [ENOSYS] error is removed.

Aligned with ISO/IEC 9899:1990/Amendment 1:1995 (E). Specifically, the type of the *format* argument is changed from **const char *** to **const wchar_t ***.

Issue 6

The *wcsftime*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

wcslen — get wide-character string length

SYNOPSIS

```
#include <wchar.h>

size_t wcslen(const wchar_t *ws);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcslen*( ) function shall compute the number of wide-character codes in the wide-character string to which *ws* points, not including the terminating null wide-character code.

RETURN VALUE

The *wcslen*( ) function shall return the length of *ws*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

NAME

wcsncat — concatenate a wide-character string with part of another

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcsncat(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcsncat*( ) function shall append not more than *n* wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by *ws2* to the end of the wide-character string pointed to by *ws1*. The initial wide-character code of *ws2* shall overwrite the null wide-character code at the end of *ws1*. A terminating null wide-character code shall always be appended to the result. If copying takes place between objects that overlap, the behavior is undefined.

RETURN VALUE

The *wcsncat*( ) function shall return *ws1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

NAME

wcsncmp — compare part of two wide-character strings

SYNOPSIS

```
#include <wchar.h>

int wcsncmp(const wchar_t *ws1, const wchar_t *ws2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcsncmp*( ) function shall compare not more than *n* wide-character codes (wide-character codes that follow a null wide-character code are not compared) from the array pointed to by *ws1* to the array pointed to by *ws2*.

The sign of a non-zero return value shall be determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. |

RETURN VALUE

Upon successful completion, *wcsncmp*( ) shall return an integer greater than, equal to, or less than 0, if the possibly null-terminated array pointed to by *ws1* is greater than, equal to, or less than the possibly null-terminated array pointed to by *ws2*, respectively.

ERRORS

No errors are defined.

NAME

wcsncpy — copy part of a wide-character string

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcsncpy(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcsncpy*( ) function shall copy not more than *n* wide-character codes (wide-character codes that follow a null wide-character code are not copied) from the array pointed to by *ws2* to the array pointed to by *ws1*. If copying takes place between objects that overlap, the behavior is undefined.

If the array pointed to by *ws2* is a wide-character string that is shorter than *n* wide-character codes, null wide-character codes shall be appended to the copy in the array pointed to by *ws1*, until *n* wide-character codes in all are written.

RETURN VALUE

The *wcsncpy*( ) function shall return *ws1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

If there is no null wide-character code in the first *n* wide-character codes of the array pointed to by *ws2*, the result is not null-terminated.

NAME

wcsrtombs — convert a wide-character string to a character string (restartable)

SYNOPSIS

```
#include <wchar.h>

size_t wcsrtombs(char *restrict dst, const wchar_t **restrict src,
    size_t len, mbstate_t *restrict ps);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcsrtombs*( ) function shall convert a sequence of wide characters from the array indirectly pointed to by *src* into a sequence of corresponding characters, beginning in the conversion state described by the object pointed to by *ps*. If *dst* is not a null pointer, the converted characters shall then be stored into the array pointed to by *dst*. Conversion continues up to and including a terminating null wide character, which shall also be stored. Conversion shall stop earlier in the following cases:

- When a code is reached that does not correspond to a valid character
- When the next character would exceed the limit of *len* total bytes to be stored in the array pointed to by *dst* (and *dst* is not a null pointer)

Each conversion shall take place as if by a call to the *wcrtomb*( ) function.

If *dst* is not a null pointer, the pointer object pointed to by *src* shall be assigned either a null pointer (if conversion stopped due to reaching a terminating null wide character) or the address just past the last wide character converted (if any). If conversion stopped due to reaching a terminating null wide character, the resulting state described shall be the initial conversion state.

If *ps* is a null pointer, the *wcsrtombs*( ) function shall use its own internal **mbstate_t** object, which is initialized at program start-up to the initial conversion state. Otherwise, the **mbstate_t** object pointed to by *ps* shall be used to completely describe the current conversion state of the associated character sequence. The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *wcsrtombs*( ).

CX If the application uses any of the _POSIX_THREAD_SAFE_FUNCTIONS or _POSIX_THREADS functions, the application shall ensure that the *wcsrtombs*( ) function is called with a non-NULL *ps* argument.

The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale.

RETURN VALUE

If conversion stops because a code is reached that does not correspond to a valid character, an encoding error occurs. In this case, the *wcsrtombs*( ) function shall store the value of the macro [EILSEQ] in *errno* and return (**size_t**)−1; the conversion state is undefined. Otherwise, it shall return the number of bytes in the resulting character sequence, not including the terminating null (if any).

ERRORS

The *wcsrtombs*( ) function may fail if:

CX	[EINVAL]	*ps* points to an object that contains an invalid conversion state.
	[EILSEQ]	A wide-character code does not correspond to a valid character.

EXAMPLES

None.

APPLICATION USAGE

NAME

wcsspn — get length of a wide substring

SYNOPSIS

```
#include <wchar.h>

size_t wcsspn(const wchar_t *ws1, const wchar_t *ws2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcsspn*( ) function shall compute the length (in wide characters) of the maximum initial segment of the wide-character string pointed to by *ws1* which consists entirely of wide-character codes from the wide-character string pointed to by *ws2*.

RETURN VALUE

The *wcsspn*( ) function shall return the length of the initial substring of *ws1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

The RETURN VALUE section is updated to indicate that *wcsspn*( ) returns the length of *ws1* rather that *ws1* itself.

NAME

wcsstr — find a wide-character substring

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcsstr(const wchar_t *restrict ws1, const wchar_t *restrict ws2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcsstr*( ) function shall locate the first occurrence in the wide-character string pointed to by *ws1* of the sequence of wide characters (excluding the terminating null wide character) in the wide-character string pointed to by *ws2*.

RETURN VALUE

Upon successful completion, *wcsstr*( ) shall return a pointer to the located wide-character string, or a null pointer if the wide-character string is not found.

If *ws2* points to a wide-character string with zero length, the function shall return *ws1*.

ERRORS

No errors are defined.

Issue 6

The *wcsstr*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

wcstod, wcstof, wcstold — convert a wide-character string to a double-precision number

SYNOPSIS

```
#include <wchar.h>

double wcstod(const wchar_t *restrict nptr, wchar_t **restrict endptr);
float wcstof(const wchar_t *restrict nptr, wchar_t **restrict endptr);
long double wcstold(const wchar_t *restrict nptr,
    wchar_t **restrict endptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall convert the initial portion of the wide-character string pointed to by *nptr* to **double**, **float**, and **long double** representation, respectively. First, they shall decompose the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by *iswspace*( ))
2. A subject sequence interpreted as a floating-point constant or representing infinity or NaN
3. A final wide-character string of one or more unrecognized wide-character codes, including the terminating null wide-character code of the input wide-character string

Then they shall attempt to convert the subject sequence to a floating-point number, and return the result.

The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character, then an optional exponent part
- A 0x or 0X, then a non-empty sequence of hexadecimal digits optionally containing a radix character, then an optional binary exponent part
- One of INF or INFINITY, or any other wide string equivalent except for case
- One of NAN or NAN(*n-wchar-sequence*$_{opt}$), or any other wide string ignoring case in the NAN part, where:

```
n-wchar-sequence:
    digit
    nondigit
    n-wchar-sequence digit
    n-wchar-sequence nondigit
```

The subject sequence is defined as the longest initial subsequence of the input wide string, starting with the first non-white-space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide string is not of the expected form.

If the subject sequence has the expected form for a floating-point number, the sequence of wide characters starting with the first digit or the radix character (whichever occurs first) shall be interpreted as a floating constant according to the rules of the C language, except that the radix character shall be used in place of a period, and that if neither an exponent part nor a radix character appears in a decimal floating-point number, or if a binary exponent part does not appear in a hexadecimal floating-point number, an exponent part of the appropriate type with value zero shall be assumed to follow the last digit in the string. If the subject sequence begins with a minus sign, the sequence shall be interpreted as negated. A wide-character sequence INF or INFINITY shall be interpreted as an infinity, if representable in the return type, else as if it were a floating constant that is too large for the range of the return type. A wide-character sequence NAN or NAN(*n-wchar-sequence*$_{opt}$) shall be interpreted as a quiet NaN, if supported in the return type, else as if it were a subject sequence part that does not have the expected form; the meaning of the *n*-wchar sequences is implementation-defined. A pointer to the final wide string shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

If the subject sequence has the hexadecimal form and FLT_RADIX is a power of 2, the conversion shall be rounded in an implementation-defined manner.

CX The radix character shall be as defined in the program's locale (category *LC_NUMERIC*). In the POSIX locale, or in a locale where the radix character is not defined, the radix character shall default to a period (`'.'`).

CX In other than the C or POSIX locales, other implementation-defined subject sequences may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion shall be performed; the value of *nptr* shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX The *wcstod*( ) function shall not change the setting of *errno* if successful.

Since 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set *errno* to 0, then call *wcstod*( ), *wcstof*( ), or *wcstold*( ), then check *errno*.

RETURN VALUE

CX Upon successful completion, these functions shall return the converted value. If no conversion could be performed, 0 shall be returned and *errno* may be set to [EINVAL].

If the correct value is outside the range of representable values, plus or minus HUGE_VAL, HUGE_VALF, or HUGE_VALL shall be returned (according to the sign of the value), and *errno* shall be set to [ERANGE].

If the correct value would cause underflow, a value whose magnitude is no greater than the smallest normalized positive number in the return type shall be returned and *errno* set to [ERANGE].

ERRORS

The *wcstod*( ) function shall fail if:

[ERANGE] The value to be returned would cause overflow or underflow.

The *wcstod*( ) function may fail if:

CX [EINVAL] No conversion could be performed.

EXAMPLES

None.

APPLICATION USAGE

If the subject sequence has the hexadecimal form and FLT_RADIX is not a power of 2, and the result is not exactly representable, the result should be one of the two numbers in the appropriate internal format that are adjacent to the hexadecimal floating source value, with the extra stipulation that the error should have a correct sign for the current rounding direction.

If the subject sequence has the decimal form and at most DECIMAL_DIG (defined in **<float.h>**) significant digits, the result should be correctly rounded. If the subject sequence *D* has the decimal form and more than DECIMAL_DIG significant digits, consider the two bounding, adjacent decimal strings *L* and *U*, both having DECIMAL_DIG significant digits, such that the values of *L*, *D*, and *U* satisfy `"L <= D <= U"`. The result should be one of the (equal or adjacent) values that would be obtained by correctly rounding *L* and *U* according to the current rounding direction, with the extra stipulation that the error with respect to *D* should have a correct sign for the current rounding direction.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

Issue 6

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

- The *wcstod*( ) prototype is updated.
- The *wcstof*( ) and *wcstold*( ) functions are added.
- If the correct value for *wcstod*( ) would cause underflow, the return value changed from 0 (as specified in Issue 5) to the smallest normalized positive number.
- The DESCRIPTION, RETURN VALUE, and APPLICATION USAGE sections are extensively updated.

ISO/IEC 9899:1999 standard, Technical Corrigendum No. 1 is incorporated.

NAME

wcstof — convert a wide-character string to a double-precision number

SYNOPSIS

```
#include <wchar.h>

float wcstof(const wchar_t *restrict nptr, wchar_t **restrict endptr);
```

DESCRIPTION

Refer to *wcstod*( ).

NAME

wcstoimax, wcstoumax — convert wide-character string to integer type

SYNOPSIS

```
#include <stddef.h>
#include <inttypes.h>

intmax_t wcstoimax(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
uintmax_t wcstoumax(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall be equivalent to the *wcstol*( ), *wcstoll*( ), *wcstoul*( ), and *wcstoull*( ) functions, respectively, except that the initial portion of the wide string shall be converted to **intmax_t** and **uintmax_t** representation, respectively.

RETURN VALUE

These functions shall return the converted value, if any.

If no conversion could be performed, zero shall be returned. If the correct value is outside the range of representable values, {INTMAX_MAX}, {INTMAX_MIN}, or {UINTMAX_MAX} shall be returned (according to the return type and sign of the value, if any), and *errno* shall be set to [ERANGE].

ERRORS

These functions shall fail if:

[EINVAL]	The value of *base* is not supported.
[ERANGE]	The value to be returned is not representable.

These functions may fail if:

[EINVAL]	No conversion could be performed.

EXAMPLES

CHANGE HISTORY

First released in Issue 6. Derived from the ISO / IEC 9899: 1999 standard.

NAME

wcstok — split wide-character string into tokens

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcstok(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    wchar_t **restrict ptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

A sequence of calls to *wcstok*( ) shall break the wide-character string pointed to by *ws1* into a sequence of tokens, each of which shall be delimited by a wide-character code from the wide-character string pointed to by *ws2*. The *ptr* argument points to a caller-provided **wchar_t** pointer into which the *wcstok*( ) function shall store information necessary for it to continue scanning the same wide-character string. |

The first call in the sequence has *ws1* as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by *ws2* may be different from call to call.

The first call in the sequence shall search the wide-character string pointed to by *ws1* for the first wide-character code that is *not* contained in the current separator string pointed to by *ws2*. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by *ws1* and *wcstok*( ) shall return a null pointer. If such a wide-character code is found, it shall be the start of the first token. |

The *wcstok*( ) function shall then search from there for a wide-character code that *is* contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by *ws1*, and subsequent searches for a token shall return a null pointer. If such a wide-character code is found, it shall be overwritten by a null wide character, which terminates the current token. The *wcstok*( ) function shall save a pointer to the following wide-character code, from which the next search for a token shall start. |

Each subsequent call, with a null pointer as the value of the first argument, shall start searching from the saved pointer and behave as described above. |

The implementation shall behave as if no function calls *wcstok*( ).

RETURN VALUE

Upon successful completion, the *wcstok*( ) function shall return a pointer to the first wide-character code of a token. Otherwise, if there is no token, *wcstok*( ) shall return a null pointer.

ERRORS

No errors are defined.

Issue 5

Aligned with ISO/IEC 9899:1990/Amendment 1:1995 (E). Specifically, a third argument is added to the definition of this function in the SYNOPSIS.

Issue 6

The *wcstok*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

wcstol, wcstoll — convert a wide-character string to a long integer

SYNOPSIS

```
#include <wchar.h>

long wcstol(const wchar_t *restrict nptr, wchar_t **restrict endptr,
    int base);
long long wcstoll(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

These functions shall convert the initial portion of the wide-character string pointed to by *nptr* to **long**, **long long**, **unsigned long**, and **unsigned long long** representation, respectively. First, they shall decompose the input string into three parts:

1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by *iswspace*( ))
2. A subject sequence interpreted as an integer represented in some radix determined by the value of *base*
3. A final wide-character string of one or more unrecognized wide-character codes, including the terminating null wide-character code of the input wide-character string

Then they shall attempt to convert the subject sequence to an integer, and return the result.

If *base* is 0, the expected form of the subject sequence is that of a decimal constant, octal constant, or hexadecimal constant, any of which may be preceded by a `'+'` or `'−'` sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix `'0'` optionally followed by a sequence of the digits `'0'` to `'7'` only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters `'a'` (or `'A'`) to `'f'` (or `'F'`) with values 10 to 15 respectively.

If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by *base*, optionally preceded by a `'+'` or `'−'` sign, but not including an integer suffix. The letters from `'a'` (or `'A'`) to `'z'` (or `'Z'`) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of *base* shall be permitted. If the value of *base* is 16, the wide-character code representations of 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white-space wide-character code that is of the expected form. The subject sequence contains no wide-character codes if the input wide-character string is empty or consists entirely of white-space wide-character code, or if the first non-white-space wide-character code is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and *base* is 0, the sequence of wide-character codes starting with the first digit shall be interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it shall be used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion shall be negated. A pointer to the final wide-character string shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX In other than the C or POSIX locales, other implementation-defined subject sequences may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion shall be performed; the value of *nptr* shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX These functions shall not change the setting of *errno* if successful.

Since 0, {LONG_MIN} or {LLONG_MIN} and {LONG_MAX} or {LLONG_MAX} are returned on error and are also valid returns on success, an application wishing to check for error situations should set *errno* to 0, then call *wcstol*( ) or *wcstoll*( ), then check *errno*.

RETURN VALUE

Upon successful completion, these functions shall return the converted value, if any. If no conversion could be performed, 0 shall be returned CX and *errno* may be set to indicate the error. If the correct value is outside the range of representable values, {LONG_MIN}, {LONG_MAX}, {LLONG_MIN}, or {LLONG_MAX} shall be returned (according to the sign of the value), and *errno* set to [ERANGE].

ERRORS

These functions shall fail if:

CX [EINVAL]	The value of *base* is not supported.
[ERANGE]	The value to be returned is not representable.

These functions may fail if:

CX [EINVAL]	No conversion could be performed.

NAME

wcstombs — convert a wide-character string to a character string

SYNOPSIS

```
#include <stdlib.h>

size_t wcstombs(char *restrict s, const wchar_t *restrict pwcs,
    size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcstombs*( ) function shall convert the sequence of wide-character codes that are in the array pointed to by *pwcs* into a sequence of characters that begins in the initial shift state and store these characters into the array pointed to by *s*, stopping if a character would exceed the limit of *n* total bytes or if a null byte is stored. Each wide-character code shall be converted as if by a call to *wctomb*( ), except that the shift state of *wctomb*( ) shall not be affected.

The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale.

No more than *n* bytes shall be modified in the array pointed to by *s*. If copying takes place between objects that overlap, the behavior is undefined. CX If *s* is a null pointer, *wcstombs*( ) shall return the length required to convert the entire array regardless of the value of *n*, but no values are stored.

The *wcstombs*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

RETURN VALUE

If a wide-character code is encountered that does not correspond to a valid character (of one or more bytes each), *wcstombs*( ) shall return (**size_t**)−1. Otherwise, *wcstombs*( ) shall return the number of bytes stored in the character array, not including any terminating null byte. The array shall not be null-terminated if the value returned is *n*.

ERRORS

The *wcstombs*( ) function may fail if:

CX [EILSEQ] A wide-character code does not correspond to a valid character.

- The [EILSEQ] error condition is added.

The *wcstombs*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

wcstoul, wcstoull — convert a wide-character string to an unsigned long

SYNOPSIS

```
#include <wchar.h>

unsigned long wcstoul(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
unsigned long long wcstoull(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcstoul*( ) and *wcstoull*( ) functions shall convert the initial portion of the wide-character string pointed to by *nptr* to **unsigned long** and **unsigned long long** representation, respectively. First, they shall decompose the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by *iswspace*( ))
2. A subject sequence interpreted as an integer represented in some radix determined by the value of *base*
3. A final wide-character string of one or more unrecognized wide-character codes, including the terminating null wide-character code of the input wide-character string

Then they shall attempt to convert the subject sequence to an unsigned integer, and return the result.

If *base* is 0, the expected form of the subject sequence is that of a decimal constant, octal constant, or hexadecimal constant, any of which may be preceded by a `'+'` or `'−'` sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix `'0'` optionally followed by a sequence of the digits `'0'` to `'7'` only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters `'a'` (or `'A'`) to `'f'` (or `'F'`) with values 10 to 15 respectively.

If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by *base*, optionally preceded by a `'+'` or `'−'` sign, but not including an integer suffix. The letters from `'a'` (or `'A'`) to `'z'` (or `'Z'`) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of *base* shall be permitted. If the value of *base* is 16, the wide-character codes 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first wide-character code that is not white space and is of the expected form. The subject sequence contains no wide-character codes if the input wide-character string is empty or consists entirely of white-space wide-character codes, or if the first wide-character code that is not white space is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and *base* is 0, the sequence of wide-character codes starting with the first digit shall be interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it shall be used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion shall be negated. A pointer to the final wide-character string shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX In other than the C or POSIX locales, other implementation-defined subject sequences may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion shall be performed; the value of *nptr* shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX The *wcstoul*( ) function shall not change the setting of *errno* if successful.

Since 0, {ULONG_MAX}, and {ULLONG_MAX} are returned on error and 0 is also a valid return on success, an application wishing to check for error situations should set *errno* to 0, then call *wcstoul*( ) or *wcstoull*( ), then check *errno*.

RETURN VALUE

Upon successful completion, the *wcstoul*( ) and *wcstoull*( ) functions shall return the converted CX value, if any. If no conversion could be performed, 0 shall be returned and *errno* may be set to indicate the error. If the correct value is outside the range of representable values, {ULONG_MAX} or {ULLONG_MAX} respectively shall be returned and *errno* set to [ERANGE].

ERRORS

These functions shall fail if:

CX [EINVAL] The value of *base* is not supported.

[ERANGE] The value to be returned is not representable.

These functions may fail if:

CX [EINVAL] No conversion could be performed.

XSI

```
#include <wchar.h>

wchar_t *wcswcs(const wchar_t *ws1, const wchar_t *ws2);
```

DESCRIPTION

The *wcswcs*( ) function shall locate the first occurrence in the wide-character string pointed to by *ws1* of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by *ws2*.

RETURN VALUE

Upon successful completion, *wcswcs*( ) shall return a pointer to the located wide-character string or a null pointer if the wide-character string is not found.

If *ws2* points to a wide-character string with zero length, the function shall return *ws1*.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

This function was not included in the final ISO/IEC 9899:1990/Amendment 1:1995 (E). Application developers are strongly encouraged to use the *wcsstr*( ) function instead.

RATIONALE

None.

FUTURE DIRECTIONS

This function may be withdrawn in a future version.

Issue 6

This function is marked LEGACY.

NAME

wcswidth — number of column positions of a wide-character string

SYNOPSIS

XSI

```
#include <wchar.h>

int wcswidth(const wchar_t *pwcs, size_t n);
```

DESCRIPTION

The *wcswidth*( ) function shall determine the number of column positions required for *n* wide-character codes (or fewer than *n* wide-character codes if a null wide-character code is encountered before *n* wide-character codes are exhausted) in the string pointed to by *pwcs*.

RETURN VALUE

The *wcswidth*( ) function either shall return 0 (if *pwcs* points to a null wide-character code), or return the number of column positions to be occupied by the wide-character string pointed to by *pwcs*, or return –1 (if any of the first *n* wide-character codes in the wide-character string pointed to by *pwcs* is not a printable wide-character code).

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

This function was removed from the final ISO/IEC 9899:1990/Amendment 1:1995 (E), and the return value for a non-printable wide character is not specified.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 6

The Open Group Corrigendum U021/11 is applied. The function is marked as an extension.

NAME

wcsxfrm — wide-character string transformation

SYNOPSIS

```
#include <wchar.h>

size_t wcsxfrm(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wcsxfrm*( ) function shall transform the wide-character string pointed to by *ws2* and place the resulting wide-character string into the array pointed to by *ws1*. The transformation shall be such that if *wcscmp*( ) is applied to two transformed wide strings, it shall return a value greater than, equal to, or less than 0, corresponding to the result of *wcscoll*( ) applied to the same two original wide-character strings. No more than *n* wide-character codes shall be placed into the resulting array pointed to by *ws1*, including the terminating null wide-character code. If *n* is 0, *ws1* is permitted to be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.

CX The *wcsxfrm*( ) function shall not change the setting of *errno* if successful.

Since no return value is reserved to indicate an error, an application wishing to check for error situations should set *errno* to 0, then call *wcsxfrm*( ), then check *errno*.

RETURN VALUE

The *wcsxfrm*( ) function shall return the length of the transformed wide-character string (not including the terminating null wide-character code). If the value returned is *n* or more, the contents of the array pointed to by *ws1* are unspecified.

CX On error, the *wcsxfrm*( ) function may set *errno*, but no return value is reserved to indicate an error.

ERRORS

The *wcsxfrm*( ) function may fail if:

CX [EINVAL] The wide-character string pointed to by *ws2* contains wide-character codes outside the domain of the collating sequence.

EXAMPLES

None.

APPLICATION USAGE

The transformation function is such that two transformed wide-character strings can be ordered by *wcscmp*( ) as appropriate to collating sequence information in the program's locale (category *LC_COLLATE*).

The fact that when *n* is 0 *ws1* is permitted to be a null pointer is useful to determine the size of the *ws1* array prior to making the transformation.

RATIONALE

None.

FUTURE DIRECTIONS

None.

wcscmp( ), *wcscoll*( ), the Base Definitions volume of IEEE Std 1003.1-200x, **<wchar.h>**

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

Moved from ENHANCED I18N to BASE and the [ENOSYS] error is removed.

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

Issue 6

In previous versions, this function was required to return –1 on error.

Extensions beyond the ISO C standard are now marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The *wcsxfrm*( ) prototype is updated for alignment with the ISO / IEC 9899: 1999 standard.

NAME

wctob — wide-character to single-byte conversion

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

int wctob(wint_t c);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wctob*( ) function shall determine whether *c* corresponds to a member of the extended character set whose character representation is a single byte when in the initial shift state.

The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale.

RETURN VALUE

The *wctob*( ) function shall return EOF if *c* does not correspond to a character with length one in the initial shift state. Otherwise, it shall return the single-byte representation of that character as an **unsigned char** converted to **int**.

ERRORS

No errors are defined.

NAME

wctomb — convert a wide-character code to a character

SYNOPSIS

```
#include <stdlib.h>

int wctomb(char *s, wchar_t wchar);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wctomb*( ) function shall determine the number of bytes needed to represent the character corresponding to the wide-character code whose value is *wchar* (including any change in the shift state). It shall store the character representation (possibly multiple bytes and any special bytes to change shift state) in the array object pointed to by *s* (if *s* is not a null pointer). At most {MB_CUR_MAX} bytes shall be stored. If *wchar* is 0, a null byte shall be stored, preceded by any shift sequence needed to restore the initial shift state, and *wctomb*( ) shall be left in the initial shift state.

CX The behavior of this function is affected by the *LC_CTYPE* category of the current locale. For a state-dependent encoding, this function shall be placed into its initial state by a call for which its character pointer argument, *s*, is a null pointer. Subsequent calls with *s* as other than a null pointer shall cause the internal state of the function to be altered as necessary. A call with *s* as a null pointer shall cause this function to return a non-zero value if encodings have state dependency, and 0 otherwise. Changing the *LC_CTYPE* category causes the shift state of this function to be unspecified.

The *wctomb*( ) function need not be reentrant. A function that is not required to be reentrant is not required to be thread-safe.

The implementation shall behave as if no function defined in this volume of IEEE Std 1003.1-200x calls *wctomb*( ).

RETURN VALUE

If *s* is a null pointer, *wctomb*( ) shall return a non-zero or 0 value, if character encodings, respectively, do or do not have state-dependent encodings. If *s* is not a null pointer, *wctomb*( ) shall return −1 if the value of *wchar* does not correspond to a valid character, or return the number of bytes that constitute the character corresponding to the value of *wchar*.

In no case shall the value returned be greater than the value of the {MB_CUR_MAX} macro.

ERRORS

No errors are defined.

CHANGE HISTORY

First released in Issue 4. Derived from the ANSI C standard.

Issue 6

Extensions beyond the ISO C standard are now marked.

In the DESCRIPTION, a note about reentrancy and thread-safety is added.

NAME

wctrans — define character mapping

SYNOPSIS

```
#include <wctype.h>

wctrans_t wctrans(const char *charclass);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wctrans*( ) function is defined for valid character mapping names identified in the current locale. The *charclass* is a string identifying a generic character mapping name for which codeset-specific information is required. The following character mapping names are defined in all locales: **tolower** and **toupper**.

The function shall return a value of type **wctrans_t**, which can be used as the second argument to subsequent calls of *towctrans*( ). The *wctrans*( ) function shall determine values of **wctrans_t** according to the rules of the coded character set defined by character mapping information in the program's locale (category *LC_CTYPE*). The values returned by *wctrans*( ) shall be valid until a call to *setlocale*( ) that modifies the category *LC_CTYPE*.

RETURN VALUE

CX The *wctrans*( ) function shall return 0 and may set *errno* to indicate the error if the given character mapping name is not valid for the current locale (category *LC_CTYPE*); otherwise, it shall return a non-zero object of type **wctrans_t** that can be used in calls to *towctrans*( ).

ERRORS

The *wctrans*( ) function may fail if:

CX [EINVAL] The character mapping name pointed to by *charclass* is not valid in the current locale.

NAME

wctype — define character class

SYNOPSIS

```
#include <wctype.h>

wctype_t wctype(const char *property);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wctype*( ) function is defined for valid character class names as defined in the current locale. The *property* argument is a string identifying a generic character class for which codeset-specific type information is required. The following character class names shall be defined in all locales:

alnum	**digit**	**punct**
alpha	**graph**	**space**
blank	**lower**	**upper**
cntrl	**print**	**xdigit**

Additional character class names defined in the locale definition file (category *LC_CTYPE*) can also be specified.

The function shall return a value of type **wctype_t**, which can be used as the second argument to subsequent calls of *iswctype*( ). The *wctype*( ) function shall determine values of **wctype_t** according to the rules of the coded character set defined by character type information in the program's locale (category *LC_CTYPE*). The values returned by *wctype*( ) shall be valid until a call to *setlocale*( ) that modifies the category *LC_CTYPE*.

RETURN VALUE

The *wctype*( ) function shall return 0 if the given character class name is not valid for the current locale (category *LC_CTYPE*); otherwise, it shall return an object of type **wctype_t** that can be used in calls to *iswctype*( ).

ERRORS

No errors are defined.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The following change has been made in this issue for alignment with ISO / IEC 9899: 1990 / Amendment 1: 1995 (E):

- The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

NAME

wcwidth — number of column positions of a wide-character code

SYNOPSIS

XSI
```
#include <wchar.h>

int wcwidth(wchar_t wc);
```

DESCRIPTION

The *wcwidth*( ) function shall determine the number of column positions required for the wide character *wc*. The application shall ensure that the value of *wc* is a character representable as a **wchar_t**, and is a wide-character code corresponding to a valid character in the current locale.

RETURN VALUE

The *wcwidth*( ) function shall either return 0 (if *wc* is a null wide-character code), or return the number of column positions to be occupied by the wide-character code *wc*, or return −1 (if *wc* does not correspond to a printable wide-character code).

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

This function was removed from the final ISO/IEC 9899:1990/Amendment 1:1995 (E), and the return value for a non-printable wide character is not specified.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released as a World-wide Portability Interface in Issue 4. Derived from MSE working draft.

Issue 6

The Open Group Corrigendum U021/12 is applied. This function is marked as an extension.

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

NAME

wmemchr — find a wide character in memory

SYNOPSIS

```
#include <wchar.h>

wchar_t *wmemchr(const wchar_t *ws, wchar_t wc, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wmemchr*( ) function shall locate the first occurrence of *wc* in the initial *n* wide characters of the object pointed to by *ws*. This function shall not be affected by locale and all **wchar_t** values shall be treated identically. The null wide character and **wchar_t** values not corresponding to valid characters shall not be treated specially. |

If *n* is zero, the application shall ensure that *ws* is a valid pointer and the function behaves as if no valid occurrence of *wc* is found.

RETURN VALUE

The *wmemchr*( ) function shall return a pointer to the located wide character, or a null pointer if the wide character does not occur in the object.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

NAME

wmemcmp — compare wide characters in memory

SYNOPSIS

```
#include <wchar.h>

int wmemcmp(const wchar_t *ws1, const wchar_t *ws2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wmemcmp*( ) function shall compare the first *n* wide characters of the object pointed to by *ws1* to the first *n* wide characters of the object pointed to by *ws2*. This function shall not be affected by locale and all **wchar_t** values shall be treated identically. The null wide character and **wchar_t** values not corresponding to valid characters shall not be treated specially. |

If *n* is zero, the application shall ensure that *ws1* and *ws2* are valid pointers, and the function shall behave as if the two objects compare equal. |

RETURN VALUE

The *wmemcmp*( ) function shall return an integer greater than, equal to, or less than zero, respectively, as the object pointed to by *ws1* is greater than, equal to, or less than the object pointed to by *ws2*.

ERRORS

No errors are defined.

NAME

wmemmove — copy wide characters in memory with overlapping areas

SYNOPSIS

```
#include <wchar.h>

wchar_t *wmemmove(wchar_t *ws1, const wchar_t *ws2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of IEEE Std 1003.1-200x defers to the ISO C standard.

The *wmemmove*( ) function shall copy *n* wide characters from the object pointed to by *ws2* to the object pointed to by *ws1*. Copying shall take place as if the *n* wide characters from the object pointed to by *ws2* are first copied into a temporary array of *n* wide characters that does not overlap the objects pointed to by *ws1* or *ws2*, and then the *n* wide characters from the temporary array are copied into the object pointed to by *ws1*. |

This function shall not be affected by locale and all **wchar_t** values shall be treated identically. The null wide character and **wchar_t** values not corresponding to valid characters shall not be treated specially. |

If *n* is zero, the application shall ensure that *ws1* and *ws2* are valid pointers, and the function shall copy zero wide characters. |

RETURN VALUE

The *wmemmove*( ) function shall return the value of *ws1*.

NAME

wordexp, wordfree — perform word expansions

SYNOPSIS

```
#include <wordexp.h>

int wordexp(const char *restrict words, wordexp_t *restrict pwordexp,
    int flags);
void wordfree(wordexp_t *pwordexp);
```

DESCRIPTION

The *wordexp*( ) function shall perform word expansions as described in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.6, Word Expansions, subject to quoting as in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.2, Quoting, and place the list of expanded words into the structure pointed to by *pwordexp*.

The *words* argument is a pointer to a string containing one or more words to be expanded. The expansions shall be the same as would be performed by the command line interpreter if *words* were the part of a command line representing the arguments to a utility. Therefore, the application shall ensure that *words* does not contain an unquoted <newline> or any of the unquoted shell special characters '|', '&', ';', '<', '>' except in the context of command substitution as specified in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.6.3, Command Substitution. It also shall not contain unquoted parentheses or braces, except in the context of command or variable substitution. The application shall ensure that every member of *words* which it expects to have expanded by *wordexp*( ) does not contain an unquoted initial comment character. The application shall also ensure that any words which it intends to be ignored (because they begin or continue a comment) are deleted from *words*. If the argument *words* contains an unquoted comment character (number sign) that is the beginning of a token, *wordexp*( ) shall either treat the comment character as a regular character, or interpret it as a comment indicator and ignore the remainder of *words*.

The structure type **wordexp_t** is defined in the **<wordexp.h>** header and includes at least the following members:

Member Type	Member Name	Description
size_t	*we_wordc*	Count of words matched by *words*.
char **	*we_wordv*	Pointer to list of expanded words.
size_t	*we_offs*	Slots to reserve at the beginning of *pwordexp*->*we_wordv*.

The *wordexp*( ) function shall store the number of generated words into *pwordexp*->*we_wordc* and a pointer to a list of pointers to words in *pwordexp*->*we_wordv*. Each individual field created during field splitting (see the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.6.5, Field Splitting) or pathname expansion (see the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.6.6, Pathname Expansion) shall be a separate word in the *pwordexp*->*we_wordv* list. The words shall be in order as described in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.6, Word Expansions. The first pointer after the last word pointer shall be a null pointer. The expansion of special parameters described in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.5.2, Special Parameters is unspecified.

It is the caller's responsibility to allocate the storage pointed to by *pwordexp*. The *wordexp*( ) function shall allocate other space as needed, including memory pointed to by *pwordexp*->*we_wordv*. The *wordfree*( ) function frees any memory associated with *pwordexp* from a previous call to *wordexp*( ).

The *flags* argument is used to control the behavior of *wordexp*( ). The value of *flags* is the bitwise-inclusive OR of zero or more of the following constants, which are defined in **<wordexp.h>**:

WRDE_APPEND	Append words generated to the ones from a previous call to *wordexp*( ).
WRDE_DOOFFS	Make use of *pwordexp->we_offs*. If this flag is set, *pwordexp->we_offs* is used to specify how many null pointers to add to the beginning of *pwordexp->we_wordv*. In other words, *pwordexp->we_wordv* shall point to *pwordexp->we_offs* null pointers, followed by *pwordexp->we_wordc* word pointers, followed by a null pointer.
WRDE_NOCMD	If the implementation supports the utilities defined in the Shell and Utilities volume of IEEE Std 1003.1-200x, fail if command substitution, as specified in the Shell and Utilities volume of IEEE Std 1003.1-200x, Section 2.6.3, Command Substitution, is requested.
WRDE_REUSE	The *pwordexp* argument was passed to a previous successful call to *wordexp*( ), and has not been passed to *wordfree*( ). The result shall be the same as if the application had called *wordfree*( ) and then called *wordexp*( ) without WRDE_REUSE.
WRDE_SHOWERR	Do not redirect *stderr* to **/dev/null**.
WRDE_UNDEF	Report error on an attempt to expand an undefined shell variable.

The WRDE_APPEND flag can be used to append a new set of words to those generated by a previous call to *wordexp*( ). The following rules apply to applications when two or more calls to *wordexp*( ) are made with the same value of *pwordexp* and without intervening calls to *wordfree*( ):

1. The first such call shall not set WRDE_APPEND. All subsequent calls shall set it.
2. All of the calls shall set WRDE_DOOFFS, or all shall not set it.
3. After the second and each subsequent call, *pwordexp->we_wordv* shall point to a list containing the following:
   a. Zero or more null pointers, as specified by WRDE_DOOFFS and *pwordexp->we_offs*
   b. Pointers to the words that were in the *pwordexp->we_wordv* list before the call, in the same order as before
   c. Pointers to the new words generated by the latest call, in the specified order
4. The count returned in *pwordexp->we_wordc* shall be the total number of words from all of the calls.
5. The application can change any of the fields after a call to *wordexp*( ), but if it does it shall reset them to the original value before a subsequent call, using the same *pwordexp* value, to *wordfree*( ) or *wordexp*( ) with the WRDE_APPEND or WRDE_REUSE flag.

If the implementation supports the utilities defined in the Shell and Utilities volume of IEEE Std 1003.1-200x, and *words* contains an unquoted character—<newline>, '|', '&', ';', '<', '>', '(', ')', '{', '}'—in an inappropriate context, *wordexp*( ) shall fail, and the number of expanded words shall be 0.

Unless WRDE_SHOWERR is set in *flags*, *wordexp*( ) shall redirect *stderr* to **/dev/null** for any utilities executed as a result of command substitution while expanding *words*. If WRDE_SHOWERR is set, *wordexp*( ) may write messages to *stderr* if syntax errors are detected while expanding *words*.

The application shall ensure that if WRDE_DOOFFS is set, then *pwordexp*->*we_offs* has the same value for each *wordexp*( ) call and *wordfree*( ) call using a given *pwordexp*.

The following constants are defined as error return values:

WRDE_BADCHAR	One of the unquoted characters—<newline>, '|', '&', ';', '<', '>', '(', ')', '{', '}'—appears in *words* in an inappropriate context.
WRDE_BADVAL	Reference to undefined shell variable when WRDE_UNDEF is set in *flags*.
WRDE_CMDSUB	Command substitution requested when WRDE_NOCMD was set in flags.
WRDE_NOSPACE	Attempt to allocate memory failed.
WRDE_SYNTAX	Shell syntax error, such as unbalanced parentheses or unterminated string.

RETURN VALUE

Upon successful completion, *wordexp*( ) shall return 0. Otherwise, a non-zero value, as described in **<wordexp.h>**, shall be returned to indicate an error. If *wordexp*( ) returns the value WRDE_NOSPACE, then *pwordexp*->*we_wordc* and *pwordexp*->*we_wordv* shall be updated to reflect any words that were successfully expanded. In other cases, they shall not be modified.

The *wordfree*( ) function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The *wordexp*( ) function is intended to be used by an application that wants to do all of the shell's expansions on a word or words obtained from a user. For example, if the application prompts for a filename (or list of filenames) and then uses *wordexp*( ) to process the input, the user could respond with anything that would be valid as input to the shell.

The WRDE_NOCMD flag is provided for applications that, for security or other reasons, want to prevent a user from executing shell commands. Disallowing unquoted shell special characters also prevents unwanted side effects, such as executing a command or writing a file.

RATIONALE

This function was included as an alternative to *glob*( ). There had been continuing controversy over exactly what features should be included in *glob*( ). It is hoped that by providing *wordexp*( ) (which provides all of the shell word expansions, but which may be slow to execute) and *glob*( ) (which is faster, but which only performs pathname expansion, without tilde or parameter expansion) this will satisfy the majority of applications.

While *wordexp*( ) could be implemented entirely as a library routine, it is expected that most implementations run a shell in a subprocess to do the expansion.

Two different approaches have been proposed for how the required information might be presented to the shell and the results returned. They are presented here as examples.

One proposal is to extend the *echo* utility by adding a **−q** option. This option would cause *echo* to add a backslash before each backslash and <blank> that occurs within an argument. The *wordexp*( ) function could then invoke the shell as follows:

```
(void) strcpy(buffer, "echo -q");
(void) strcat(buffer, words);
if ((flags & WRDE_SHOWERR) == 0)
```

```
        (void) strcat(buffer, "2>/dev/null");
    f = popen(buffer, "r");
```

The *wordexp*( ) function would read the resulting output, remove unquoted backslashes, and break into words at unquoted <blank>s. If the WRDE_NOCMD flag was set, *wordexp*( ) would have to scan *words* before starting the subshell to make sure that there would be no command substitution. In any case, it would have to scan *words* for unquoted special characters.

Another proposal is to add the following options to *sh*:

−w *wordlist*
This option provides a wordlist expansion service to applications. The words in *wordlist* shall be expanded and the following written to standard output:

1. The count of the number of words after expansion, in decimal, followed by a null byte
2. The number of bytes needed to represent the expanded words (not including null separators), in decimal, followed by a null byte
3. The expanded words, each terminated by a null byte

If an error is encountered during word expansion, *sh* exits with a non-zero status after writing the former to report any words successfully expanded

−P Run in ‘‘protected’’ mode. If specified with the −**w** option, no command substitution shall be performed.

With these options, *wordexp*( ) could be implemented fairly simply by creating a subprocess using *fork*( ) and executing *sh* using the line:

```
execl(<shell path>, "sh", "-P", "-w", words, (char *)0);
```

after directing standard error to **/dev/null**.

It seemed objectionable for a library routine to write messages to standard error, unless explicitly requested, so *wordexp*( ) is required to redirect standard error to **/dev/null** to ensure that no messages are generated, even for commands executed for command substitution. The WRDE_SHOWERR flag can be specified to request that error messages be written.

The WRDE_REUSE flag allows the implementation to avoid the expense of freeing and reallocating memory, if that is possible. A minimal implementation can call *wordfree*( ) when WRDE_REUSE is set.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4. Derived from the ISO POSIX-2 standard.

Issue 5

Moved from POSIX2 C-language Binding to BASE.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The **restrict** keyword is added to the *wordexp*( ) prototype for alignment with the ISO/IEC 9899:1999 standard.

NAME

wprintf — print formatted wide-character output

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

int wprintf(const wchar_t *restrict format, ...);
```

DESCRIPTION

Refer to *fwprintf*( ).

NAME

pwrite, write — write on a file

SYNOPSIS

```
#include <unistd.h>

XSI ssize_t pwrite(int fildes, const void *buf, size_t nbyte,
        off_t offset);
    ssize_t write(int fildes, const void *buf, size_t nbyte);
```

DESCRIPTION

The *write*( ) function shall attempt to write *nbyte* bytes from the buffer pointed to by *buf* to the file associated with the open file descriptor, *fildes*.

Before any action described below is taken, and if *nbyte* is zero and the file is a regular file, the *write*( ) function may detect and return errors as described below. In the absence of errors, or if error detection is not performed, the *write*( ) function shall return zero and have no other results. If *nbyte* is zero and the file is not a regular file, the results are unspecified.

On a regular file or other file capable of seeking, the actual writing of data shall proceed from the position in the file indicated by the file offset associated with *fildes*. Before successful return from *write*( ), the file offset shall be incremented by the number of bytes actually written. On a regular file, if this incremented file offset is greater than the length of the file, the length of the file shall be set to this file offset.

On a file not capable of seeking, writing shall always take place starting at the current position. The value of a file offset associated with such a device is undefined.

If the O_APPEND flag of the file status flags is set, the file offset shall be set to the end of the file prior to each write and no intervening file modification operation shall occur between changing the file offset and the write operation.

XSI If a *write*( ) requests that more bytes be written than there is room for (for example, the process' file size limit or the physical end of a medium), only as many bytes as there is room for shall be written. For example, suppose there is space for 20 bytes more in a file before reaching a limit. A write of 512 bytes will return 20. The next write of a non-zero number of bytes would give a failure return (except as noted below).

XSI If the request would cause the file size to exceed the soft file size limit for the process and there is no room for any bytes to be written, the request shall fail and the implementation shall generate the SIGXFSZ signal for the thread.

If *write*( ) is interrupted by a signal before it writes any data, it shall return −1 with *errno* set to [EINTR].

If *write*( ) is interrupted by a signal after it successfully writes some data, it shall return the number of bytes written.

If the value of *nbyte* is greater than {SSIZE_MAX}, the result is implementation-defined.

After a *write*( ) to a regular file has successfully returned:

- Any successful *read*( ) from each byte position in the file that was modified by that write shall return the data specified by the *write*( ) for that position until such byte positions are again modified.

- Any subsequent successful *write*( ) to the same byte position in the file shall overwrite that file data.

Write requests to a pipe or FIFO shall be handled in the same way as a regular file with the following exceptions:

- There is no file offset associated with a pipe, hence each write request shall append to the end of the pipe.
- Write requests of {PIPE_BUF} bytes or less shall not be interleaved with data from other processes doing writes on the same pipe. Writes of greater than {PIPE_BUF} bytes may have data interleaved, on arbitrary boundaries, with writes by other processes, whether or not the O_NONBLOCK flag of the file status flags is set.
- If the O_NONBLOCK flag is clear, a write request may cause the thread to block, but on normal completion it shall return *nbyte*.
- If the O_NONBLOCK flag is set, *write*( ) requests shall be handled differently, in the following ways:
  - — The *write*( ) function shall not block the thread.
  - — A write request for {PIPE_BUF} or fewer bytes shall have the following effect: if there is sufficient space available in the pipe, *write*( ) shall transfer all the data and return the number of bytes requested. Otherwise, *write*( ) shall transfer no data and return –1 with *errno* set to [EAGAIN].
  - — A write request for more than {PIPE_BUF} bytes shall cause one of the following:
    - — When at least one byte can be written, transfer what it can and return the number of bytes written. When all data previously written to the pipe is read, it shall transfer at least {PIPE_BUF} bytes.
    - — When no data can be written, transfer no data, and return –1 with *errno* set to [EAGAIN].

When attempting to write to a file descriptor (other than a pipe or FIFO) that supports non-blocking writes and cannot accept the data immediately:

- If the O_NONBLOCK flag is clear, *write*( ) shall block the calling thread until the data can be accepted.
- If the O_NONBLOCK flag is set, *write*( ) shall not block the thread. If some data can be written without blocking the thread, *write*( ) shall write what it can and return the number of bytes written. Otherwise, it shall return –1 and set *errno* to [EAGAIN].

Upon successful completion, where *nbyte* is greater than 0, *write*( ) shall mark for update the *st_ctime* and *st_mtime* fields of the file, and if the file is a regular file, the S_ISUID and S_ISGID bits of the file mode may be cleared.

For regular files, no data transfer shall occur past the offset maximum established in the open file description associated with *fildes*.

If *fildes* refers to a socket, *write*( ) shall be equivalent to *send*( ) with no flags set.

SIO If the O_DSYNC bit has been set, write I/O operations on the file descriptor shall complete as defined by synchronized I/O data integrity completion.

If the O_SYNC bit has been set, write I/O operations on the file descriptor shall complete as defined by synchronized I/O file integrity completion.

SHM If *fildes* refers to a shared memory object, the result of the *write*( ) function is unspecified.

TYM If *fildes* refers to a typed memory object, the result of the *write*( ) function is unspecified.

XSR If *fildes* refers to a STREAM, the operation of *write*( ) shall be determined by the values of the minimum and maximum *nbyte* range (packet size) accepted by the STREAM. These values are determined by the topmost STREAM module. If *nbyte* falls within the packet size range, *nbyte* bytes shall be written. If *nbyte* does not fall within the range and the minimum packet size value is 0, *write*( ) shall break the buffer into maximum packet size segments prior to sending the data downstream (the last segment may contain less than the maximum packet size). If *nbyte* does not fall within the range and the minimum value is non-zero, *write*( ) shall fail with *errno* set to [ERANGE]. Writing a zero-length buffer (*nbyte* is 0) to a STREAMS device sends 0 bytes with 0 returned. However, writing a zero-length buffer to a STREAMS-based pipe or FIFO sends no message and 0 is returned. The process may issue I_SWROPT *ioctl*( ) to enable zero-length messages to be sent across the pipe or FIFO.

When writing to a STREAM, data messages are created with a priority band of 0. When writing to a STREAM that is not a pipe or FIFO:

- If O_NONBLOCK is clear, and the STREAM cannot accept data (the STREAM write queue is full due to internal flow control conditions), *write*( ) shall block until data can be accepted.
- If O_NONBLOCK is set and the STREAM cannot accept data, *write*( ) shall return −1 and set *errno* to [EAGAIN].
- If O_NONBLOCK is set and part of the buffer has been written while a condition in which the STREAM cannot accept additional data occurs, *write*( ) shall terminate and return the number of bytes written.

In addition, *write*( ) shall fail if the STREAM head has processed an asynchronous error before the call. In this case, the value of *errno* does not reflect the result of *write*( ), but reflects the prior error.

XSI The *pwrite*( ) function shall be equivalent to *write*( ), except that it writes into a given position without changing the file pointer. The first three arguments to *pwrite*( ) are the same as *write*( ) with the addition of a fourth argument offset for the desired position inside the file.

RETURN VALUE

XSI Upon successful completion, *write*( ) and *pwrite*( ) shall return the number of bytes actually written to the file associated with *fildes*. This number shall never be greater than *nbyte*. Otherwise, −1 shall be returned and *errno* set to indicate the error.

ERRORS

XSI The *write*( ) and *pwrite*( ) functions shall fail if:

[EAGAIN]	The O_NONBLOCK flag is set for the file descriptor and the thread would be delayed in the *write*( ) operation.
[EBADF]	The *fildes* argument is not a valid file descriptor open for writing.
[EFBIG]	An attempt was made to write a file that exceeds the implementation-defined maximum file size XSI or the process' file size limit, and there was no room for any bytes to be written.
[EFBIG]	The file is a regular file, *nbyte* is greater than 0, and the starting position is greater than or equal to the offset maximum established in the open file description associated with *fildes*.
[EINTR]	The write operation was terminated due to the receipt of a signal, and no data was transferred.
[EIO]	The process is a member of a background process group attempting to write to its controlling terminal, TOSTOP is set, the process is neither ignoring nor

	blocking SIGTTOU, and the process group of the process is orphaned. This error may also be returned under implementation-defined conditions.
[ENOSPC]	There was no free space remaining on the device containing the file.
[EPIPE]	An attempt is made to write to a pipe or FIFO that is not open for reading by any process, or that only has one end open. A SIGPIPE signal shall also be sent to the thread.
XSR [ERANGE]	The transfer request size was outside the range supported by the STREAMS file associated with *fildes*.

The *write*( ) function shall fail if:

[EAGAIN] or [EWOULDBLOCK]	The file descriptor is for a socket, is marked O_NONBLOCK, and write would block.
[ECONNRESET]	A write was attempted on a socket that is not connected.
[EPIPE]	A write was attempted on a socket that is shut down for writing, or is no longer connected. In the latter case, if the socket is of type SOCK_STREAM, the SIGPIPE signal is generated to the calling process.

XSI The *write*( ) and *pwrite*( ) functions may fail if:

XSR [EINVAL]	The STREAM or multiplexer referenced by *fildes* is linked (directly or indirectly) downstream from a multiplexer.
[EIO]	A physical I/O error has occurred.
[ENOBUFS]	Insufficient resources were available in the system to perform the operation.
[ENXIO]	A request was made of a nonexistent device, or the request was outside the capabilities of the device.
XSR [ENXIO]	A hangup occurred on the STREAM being written to.

XSR A write to a STREAMS file may fail if an error message has been received at the STREAM head. In this case, *errno* is set to the value included in the error message.

The *write*( ) function may fail if:

[EACCES]	A write was attempted on a socket and the calling process does not have appropriate privileges.
[ENETDOWN]	A write was attempted on a socket and the local network interface used to reach the destination is down.
[ENETUNREACH]	A write was attempted on a socket and no route to the network is present.

XSI The *pwrite*( ) function shall fail and the file pointer remain unchanged if:

XSI [EINVAL]	The *offset* argument is invalid. The value is negative.
XSI [ESPIPE]	*fildes* is associated with a pipe or FIFO.

EXAMPLES

Writing from a Buffer

The following example writes data from the buffer pointed to by *buf* to the file associated with the file descriptor *fd*.

```
#include <sys/types.h>
#include <string.h>
...
char buf[20];
size_t nbytes;
ssize_t bytes_written;
int fd;
...
strcpy(buf, "This is a test\n");
nbytes = strlen(buf);

bytes_written = write(fd, buf, nbytes);
...
```

APPLICATION USAGE

None.

RATIONALE

See also the RATIONALE section in *read*( ).

An attempt to write to a pipe or FIFO has several major characteristics:

- *Atomic/non-atomic*: A write is atomic if the whole amount written in one operation is not interleaved with data from any other process. This is useful when there are multiple writers sending data to a single reader. Applications need to know how large a write request can be expected to be performed atomically. This maximum is called {PIPE_BUF}. This volume of IEEE Std 1003.1-200x does not say whether write requests for more than {PIPE_BUF} bytes are atomic, but requires that writes of {PIPE_BUF} or fewer bytes shall be atomic.

- *Blocking/immediate*: Blocking is only possible with O_NONBLOCK clear. If there is enough space for all the data requested to be written immediately, the implementation should do so. Otherwise, the process may block; that is, pause until enough space is available for writing. The effective size of a pipe or FIFO (the maximum amount that can be written in one operation without blocking) may vary dynamically, depending on the implementation, so it is not possible to specify a fixed value for it.

- *Complete/partial/deferred*: A write request:

  ```
  int fildes;
  size_t nbyte;
  ssize_t ret;
  char *buf;

  ret = write(fildes, buf, nbyte);
  ```

  may return:

complete	$\mathit{ret}=\mathit{nbyte}$
partial	$\mathit{ret}<\mathit{nbyte}$ This shall never happen if $\mathit{nbyte}\leq$ {PIPE_BUF}. If it does happen (with $\mathit{nbyte}>$ {PIPE_BUF}), this volume of IEEE Std 1003.1-200x does not guarantee

atomicity, even if *ret*≤{PIPE_BUF}, because atomicity is guaranteed according to the amount *requested*, not the amount *written*.

deferred: *ret*=−1, *errno*=[EAGAIN]

This error indicates that a later request may succeed. It does not indicate that it *shall* succeed, even if *nbyte*≤{PIPE_BUF}, because if no process reads from the pipe or FIFO, the write never succeeds. An application could usefully count the number of times [EAGAIN] is caused by a particular value of *nbyte*>{PIPE_BUF} and perhaps do later writes with a smaller value, on the assumption that the effective size of the pipe may have decreased.

Partial and deferred writes are only possible with O_NONBLOCK set.

The relations of these properties are shown in the following tables:

Write to a Pipe or FIFO with O_NONBLOCK *clear*

Immediately Writable:	**None**	**Some**	*nbyte*
nbyte≤{PIPE_BUF}	Atomic blocking *nbyte*	Atomic blocking *nbyte*	Atomic immediate *nbyte*
nbyte>{PIPE_BUF}	Blocking *nbyte*	Blocking *nbyte*	Blocking *nbyte*

If the O_NONBLOCK flag is clear, a write request shall block if the amount writable immediately is less than that requested. If the flag is set (by *fcntl*( )), a write request shall never block.

Write to a Pipe or FIFO with O_NONBLOCK *set*

Immediately Writable:	**None**	**Some**	*nbyte*
nbyte≤{PIPE_BUF}	−1, [EAGAIN]	−1, [EAGAIN]	Atomic *nbyte*
nbyte>{PIPE_BUF}	−1, [EAGAIN]	<*nbyte* or −1, [EAGAIN]	≤*nbyte* or −1, [EAGAIN]

There is no exception regarding partial writes when O_NONBLOCK is set. With the exception of writing to an empty pipe, this volume of IEEE Std 1003.1-200x does not specify exactly when a partial write is performed since that would require specifying internal details of the implementation. Every application should be prepared to handle partial writes when O_NONBLOCK is set and the requested amount is greater than {PIPE_BUF}, just as every application should be prepared to handle partial writes on other kinds of file descriptors.

The intent of forcing writing at least one byte if any can be written is to assure that each write makes progress if there is any room in the pipe. If the pipe is empty, {PIPE_BUF} bytes must be written; if not, at least some progress must have been made.

Where this volume of IEEE Std 1003.1-200x requires −1 to be returned and *errno* set to [EAGAIN], most historical implementations return zero (with the O_NDELAY flag set, which is the historical predecessor of O_NONBLOCK, but is not itself in this volume of IEEE Std 1003.1-200x). The error indications in this volume of IEEE Std 1003.1-200x were chosen so that an application can distinguish these cases from end-of-file. While *write*( ) cannot receive an indication of end-of-file, *read*( ) can, and the two functions have similar return values. Also, some existing systems (for example, Eighth Edition) permit a write of zero bytes to mean that the reader should get an end-of-file indication; for those systems, a return value of zero from *write*( ) indicates a successful write of an end-of-file indication.

Implementations are allowed, but not required, to perform error checking for *write*( ) requests of zero bytes.

The concept of a {PIPE_MAX} limit (indicating the maximum number of bytes that can be written to a pipe in a single operation) was considered, but rejected, because this concept would unnecessarily limit application writing.

See also the discussion of O_NONBLOCK in *read*( ).

Writes can be serialized with respect to other reads and writes. If a *read*( ) of file data can be proven (by any means) to occur after a *write*( ) of the data, it must reflect that *write*( ), even if the calls are made by different processes. A similar requirement applies to multiple write operations to the same file position. This is needed to guarantee the propagation of data from *write*( ) calls to subsequent *read*( ) calls. This requirement is particularly significant for networked file systems, where some caching schemes violate these semantics.

Note that this is specified in terms of *read*( ) and *write*( ). The XSI extensions *readv*( ) and *writev*( ) also obey these semantics. A new ''high-performance'' write analog that did not follow these serialization requirements would also be permitted by this wording. This volume of IEEE Std 1003.1-200x is also silent about any effects of application-level caching (such as that done by *stdio*).

This volume of IEEE Std 1003.1-200x does not specify the value of the file offset after an error is returned; there are too many cases. For programming errors, such as [EBADF], the concept is meaningless since no file is involved. For errors that are detected immediately, such as [EAGAIN], clearly the pointer should not change. After an interrupt or hardware error, however, an updated value would be very useful and is the behavior of many implementations.

This volume of IEEE Std 1003.1-200x does not specify behavior of concurrent writes to a file from multiple processes. Applications should use some form of concurrency control.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Large File Summit extensions are added.

The *pwrite*( ) function is added.

Issue 6

The DESCRIPTION states that the *write*( ) function does not block the thread. Previously this said ''process'' rather than ''thread''.

The DESCRIPTION and ERRORS sections are updated so that references to STREAMS are marked as part of the XSI STREAMS Option Group.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION now states that if *write*( ) is interrupted by a signal after it has successfully written some data, it returns the number of bytes written. In earlier versions of this volume of IEEE Std 1003.1-200x, it was optional whether *write*( ) returned the number of bytes written, or whether it returned –1 with *errno* set to [EINTR]. This is a FIPS requirement.
- The following changes are made to support large files:
  - — For regular files, no data transfer occurs past the offset maximum established in the open file description associated with the *fildes*.
  - — A second [EFBIG] error condition is added.
- The [EIO] error condition is added.
- The [EPIPE] error condition is added for when a pipe has only one end open.
- The [ENXIO] optional error condition is added.

Text referring to sockets is added to the DESCRIPTION.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The effect of reading zero bytes is clarified.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that *write*( ) results are unspecified for typed memory objects.

The following error conditions are added for operations on sockets: [EAGAIN], [EWOULDBLOCK], [ECONNRESET], [ENOTCONN], and [EPIPE].

The [EIO] error is changed to ''may fail''.

The [ENOBUFS] error is added for sockets.

The following error conditions are added for operations on sockets: [EACCES], [ENETDOWN], and [ENETUNREACH].

The *writev*( ) function is split out into a separate reference page.

NAME

writev — write a vector

SYNOPSIS

XSI

```
#include <sys/uio.h>

ssize_t writev(int fildes, const struct iovec *iov, int iovcnt);
```

DESCRIPTION

The *writev*( ) function shall be equivalent to *write*( ), except as described below. The *writev*( ) function shall gather output data from the *iovcnt* buffers specified by the members of the *iov* array: *iov*[0], *iov*[1], . . ., *iov*[*iovcnt*–1]. The *iovcnt* argument is valid if greater than 0 and less than or equal to {IOV_MAX}, defined in **<limits.h>**.

Each *iovec* entry specifies the base address and length of an area in memory from which data should be written. The *writev*( ) function shall always write a complete area before proceeding to the next.

If *fildes* refers to a regular file and all of the *iov_len* members in the array pointed to by *iov* are 0, *writev*( ) shall return 0 and have no other effect. For other file types, the behavior is unspecified.

If the sum of the *iov_len* values is greater than {SSIZE_MAX}, the operation shall fail and no data shall be transferred.

RETURN VALUE

Upon successful completion, *writev*( ) shall return the number of bytes actually written. Otherwise, it shall return a value of –1, the file-pointer shall remain unchanged, and *errno* shall be set to indicate an error.

ERRORS

Refer to *write*( ).

In addition, the *writev*( ) function shall fail if:

[EINVAL] The sum of the *iov_len* values in the *iov* array would overflow an **ssize_t**.

The *writev*( ) function may fail and set *errno* to:

[EINVAL] The *iovcnt* argument was less than or equal to 0, or greater than {IOV_MAX}.

EXAMPLES

Writing Data from an Array

The following example writes data from the buffers specified by members of the *iov* array to the file associated with the file descriptor *fd*.

```
#include <sys/types.h>
#include <sys/uio.h>
#include <unistd.h>
...
ssize_t bytes_written;
int fd;
char *buf0 = "short string\n";
char *buf1 = "This is a longer string\n";
char *buf2 = "This is the longest string in this example\n";
int iovcnt;
struct iovec iov[3];
```

```
        iov[0].iov_base = buf0;
        iov[0].iov_len = strlen(buf0);
        iov[1].iov_base = buf1;
        iov[1].iov_len = strlen(buf1);
        iov[2].iov_base = buf2;
        iov[2].iov_len = strlen(buf2);
        ...
        iovcnt = sizeof(iov) / sizeof(struct iovec);

        bytes_written = writev(fd, iov, iovcnt);
        ...
```

CHANGE HISTORY

First released in Issue 4, Version 2.

Issue 6

Split out from the *write*( ) reference page.

NAME

wscanf — convert formatted wide-character input

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

int wscanf(const wchar_t *restrict format, ... );
```

DESCRIPTION

Refer to *fwscanf*( ).

NAME

y0, y1, yn — Bessel functions of the second kind

SYNOPSIS

XSI

```
#include <math.h>

double y0(double x);
double y1(double x);
double yn(int n, double x);
```

DESCRIPTION

The *y0*( ), *y1*( ), and *yn*( ) functions shall compute Bessel functions of *x* of the second kind of orders 0, 1, and *n*, respectively.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the relevant Bessel value of *x* of the second kind.

If *x* is NaN, NaN shall be returned.

If the *x* argument to these functions is negative, −HUGE_VAL or NaN shall be returned, and a domain error may occur.

If *x* is 0.0, −HUGE_VAL shall be returned and a range error may occur.

If the correct result would cause underflow, 0.0 shall be returned and a range error may occur.

If the correct result would cause overflow, −HUGE_VAL or 0.0 shall be returned and a range error may occur.

ERRORS

These functions may fail if:

Domain Error — The value of *x* is negative.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

Range Error — The value of *x* is 0.0, or the correct result would cause overflow.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

Range Error — The value of *x* is too large in magnitude, or the correct result would cause underflow.

If the integer expression (math_errhandling & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (math_errhandling & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (math_errhandling & MATH_ERRNO) and (math_errhandling & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6

The DESCRIPTION is updated to avoid use of the term ‘‘must’’ for application requirements.

The RETURN VALUE and ERRORS sections are reworked for alignment of the error handling with the ISO/IEC 9899:1999 standard.

Index

Chapter 1

Introduction

1.1 Scope

The scope of IEEE Std 1003.1-200x is described in the Base Definitions volume of IEEE Std 1003.1-200x.

1.2 Conformance

Conformance requirements for IEEE Std 1003.1-200x are defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 2, Conformance.

1.3 Normative References

Normative references for IEEE Std 1003.1-200x are defined in the Base Definitions volume of IEEE Std 1003.1-200x.

1.4 Change History

Change history is described in the Rationale (Informative) volume of IEEE Std 1003.1-200x, and in the CHANGE HISTORY section of reference pages.

1.5 Terminology

This section appears in the Base Definitions volume of IEEE Std 1003.1-200x, but is repeated here for convenience:

For the purposes of IEEE Std 1003.1-200x, the following terminology definitions apply:

can

Describes a permissible optional feature or behavior available to the user or application. The feature or behavior is mandatory for an implementation that conforms to IEEE Std 1003.1-200x. An application can rely on the existence of the feature or behavior.

implementation-defined

Describes a value or behavior that is not defined by IEEE Std 1003.1-200x but is selected by an implementor. The value or behavior may vary among implementations that conform to IEEE Std 1003.1-200x. An application should not rely on the existence of the value or behavior. An application that relies on such a value or behavior cannot be assured to be portable across conforming implementations.

The implementor shall document such a value or behavior so that it can be used correctly by an application.

legacy

Describes a feature or behavior that is being retained for compatibility with older applications, but which has limitations which make it inappropriate for developing portable applications. New applications should use alternative means of obtaining equivalent functionality.

may

Describes a feature or behavior that is optional for an implementation that conforms to IEEE Std 1003.1-200x. An application should not rely on the existence of the feature or behavior. An application that relies on such a feature or behavior cannot be assured to be portable across conforming implementations.

To avoid ambiguity, the opposite of *may* is expressed as *need not*, instead of *may not*.

shall

For an implementation that conforms to IEEE Std 1003.1-200x, describes a feature or behavior that is mandatory. An application can rely on the existence of the feature or behavior.

For an application or user, describes a behavior that is mandatory.

should

For an implementation that conforms to IEEE Std 1003.1-200x, describes a feature or behavior that is recommended but not mandatory. An application should not rely on the existence of the feature or behavior. An application that relies on such a feature or behavior cannot be assured to be portable across conforming implementations.

For an application, describes a feature or behavior that is recommended programming practice for optimum portability.

undefined

Describes the nature of a value or behavior not defined by IEEE Std 1003.1-200x which results from use of an invalid program construct or invalid data input.

The value or behavior may vary among implementations that conform to IEEE Std 1003.1-200x. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.

unspecified

Describes the nature of a value or behavior not specified by IEEE Std 1003.1-200x which results from use of a valid program construct or valid data input.

The value or behavior may vary among implementations that conform to IEEE Std 1003.1-200x. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.

1.6 Definitions

Concepts and definitions are defined in the Base Definitions volume of IEEE Std 1003.1-200x.

1.7 Relationship to Other Documents

1.7.1 System Interfaces

This subsection describes some of the features provided by the System Interfaces volume of IEEE Std 1003.1-200x that are assumed to be globally available by all systems conforming to this volume of IEEE Std 1003.1-200x. This subsection does not attempt to detail all of the features defined in the System Interfaces volume of IEEE Std 1003.1-200x that are required by all of the utilities defined in this volume of IEEE Std 1003.1-200x; the utility and function descriptions point out additional functionality required to provide the corresponding specific features needed by each.

The following subsections describe frequently used concepts. Many of these concepts are described in the Base Definitions volume of IEEE Std 1003.1-200x. Utility and function description statements override these defaults when appropriate.

1.7.1.1 Process Attributes

The following process attributes, as described in the System Interfaces volume of IEEE Std 1003.1-200x, are assumed to be supported for all processes in this volume of IEEE Std 1003.1-200x:

Controlling Terminal
Current Working Directory
Effective Group ID
Effective User ID
File Descriptors
File Mode Creation Mask
Process Group ID
Process ID
Real Group ID
Real User ID
Root Directory
Saved Set-Group-ID
Saved Set-User-ID
Session Membership
Supplementary Group IDs

A conforming implementation may include additional process attributes.

1.7.1.2 Concurrent Execution of Processes

The following functionality of the *fork*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x shall be available on all systems conforming to this volume of IEEE Std 1003.1-200x:

1. Independent processes shall be capable of executing independently without either process terminating.

2. A process shall be able to create a new process with all of the attributes referenced in Section 1.7.1.1, determined according to the semantics of a call to the *fork*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x followed by a call in the child process to one of the *exec* functions defined in the System Interfaces volume of IEEE Std 1003.1-200x.

1.7.1.3 *File Access Permissions*

The file access control mechanism described by the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.4, File Access Permissions shall apply to all files on an implementation conforming to this volume of IEEE Std 1003.1-200x.

1.7.1.4 *File Read, Write, and Creation*

If a file that does not exist is to be written, it shall be created as described below, unless the utility description states otherwise.

When a file that does not exist is created, the following features defined in the System Interfaces volume of IEEE Std 1003.1-200x shall apply unless the utility or function description states otherwise:

1. The user ID of the file shall be set to the effective user ID of the calling process.
2. The group ID of the file shall be set to the effective group ID of the calling process or the group ID of the directory in which the file is being created.
3. If the file is a regular file, the permission bits of the file shall be set to:

   S_IROTH | S_IWOTH | S_IRGRP | S_IWGRP | S_IRUSR | S_IWUSR

   (see the description of *File Modes* in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers, **<sys/stat.h>**) except that the bits specified by the file mode creation mask of the process shall be cleared. If the file is a directory, the permission bits shall be set to:

   S_IRWXU | S_IRWXG | S_IRWXO

   except that the bits specified by the file mode creation mask of the process shall be cleared.
4. The *st_atime*, *st_ctime*, and *st_mtime* fields of the file shall be updated as specified in the System Interfaces volume of IEEE Std 1003.1-200x, Section 2.5, Standard I/O Streams.
5. If the file is a directory, it shall be an empty directory; otherwise, the file shall have length zero.
6. If the file is a symbolic link, the effect shall be undefined unless the {POSIX2_SYMLINKS} variable is in effect for the directory in which the symbolic link would be created.
7. Unless otherwise specified, the file created shall be a regular file.

When an attempt is made to create a file that already exists, the action shall depend on the type of the file the utility is trying to create and on the type of the existing file as shown in Table 1-1 (on page 2205).

Table 1-1 Actions when Creating a File that Already Exists

		New Type												Function
	Existing Type	**A**	**B**	**C**	**D**	**F**	**L**	**M**	**P**	**Q**	**R**	**S**	**T**	**Creating New**
A	*fattach*( )-ed STREAM	—	—	—	—	—	—	—	—	—	OF	—	—	*fattach*( )
B	Block Special	—	—	—	—	—	—	—	—	—	OF	—	—	*mknod*( )**
C	Character Special	—	—	—	—	—	—	—	—	—	OF	—	—	*mknod*( )**
D	Directory	—	—	—	F	F	—	—	—	—	OD	—	—	*mkdir*( )
F	FIFO Special File	—	—	—	F	F	—	—	—	—	O	—	—	*mkfifo*( )
L	Symbolic Link	FL	FL	FL	FL	FL	FL	FL	FL	FL	FL	FL	FL	*symlink*( )
M	Shared Memory	—	—	—	—	—	—	—	—	—	—	—	—	*shm_open*( )
P	Semaphore	—	—	—	—	—	—	—	—	—	—	—	—	*sem_open*( )
Q	Message Queue	—	—	—	—	—	—	—	—	—	—	—	—	*mq_open*( )
R	Regular File	—	—	—	F	F	—	—	—	—	RF	—	—	*open*( )
S	Socket	—	—	—	—	—	—	—	—	—	—	—	—	*bind*( )
T	Typed Memory	—	—	—	—	—	—	—	—	—	—	—	—	*
	None.	—	—	—	NF	NF	NF	—	—	—	CF	NF	—	

The following codes are used in Table 1-1:

CF Create a new file as defined in Section 1.7.1.4 (on page 2204), items 1 through 7.

F Fail. When attempting to create a directory or FIFO special file, and the existing file is a directory, FIFO special file, or regular file, the attempt shall fail and the utility shall either continue with its operation or exit immediately with a non-zero exit status, depending on the description of the utility.

FL Follow link. Unless otherwise specified, the symbolic links shall be followed as specified for pathname resolution, and the operation performed shall be as if the target of the symbolic link (after all resolution) had been named. If the target of the symbolic link does not exist, it shall be as if that nonexistent target had been named directly.

NF Create a new file as described by the appropriate function.

O Open FIFO. When attempting to create a regular file, and the existing file is a FIFO special file:

1. If the FIFO is not already open for reading, the attempt shall block until the FIFO is opened for reading.
2. Once the FIFO is open for reading, the utility shall open the FIFO for writing and continue with its operation.

OD The directory shall be opened.

OF The named file shall be opened with the consequences defined for that file type.

RF Regular file. When attempting to create a regular file, and the existing file is a regular file:

1. The user ID, group ID, and permission bits of the file shall not be changed.
2. The file shall be truncated to zero length.
3. The *st_ctime* and *st_mtime* fields shall be marked for update.

— The effect is implementation-defined unless specified by the utility description.

* There is no portable way to create a file of this type.

** Not portable.

When a file is to be appended, the file shall be opened in a manner equivalent to using the O_APPEND flag, without the O_TRUNC flag, in the *open*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x.

When a file is to be read or written, the file shall be opened with an access mode corresponding to the operation to be performed. If file access permissions deny access, the requested operation shall fail.

1.7.1.5 File Removal

When a directory that is the root directory or current working directory of any process is removed, the effect is implementation-defined. If file access permissions deny access, the requested operation shall fail. Otherwise, when a file is removed:

1. Its directory entry shall be removed from the file system.
2. The link count of the file shall be decremented.
3. If the file is an empty directory (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.143, Empty Directory):
    a. If no process has the directory open, the space occupied by the directory shall be freed and the directory shall no longer be accessible.
    b. If one or more processes have the directory open, the directory contents shall be preserved until all references to the file have been closed.
4. If the file is a directory that is not empty, the *st_ctime* field shall be marked for update.
5. If the file is not a directory:
    a. If the link count becomes zero:
        i. If no process has the file open, the space occupied by the file shall be freed and the file shall no longer be accessible.
        ii. If one or more processes have the file open, the file contents shall be preserved until all references to the file have been closed.
    b. If the link count is not reduced to zero, the *st_ctime* field shall be marked for update.
6. The *st_ctime* and *st_mtime* fields of the containing directory shall be marked for update.

1.7.1.6 File Time Values

All files shall have the three time values described by the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.7, File Times Update.

1.7.1.7 File Contents

When a reference is made to the contents of a file, *pathname*, this means the equivalent of all of the data placed in the space pointed to by *buf* when performing the *read*( ) function calls in the following operations defined in the System Interfaces volume of IEEE Std 1003.1-200x:

```
while (read (fildes, buf, nbytes) > 0)
    ;
```

If the file is indicated by a pathname *pathname*, the file descriptor shall be determined by the equivalent of the following operation defined in the System Interfaces volume of IEEE Std 1003.1-200x:

```
fildes = open (pathname, O_RDONLY);
```

The value of *nbytes* in the above sequence is unspecified; if the file is of a type where the data returned by *read*( ) would vary with different values, the value shall be one that results in the most data being returned.

If the *read*( ) function calls would return an error, it is unspecified whether the contents of the file are considered to include any data from offsets in the file beyond where the error would be returned.

1.7.1.8 Pathname Resolution

The pathname resolution algorithm, described by the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.11, Pathname Resolution, shall be used by implementations conforming to this volume of IEEE Std 1003.1-200x; see also the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.5, File Hierarchy.

1.7.1.9 Changing the Current Working Directory

When the current working directory (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.436, Working Directory) is to be changed, unless the utility or function description states otherwise, the operation shall succeed unless a call to the *chdir*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x would fail when invoked with the new working directory pathname as its argument.

1.7.1.10 Establish the Locale

The functionality of the *setlocale*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x shall be available on all systems conforming to this volume of IEEE Std 1003.1-200x; that is, utilities that require the capability of establishing an international operating environment shall be permitted to set the specified category of the international environment.

1.7.1.11 Actions Equivalent to Functions

Some utility descriptions specify that a utility performs actions equivalent to a function defined in the System Interfaces volume of IEEE Std 1003.1-200x. Such specifications require only that the external effects be equivalent, not that any effect within the utility and visible only to the utility be equivalent.

1.7.2 Concepts Derived from the ISO C Standard

Some of the standard utilities perform complex data manipulation using their own procedure and arithmetic languages, as defined in their EXTENDED DESCRIPTION or OPERANDS sections. Unless otherwise noted, the arithmetic and semantic concepts (precision, type conversion, control flow, and so on) shall be equivalent to those defined in the ISO C standard, as described in the following sections. Note that there is no requirement that the standard utilities be implemented in any particular programming language.

1.7.2.1 Arithmetic Precision and Operations

Integer variables and constants, including the values of operands and option-arguments, used by the standard utilities listed in this volume of IEEE Std 1003.1-200x shall be implemented as equivalent to the ISO C standard **signed long** data type; floating point shall be implemented as equivalent to the ISO C standard **double** type. Conversions between types shall be as described in the ISO C standard. All variables shall be initialized to zero if they are not otherwise assigned by the input to the application.

Arithmetic operators and functions shall be implemented as equivalent to those in the cited ISO C standard section, as listed in Table 1-2 (on page 2209).

Table 1-2 ISO C Standard Operators and Functions

Operation	ISO C Standard Equivalent Reference
()	Section 6.5.1, Primary Expressions
postfix ++ postfix --	Section 6.5.2, Postfix Operators
unary + unary - prefix ++ prefix -- ~ ! *sizeof*()	Section 6.5.3, Unary Operators
* / %	Section 6.5.5, Multiplicative Operators
+ -	Section 6.5.6, Additive Operators
<< >>	Section 6.5.7, Bitwise Shift Operators
<, <= >, >=	Section 6.5.8, Relational Operators
== !=	Section 6.5.9, Equality Operators
&	Section 6.5.10, Bitwise AND Operator
^	Section 6.5.11, Bitwise Exclusive OR Operator
|	Section 6.5.12, Bitwise Inclusive OR Operator
&&	Section 6.5.13, Logical AND Operator
||	Section 6.5.14, Logical OR Operator
expr?*expr*:*expr*	Section 6.5.15, Conditional Operator
=, *=, /=, %=, +=, -= <<=, >>=, &=, ^=, |=	Section 6.5.16, Assignment Operators
if () **if** () . . . **else** **switch** ()	Section 6.8.4, Selection Statements
while () **do** . . . **while** () **for** ()	Section 6.8.5, Iteration Statements
goto **continue** **break** **return**	Section 6.8.6, Jump Statements

The evaluation of arithmetic expressions shall be equivalent to that described in Section 6.5, Expressions, of the ISO C standard.

1.7.2.2 Mathematical Functions

Any mathematical functions with the same names as those in the following sections of the ISO C standard:

- Section 7.12, Mathematics, `<math.h>`
- Section 7.20.2, Pseudo-Random Sequence Generation Functions

shall be implemented to return the results equivalent to those returned from a call to the corresponding function described in the ISO C standard.

1.8 Portability

Some of the utilities in the Shell and Utilities volume of IEEE Std 1003.1-200x and functions in the System Interfaces volume of IEEE Std 1003.1-200x describe functionality that might not be fully portable to systems meeting the requirements for POSIX conformance (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 2, Conformance).

Where optional, enhanced, or reduced functionality is specified, the text is shaded and a code in the margin identifies the nature of the option, extension, or warning (see Section 1.8.1). For maximum portability, an application should avoid such functionality.

Unless the primary task of a utility is to produce textual material on its standard output, application developers should not rely on the format or content of any such material that may be produced. Where the primary task *is* to provide such material, but the output format is incompletely specified, the description is marked with the OF margin code and shading. Application developers are warned not to expect that the output of such an interface on one system is any guide to its behavior on another system.

1.8.1 Codes

Codes and their meanings are listed in the Base Definitions volume of IEEE Std 1003.1-200x, but are repeated here for convenience:

ADV Advisory Information
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the ADV margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the ADV margin legend.

AIO Asynchronous Input and Output
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the AIO margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the AIO margin legend.

BAR Barriers
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the BAR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the BAR margin legend.

BE Batch Environment Services and Utilities

The functionality described is optional.

Where applicable, utilities are marked with the BE margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the BE margin legend.

CD C-Language Development Utilities

The functionality described is optional.

Where applicable, utilities are marked with the CD margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the CD margin legend.

CPT Process CPU-Time Clocks

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the CPT margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the CPT margin legend.

CS Clock Selection

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the CS margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the CS margin legend.

CX Extension to the ISO C standard

The functionality described is an extension to the ISO C standard. Application writers may make use of an extension as it is supported on all IEEE Std 1003.1-200x-conforming systems.

With each function or header from the ISO C standard, a statement to the effect that ‘‘any conflict is unintentional’’ is included. That is intended to refer to a direct conflict. IEEE Std 1003.1-200x acts in part as a profile of the ISO C standard, and it may choose to further constrain behaviors allowed to vary by the ISO C standard. Such limitations are not considered conflicts.

FD FORTRAN Development Utilities

The functionality described is optional.

Where applicable, utilities are marked with the FD margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the FD margin legend.

FR FORTRAN Runtime Utilities

The functionality described is optional.

Where applicable, utilities are marked with the FR margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the FR margin legend.

FSC File Synchronization

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the FSC margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the FSC margin legend.

IP6 IPV6
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the IP6 margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the IP6 margin legend.

MC1 Advisory Information and either Memory Mapped Files or Shared Memory Objects
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

This is a shorthand notation for combinations of multiple option codes.

Where applicable, functions are marked with the MC1 margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MC1 margin legend.

Refer to the Base Definitions volume of IEEE Std 1003.1-200x, Section 1.5.2, Margin Code Notation.

MC2 Memory Mapped Files, Shared Memory Objects, or Memory Protection
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

This is a shorthand notation for combinations of multiple option codes.

Where applicable, functions are marked with the MC2 margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MC2 margin legend.

Refer to the Base Definitions volume of IEEE Std 1003.1-200x, Section 1.5.2, Margin Code Notation.

MF Memory Mapped Files
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the MF margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MF margin legend.

ML Process Memory Locking
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the ML margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the ML margin legend.

MLR Range Memory Locking
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the MLR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MLR margin legend.

MON Monotonic Clock

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the MON margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MON margin legend.

MPR Memory Protection

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the MPR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MPR margin legend.

MSG Message Passing

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the MSG margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MSG margin legend.

MX IEC 60559 Floating-Point Option

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the MX margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MX margin legend.

OB Obsolescent

The functionality described may be withdrawn in a future version of this volume of IEEE Std 1003.1-200x. Strictly Conforming POSIX Applications and Strictly Conforming XSI Applications shall not use obsolescent features.

OF Output Format Incompletely Specified

The functionality described is an XSI extension. The format of the output produced by the utility is not fully specified. It is therefore not possible to post-process this output in a consistent fashion. Typical problems include unknown length of strings and unspecified field delimiters.

OH Optional Header

In the SYNOPSIS section of some interfaces in the System Interfaces volume of IEEE Std 1003.1-200x an included header is marked as in the following example:

OH
```
#include <sys/types.h>
#include <grp.h>
struct group *getgrnam(const char *name);
```

This indicates that the marked header is not required on XSI-conformant systems.

PIO Prioritized Input and Output

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the PIO margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the PIO margin legend.

PS Process Scheduling

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the PS margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the PS margin legend.

RS Raw Sockets

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the RS margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the RS margin legend.

RTS Realtime Signals Extension

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the RTS margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the RTS margin legend.

SD Software Development Utilities

The functionality described is optional.

Where applicable, utilities are marked with the SD margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the SD margin legend.

SEM Semaphores

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the SEM margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the SEM margin legend.

SHM Shared Memory Objects

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the SHM margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the SHM margin legend.

SIO Synchronized Input and Output

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the SIO margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the SIO margin legend.

SPI Spin Locks

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the SPI margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the SPI margin legend.

SPN Spawn
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the SPN margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the SPN margin legend.

SS Process Sporadic Server
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the SS margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the SS margin legend.

TCT Thread CPU-Time Clocks
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TCT margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TCT margin legend.

TEF Trace Event Filter
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TEF margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TEF margin legend.

THR Threads
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the THR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the THR margin legend.

TMO Timeouts
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TMO margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TMO margin legend.

TMR Timers
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TMR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TMR margin legend.

TPI Thread Priority Inheritance

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TPI margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TPI margin legend.

TPP Thread Priority Protection

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TPP margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TPP margin legend.

TPS Thread Execution Scheduling

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TPS margin legend for the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TPS margin legend.

TRC Trace

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TRC margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TRC margin legend.

TRI Trace Inherit

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TRI margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TRI margin legend.

TRL Trace Log

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TRL margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TRL margin legend.

TSA Thread Stack Address Attribute

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TSA margin legend for the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TSA margin legend.

TSF Thread-Safe Functions

The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TSF margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TSF margin legend.

TSH Thread Process-Shared Synchronization
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TSH margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TSH margin legend.

TSP Thread Sporadic Server
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TSP margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TSP margin legend.

TSS Thread Stack Address Size
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TSS margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TSS margin legend.

TYM Typed Memory Objects
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TYM margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TYM margin legend. |

UP User Portability Utilities
The functionality described is optional.

Where applicable, utilities are marked with the UP margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the UP margin legend.

XSI Extension
The functionality described is an XSI extension. Functionality marked XSI is also an extension to the ISO C standard. Application writers may confidently make use of an extension on all systems supporting the X/Open System Interfaces Extension.

If an entire SYNOPSIS section is shaded and marked XSI, all the functionality described in that reference page is an extension. See the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.439, XSI.

XSR XSI STREAMS
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the XSR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the XSR margin legend.

1.9 Utility Limits

This section lists magnitude limitations imposed by a specific implementation. The braces notation, {LIMIT}, is used in this volume of IEEE Std 1003.1-200x to indicate these values, but the braces are not part of the name.

Table 1-3 Utility Limit Minimum Values

Name	Description	Value
{POSIX2_BC_BASE_MAX}	The maximum *obase* value allowed by the *bc* utility.	99
{POSIX2_BC_DIM_MAX}	The maximum number of elements permitted in an array by the *bc* utility.	2048
{POSIX2_BC_SCALE_MAX}	The maximum *scale* value allowed by the *bc* utility.	99
{POSIX2_BC_STRING_MAX}	The maximum length of a string constant accepted by the *bc* utility.	1000
{POSIX2_COLL_WEIGHTS_MAX}	The maximum number of weights that can be assigned to an entry of the *LC_COLLATE* **order** keyword in the locale definition file; see the **border_start** keyword in the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3.2, LC_COLLATE.	2
{POSIX2_EXPR_NEST_MAX}	The maximum number of expressions that can be nested within parentheses by the *expr* utility.	32
{POSIX2_LINE_MAX}	Unless otherwise noted, the maximum length, in bytes, of the input line of a utility (either standard input or another file), when the utility is described as processing text files. The length includes room for the trailing newline.	2048
{POSIX2_RE_DUP_MAX}	The maximum number of repeated occurrences of a BRE permitted when using the interval notation \\{*m*,*n*\\}; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3.6, BREs Matching Multiple Characters.	255
{POSIX2_VERSION}	This value indicates the version of the utilities in this volume of IEEE Std 1003.1-200x that are provided by the implementation. It changes with each published version.	200xxxL

The values specified in Table 1-3 represent the lowest values conforming implementations shall provide and, consequently, the largest values on which an application can rely without further enquiries, as described below. These values shall be accessible to applications via the *getconf* utility (see *getconf* (on page 2683)) and through the *sysconf*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x. The literal names shown in Table 1-3 apply only to the *getconf* utility; the high-level language binding describes the exact form of each name to be used by the interfaces in that binding.

Implementations may provide more liberal, or less restrictive, values than shown in Table 1-3. These possibly more liberal values are accessible using the symbols in Table 1-4 (on page 2219).

The *sysconf*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x or the *getconf* utility return the value of each symbol on each specific implementation. The value so retrieved is the largest, or most liberal, value that is available throughout the session lifetime, as determined at session creation. The literal names shown in the table apply only to the *getconf* utility; the high-level language binding describes the exact form of each name to be used by the interfaces in that binding.

All numeric limits defined by the System Interfaces volume of IEEE Std 1003.1-200x, such as {PATH_MAX}, shall also apply to this volume of IEEE Std 1003.1-200x. All the utilities defined by this volume of IEEE Std 1003.1-200x are implicitly limited by these values, unless otherwise noted in the utility descriptions.

It is not guaranteed that the application can actually reach the specified limit of an implementation in any given case, or at all, as a lack of virtual memory or other resources may prevent this. The limit value indicates only that the implementation does not specifically impose any arbitrary, more restrictive limit.

Table 1-4 Symbolic Utility Limits

Name	Description	Minimum Value
{BC_BASE_MAX}	The maximum *obase* value allowed by the *bc* utility.	{POSIX2_BC_BASE_MAX}
{BC_DIM_MAX}	The maximum number of elements permitted in an array by the *bc* utility.	{POSIX2_BC_DIM_MAX}
{BC_SCALE_MAX}	The maximum *scale* value allowed by the *bc* utility.	{POSIX2_BC_SCALE_MAX}
{BC_STRING_MAX}	The maximum length of a string constant accepted by the *bc* utility.	{POSIX2_BC_STRING_MAX}
{COLL_WEIGHTS_MAX}	The maximum number of weights that can be assigned to an entry of the *LC_COLLATE* **order** keyword in the locale definition file; see the **order_start** keyword in the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3.2, LC_COLLATE.	{POSIX2_COLL_WEIGHTS_MAX}
{EXPR_NEST_MAX}	The maximum number of expressions that can be nested within parentheses by the *expr* utility.	{POSIX2_EXPR_NEST_MAX}
{LINE_MAX}	Unless otherwise noted, the maximum length, in bytes, of the input line of a utility (either standard input or another file), when the utility is described as	{POSIX2_LINE_MAX}

Name	Description	Minimum Value
	processing text files. The length includes room for the trailing newline.	
{RE_DUP_MAX}	The maximum number of repeated occurrences of a BRE permitted when using the interval notation \{*m*,*n*\}; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3.6, BREs Matching Multiple Characters.	{POSIX2_RE_DUP_MAX}

The following value may be a constant within an implementation or may vary from one pathname to another.

{POSIX2_SYMLINKS}
When referring to a directory, the system supports the creation of symbolic links within that directory; for non-directory files, the meaning of {POSIX2_SYMLINKS} is undefined.

1.10 Grammar Conventions

Portions of this volume of IEEE Std 1003.1-200x are expressed in terms of a special grammar notation. It is used to portray the complex syntax of certain program input. The grammar is based on the syntax used by the *yacc* utility. However, it does not represent fully functional *yacc* input, suitable for program use; the lexical processing and all semantic requirements are described only in textual form. The grammar is not based on source used in any traditional implementation and has not been tested with the semantic code that would normally be required to accompany it. Furthermore, there is no implication that the partial *yacc* code presented represents the most efficient, or only, means of supporting the complex syntax within the utility. Implementations may use other programming languages or algorithms, as long as the syntax supported is the same as that represented by the grammar.

The following typographical conventions are used in the grammar; they have no significance except to aid in reading.

- The identifiers for the reserved words of the language are shown with a leading capital letter. (These are terminals in the grammar; for example, **While**, **Case**.)
- The identifiers for terminals in the grammar are all named with uppercase letters and underscores; for example, **NEWLINE**, **ASSIGN_OP**, **NAME**.
- The identifiers for non-terminals are all lowercase.

1.11 Utility Description Defaults

This section describes all of the subsections used within the utility descriptions, including:

- Intended usage of the section
- Global defaults that affect all the standard utilities
- The meanings of notations used in this volume of IEEE Std 1003.1-200x that are specific to individual utility sections

NAME

This section gives the name or names of the utility and briefly states its purpose.

SYNOPSIS

The SYNOPSIS section summarizes the syntax of the calling sequence for the utility, including options, option-arguments, and operands. Standards for utility naming are described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines; for describing the utility's arguments in the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.1, Utility Argument Syntax.

DESCRIPTION

The DESCRIPTION section describes the actions of the utility. If the utility has a very complex set of subcommands or its own procedural language, an EXTENDED DESCRIPTION section is also provided. Most explanations of optional functionality are omitted here, as they are usually explained in the OPTIONS section.

As stated in Section 1.7.1.11 (on page 2207), some functions are described in terms of equivalent functionality. When specific functions are cited, the implementation shall provide equivalent functionality including side effects associated with successful execution of the function. The treatment of errors and intermediate results from the individual functions cited is generally not specified by this volume of IEEE Std 1003.1-200x. See the utility's EXIT STATUS and CONSEQUENCES OF ERRORS sections for all actions associated with errors encountered by the utility.

OPTIONS

The OPTIONS section describes the utility options and option-arguments, and how they modify the actions of the utility. Standard utilities that have options either fully comply with the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines or describe all deviations. Apparent disagreements between functionality descriptions in the OPTIONS and DESCRIPTION (or EXTENDED DESCRIPTION) sections are always resolved in favor of the OPTIONS section.

Each OPTIONS section that uses the phrase ''The ... utility shall conform to the Utility Syntax Guidelines ...'' refers only to the use of the utility as specified by this volume of IEEE Std 1003.1-200x; implementation extensions should also conform to the guidelines, but may allow exceptions for historical practice.

Unless otherwise stated in the utility description, when given an option unrecognized by the implementation, or when a required option-argument is not provided, standard utilities shall issue a diagnostic message to standard error and exit with a non-zero exit status.

All utilities in this volume of IEEE Std 1003.1-200x shall be capable of processing arguments using eight-bit transparency.

Default Behavior: When this section is listed as ''None.'', it means that the implementation need not support any options. Standard utilities that do not accept options, but that do accept operands, shall recognize "−−" as a first argument to be discarded.

The requirement for recognizing "−−" is because conforming applications need a way to shield their operands from any arbitrary options that the implementation may provide as an extension. For example, if the standard utility *foo* is listed as taking no options, and the application needed to give it a pathname with a leading hyphen, it could safely do it as:

```
foo −− −myfile
```

and avoid any problems with **−m** used as an extension.

OPERANDS

The OPERANDS section describes the utility operands, and how they affect the actions of the utility. Apparent disagreements between functionality descriptions in the OPERANDS and DESCRIPTION (or EXTENDED DESCRIPTION) sections shall be resolved in favor of the OPERANDS section.

If an operand naming a file can be specified as ′−′, which means to use the standard input instead of a named file, this is explicitly stated in this section. Unless otherwise stated, the use of multiple instances of ′−′ to mean standard input in a single command produces unspecified results.

Unless otherwise stated, the standard utilities that accept operands shall process those operands in the order specified in the command line.

Default Behavior: When this section is listed as ‘‘None.’’, it means that the implementation need not support any operands.

STDIN

The STDIN section describes the standard input of the utility. This section is frequently merely a reference to the following section, as many utilities treat standard input and input files in the same manner. Unless otherwise stated, all restrictions described in the INPUT FILES section shall apply to this section as well.

Use of a terminal for standard input can cause any of the standard utilities that read standard input to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.

The specified standard input format of the standard utilities shall not depend on the existence or value of the environment variables defined in this volume of IEEE Std 1003.1-200x, except as provided by this volume of IEEE Std 1003.1-200x.

Default Behavior: When this section is listed as ‘‘Not used.’’, it means that the standard input shall not be read when the utility is used as described by this volume of IEEE Std 1003.1-200x.

INPUT FILES

The INPUT FILES section describes the files, other than the standard input, used as input by the utility. It includes files named as operands and option-arguments as well as other files that are referred to, such as start-up and initialization files, databases, and so on. Commonly-used files are generally described in one place and cross-referenced by other utilities.

All utilities in this volume of IEEE Std 1003.1-200x shall be capable of processing input files using eight-bit transparency.

When a standard utility reads a seekable input file and terminates without an error before it reaches end-of-file, the utility shall ensure that the file offset in the open file description is properly positioned just past the last byte processed by the utility. For files that are not seekable, the state of the file offset in the open file description for that file is unspecified. A conforming application shall not assume that the following three commands are equivalent:

```
tail −n +2 file
(sed −n 1q; cat) < file
cat file | (sed −n 1q; cat)
```

The second command is equivalent to the first only when the file is seekable. The third command leaves the file offset in the open file description in an unspecified state. Other utilities, such as *head*, *read*, and *sh*, have similar properties.

Some of the standard utilities, such as filters, process input files a line or a block at a time and have no restrictions on the maximum input file size. Some utilities may have size limitations that are not as obvious as file space or memory limitations. Such limitations should reflect resource limitations of some sort, not arbitrary limits set by implementors. Implementations shall document those utilities that are limited by constraints other than file system space, available memory, and other limits specifically cited by this volume of IEEE Std 1003.1-200x, and identify what the constraint is and indicate a way of estimating when the constraint would be reached. Similarly, some utilities descend the directory tree (recursively). Implementations shall also document any limits that they may have in descending the directory tree that are beyond limits cited by this volume of IEEE Std 1003.1-200x.

When an input file is described as a *text file*, the utility produces undefined results if given input that is not from a text file, unless otherwise stated. Some utilities (for example, *make*, *read*, *sh*) allow for continued input lines using an escaped <newline> convention; unless otherwise stated, the utility need not be able to accumulate more than {LINE_MAX} bytes from a set of multiple, continued input lines. Thus, for a conforming application the total of all the continued lines in a set cannot exceed {LINE_MAX}. If a utility using the escaped <newline> convention detects an end-of-file condition immediately after an escaped <newline>, the results are unspecified.

Record formats are described in a notation similar to that used by the C-language function, *printf*( ). See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation for a description of this notation. The format description is intended to be sufficiently rigorous to allow other applications to generate these input files. However, since <blank>s can legitimately be included in some of the fields described by the standard utilities, particularly in locales other than the POSIX locale, this intent is not always realized.

Default Behavior: When this section is listed as ‘‘None.’’, it means that no input files are required to be supplied when the utility is used as described by this volume of IEEE Std 1003.1-200x.

ENVIRONMENT VARIABLES

The ENVIRONMENT VARIABLES section lists what variables affect the utility’s execution.

The entire manner in which environment variables described in this volume of IEEE Std 1003.1-200x affect the behavior of each utility is described in the ENVIRONMENT VARIABLES section for that utility, in conjunction with the global effects of the *LANG*, *LC_ALL*, and XSI *NLSPATH* environment variables described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables. The existence or value of environment variables described in this volume of

IEEE Std 1003.1-200x shall not otherwise affect the specified behavior of the standard utilities. Any effects of the existence or value of environment variables not described by this volume of IEEE Std 1003.1-200x upon the standard utilities are unspecified.

For those standard utilities that use environment variables as a means for selecting a utility to execute (such as *CC* in *make*), the string provided to the utility is subjected to the path search described for *PATH* in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

All utilities in this volume of IEEE Std 1003.1-200x shall be capable of processing environment variable names and values using eight-bit transparency.

Default Behavior: When this section is listed as ''None.'', it means that the behavior of the utility is not directly affected by environment variables described by this volume of IEEE Std 1003.1-200x when the utility is used as described by this volume of IEEE Std 1003.1-200x.

ASYNCHRONOUS EVENTS

The ASYNCHRONOUS EVENTS section lists how the utility reacts to such events as signals and what signals are caught.

Default Behavior: When this section is listed as ''Default.'', or it refers to ''the standard action for all other signals; see Section 1.11 (on page 2221)'' it means that the action taken as a result of the signal shall be one of the following:

1. The action shall be that inherited from the parent according to the rules of inheritance of signal actions defined in the System Interfaces volume of IEEE Std 1003.1-200x.
2. When no action has been taken to change the default, the default action shall be that specified by the System Interfaces volume of IEEE Std 1003.1-200x.
3. The result of the utility's execution is as if default actions had been taken.

A utility is permitted to catch a signal, perform some additional processing (such as deleting temporary files), restore the default signal action (or action inherited from the parent process), and resignal itself.

STDOUT

The STDOUT section completely describes the standard output of the utility. This section is frequently merely a reference to the following section, OUTPUT FILES, because many utilities treat standard output and output files in the same manner.

Use of a terminal for standard output may cause any of the standard utilities that write standard output to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.

Record formats are described in a notation similar to that used by the C-language function, *printf*( ). See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation for a description of this notation.

The specified standard output of the standard utilities shall not depend on the existence or value of the environment variables defined in this volume of IEEE Std 1003.1-200x, except as provided by this volume of IEEE Std 1003.1-200x.

Some of the standard utilities describe their output using the verb *display*, defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.132, Display. Output described in the STDOUT sections of such utilities may be produced using means other than standard output. When standard output is directed to a terminal, the output described shall be written directly to the terminal. Otherwise, the results are undefined.

Default Behavior: When this section is listed as ''Not used.'', it means that the standard output shall not be written when the utility is used as described by this volume of IEEE Std 1003.1-200x.

STDERR

The STDERR section describes the standard error output of the utility. Only those messages that are purposely sent by the utility are described.

Use of a terminal for standard error may cause any of the standard utilities that write standard error output to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.

The format of diagnostic messages for most utilities is unspecified, but the language and cultural conventions of diagnostic and informative messages whose format is unspecified by this volume of IEEE Std 1003.1-200x should be affected by the setting of XSI *LC_MESSAGES* and *NLSPATH*.

The specified standard error output of standard utilities shall not depend on the existence or value of the environment variables defined in this volume of IEEE Std 1003.1-200x, except as provided by this volume of IEEE Std 1003.1-200x.

Default Behavior: When this section is listed as ''Used only for diagnostic messages.'', it means that, unless otherwise stated, the diagnostic messages shall be sent to the standard error only when the exit status is non-zero and the utility is used as described by this volume of IEEE Std 1003.1-200x.

When this section is listed as ''Not used.'', it means that the standard error shall not be used when the utility is used as described in this volume of IEEE Std 1003.1-200x.

OUTPUT FILES

The OUTPUT FILES section completely describes the files created or modified by the utility. Temporary or system files that are created for internal usage by this utility or other parts of the implementation (for example, spool, log, and audit files) are not described in this, or any, section. The utilities creating such files and the names of such files are unspecified. If applications are written to use temporary or intermediate files, they should use the *TMPDIR* environment variable, if it is set and represents an accessible directory, to select the location of temporary files.

Implementations shall ensure that temporary files, when used by the standard utilities, are named so that different utilities or multiple instances of the same utility can operate simultaneously without regard to their working directories, or any other process characteristic other than process ID. There are two exceptions to this rule:

1. Resources for temporary files other than the name space (for example, disk space, available directory entries, or number of processes allowed) are not guaranteed.
2. Certain standard utilities generate output files that are intended as input for other utilities (for example, *lex* generates **lex.yy.c**), and these cannot have unique names. These cases are explicitly identified in the descriptions of the respective utilities.

Any temporary file created by the implementation shall be removed by the implementation upon a utility's successful exit, exit because of errors, or before termination by any of the SIGHUP, SIGINT, or SIGTERM signals, unless specified otherwise by the utility description.

Receipt of the SIGQUIT signal should generally cause termination (unless in some debugging mode) that would bypass any attempted recovery actions.

Record formats are described in a notation similar to that used by the C-language function, *printf*( ); see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation for a description of this notation.

Default Behavior: When this section is listed as ‘‘None.’’, it means that no files are created or modified as a consequence of direct action on the part of the utility when the utility is used as described by this volume of IEEE Std 1003.1-200x. However, the utility may create or modify system files, such as log files, that are outside the utility’s normal execution environment.

EXTENDED DESCRIPTION

The EXTENDED DESCRIPTION section provides a place for describing the actions of very complicated utilities, such as text editors or language processors, which typically have elaborate command languages.

Default Behavior: When this section is listed as ‘‘None.’’, no further description is necessary.

EXIT STATUS

The EXIT STATUS section describes the values the utility shall return to the calling program, or shell, and the conditions that cause these values to be returned. Usually, utilities return zero for successful completion and values greater than zero for various error conditions. If specific numeric values are listed in this section, the system shall use those values for the errors described. In some cases, status values are listed more loosely, such as >0. A strictly conforming application shall not rely on any specific value in the range shown and shall be prepared to receive any value in the range.

For example, a utility may list zero as a successful return, 1 as a failure for a specific reason, and >1 as ‘‘an error occurred’’. In this case, unspecified conditions may cause a 2 or 3, or other value, to be returned. A conforming application should be written so that it tests for successful exit status values (zero in this case), rather than relying upon the single specific error value listed in this volume of IEEE Std 1003.1-200x. In that way, it has maximum portability, even on implementations with extensions.

Unspecified error conditions may be represented by specific values not listed in this volume of IEEE Std 1003.1-200x.

CONSEQUENCES OF ERRORS

The CONSEQUENCES OF ERRORS section describes the effects on the environment, file systems, process state, and so on, when error conditions occur. It does not describe error messages produced or exit status values used.

The many reasons for failure of a utility are generally not specified by the utility descriptions. Utilities may terminate prematurely if they encounter: invalid usage of options, arguments, or environment variables; invalid usage of the complex syntaxes expressed in EXTENDED DESCRIPTION sections; difficulties accessing, creating, reading, or writing files; or difficulties associated with the privileges of the process.

The following shall apply to each utility, unless otherwise stated:

- If the requested action cannot be performed on an operand representing a file, directory, user, process, and so on, the utility shall issue a diagnostic message to standard error and continue processing the next operand in sequence, but the final exit status shall be returned as non-zero.

For a utility that recursively traverses a file hierarchy (such as *find* or *chown* −**R**), if the requested action cannot be performed on a file or directory encountered in the hierarchy, the utility shall issue a diagnostic message to standard error and continue processing the remaining files in the hierarchy, but the final exit status shall be returned as non-zero.

- If the requested action characterized by an option or option-argument cannot be performed, the utility shall issue a diagnostic message to standard error and the exit status returned shall be non-zero.
- When an unrecoverable error condition is encountered, the utility shall exit with a non-zero exit status.
- A diagnostic message shall be written to standard error whenever an error condition occurs.

When a utility encounters an error condition several actions are possible, depending on the severity of the error and the state of the utility. Included in the possible actions of various utilities are: deletion of temporary or intermediate work files; deletion of incomplete files; validity checking of the file system or directory.

Default Behavior: When this section is listed as ‘‘Default.’’, it means that any changes to the environment are unspecified.

APPLICATION USAGE

This section is non-normative.

The APPLICATION USAGE section gives advice to the application programmer or user about the way the utility should be used.

EXAMPLES

This section is non-normative.

The EXAMPLES section gives one or more examples of usage, where appropriate. In the event of conflict between an example and a normative part of the specification, the normative material is to be taken as correct.

In all examples, quoting has been used, showing how sample commands (utility names combined with arguments) could be passed correctly to a shell (see *sh*) or as a string to the *system*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x. Such quoting would not be used if the utility is invoked using one of the *exec* functions defined in the System Interfaces volume of IEEE Std 1003.1-200x.

RATIONALE

This section is non-normative.

This section contains historical information concerning the contents of this volume of IEEE Std 1003.1-200x and why features were included or discarded by the standard developers.

FUTURE DIRECTIONS

This section is non-normative.

The FUTURE DIRECTIONS section should be used as a guide to current thinking; there is not necessarily a commitment to implement all of these future directions in their entirety.

SEE ALSO

This section is non-normative.

The SEE ALSO section lists related entries.

CHANGE HISTORY

This section is non-normative.

The CHANGE HISTORY section shows the derivation of the description used by this volume of IEEE Std 1003.1-200x and lists the functional differences between Issues 4 and 6.

Certain of the standard utilities describe how they can invoke other utilities or applications, such as by passing a command string to the command interpreter. The external influences (STDIN, ENVIRONMENT VARIABLES, and so on) and external effects (STDOUT, CONSEQUENCES OF ERRORS, and so on) of such invoked utilities are not described in the section concerning the standard utility that invokes them.

1.12 Considerations for Utilities in Support of Files of Arbitrary Size

The following utilities support files of any size up to the maximum that can be created by the implementation. This support includes correct writing of file size-related values (such as file sizes and offsets, line numbers, and block counts) and correct interpretation of command line arguments that contain such values.

basename	Return non-directory portion of pathname.
cat	Concatenate and print files.
cd	Change working directory.
chgrp	Change file group ownership.
chmod	Change file modes.
chown	Change file ownership.
cksum	Write file checksums and sizes.
cmp	Compare two files.
cp	Copy files.
dd	Convert and copy a file.
df	Report free disk space.
dirname	Return directory portion of pathname.
du	Estimate file space usage.
find	Find files.
ln	Link files.
ls	List directory contents.
mkdir	Make directories.
mv	Move files.
pathchk	Check pathnames.
pwd	Return working directory name.

rm	Remove directory entries.
rmdir	Remove directories.
sh	Shell, the standard command language interpreter.
sum	Print checksum and block or byte count of a file.
test	Evaluate expression.
touch	Change file access and modification times.
ulimit	Set or report file size limit.

Exceptions to the requirement that utilities support files of any size up to the maximum are as follows:

1. Uses of files as command scripts, or for configuration or control, are exempt. For example, it is not required that *sh* be able to read an arbitrarily large **.profile**.
2. Shell input and output redirection are exempt. For example, it is not required that the redirections *sum* < *file* or *echo foo* > *file* succeed for an arbitrarily large existing file.

1.13 Built-In Utilities

Any of the standard utilities may be implemented as *regular built-in* utilities within the command language interpreter. This is usually done to increase the performance of frequently used utilities or to achieve functionality that would be more difficult in a separate environment. The utilities named in Table 1-5 are frequently provided in built-in form. All of the utilities named in the table have special properties in terms of command search order within the shell, as described in Section 2.9.1.1 (on page 2249).

Table 1-5 Regular Built-in Utilities

alias	*false*	*jobs*	*true*
bg	*fc*	*kill*	*umask*
cd	*fg*	*newgrp*	*unalias*
command	*getopts*	*read*	*wait*

However, all of the standard utilities, including the regular built-ins in the table, but not the special built-ins described in Section 2.14 (on page 2266), shall be implemented in a manner so that they can be accessed via the *exec* family of functions as defined in the System Interfaces volume of IEEE Std 1003.1-200x and can be invoked directly by those standard utilities that require it (*env*, *find*, *nice*, *nohup*, *time*, *xargs*).

Since *exec*-able versions shall be provided for all utilities except for those listed in Section 2.14 (on page 2266), an application running on a system that conforms to IEEE Std 1003.1-200x can use the *exec* family of functions, in addition to the shell command interface provided by the *system*( ) and *popen*( ) functions, to execute any of these utilities.

Chapter 2

Shell Command Language

This chapter contains the definition of the Shell Command Language.

2.1 Shell Introduction

The shell is a command language interpreter. This chapter describes the syntax of that command language as it is used by the *sh* utility and the *system*( ) and *popen*( ) functions defined in the System Interfaces volume of IEEE Std 1003.1-200x.

The shell operates according to the following general overview of operations. The specific details are included in the cited sections of this chapter.

1. The shell reads its input from a file (see *sh*), from the −**c** option or from the *system*( ) and *popen*( ) functions defined in the System Interfaces volume of IEEE Std 1003.1-200x. If the first line of a file of shell commands starts with the characters `"#!"`, the results are unspecified.
2. The shell breaks the input into tokens: words and operators; see Section 2.3 (on page 2233).
3. The shell parses the input into simple commands (see Section 2.9.1 (on page 2248)) and compound commands (see Section 2.9.4 (on page 2253)).
4. The shell performs various expansions (separately) on different parts of each command, resulting in a list of pathnames and fields to be treated as a command and arguments; see Section 2.6 (on page 2238).
5. The shell performs redirection (see Section 2.7 (on page 2244)) and removes redirection operators and their operands from the parameter list.
6. The shell executes a function (see Section 2.9.5 (on page 2256)), built-in (see Section 2.14 (on page 2266)), executable file, or script, giving the names of the arguments as positional parameters numbered 1 to *n*, and the name of the command (or in the case of a function within a script, the name of the script) as the positional parameter numbered 0 (see Section 2.9.1.1 (on page 2249)).
7. The shell optionally waits for the command to complete and collects the exit status (see Section 2.8.2 (on page 2248)).

2.2 Quoting

Quoting is used to remove the special meaning of certain characters or words to the shell. Quoting can be used to preserve the literal meaning of the special characters in the next paragraph, prevent reserved words from being recognized as such, and prevent parameter expansion and command substitution within here-document processing (see Section 2.7.4 (on page 2246)).

The application shall quote the following characters if they are to represent themselves:

```
|  &  ;  <  >  (  )  $  `  \  "  '  <space>  <tab>  <newline>
```

and the following may need to be quoted under certain circumstances. That is, these characters may be special depending on conditions described elsewhere in this volume of IEEE Std 1003.1-200x:

```
*   ?   [   #   ~   =   %
```

The various quoting mechanisms are the escape character, single-quotes, and double-quotes. The here-document represents another form of quoting; see Section 2.7.4 (on page 2246).

2.2.1 Escape Character (Backslash)

A backslash that is not quoted shall preserve the literal value of the following character, with the exception of a <newline>. If a <newline> follows the backslash, the shell shall interpret this as line continuation. The backslash and <newline>s shall be removed before splitting the input into tokens. Since the escaped <newline> is removed entirely from the input and is not replaced by any white space, it cannot serve as a token separator.

2.2.2 Single-Quotes

Enclosing characters in single-quotes (`''`) shall preserve the literal value of each character within the single-quotes. A single-quote cannot occur within single-quotes.

2.2.3 Double-Quotes

Enclosing characters in double-quotes (`""`) shall preserve the literal value of all characters within the double-quotes, with the exception of the characters dollar sign, backquote, and backslash, as follows:

`$` The dollar sign shall retain its special meaning introducing parameter expansion (see Section 2.6.2 (on page 2239)), a form of command substitution (see Section 2.6.3 (on page 2242)), and arithmetic expansion (see Section 2.6.4 (on page 2243)).

The input characters within the quoted string that are also enclosed between `"$("` and the matching `')'` is not affected by the double-quotes, but rather shall define that command whose output replaces the `"$(...)"` when the word is expanded. The tokenizing rules in Section 2.3 (on page 2233), not including the alias substitutions in Section 2.3.1 (on page 2234), shall be applied recursively to find the matching `')'`.

Within the string of characters from an enclosed `"${"` to the matching `'}'`, an even number of unescaped double-quotes or single-quotes, if any, shall occur. A preceding backslash character shall be used to escape a literal `'{'` or `'}'`. The rule in Section 2.6.2 (on page 2239) shall be used to determine the matching `'}'`.

`` ` `` The backquote shall retain its special meaning introducing the other form of command substitution (see Section 2.6.3 (on page 2242)). The portion of the quoted string from the initial backquote and the characters up to the next backquote that is not preceded by a backslash, having escape characters removed, defines that command whose output replaces `"‘...‘"` when the word is expanded. Either of the following cases produces undefined results:

- A single-quoted or double-quoted string that begins, but does not end, within the `"‘...‘"` sequence
- A `"‘...‘"` sequence that begins, but does not end, within the same double-quoted string

\ The backslash shall retain its special meaning as an escape character (see Section 2.2.1 (on page 2232)) only when followed by one of the following characters when considered special:

`$ ‘ " \ <newline>`

The application shall ensure that a double-quote is preceded by a backslash to be included within double-quotes. The parameter `’@’` has special meaning inside double-quotes and is described in Section 2.5.2 (on page 2235).

2.3 Token Recognition

The shell shall read its input in terms of lines from a file, from a terminal in the case of an interactive shell, or from a string in the case of *sh* **–c** or *system*( ). The input lines can be of unlimited length. These lines shall be parsed using two major modes: ordinary token recognition and processing of here-documents.

When an **io_here** token has been recognized by the grammar (see Section 2.10 (on page 2257)), one or more of the subsequent lines immediately following the next **NEWLINE** token form the body of one or more here-documents and shall be parsed according to the rules of Section 2.7.4 (on page 2246).

When it is not processing an **io_here**, the shell shall break its input into tokens by applying the first applicable rule below to the next character in its input. The token shall be from the current position in the input until a token is delimited according to one of the rules below; the characters forming the token are exactly those in the input, including any quoting characters. If it is indicated that a token is delimited, and no characters have been included in a token, processing shall continue until an actual token is delimited.

1. If the end of input is recognized, the current token shall be delimited. If there is no current token, the end-of-input indicator shall be returned as the token.
2. If the previous character was used as part of an operator and the current character is not quoted and can be used with the current characters to form an operator, it shall be used as part of that (operator) token.
3. If the previous character was used as part of an operator and the current character cannot be used with the current characters to form an operator, the operator containing the previous character shall be delimited.
4. If the current character is backslash, single-quote, or double-quote (`’\\’`, `’\’’`, or `’"’`) and it is not quoted, it shall affect quoting for subsequent characters up to the end of the quoted text. The rules for quoting are as described in Section 2.2 (on page 2232). During token recognition no substitutions shall be actually performed, and the result token shall contain exactly the characters that appear in the input (except for <newline> joining), unmodified, including any embedded or enclosing quotes or substitution operators, between the quote mark and the end of the quoted text. The token shall not be delimited by the end of the quoted field.

5. If the current character is an unquoted `'$'` or `'``'`, the shell shall identify the start of any candidates for parameter expansion (Section 2.6.2 (on page 2239)), command substitution (Section 2.6.3 (on page 2242)), or arithmetic expansion (Section 2.6.4 (on page 2243)) from their introductory unquoted character sequences: `'$'` or `"${"`, `"$("` or `'``'`, and `"$(("`, respectively. The shell shall read sufficient input to determine the end of the unit to be expanded (as explained in the cited sections). While processing the characters, if instances of expansions or quoting are found nested within the substitution, the shell shall recursively process them in the manner specified for the construct that is found. The characters found from the beginning of the substitution to its end, allowing for any recursion necessary to recognize embedded constructs, shall be included unmodified in the result token, including any embedded or enclosing substitution operators or quotes. The token shall not be delimited by the end of the substitution.

6. If the current character is not quoted and can be used as the first character of a new operator, the current token (if any) shall be delimited. The current character shall be used as the beginning of the next (operator) token.

7. If the current character is an unquoted <newline>, the current token shall be delimited.

8. If the current character is an unquoted <blank>, any token containing the previous character is delimited and the current character shall be discarded.

9. If the previous character was part of a word, the current character shall be appended to that word.

10. If the current character is a `'#'`, it and all subsequent characters up to, but excluding, the next <newline> shall be discarded as a comment. The <newline> that ends the line is not considered part of the comment.

11. The current character is used as the start of a new word.

Once a token is delimited, it is categorized as required by the grammar in Section 2.10 (on page 2257).

2.3.1 Alias Substitution

UP XSI The processing of aliases shall be supported on all XSI-conformant systems or if the system supports the User Portability Utilities option (and the rest of this section is not further shaded for these options).

After a token has been delimited, but before applying the grammatical rules in Section 2.10 (on page 2257), a resulting word that is identified to be the command name word of a simple command shall be examined to determine whether it is an unquoted, valid alias name. However, reserved words in correct grammatical context shall not be candidates for alias substitution. A valid alias name (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.10, Alias Name) shall be one that has been defined by the *alias* utility and not subsequently undefined using *unalias*. Implementations also may provide predefined valid aliases that are in effect when the shell is invoked. To prevent infinite loops in recursive aliasing, if the shell is not currently processing an alias of the same name, the word shall be replaced by the value of the alias; otherwise, it shall not be replaced.

If the value of the alias replacing the word ends in a <blank>, the shell shall check the next command word for alias substitution; this process shall continue until a word is found that is not a valid alias or an alias value does not end in a <blank>.

When used as specified by this volume of IEEE Std 1003.1-200x, alias definitions shall not be inherited by separate invocations of the shell or by the utility execution environments invoked by the shell; see Section 2.12 (on page 2263).

2.4 Reserved Words

Reserved words are words that have special meaning to the shell; see Section 2.9 (on page 2248). The following words shall be recognized as reserved words:

!
{
}
case
do
done
elif
else
esac
fi
for
if
in
then
until
while

This recognition shall only occur when none of the characters is quoted and when the word is used as:

- The first word of a command
- The first word following one of the reserved words other than **case**, **for**, or **in**
- The third word in a **case** or **for** command (only **in** is valid in this case)

See the grammar in Section 2.10 (on page 2257).

The following words may be recognized as reserved words on some implementations (when none of the characters are quoted), causing unspecified results:

[[
]]
function
select

Words that are the concatenation of a name and a colon (`':'`) are reserved; their use produces unspecified results.

2.5 Parameters and Variables

A parameter can be denoted by a name, a number, or one of the special characters listed in Section 2.5.2. A variable is a parameter denoted by a name.

A parameter is set if it has an assigned value (null is a valid value). Once a variable is set, it can only be unset by using the *unset* special built-in command.

2.5.1 Positional Parameters

A positional parameter is a parameter denoted by the decimal value represented by one or more digits, other than the single digit 0. The digits denoting the positional parameters shall always be interpreted as a decimal value, even if there is a leading zero. When a positional parameter with more than one digit is specified, the application shall enclose the digits in braces (see Section 2.6.2 (on page 2239)). Positional parameters are initially assigned when the shell is invoked (see *sh*), temporarily replaced when a shell function is invoked (see Section 2.9.5 (on page 2256)), and can be reassigned with the *set* special built-in command.

2.5.2 Special Parameters

Listed below are the special parameters and the values to which they shall expand. Only the values of the special parameters are listed; see Section 2.6 (on page 2238) for a detailed summary of all the stages involved in expanding words.

`@` Expands to the positional parameters, starting from one. When the expansion occurs within double-quotes, and where field splitting (see Section 2.6.5 (on page 2243)) is performed, each positional parameter shall expand as a separate field, with the provision that the expansion of the first parameter shall still be joined with the beginning part of the original word (assuming that the expanded parameter was embedded within a word), and the expansion of the last parameter shall still be joined with the last part of the original word. If there are no positional parameters, the expansion of `'@'` shall generate zero fields, even when `'@'` is double-quoted.

* Expands to the positional parameters, starting from one. When the expansion occurs within a double-quoted string (see Section 2.2.3 (on page 2232)), it shall expand to a single field with the value of each parameter separated by the first character of the *IFS* variable, or by a <space> if *IFS* is unset. If *IFS* is set to a null string, this is not equivalent to unsetting it; its first character does not exist, so the parameter values are concatenated.

Expands to the decimal number of positional parameters. The command name (parameter 0) shall not be counted in the number given by `'#'` because it is a special parameter, not a positional parameter.

? Expands to the decimal exit status of the most recent pipeline (see Section 2.9.2 (on page 2250)).

– (Hyphen.) Expands to the current option flags (the single-letter option names concatenated into a string) as specified on invocation by the *set* special built-in command or implicitly by the shell.

$ Expands to the decimal process ID of the invoked shell. In a subshell (see Section 2.12 (on page 2263)), `'$'` shall expand to the same value as that of the current shell.

! Expands to the decimal process ID of the most recent background command (see Section 2.9.3 (on page 2251)) executed from the current shell. (For example, background commands executed from subshells do not affect the value of `"$!"` in the current shell environment.) For a pipeline, the process ID is that of the last command in the pipeline.

0 (Zero.) Expands to the name of the shell or shell script. See *sh* (on page 3048) for a detailed description of how this name is derived.

See the description of the *IFS* variable in Section 2.5.3.

2.5.3 Shell Variables

Variables shall be initialized from the environment (as defined by the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables and the *exec* function in the System Interfaces volume of IEEE Std 1003.1-200x) and can be given new values with variable assignment commands. If a variable is initialized from the environment, it shall be marked for export immediately; see the *export* special built-in. New variables can be defined and initialized with variable assignments, with the *read* or *getopts* utilities, with the *name* parameter in a **for** loop, with the ${*name*=*word*} expansion, or with other mechanisms provided as implementation extensions.

The following variables shall affect the execution of the shell.

UP XSI *ENV* The processing of the *ENV* shell variable shall be supported on all XSI-conformant systems or if the system supports the User Portability Utilities option.

This variable, when and only when an interactive shell is invoked, shall be subjected to parameter expansion (see Section 2.6.2 (on page 2239)) by the shell and the resulting value shall be used as a pathname of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of *ENV* is not an absolute pathname, the results are unspecified. *ENV* shall be ignored if the user's real and effective user IDs or real and effective group IDs are different.

HOME	The pathname of the user's home directory. The contents of *HOME* are used in tilde expansion (see Section 2.6.1 (on page 2239)).
IFS	(Input Field Separators.) A string treated as a list of characters that is used for field splitting and to split lines into fields with the *read* command. If *IFS* is not set, the shell shall behave as if the value of *IFS* is <space>, <tab>, and <newline>; see Section 2.6.5 (on page 2243).
LANG	The default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale is used. If any of the internationalization variables contains an invalid setting, the utility behaves as if none of the variables had been defined.
LC_ALL	The default value for the *LC_** variables, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.
LC_COLLATE	Determine the behavior of range expressions, equivalence classes, and multi-character collating elements within pattern matching.
LC_CTYPE	Determine the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters), which characters are defined as letters (character class **alpha**) and <blank>s (character class **blank**), and the behavior of character classes within pattern matching. Changing the value of *LC_CTYPE* after the shell has started shall not affect the lexical processing of shell commands in the current shell execution environment or its subshells. Invoking a shell script or performing *exec sh* subjects the new shell to the changes in *LC_CTYPE*.
LC_MESSAGES	Determine the language in which messages should be written.
LINENO	Set by the shell to a decimal number representing the current sequential line number (numbered starting with 1) within a script or function before it executes each command. If the user unsets or resets *LINENO*, the variable may lose its special meaning for the life of the shell. If the shell is not currently executing a script or function, the value of *LINENO* is unspecified. This volume of IEEE Std 1003.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PATH	A string formatted as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables, used to effect command interpretation; see Section 2.9.1.1 (on page 2249).
PPID	Set by the shell to the decimal process ID of the process that invoked this shell. In a subshell (see Section 2.12 (on page 2263)), *PPID* shall be set to the same value as that of the parent of the current shell. For example, *echo*$*PPID* and (*echo*$*PPID*) would produce the same value. This volume of IEEE Std 1003.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option.
PS1	Each time an interactive shell is ready to read a command, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value shall be `"$ "`. For users who have specific additional implementation-defined privileges, the default may be another, implementation-defined value. The shell shall replace each instance of the

	character `'!'` in *PS1* with the history file number of the next command to be typed. Escaping the `'!'` with another `'!'` (that is, `"!!"`) shall place the literal character `'!'` in the prompt. This volume of IEEE Std 1003.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option.
PS2	Each time the user enters a <newline> prior to completing a command line in an interactive shell, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value is `"> "`. This volume of IEEE Std 1003.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option.
PS4	When an execution trace (*set* −**x**) is being performed in an interactive shell, before each line in the execution trace, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value is `"+ "`. This volume of IEEE Std 1003.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option.
PWD	Set by the shell to be an absolute pathname of the current working directory, containing no components of type symbolic link, no components that are dot, and no components that are dot-dot when the shell is initialized. If an application sets or unsets the value of *PWD*, the behaviors of the *cd* and *pwd* utilities are unspecified.

2.6 Word Expansions

This section describes the various expansions that are performed on words. Not all expansions are performed on every word, as explained in the following sections.

Tilde expansions, parameter expansions, command substitutions, arithmetic expansions, and quote removals that occur within a single word expand to a single field. It is only field splitting or pathname expansion that can create multiple fields from a single word. The single exception to this rule is the expansion of the special parameter `'@'` within double-quotes, as described in Section 2.5.2 (on page 2235).

The order of word expansion shall be as follows:

1. Tilde expansion (see Section 2.6.1 (on page 2239)), parameter expansion (see Section 2.6.2 (on page 2239)), command substitution (see Section 2.6.3 (on page 2242)), and arithmetic expansion (see Section 2.6.4 (on page 2243)) shall be performed, beginning to end. See item 5 in Section 2.3 (on page 2233).
2. Field splitting (see Section 2.6.5 (on page 2243)) shall be performed on the portions of the fields generated by step 1, unless *IFS* is null.
3. Pathname expansion (see Section 2.6.6 (on page 2244)) shall be performed, unless *set* −**f** is in effect.
4. Quote removal (see Section 2.6.7 (on page 2244)) shall always be performed last.

The expansions described in this section shall occur in the same shell environment as that in which the command is executed.

If the complete expansion appropriate for a word results in an empty field, that empty field shall be deleted from the list of fields that form the completely expanded command, unless the original word contained single-quote or double-quote characters.

The `'$'` character is used to introduce parameter expansion, command substitution, or arithmetic evaluation. If an unquoted `'$'` is followed by a character that is either not numeric, the name of one of the special parameters (see Section 2.5.2 (on page 2235)), a valid first character of a variable name, a left curly brace (`'{'`) or a left parenthesis, the result is unspecified.

2.6.1 Tilde Expansion

A *tilde-prefix* consists of an unquoted tilde character at the beginning of a word, followed by all of the characters preceding the first unquoted slash in the word, or all the characters in the word if there is no slash. In an assignment (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.21, Variable Assignment), multiple tilde-prefixes can be used: at the beginning of the word (that is, following the equal sign of the assignment), following any unquoted colon, or both. A tilde-prefix in an assignment is terminated by the first unquoted colon or slash. If none of the characters in the tilde-prefix are quoted, the characters in the tilde-prefix following the tilde are treated as a possible login name from the user database. A portable login name cannot contain characters outside the set given in the description of the *LOGNAME* environment variable in the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.3, Other Environment Variables. If the login name is null (that is, the tilde-prefix contains only the tilde), the tilde-prefix is replaced by the value of the variable *HOME*. If *HOME* is unset, the results are unspecified. Otherwise, the tilde-prefix shall be replaced by a pathname of the initial working directory associated with the login name obtained using the *getpwnam*( ) function as defined in the System Interfaces volume of IEEE Std 1003.1-200x. If the system does not recognize the login name, the results are undefined.

2.6.2 Parameter Expansion

The format for parameter expansion is as follows:

```
${expression}
```

where *expression* consists of all characters until the matching `'}'`. Any `'}'` escaped by a backslash or within a quoted string, and characters in embedded arithmetic expansions, command substitutions, and variable expansions, shall not be examined in determining the matching `'}'`.

The simplest form for parameter expansion is:

```
${parameter}
```

The value, if any, of *parameter* shall be substituted.

The parameter name or symbol can be enclosed in braces, which are optional except for positional parameters with more than one digit or when *parameter* is followed by a character that could be interpreted as part of the name. The matching closing brace shall be determined by counting brace levels, skipping over enclosed quoted strings, and command substitutions.

If the parameter name or symbol is not enclosed in braces, the expansion shall use the longest valid name (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.230, Name), whether or not the symbol represented by that name exists.

If a parameter expansion occurs inside double-quotes:

- Pathname expansion shall not be performed on the results of the expansion.
- Field splitting shall not be performed on the results of the expansion, with the exception of `'@'`; see Section 2.5.2 (on page 2235).

In addition, a parameter expansion can be modified by using one of the following formats. In each case that a value of *word* is needed (based on the state of *parameter*, as described below), *word* shall be subjected to tilde expansion, parameter expansion, command substitution, and arithmetic expansion. If *word* is not needed, it shall not be expanded. The `'}'` character that delimits the following parameter expansion modifications shall be determined as described previously in this section and in Section 2.2.3 (on page 2232). (For example, ${**foo-bar**}**xyz**} would result in the expansion of **foo** followed by the string **xyz**} if **foo** is set, else the string `"barxyz}"`).

${*parameter*:−*word*} **Use Default Values**. If *parameter* is unset or null, the expansion of *word* shall be substituted; otherwise, the value of *parameter* shall be substituted.

${*parameter*:=*word*} **Assign Default Values**. If *parameter* is unset or null, the expansion of *word* shall be assigned to *parameter*. In all cases, the final value of *parameter* shall be substituted. Only variables, not positional parameters or special parameters, can be assigned in this way.

${*parameter*:?**[***word***]**} **Indicate Error if Null or Unset**. If *parameter* is unset or null, the expansion of *word* (or a message indicating it is unset if *word* is omitted) shall be written to standard error and the shell exits with a non-zero exit status. Otherwise, the value of *parameter* shall be substituted. An interactive shell need not exit.

${*parameter*:+*word*} **Use Alternative Value**. If *parameter* is unset or null, null shall be substituted; otherwise, the expansion of *word* shall be substituted.

In the parameter expansions shown previously, use of the colon in the format shall result in a test for a parameter that is unset or null; omission of the colon shall result in a test for a parameter that is only unset. The following table summarizes the effect of the colon:

	parameter **Set and Not Null**	*parameter* **Set But Null**	*parameter* **Unset**
${*parameter***:−***word***}**	substitute *parameter*	substitute *word*	substitute *word*
${*parameter***−***word***}**	substitute *parameter*	substitute null	substitute *word*
${*parameter***:=***word***}**	substitute *parameter*	assign *word*	assign *word*
${*parameter***=***word***}**	substitute *parameter*	substitute *parameter*	assign null
${*parameter***:?***word***}**	substitute *parameter*	error, exit	error, exit
${*parameter***?***word***}**	substitute *parameter*	substitute null	error, exit
${*parameter***:+***word***}**	substitute *word*	substitute null	substitute null
${*parameter***+***word***}**	substitute *word*	substitute *word*	substitute null

In all cases shown with ‘‘substitute’’, the expression is replaced with the value shown. In all cases shown with ‘‘assign’’, *parameter* is assigned that value, which also replaces the expression.

${#*parameter*} **String Length**. The length in characters of the value of *parameter* shall be substituted. If *parameter* is `'*'` or `'@'`, the result of the expansion is unspecified.

The following four varieties of parameter expansion provide for substring processing. In each case, pattern matching notation (see Section 2.13 (on page 2264)), rather than regular expression notation, shall be used to evaluate the patterns. If *parameter* is `'*'` or `'@'`, the result of the expansion is unspecified. Enclosing the full parameter expansion string in double-quotes shall not cause the following four varieties of pattern characters to be quoted, whereas quoting characters within the braces shall have this effect.

${*parameter*%*word*} **Remove Smallest Suffix Pattern**. The *word* shall be expanded to produce a pattern. The parameter expansion shall then result in *parameter*, with the smallest portion of the suffix matched by the *pattern* deleted.

${*parameter*%%*word*} **Remove Largest Suffix Pattern**. The *word* shall be expanded to produce a pattern. The parameter expansion shall then result in *parameter*, with the largest portion of the suffix matched by the *pattern* deleted.

${*parameter*#*word*} **Remove Smallest Prefix Pattern**. The *word* shall be expanded to produce a pattern. The parameter expansion shall then result in *parameter*, with the smallest portion of the prefix matched by the *pattern* deleted.

${*parameter*##*word*} **Remove Largest Prefix Pattern**. The *word* shall be expanded to produce a pattern. The parameter expansion shall then result in *parameter*, with the largest portion of the prefix matched by the *pattern* deleted.

Examples

${*parameter*:−*word*}

In this example, *ls* is executed only if *x* is null or unset. (The $(*ls*) command substitution notation is explained in Section 2.6.3 (on page 2242).)

```
${x:−$(ls)}
```

${*parameter*:=*word*}

```
unset X
echo ${X:=abc}
abc
```

${*parameter*:?*word*}

```
unset posix
echo ${posix:?}
sh: posix: parameter null or not set
```

${*parameter*:+*word*}

```
set a b c
echo ${3:+posix}
posix
```

${#*parameter*}

```
HOME=/usr/posix
echo ${#HOME}
10
```

${*parameter*%*word*}

```
x=file.c
echo ${x%.c}.o
file.o
```

${*parameter*%%*word*}

```
x=posix/src/std
echo ${x%%/*}
posix
```

${*parameter*#*word*}

```
x=$HOME/src/cmd
echo ${x#$HOME}
/src/cmd
```

${*parameter*##*word*}

```
x=/one/two/three
```

```
echo ${x##*/}
three
```

The double-quoting of patterns is different depending on where the double-quotes are placed:

`"${x#*}"` The asterisk is a pattern character.

`${x#"*"}` The literal asterisk is quoted and not special.

2.6.3 Command Substitution

Command substitution allows the output of a command to be substituted in place of the command name itself. Command substitution shall occur when the command is enclosed as follows:

```
$(command)
```

or (backquoted version):

```
‘command‘
```

The shell shall expand the command substitution by executing *command* in a subshell environment (see Section 2.12 (on page 2263)) and replacing the command substitution (the text of *command* plus the enclosing `"$()"` or backquotes) with the standard output of the command, removing sequences of one or more <newline>s at the end of the substitution. Embedded <newline>s before the end of the output shall not be removed; however, they may be treated as field delimiters and eliminated during field splitting, depending on the value of *IFS* and quoting that is in effect.

Within the backquoted style of command substitution, backslash shall retain its literal meaning, except when followed by: `’$’`, `’‘’`, or `’\\’` (dollar sign, backquote, backslash). The search for the matching backquote shall be satisfied by the first backquote found without a preceding backslash; during this search, if a non-escaped backquote is encountered within a shell comment, a here-document, an embedded command substitution of the $(*command*) form, or a quoted string, undefined results occur. A single-quoted or double-quoted string that begins, but does not end, within the `"‘...‘"` sequence produces undefined results.

With the $(*command*) form, all characters following the open parenthesis to the matching closing parenthesis constitute the *command*. Any valid shell script can be used for *command*, except:

- A script consisting solely of redirections produces unspecified results
- See the restriction on single subshells described below

The results of command substitution shall not be processed for further tilde expansion, parameter expansion, command substitution, or arithmetic expansion. If a command substitution occurs inside double-quotes, it shall not be performed on the results of the substitution.

Command substitution can be nested. To specify nesting within the backquoted version, the application shall precede the inner backquotes with backslashes, for example:

```
\‘command\‘
```

If the command substitution consists of a single subshell, such as:

```
$( (command) )
```

a conforming application shall separate the `"$("` and `’(’` into two tokens (that is, separate them with white space). This is required to avoid any ambiguities with arithmetic expansion.

2.6.4 Arithmetic Expansion

Arithmetic expansion provides a mechanism for evaluating an arithmetic expression and substituting its value. The format for arithmetic expansion shall be as follows:

```
$((expression))
```

The expression shall be treated as if it were in double-quotes, except that a double-quote inside the expression is not treated specially. The shell shall expand all tokens in the expression for parameter expansion, command substitution, and quote removal.

Next, the shell shall treat this as an arithmetic expression and substitute the value of the expression. The arithmetic expression shall be processed according to the rules given in Section 1.7.2.1 (on page 2207), with the following exceptions:

- Only signed long integer arithmetic is required.
- Only the decimal-constant, octal-constant, and hexadecimal-constant constants specified in the ISO C standard, Subclause 6.4.4.1 are required to be recognized as constants.
- The *sizeof*( ) operator and the prefix and postfix "++" and "−−" operators are not required.
- Selection, iteration, and jump statements are not supported.

As an extension, the shell may recognize arithmetic expressions beyond those listed. The shell may use a signed integer type with a rank larger than the rank of **signed long**. The shell may use a real-floating type instead of **signed long** as long as it does not affect the results in cases where there is no overflow. If the expression is invalid, the expansion fails and the shell shall write a message to standard error indicating the failure.

Examples

A simple example using arithmetic expansion:

```
# repeat a command 100 times
x=100
while [ $x −gt 0 ]
do
    command
    x=$(($x−1))
done
```

2.6.5 Field Splitting

After parameter expansion (Section 2.6.2 (on page 2239)), command substitution (Section 2.6.3 (on page 2242)), and arithmetic expansion (Section 2.6.4), the shell shall scan the results of expansions and substitutions that did not occur in double-quotes for field splitting and multiple fields can result.

The shell shall treat each character of the *IFS* as a delimiter and use the delimiters to split the results of parameter expansion and command substitution into fields.

1. If the value of *IFS* is a <space>, <tab>, and <newline>, or if it is unset, any sequence of <space>s, <tab>s, or <newline>s at the beginning or end of the input shall be ignored and any sequence of those characters within the input shall delimit a field. For example, the input:

   ```
   <newline><space><tab>foo<tab><tab>bar<space>
   ```

yields two fields, **foo** and **bar**.

2. If the value of *IFS* is null, no field splitting shall be performed.

3. Otherwise, the following rules shall be applied in sequence. The term ''*IFS* white space'' is used to mean any sequence (zero or more instances) of white space characters that are in the *IFS* value (for example, if *IFS* contains <space>/<comma>/<tab>, any sequence of <space>s and <tab>s is considered *IFS* white space).

   a. *IFS* white space shall be ignored at the beginning and end of the input.

   b. Each occurrence in the input of an *IFS* character that is not *IFS* white space, along with any adjacent *IFS* white space, shall delimit a field, as described previously.

   c. Non-zero-length *IFS* white space shall delimit a field.

2.6.6 Pathname Expansion

After field splitting, if *set* **−f** is not in effect, each field in the resulting command line shall be expanded using the algorithm described in Section 2.13 (on page 2264), qualified by the rules in Section 2.13.3 (on page 2265).

2.6.7 Quote Removal

The quote characters: `'\'`, `'\''`, and `'"'` (backslash, single-quote, double-quote) that were present in the original word shall be removed unless they have themselves been quoted.

2.7 Redirection

Redirection is used to open and close files for the current shell execution environment (see Section 2.12 (on page 2263)) or for any command. *Redirection operators* can be used with numbers representing file descriptors (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.165, File Descriptor) as described below.

The overall format used for redirection is:

```
[n]redir-op word
```

The number *n* is an optional decimal number designating the file descriptor number; the application shall ensure it is delimited from any preceding text and immediately precede the redirection operator *redir-op*. If *n* is quoted, the number shall not be recognized as part of the redirection expression. For example:

```
echo \2>a
```

writes the character 2 into file **a**. If any part of *redir-op* is quoted, no redirection expression is recognized. For example:

```
echo 2\>a
```

writes the characters 2>*a* to standard output. The optional number, redirection operator, and *word* shall not appear in the arguments provided to the command to be executed (if any).

Open files are represented by decimal numbers starting with zero. The largest possible value is implementation-defined; however, all implementations shall support at least 0 to 9, inclusive, for use by the application. These numbers are called *file descriptors*. The values 0, 1, and 2 have special meaning and conventional uses and are implied by certain redirection operations; they are referred to as *standard input*, *standard output*, and *standard error*, respectively. Programs usually take their input from standard input, and write output on standard output. Error messages are usually written on standard error. The redirection operators can be preceded by one or more digits (with no intervening <blank>s allowed) to designate the file descriptor number.

If the redirection operator is `"<<"` or `"<<–"`, the word that follows the redirection operator shall be subjected to quote removal; it is unspecified whether any of the other expansions occur. For the other redirection operators, the word that follows the redirection operator shall be subjected to tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal. Pathname expansion shall not be performed on the word by a non-interactive shell; an interactive shell may perform it, but shall do so only when the expansion would result in one word.

If more than one redirection operator is specified with a command, the order of evaluation is from beginning to end.

A failure to open or create a file shall cause a redirection to fail.

2.7.1 Redirecting Input

Input redirection shall cause the file whose name results from the expansion of *word* to be opened for reading on the designated file descriptor, or standard input if the file descriptor is not specified.

The general format for redirecting input is:

```
[n]<word
```

where the optional *n* represents the file descriptor number. If the number is omitted, the redirection shall refer to standard input (file descriptor 0).

2.7.2 Redirecting Output

The two general formats for redirecting output are:

```
[n]>word
[n]>|word
```

where the optional *n* represents the file descriptor number. If the number is omitted, the redirection shall refer to standard output (file descriptor 1).

Output redirection using the `'>'` format shall fail if the *noclobber* option is set (see the description of *set* **–C**) and the file named by the expansion of *word* exists and is a regular file. Otherwise, redirection using the `'>'` or `">|"` formats shall cause the file whose name results from the expansion of *word* to be created and opened for output on the designated file descriptor, or standard output if none is specified. If the file does not exist, it shall be created; otherwise, it shall be truncated to be an empty file after being opened.

2.7.3 Appending Redirected Output

Appended output redirection shall cause the file whose name results from the expansion of word to be opened for output on the designated file descriptor. The file is opened as if the *open*( ) function as defined in the System Interfaces volume of IEEE Std 1003.1-200x was called with the O_APPEND flag. If the file does not exist, it shall be created.

The general format for appending redirected output is as follows:

```
[n]>>word
```

where the optional *n* represents the file descriptor number. If the number is omitted, the redirection refers to standard output (file descriptor 1).

2.7.4 Here-Document

The redirection operators `"<<"` and `"<<−"` both allow redirection of lines contained in a shell input file, known as a *here-document*, to the input of a command.

The here-document shall be treated as a single word that begins after the next <newline> and continues until there is a line containing only the delimiter and a <newline>, with no <blank>s in between. Then the next here-document starts, if there is one. The format is as follows:

```
[n]<<word
    here-document
delimiter
```

where the optional *n* represents the file descriptor number. If the number is omitted, the here-document refers to standard input (file descriptor 0).

If any character in *word* is quoted, the delimiter shall be formed by performing quote removal on *word*, and the here-document lines shall not be expanded. Otherwise, the delimiter shall be the *word* itself.

If no characters in *word* are quoted, all lines of the here-document shall be expanded for parameter expansion, command substitution, and arithmetic expansion. In this case, the backslash in the input behaves as the backslash inside double-quotes (see Section 2.2.3 (on page 2232)). However, the double-quote character (`'"'`) shall not be treated specially within a here-document, except when the double-quote appears within `"$()"`, ``"``"``, or `"${}"`.

If the redirection symbol is `"<<−"`, all leading tab characters shall be stripped from input lines and the line containing the trailing delimiter. If more than one `"<<"` or `"<<−"` operator is specified on a line, the here-document associated with the first operator shall be supplied first by the application and shall be read first by the shell.

Examples

An example of a here-document follows:

```
cat <<eof1; cat <<eof2
Hi,
eof1
Helene.
eof2
```

2.7.5 Duplicating an Input File Descriptor

The redirection operator:

```
[n]<&word
```

shall duplicate one input file descriptor from another, or shall close one. If *word* evaluates to one or more digits, the file descriptor denoted by *n*, or standard input if *n* is not specified, shall be made to be a copy of the file descriptor denoted by *word*; if the digits in *word* do not represent a file descriptor already open for input, a redirection error shall result; see Section 2.8.1 (on page 2247). If *word* evaluates to `'−'`, file descriptor *n*, or standard input if *n* is not specified, shall be closed. If *word* evaluates to something else, the behavior is unspecified.

2.7.6 Duplicating an Output File Descriptor

The redirection operator:

```
[n]>&word
```

shall duplicate one output file descriptor from another, or shall close one. If *word* evaluates to one or more digits, the file descriptor denoted by *n*, or standard output if *n* is not specified, shall be made to be a copy of the file descriptor denoted by *word*; if the digits in *word* do not represent a file descriptor already open for output, a redirection error shall result; see Section 2.8.1. If *word* evaluates to `'−'`, file descriptor *n*, or standard output if *n* is not specified, is closed. If *word* evaluates to something else, the behavior is unspecified.

2.7.7 Open File Descriptors for Reading and Writing

The redirection operator:

```
[n]<>word
```

shall cause the file whose name is the expansion of *word* to be opened for both reading and writing on the file descriptor denoted by *n*, or standard input if *n* is not specified. If the file does not exist, it shall be created.

2.8 Exit Status and Errors

2.8.1 Consequences of Shell Errors

For a non-interactive shell, an error condition encountered by a special built-in (see Section 2.14 (on page 2266)) or other type of utility shall cause the shell to write a diagnostic message to standard error and exit as shown in the following table:

Error	Special Built-In	Other Utilities
Shell language syntax error	Shall exit	Shall exit
Utility syntax error (option or operand error)	Shall exit	Shall not exit
Redirection error	Shall exit	Shall not exit
Variable assignment error	Shall exit	Shall not exit
Expansion error	Shall exit	Shall exit
Command not found	N/A	May exit
Dot script not found	Shall exit	N/A

An expansion error is one that occurs when the shell expansions defined in Section 2.6 (on page 2238) are carried out (for example, `"${x!y}"`, because `'!'` is not a valid operator); an implementation may treat these as syntax errors if it is able to detect them during tokenization, rather than during expansion.

If any of the errors shown as ‘‘shall exit’’ or ‘‘(may) exit’’ occur in a subshell, the subshell shall (respectively may) exit with a non-zero status, but the script containing the subshell shall not exit because of the error.

In all of the cases shown in the table, an interactive shell shall write a diagnostic message to standard error without exiting.

2.8.2 Exit Status for Commands

Each command has an exit status that can influence the behavior of other shell commands. The exit status of commands that are not utilities is documented in this section. The exit status of the standard utilities is documented in their respective sections.

If a command is not found, the exit status shall be 127. If the command name is found, but it is not an executable utility, the exit status shall be 126. Applications that invoke utilities without using the shell should use these exit status values to report similar errors.

If a command fails during word expansion or redirection, its exit status shall be greater than zero.

Internally, for purposes of deciding whether a command exits with a non-zero exit status, the shell shall recognize the entire status value retrieved for the command by the equivalent of the *wait*( ) function WEXITSTATUS macro (as defined in the System Interfaces volume of IEEE Std 1003.1-200x). When reporting the exit status with the special parameter `'?'`, the shell shall report the full eight bits of exit status available. The exit status of a command that terminated because it received a signal shall be reported as greater than 128.

2.9 Shell Commands

This section describes the basic structure of shell commands. The following command descriptions each describe a format of the command that is only used to aid the reader in recognizing the command type, and does not formally represent the syntax. Each description discusses the semantics of the command; for a formal definition of the command language, consult Section 2.10 (on page 2257).

A *command* is one of the following:

- *Simple command* (see Section 2.9.1)
- *Pipeline* (see Section 2.9.2 (on page 2250))
- *List* or *compound-list* (see Section 2.9.3 (on page 2251))
- *Compound command* (see Section 2.9.4 (on page 2253))
- *Function definition* (see Section 2.9.5 (on page 2256))

Unless otherwise stated, the exit status of a command shall be that of the last simple command executed by the command. There shall be no limit on the size of any shell command other than that imposed by the underlying system (memory constraints, {ARG_MAX}, and so on).

2.9.1 Simple Commands

A *simple command* is a sequence of optional variable assignments and redirections, in any sequence, optionally followed by words and redirections, terminated by a control operator.

When a given simple command is required to be executed (that is, when any conditional construct such as an AND-OR list or a **case** statement has not bypassed the simple command), the following expansions, assignments, and redirections shall all be performed from the beginning of the command text to the end:

1. The words that are recognized as variable assignments or redirections according to Section 2.10.2 (on page 2257) are saved for processing in steps 3 and 4.
2. The words that are not variable assignments or redirections shall be expanded. If any fields remain following their expansion, the first field shall be considered the command name

and remaining fields are the arguments for the command.

3. Redirections shall be performed as described in Section 2.7 (on page 2244).
4. Each variable assignment shall be expanded for tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal prior to assigning the value.

In the preceding list, the order of steps 3 and 4 may be reversed for the processing of special built-in utilities; see Section 2.14 (on page 2266).

If no command name results, variable assignments shall affect the current execution environment. Otherwise, the variable assignments shall be exported for the execution environment of the command and shall not affect the current execution environment (except for special built-ins). If any of the variable assignments attempt to assign a value to a read-only variable, a variable assignment error shall occur. See Section 2.8.1 (on page 2247) for the consequences of these errors.

If there is no command name, any redirections shall be performed in a subshell environment; it is unspecified whether this subshell environment is the same one as that used for a command substitution within the command. (To affect the current execution environment, see the *exec* (on page 2277) special built-in.) If any of the redirections performed in the current shell execution environment fail, the command shall immediately fail with an exit status greater than zero, and the shell shall write an error message indicating the failure. See Section 2.8.1 (on page 2247) for the consequences of these failures on interactive and non-interactive shells.

If there is a command name, execution shall continue as described in Section 2.9.1.1. If there is no command name, but the command contained a command substitution, the command shall complete with the exit status of the last command substitution performed. Otherwise, the command shall complete with a zero exit status.

2.9.1.1 Command Search and Execution

If a simple command results in a command name and an optional list of arguments, the following actions shall be performed:

1. If the command name does not contain any slashes, the first successful step in the following sequence shall occur:
    a. If the command name matches the name of a special built-in utility, that special built-in utility shall be invoked.

    b. If the command name matches the name of a function known to this shell, the function shall be invoked as described in Section 2.9.5 (on page 2256). If the implementation has provided a standard utility in the form of a function, it shall not be recognized at this point. It shall be invoked in conjunction with the path search in step 1d.

    c. If the command name matches the name of a utility listed in the following table, that utility shall be invoked.

    alias
    bg
    cd
    command
    false
    fc
    fg
    getopts
    jobs
    kill
    newgrp
    read
    true
    umask
    unalias
    wait

    d. Otherwise, the command shall be searched for using the *PATH* environment variable as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables:

i. If the search is successful:

a. If the system has implemented the utility as a regular built-in or as a shell function, it shall be invoked at this point in the path search.

b. Otherwise, the shell executes the utility in a separate utility environment (see Section 2.12 (on page 2263)) with actions equivalent to calling the *execve*( ) function as defined in the System Interfaces volume of IEEE Std 1003.1-200x with the *path* argument set to the pathname resulting from the search, *arg*0 set to the command name, and the remaining arguments set to the operands, if any.

If the *execve*( ) function fails due to an error equivalent to the [ENOEXEC] error defined in the System Interfaces volume of IEEE Std 1003.1-200x, the shell shall execute a command equivalent to having a shell invoked with the command name as its first operand, with any remaining arguments passed to the new shell. If the executable file is not a text file, the shell may bypass this command execution. In this case, it shall write an error message, and shall return an exit status of 126.

Once a utility has been searched for and found (either as a result of this specific search or as part of an unspecified shell start-up activity), an implementation may remember its location and need not search for the utility again unless the *PATH* variable has been the subject of an assignment. If the remembered location fails for a subsequent invocation, the shell shall repeat the search to find the new location for the utility, if any.

ii. If the search is unsuccessful, the command shall fail with an exit status of 127 and the shell shall write an error message.

2. If the command name contains at least one slash, the shell shall execute the utility in a separate utility environment with actions equivalent to calling the *execve*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x with the *path* and *arg*0 arguments set to the command name, and the remaining arguments set to the operands, if any.

   If the *execve*( ) function fails due to an error equivalent to the [ENOEXEC] error, the shell shall execute a command equivalent to having a shell invoked with the command name as its first operand, with any remaining arguments passed to the new shell. If the executable file is not a text file, the shell may bypass this command execution. In this case, it shall write an error message and shall return an exit status of 126.

2.9.2 Pipelines

A *pipeline* is a sequence of one or more commands separated by the control operator `'|'`. The standard output of all but the last command shall be connected to the standard input of the next command.

The format for a pipeline is:

```
[!] command1 [ | command2 ...]
```

The standard output of *command1* shall be connected to the standard input of *command2*. The standard input, standard output, or both of a command shall be considered to be assigned by the pipeline before any redirection specified by redirection operators that are part of the command (see Section 2.7 (on page 2244)).

If the pipeline is not in the background (see Section 2.9.3.1 (on page 2252)), the shell shall wait for the last command specified in the pipeline to complete, and may also wait for all commands to complete.

Exit Status

If the reserved word `!` does not precede the pipeline, the exit status shall be the exit status of the last command specified in the pipeline. Otherwise, the exit status shall be the logical NOT of the exit status of the last command. That is, if the last command returns zero, the exit status shall be 1; if the last command returns greater than zero, the exit status shall be zero.

2.9.3 Lists

An *AND-OR list* is a sequence of one or more pipelines separated by the operators `"&&"` and `"||"`.

A *list* is a sequence of one or more AND-OR lists separated by the operators `';'` and `'&'` and optionally terminated by `';'`, `'&'`, or <newline>.

The operators `"&&"` and `"||"` shall have equal precedence and shall be evaluated with left associativity. For example, both of the following commands write solely **bar** to standard output:

```
false && echo foo || echo bar
true || echo foo && echo bar
```

A `';'` or <newline> terminator shall cause the preceding AND-OR list to be executed sequentially; an `'&'` shall cause asynchronous execution of the preceding AND-OR list.

The term *compound-list* is derived from the grammar in Section 2.10 (on page 2257); it is equivalent to a sequence of *lists*, separated by <newline>s, that can be preceded or followed by an arbitrary number of <newline>s.

Examples

The following is an example that illustrates <newline>s in compound-lists:

```
while
    # a couple of <newline>s

    # a list
    date && who || ls; cat file
    # a couple of <newline>s

    # another list
    wc file > output & true

do
    # 2 lists
    ls
    cat file
done
```

2.9.3.1 *Asynchronous Lists*

If a command is terminated by the control operator ampersand (`'&'`), the shell shall execute the command asynchronously in a subshell. This means that the shell shall not wait for the command to finish before executing the next command.

The format for running a command in the background is:

```
command1 & [command2 & ... ]
```

The standard input for an asynchronous list, before any explicit redirections are performed, shall be considered to be assigned to a file that has the same properties as **/dev/null**. If it is an interactive shell, this need not happen. In all cases, explicit redirection of standard input shall override this activity.

When an element of an asynchronous list (the portion of the list ended by an ampersand, such as *command1*, above) is started by the shell, the process ID of the last command in the asynchronous list element shall become known in the current shell execution environment; see Section 2.12 (on page 2263). This process ID shall remain known until:

1. The command terminates and the application waits for the process ID.
2. Another asynchronous list invoked before `"$!"` (corresponding to the previous asynchronous list) is expanded in the current execution environment.

The implementation need not retain more than the {CHILD_MAX} most recent entries in its list of known process IDs in the current shell execution environment.

Exit Status

The exit status of an asynchronous list shall be zero.

2.9.3.2 *Sequential Lists*

Commands that are separated by a semicolon (`';'`) shall be executed sequentially.

The format for executing commands sequentially shall be:

```
command1 [; command2] ...
```

Each command shall be expanded and executed in the order specified.

Exit Status

The exit status of a sequential list shall be the exit status of the last command in the list.

2.9.3.3 *AND Lists*

The control operator `"&&"` denotes an AND list. The format shall be:

```
command1 [ && command2] ...
```

First *command1* shall be executed. If its exit status is zero, *command2* shall be executed, and so on, until a command has a non-zero exit status or there are no more commands left to execute. The commands are expanded only if they are executed.

Exit Status

The exit status of an AND list shall be the exit status of the last command that is executed in the list.

2.9.3.4 *OR Lists*

The control operator `"||"` denotes an OR List. The format shall be:

```
command1 [ || command2] ...
```

First, *command1* shall be executed. If its exit status is non-zero, *command2* shall be executed, and so on, until a command has a zero exit status or there are no more commands left to execute.

Exit Status

The exit status of an OR list shall be the exit status of the last command that is executed in the list.

2.9.4 Compound Commands

The shell has several programming constructs that are *compound commands*, which provide control flow for commands. Each of these compound commands has a reserved word or control operator at the beginning, and a corresponding terminator reserved word or operator at the end. In addition, each can be followed by redirections on the same line as the terminator. Each redirection shall apply to all the commands within the compound command that do not explicitly override that redirection.

2.9.4.1 *Grouping Commands*

The format for grouping commands is as follows:

(*compound-list*)	Execute *compound-list* in a subshell environment; see Section 2.12 (on page 2263). Variable assignments and built-in commands that affect the environment shall not remain in effect after the list finishes.
{ *compound-list*;}	Execute *compound-list* in the current process environment. The semicolon shown here is an example of a control operator delimiting the **}** reserved word. Other delimiters are possible, as shown in Section 2.10 (on page 2257); a <newline> is frequently used.

Exit Status

The exit status of a grouping command shall be the exit status of *list*.

2.9.4.2 *For Loop*

The **for** loop shall execute a sequence of commands for each member in a list of *items*. The **for** loop requires that the reserved words **do** and **done** be used to delimit the sequence of commands.

The format for the **for** loop is as follows:

```
for name [ in [word ... ]]
do
    compound-list
done
```

First, the list of words following **in** shall be expanded to generate a list of items. Then, the variable *name* shall be set to each item, in turn, and the *compound-list* executed each time. If no items result from the expansion, the *compound-list* shall not be executed. Omitting:

```
in word ...
```

shall be equivalent to:

```
in "$@"
```

Exit Status

The exit status of a **for** command shall be the exit status of the last command that executes. If there are no items, the exit status shall be zero.

2.9.4.3 *Case Conditional Construct*

The conditional construct **case** shall execute the *compound-list* corresponding to the first one of several *patterns* (see Section 2.13 (on page 2264)) that is matched by the string resulting from the tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal of the given word. The reserved word **in** shall denote the beginning of the patterns to be matched. Multiple patterns with the same *compound-list* shall be delimited by the `'|'` symbol. The control operator `')'` terminates a list of patterns corresponding to a given action. The *compound-list* for each list of patterns, with the possible exception of the last, shall be terminated with `";;"`. The **case** construct terminates with the reserved word **esac** (**case** reversed).

The format for the **case** construct is as follows:

```
case word in
    [(]pattern1) compound-list;;
    [[(]pattern[ | pattern] ... ) compound-list;;] ...
    [[(]pattern[ | pattern] ... ) compound-list]
esac
```

The `";;"` is optional for the last *compound-list*.

In order from the beginning to the end of the **case** statement, each *pattern* that labels a *compound-list* shall be subjected to tilde expansion, parameter expansion, command substitution, and arithmetic expansion, and the result of these expansions shall be compared against the expansion of *word*, according to the rules described in Section 2.13 (on page 2264) (which also describes the effect of quoting parts of the pattern). After the first match, no more patterns shall be expanded, and the *compound-list* shall be executed. The order of expansion and comparison of multiple *pattern*s that label a *compound-list* statement is unspecified.

Exit Status

The exit status of **case** shall be zero if no patterns are matched. Otherwise, the exit status shall be the exit status of the last command executed in the *compound-list*.

2.9.4.4 *If Conditional Construct*

The **if** command shall execute a *compound-list* and use its exit status to determine whether to execute another *compound-list*.

The format for the **if** construct is as follows:

```
if compound-list
then
    compound-list
[elif compound-list
then
    compound-list] ...
[else
    compound-list]
```

The **if** *compound-list* shall be executed; if its exit status is zero, the **then** *compound-list* shall be executed and the command shall complete. Otherwise, each **elif** *compound-list* shall be executed, in turn, and if its exit status is zero, the **then** *compound-list* shall be executed and the command shall complete. Otherwise, the **else** *compound-list* shall be executed.

Exit Status

The exit status of the **if** command shall be the exit status of the **then** or **else** *compound-list* that was executed, or zero, if none was executed.

2.9.4.5 *While Loop*

The **while** loop shall continuously execute one *compound-list* as long as another *compound-list* has a zero exit status.

The format of the **while** loop is as follows:

```
while compound-list-1
do
    compound-list-2
done
```

The *compound-list-1* shall be executed, and if it has a non-zero exit status, the **while** command shall complete. Otherwise, the *compound-list-2* shall be executed, and the process shall repeat.

Exit Status

The exit status of the **while** loop shall be the exit status of the last *compound-list-2* executed, or zero if none was executed.

2.9.4.6 *Until Loop*

The **until** loop shall continuously execute one *compound-list* as long as another *compound-list* has a non-zero exit status.

The format of the **until** loop is as follows:

```
until compound-list-1
do
    compound-list-2
done
```

The *compound-list-1* shall be executed, and if it has a zero exit status, the **until** command completes. Otherwise, the *compound-list-2* shall be executed, and the process repeats.

Exit Status

The exit status of the **until** loop shall be the exit status of the last *compound-list-2* executed, or zero if none was executed.

2.9.5 Function Definition Command

A function is a user-defined name that is used as a simple command to call a compound command with new positional parameters. A function is defined with a *function definition command*.

The format of a function definition command is as follows:

```
fname() compound-command[io-redirect ...]
```

The function is named *fname*; the application shall ensure that it is a name (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.230, Name). An implementation may allow other characters in a function name as an extension. The implementation shall maintain separate name spaces for functions and variables.

The argument *compound-command* represents a compound command, as described in Section 2.9.4 (on page 2253).

When the function is declared, none of the expansions in Section 2.6 (on page 2238) shall be performed on the text in *compound-command* or *io-redirect*; all expansions shall be performed as normal each time the function is called. Similarly, the optional *io-redirect* redirections and any variable assignments within *compound-command* shall be performed during the execution of the function itself, not the function definition. See Section 2.8.1 (on page 2247) for the consequences of failures of these operations on interactive and non-interactive shells.

When a function is executed, it shall have the syntax-error and variable-assignment properties described for special built-in utilities in the enumerated list at the beginning of Section 2.14 (on page 2266).

The *compound-command* shall be executed whenever the function name is specified as the name of a simple command (see Section 2.9.1.1 (on page 2249)). The operands to the command temporarily shall become the positional parameters during the execution of the *compound-command*; the special parameter `'#'` also shall be changed to reflect the number of operands. The special parameter 0 shall be unchanged. When the function completes, the values of the positional parameters and the special parameter `'#'` shall be restored to the values they had before the function was executed. If the special built-in *return* is executed in the *compound-command*, the function completes and execution shall resume with the next command after the function call.

Exit Status

The exit status of a function definition shall be zero if the function was declared successfully; otherwise, it shall be greater than zero. The exit status of a function invocation shall be the exit status of the last command executed by the function.

2.10 Shell Grammar

The following grammar defines the Shell Command Language. This formal syntax shall take precedence over the preceding text syntax description.

2.10.1 Shell Grammar Lexical Conventions

The input language to the shell must be first recognized at the character level. The resulting tokens shall be classified by their immediate context according to the following rules (applied in order). These rules shall be used to determine what a ‘‘token’’ is that is subject to parsing at the token level. The rules for token recognition in Section 2.3 (on page 2233) shall apply.

1. A <newline> shall be returned as the token identifier **NEWLINE**.
2. If the token is an operator, the token identifier for that operator shall result.
3. If the string consists solely of digits and the delimiter character is one of `'<'` or `'>'`, the token identifier **IO_NUMBER** shall be returned.
4. Otherwise, the token identifier **TOKEN** results.

Further distinction on **TOKEN** is context-dependent. It may be that the same **TOKEN** yields **WORD**, a **NAME**, an **ASSIGNMENT**, or one of the reserved words below, dependent upon the context. Some of the productions in the grammar below are annotated with a rule number from the following list. When a **TOKEN** is seen where one of those annotated productions could be used to reduce the symbol, the applicable rule shall be applied to convert the token identifier type of the **TOKEN** to a token identifier acceptable at that point in the grammar. The reduction shall then proceed based upon the token identifier type yielded by the rule applied. When more than one rule applies, the highest numbered rule shall apply (which in turn may refer to another rule). (Note that except in rule 7, the presence of an `'='` in the token has no effect.)

The **WORD** tokens shall have the word expansion rules applied to them immediately before the associated command is executed, not at the time the command is parsed.

2.10.2 Shell Grammar Rules

1. [Command Name]

   When the **TOKEN** is exactly a reserved word, the token identifier for that reserved word shall result. Otherwise, the token **WORD** shall be returned. Also, if the parser is in any state where only a reserved word could be the next correct token, proceed as above.

   Note: Because at this point quote marks are retained in the token, quoted strings cannot be recognized as reserved words. This rule also implies that reserved words are not recognized except in certain positions in the input, such as after a <newline> or semicolon; the grammar presumes that if the reserved word is intended, it is properly delimited by the user, and does not attempt to reflect that requirement directly. Also note that line joining is done before tokenization, as described in Section 2.2.1 (on page 2232), so escaped <newline>s are already removed at this point.

   Rule 1 is not directly referenced in the grammar, but is referred to by other rules, or applies globally.

2. [Redirection to or from filename]

   The expansions specified in Section 2.7 (on page 2244) shall occur. As specified there, exactly one field can result (or the result is unspecified), and there are additional requirements on pathname expansion.

3. [Redirection from here-document]

   Quote removal shall be applied to the word to determine the delimiter that is used to find the end of the here-document that begins after the next <newline>.

4. [Case statement termination]

   When the **TOKEN** is exactly the reserved word **esac**, the token identifier for **esac** shall result. Otherwise, the token **WORD** shall be returned.

5. [**NAME** in **for**]

   When the **TOKEN** meets the requirements for a name (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.230, Name), the token identifier **NAME** shall result. Otherwise, the token **WORD** shall be returned.

6. [Third word of **for** and **case**]

   When the **TOKEN** is exactly the reserved word **in**, the token identifier for **in** shall result. Otherwise, the token **WORD** shall be returned. (As indicated in the grammar, a *linebreak* precedes the token **in**. If <newline>s are present at the indicated location, it is the token after them that is treated in this fashion.)

7. [Assignment preceding command name]

   a. [When the first word]

      If the **TOKEN** does not contain the character `'='`, rule 1 is applied. Otherwise, 7b shall be applied.

   b. [Not the first word]

      If the **TOKEN** contains the equal sign character:

      — If it begins with `'='`, the token **WORD** shall be returned.

      — If all the characters preceding `'='` form a valid name (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.230, Name), the token **ASSIGNMENT_WORD** shall be returned. (Quoted characters cannot participate in forming a valid name.)

      — Otherwise, it is unspecified whether it is **ASSIGNMENT_WORD** or **WORD** that is returned.

   Assignment to the **NAME** shall occur as specified in Section 2.9.1 (on page 2248).

8. [**NAME** in function]

   When the **TOKEN** is exactly a reserved word, the token identifier for that reserved word shall result. Otherwise, when the **TOKEN** meets the requirements for a name, the token identifier **NAME** shall result. Otherwise, rule 7 applies.

9. [Body of function]

   Word expansion and assignment shall never occur, even when required by the rules above, when this rule is being parsed. Each **TOKEN** that might either be expanded or have assignment applied to it shall instead be returned as a single **WORD** consisting only of characters that are exactly the token described in Section 2.3 (on page 2233).

                    | newline_list
                    ;
```

2.11 Signals and Error Handling

When a command is in an asynchronous list, the shell shall prevent SIGQUIT and SIGINT signals from the keyboard from interrupting the command. Otherwise, signals shall have the values inherited by the shell from its parent (see also the *trap* (on page 2297) special built-in).

When a signal for which a trap has been set is received while the shell is waiting for the completion of a utility executing a foreground command, the trap associated with that signal shall not be executed until after the foreground command has completed. When the shell is waiting, by means of the *wait* utility, for asynchronous commands to complete, the reception of a signal for which a trap has been set shall cause the *wait* utility to return immediately with an exit status >128, immediately after which the trap associated with that signal shall be taken.

If multiple signals are pending for the shell for which there are associated trap actions, the order of execution of trap actions is unspecified.

2.12 Shell Execution Environment

A shell execution environment consists of the following:

- Open files inherited upon invocation of the shell, plus open files controlled by *exec*
- Working directory as set by *cd*
- File creation mask set by *umask*
- Current traps set by *trap*
- Shell parameters that are set by variable assignment (see the *set* (on page 2287) special built-in) or from the System Interfaces volume of IEEE Std 1003.1-200x environment inherited by the shell when it begins (see the *export* (on page 2281) special built-in)
- Shell functions; see Section 2.9.5 (on page 2256)
- Options turned on at invocation or by *set*
- Process IDs of the last commands in asynchronous lists known to this shell environment; see Section 2.9.3.1 (on page 2252)
- Shell aliases; see Section 2.3.1 (on page 2234)

Utilities other than the special built-ins (see Section 2.14 (on page 2266)) shall be invoked in a separate environment that consists of the following. The initial value of these objects shall be the same as that for the parent shell, except as noted below.

- Open files inherited on invocation of the shell, open files controlled by the *exec* special built-in plus any modifications, and additions specified by any redirections to the utility
- Current working directory
- File creation mask
- If the utility is a shell script, traps caught by the shell shall be set to the default values and traps ignored by the shell shall be set to be ignored by the utility; if the utility is not a shell script, the trap actions (default or ignore) shall be mapped into the appropriate signal handling actions for the utility
- Variables with the *export* attribute, along with those explicitly exported for the duration of the command, shall be passed to the utility as System Interfaces volume of IEEE Std 1003.1-200x environment variables

The environment of the shell process shall not be changed by the utility unless explicitly specified by the utility description (for example, *cd* and *umask*).

A subshell environment shall be created as a duplicate of the shell environment, except that signal traps set by that shell environment shall be set to the default values. Changes made to the subshell environment shall not affect the shell environment. Command substitution, commands that are grouped with parentheses, and asynchronous lists shall be executed in a subshell environment. Additionally, each command of a multi-command pipeline is in a subshell environment; as an extension, however, any or all commands in a pipeline may be executed in the current environment. All other commands shall be executed in the current shell environment.

2.13 Pattern Matching Notation

The pattern matching notation described in this section is used to specify patterns for matching strings in the shell. Historically, pattern matching notation is related to, but slightly different from, the regular expression notation described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 9, Regular Expressions. For this reason, the description of the rules for this pattern matching notation are based on the description of regular expression notation, modified to include backslash escape processing.

2.13.1 Patterns Matching a Single Character

The following *patterns matching a single character* shall match a single character: *ordinary characters*, *special pattern characters*, and *pattern bracket expressions*. The pattern bracket expression also shall match a single collating element. A backslash character shall escape the following character. The escaping backslash shall be discarded.

An ordinary character is a pattern that shall match itself. It can be any character in the supported character set except for NUL, those special shell characters in Section 2.2 (on page 2232) that require quoting, and the following three special pattern characters. Matching shall be based on the bit pattern used for encoding the character, not on the graphic representation of the character. If any character (ordinary, shell special, or pattern special) is quoted, that pattern shall match the character itself. The shell special characters always require quoting.

When unquoted and outside a bracket expression, the following three characters shall have special meaning in the specification of patterns:

? A question-mark is a pattern that shall match any character.

* An asterisk is a pattern that shall match multiple characters, as described in Section 2.13.2.

[The open bracket shall introduce a pattern bracket expression.

The description of basic regular expression bracket expressions in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3.5, RE Bracket Expression shall also apply to the pattern bracket expression, except that the exclamation mark character ('!') shall replace the circumflex character ('^') in its role in a *non-matching list* in the regular expression notation. A bracket expression starting with an unquoted circumflex character produces unspecified results.

When pattern matching is used where shell quote removal is not performed (such as in the argument to the *find name* primary when *find* is being called using one of the *exec* functions as defined in the System Interfaces volume of IEEE Std 1003.1-200x, or in the *pattern* argument to the *fnmatch*( ) function), special characters can be escaped to remove their special meaning by preceding them with a backslash character. This escaping backslash is discarded. The sequence "\\" represents one literal backslash. All of the requirements and effects of quoting on ordinary, shell special, and special pattern characters shall apply to escaping in this context.

2.13.2 Patterns Matching Multiple Characters

The following rules are used to construct *patterns matching multiple characters* from *patterns matching a single character*:

1. The asterisk ('*') is a pattern that shall match any string, including the null string.
2. The concatenation of *patterns matching a single character* is a valid pattern that shall match the concatenation of the single characters or collating elements matched by each of the concatenated patterns.

3. The concatenation of one or more *patterns matching a single character* with one or more asterisks is a valid pattern. In such patterns, each asterisk shall match a string of zero or more characters, matching the greatest possible number of characters that still allows the remainder of the pattern to match the string.

2.13.3 Patterns Used for Filename Expansion

The rules described so far in Section 2.13.1 (on page 2264) and Section 2.13.2 (on page 2264) are qualified by the following rules that apply when pattern matching notation is used for filename expansion:

1. The slash character in a pathname shall be explicitly matched by using one or more slashes in the pattern; it shall neither be matched by the asterisk or question-mark special characters nor by a bracket expression. Slashes in the pattern shall be identified before bracket expressions; thus, a slash cannot be included in a pattern bracket expression used for filename expansion. If a slash character is found following an unescaped open square bracket character before a corresponding closing square bracket is found, the open bracket shall be treated as an ordinary character. For example, the pattern `"a[b/c]d"` does not match such pathnames as **abd** or **a/d**. It only matches a pathname of literally **a[b/c]d**.

2. If a filename begins with a period (`'.'`), the period shall be explicitly matched by using a period as the first character of the pattern or immediately following a slash character. The leading period shall not be matched by:

   - The asterisk or question-mark special characters
   - A bracket expression containing a non-matching list, such as `"[!a]"`, a range expression, such as `"[%−0]"`, or a character class expression, such as `"[[:punct:]]"`

   It is unspecified whether an explicit period in a bracket expression matching list, such as `"[.abc]"`, can match a leading period in a filename.

3. Specified patterns shall be matched against existing filenames and pathnames, as appropriate. Each component that contains a pattern character shall require read permission in the directory containing that component. Any component, except the last, that does not contain a pattern character shall require search permission. For example, given the pattern:

   ```
   /foo/bar/x*/bam
   ```

   search permission is needed for directories **/** and **foo**, search and read permissions are needed for directory **bar**, and search permission is needed for each **x*** directory. If the pattern matches any existing filenames or pathnames, the pattern shall be replaced with those filenames and pathnames, sorted according to the collating sequence in effect in the current locale. If the pattern contains an invalid bracket expression or does not match any existing filenames or pathnames, the pattern string shall be left unchanged.

2.14 Special Built-In Utilities

The following *special built-in* utilities shall be supported in the shell command language. The output of each command, if any, shall be written to standard output, subject to the normal redirection and piping possible with all commands.

The term *built-in* implies that the shell can execute the utility directly and does not need to search for it. An implementation may choose to make any utility a built-in; however, the special built-in utilities described here differ from regular built-in utilities in two respects:

1. A syntax error in a special built-in utility may cause a shell executing that utility to abort, while a syntax error in a regular built-in utility shall not cause a shell executing that utility to abort. (See Section 2.8.1 (on page 2247) for the consequences of errors on interactive and non-interactive shells.) If a special built-in utility encountering a syntax error does not abort the shell, its exit value shall be non-zero.
2. Variable assignments specified with special built-in utilities remain in effect after the built-in completes; this shall not be the case with a regular built-in or other utility.

The special built-in utilities in this section need not be provided in a manner accessible via the *exec* family of functions defined in the System Interfaces volume of IEEE Std 1003.1-200x.

Some of the special built-ins are described as conforming to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines. For those that are not, the requirement in Section 1.11 (on page 2221) that "−−" be recognized as a first argument to be discarded does not apply and a conforming application shall not use that argument.

NAME

break — exit from for, while, or until loop

SYNOPSIS

```
break [n]
```

DESCRIPTION

The *break* utility shall exit from the smallest enclosing **for**, **while**, or **until** loop, if any; or from the *n*th enclosing loop if *n* is specified. The value of *n* is an unsigned decimal integer greater than or equal to 1. The default shall be equivalent to *n*=1. If *n* is greater than the number of enclosing loops, the outermost enclosing loop shall be exited. Execution shall continue with the command immediately following the loop.

EXIT STATUS

0	Successful completion.
>0	The *n* value was not an unsigned decimal integer greater than or equal to 1.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

```
for i in * do
    if test -d "$i" then break fi done
```

RATIONALE

In early proposals, consideration was given to expanding the syntax of *break* and *continue* to refer to a label associated with the appropriate loop as a preferable alternative to the *n* method. However, this volume of IEEE Std 1003.1-200x does reserve the namespace of command names ending with a colon. It is anticipated that a future implementation could take advantage of this and provide something like:

```
outofloop: for i in a b c d e
do
    for j in 0 1 2 3 4 5 6 7 8 9
    do
        if test -r "${i}${j}"
        then break outofloop
        fi
    done
done
```

and that this might be standardized after implementation experience is achieved.

NAME

colon — null utility

SYNOPSIS

`: [argument ...]`

DESCRIPTION

This utility shall only expand command *arguments*. It is used when a command is needed, as in the *then* condition of an **if** command, but nothing is to be done by the command.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

EXIT STATUS

Zero.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

```
: ${X=abc}
if     false
then   :
else   echo $X
fi
abc
```

As with any of the special built-ins, the null utility can also have variable assignments and redirections associated with it, such as:

```
x=y : > z
```

which sets variable *x* to the value *y* (so that it persists after the null utility completes) and creates or truncates file **z**.

NAME

continue — continue for, while, or until loop

SYNOPSIS

`continue [n]`

DESCRIPTION

The *continue* utility shall return to the top of the smallest enclosing **for**, **while**, or **until** loop, or to the top of the *n*th enclosing loop, if *n* is specified. This involves repeating the condition list of a **while** or **until** loop or performing the next assignment of a **for** loop, and reexecuting the loop if appropriate.

The value of *n* is a decimal integer greater than or equal to 1. The default shall be equivalent to *n*=1. If *n* is greater than the number of enclosing loops, the outermost enclosing loop shall be used.

NAME

dot — execute commands in current environment

SYNOPSIS

```
. file
```

DESCRIPTION

The shell shall execute commands from the *file* in the current environment.

If *file* does not contain a slash, the shell shall use the search path specified by *PATH* to find the directory containing *file*. Unlike normal command search, however, the file searched for by the *dot* utility need not be executable. If no readable file is found, a non-interactive shell shall abort; an interactive shell shall write a diagnostic message to standard error, but this condition shall not be considered a syntax error.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

Returns the value of the last command executed, or a zero exit status if no command is executed.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

```
cat foobar
foo=hello bar=world
. foobar
echo $foo $bar
hello world
```

RATIONALE

Some older implementations searched the current directory for the *file*, even if the value of *PATH* disallowed it. This behavior was omitted from this volume of IEEE Std 1003.1-200x due to concerns about introducing the susceptibility to trojan horses that the user might be trying to avoid by leaving *dot* out of *PATH*.

The KornShell version of *dot* takes optional arguments that are set to the positional parameters. This is a valid extension that allows a *dot* script to behave identically to a function.

CHANGE HISTORY

None.

NAME

eval — construct command by concatenating arguments

SYNOPSIS

```
eval [argument ...]
```

DESCRIPTION

The *eval* utility shall construct a command by concatenating *argument*s together, separating each with a <space>. The constructed command shall be read and executed by the shell.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

NAME

exec — execute commands and open, close, or copy file descriptors

SYNOPSIS

`exec [command [argument ...]]`

DESCRIPTION

The *exec* utility shall open, close, and/or copy file descriptors as specified by any redirections as part of the command.

If *exec* is specified without *command* or *argument*s, and any file descriptors with numbers greater than 2 are opened with associated redirection statements, it is unspecified whether those file descriptors remain open when the shell invokes another utility. Scripts concerned that child shells could misuse open file descriptors can always close them explicitly, as shown in one of the following examples.

If *exec* is specified with *command*, it shall replace the shell with *command* without creating a new process. If *argument*s are specified, they shall be arguments to *command*. Redirection affects the current shell execution environment.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If *command* is specified, *exec* shall not return to the shell; rather, the exit status of the process shall be the exit status of the program implementing *command*, which overlaid the shell. If *command* is not found, the exit status shall be 127. If *command* is found, but it is not an executable utility, the exit status shall be 126. If a redirection error occurs (see Section 2.8.1 (on page 2247)), the shell shall exit with a value in the range 1–125. Otherwise, *exec* shall return a zero exit status.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

Open *readfile* as file descriptor 3 for reading:

```
exec 3< readfile
```

Open *writefile* as file descriptor 4 for writing:

```
exec 4> writefile
```

Make file descriptor 5 a copy of file descriptor 0:

```
exec 5<&0
```

Close file descriptor 3:

```
exec 3<&–
```

Cat the file **maggie** by replacing the current shell with the *cat* utility:

```
exec cat maggie
```

RATIONALE

Most historical implementations were not conformant in that:

```
foo=bar exec cmd
```

did not pass **foo** to **cmd**.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.14 (on page 2266)

CHANGE HISTORY

None.

NAME

exit — cause the shell to exit

SYNOPSIS

`exit [n]`

DESCRIPTION

The *exit* utility shall cause the shell to exit with the exit status specified by the unsigned decimal integer *n*. If *n* is specified, but its value is not between 0 and 255 inclusively, the exit status is undefined.

A *trap* on **EXIT** shall be executed before the shell terminates, except when the *exit* utility is invoked in that *trap* itself, in which case the shell shall exit immediately.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The exit status shall be *n*, if specified. Otherwise, the value shall be the exit value of the last command executed, or zero if no command was executed. When *exit* is executed in a *trap* action, the last command is considered to be the command that executed immediately preceding the *trap* action.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

Exit with a *true* value:

```
exit 0
```

Exit with a *false* value:

```
exit 1
```

RATIONALE

As explained in other sections, certain exit status values have been reserved for special uses and should be used by applications only for those purposes:

126	A file to be executed was found, but it was not an executable utility.
127	A utility to be executed was not found.
>128	A command was interrupted by a signal.

FUTURE DIRECTIONS

None.

NAME

export — set export attribute for variables

SYNOPSIS

```
export name[=word]...
```

```
export −p
```

DESCRIPTION

The shell shall give the export attribute to the variables corresponding to the specified *name*s, which shall cause them to be in the environment of subsequently executed commands.

The *export* special built-in shall support the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

When **−p** is specified, *export* shall write to the standard output the names and values of all exported variables, in the following format:

```
"export %s=%s\n", <name>, <value>
```

if *name* is set, and:

```
"export %s\n", <name>
```

if *name* is unset.

The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same exporting results, except:

1. Read-only variables with values cannot be reset.
2. Variables that were unset at the time they were output need not be reset to the unset state if a value is assigned to the variable between the time the state was saved and the time at which the saved output is reinput to the shell.

When no arguments are given, the results are unspecified.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

EXIT STATUS

Zero.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

Export *PWD* and *HOME* variables:

```
export PWD HOME
```

Set and export the *PATH* variable:

```
export PATH=/local/bin:$PATH
```

Save and restore all exported variables:

```
export −p > temp-file
unset a lot of variables
... processing
. temp-file
```

RATIONALE

Some historical shells use the no-argument case as the functional equivalent of what is required here with **−p**. This feature was left unspecified because it is not historical practice in all shells, and some scripts may rely on the now-unspecified results on their implementations. Attempts to specify the **−p** output as the default case were unsuccessful in achieving consensus. The **−p** option was added to allow portable access to the values that can be saved and then later restored using; for example, a *dot* script.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.14 (on page 2266)

CHANGE HISTORY

Issue 6

IEEE PASC Interpretation 1003.2 #203 is applied, clarifying the format when a variable is unset.

NAME

readonly — set read-only attribute for variables

SYNOPSIS

```
readonly name[=word]...
```

```
readonly −p
```

DESCRIPTION

The variables whose *name*s are specified shall be given the *readonly* attribute. The values of variables with the *readonly* attribute cannot be changed by subsequent assignment, nor can those variables be unset by the *unset* utility.

The *readonly* special built-in shall support the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

When **−p** is specified, *readonly* writes to the standard output the names and values of all read-only variables, in the following format:

```
"readonly %s=%s\n", <name>, <value>
```

if *name* is set, and |

```
"readonly %s\n", <name>
```

|

if *name* is unset. |

The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same value and read-only attribute-setting results in a shell execution environment in which: |

1. Variables with values at the time they were output do not have the read-only attribute set. |
2. Variables that were unset at the time they were output do not have a value at the time at which the saved output is reinput to the shell. |

When no arguments are given, the results are unspecified. |

EXAMPLES

```
readonly HOME PWD
```

RATIONALE

Some historical shells preserve the read-only attribute across separate invocations. This volume of IEEE Std 1003.1-200x allows this behavior, but does not require it.

The −**p** option allows portable access to the values that can be saved and then later restored using; for example, a *dot* script. Also see the RATIONALE for *export* (on page 2281) for a description of the no-argument and −**p** output cases and a related example.

Read-only functions were considered, but they were omitted as not being historical practice or particularly useful. Furthermore, functions must not be *readonly* across invocations to preclude *spoofing* (spoofing is the term for the practice of creating a program that acts like a well-known utility with the intent of subverting the real intent of the user) of administrative or security-relevant (or security-conscious) shell scripts.

None.

STDOUT

None.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The value of the special parameter `'?'` shall be set to *n*, an unsigned decimal integer, or to the exit status of the last command executed if *n* is not specified. If the value of *n* is greater than 255, the results are undefined. When *return* is executed in a *trap* action, the last command is considered to be the command that executed immediately preceding the *trap* action.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The behavior of *return* when not in a function or *dot* script differs between the System V shell and the KornShell. In the System V shell this is an error, whereas in the KornShell, the effect is the same as *exit*.

The results of returning a number greater than 255 are undefined because of differing practices in the various historical implementations. Some shells AND out all but the low-order 8 bits; others allow larger values, but not of unlimited size.

See the discussion of appropriate exit status values under *exit* (on page 2279).

FUTURE DIRECTIONS

NAME

set — set or unset options and positional parameters

SYNOPSIS

XSI
```
set [-abCefmnuvx][-h][-o option][argument...]
set [+abCefmnuvx][+h][+o option][argument...]
set --[argument...]
set -o
set +o
```

DESCRIPTION

If no options or *argument*s are specified, *set* shall write the names and values of all shell variables in the collation sequence of the current locale. Each *name* shall start on a separate line, using the format:

`"%s=%s\n", <name>, <value>`

The *value* string shall be written with appropriate quoting so that it is suitable for reinput to the shell, setting or resetting, as far as possible, the variables that are currently set. Read-only variables cannot be reset; see the description of shell quoting in Section 2.2 (on page 2232).

When options are specified, they shall set or unset attributes of the shell, as described below. When *argument*s are specified, they cause positional parameters to be set or unset, as described below. Setting or unsetting attributes and positional parameters are not necessarily related actions, but they can be combined in a single invocation of *set*.

The *set* special built-in shall support the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines except that options can be specified with either a leading hyphen (meaning enable the option) or plus sign (meaning disable it).

Implementations shall support the options in the following list in both their hyphen and plus-sign forms. These options can also be specified as options to *sh*.

–a When this option is on, the export attribute shall be set for each variable to which an assignment is performed; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.21, Variable Assignment. If the assignment precedes a utility name in a command, the export attribute shall not persist in the current execution environment after the utility completes, with the exception that preceding one of the special built-in utilities causes the export attribute to persist after the built-in has completed. If the assignment does not precede a utility name in the command, or if the assignment is a result of the operation of the *getopts* or *read* utilities, the export attribute shall persist until the variable is unset.

–b This option shall be supported if the implementation supports the User Portability Utilities option. It shall cause the shell to notify the user asynchronously of background job completions. The following message is written to standard error:

`"[%d]%c %s%s\n", <job-number>, <current>, <status>, <job-name>`

where the fields shall be as follows:

<current> The character '+' identifies the job that would be used as a default for the *fg* or *bg* utilities; this job can also be specified using the *job_id* "%+" or "%%". The character '–' identifies the job that would become the default if the current default job were to exit; this job can also be specified using the *job_id* "%–". For other jobs, this field is a <space>. At most one job can be identified with '+' and at most one job can be identified with '–'.

If there is any suspended job, then the current job shall be a suspended job. If there are at least two suspended jobs, then the previous job also shall be a suspended job.

<job-number> A number that can be used to identify the process group to the *wait*, *fg*, *bg*, and *kill* utilities. Using these utilities, the job can be identified by prefixing the job number with `'%'`.

<status> Unspecified.

<job-name> Unspecified.

When the shell notifies the user a job has been completed, it may remove the job's process ID from the list of those known in the current shell execution environment; see Section 2.9.3.1 (on page 2252). Asynchronous notification shall not be enabled by default.

−C (Uppercase C.) Prevent existing files from being overwritten by the shell's `'>'` redirection operator (see Section 2.7.2 (on page 2245)); the `">|"` redirection operator shall override this *noclobber* option for an individual file.

−e When this option is on, if a simple command fails for any of the reasons listed in Section 2.8.1 (on page 2247) or returns an exit status value >0, and is not part of the compound list following a **while**, **until**, or **if** keyword, and is not a part of an AND or OR list, and is not a pipeline preceded by the **!** reserved word, then the shell shall immediately exit.

−f The shell shall disable pathname expansion.

XSI **−h** Locate and remember utilities invoked by functions as those functions are defined (the utilities are normally located when the function is executed).

−m This option shall be supported if the implementation supports the User Portability Utilities option. All jobs shall be run in their own process groups. Immediately before the shell issues a prompt after completion of the background job, a message reporting the exit status of the background job shall be written to standard error. If a foreground job stops, the shell shall write a message to standard error to that effect, formatted as described by the *jobs* utility. In addition, if a job changes status other than exiting (for example, if it stops for input or output or is stopped by a SIGSTOP signal), the shell shall write a similar message immediately prior to writing the next prompt. This option is enabled by default for interactive shells.

−n The shell shall read commands but does not execute them; this can be used to check for shell script syntax errors. An interactive shell may ignore this option.

−o Write the current settings of the options to standard output in an unspecified format.

+o Write the current option settings to standard output in a format that is suitable for reinput to the shell as commands that achieve the same options settings.

−o *option*

This option is supported if the system supports the User Portability Utilities option. It shall set various options, many of which shall be equivalent to the single option letters. The following values of *option* shall be supported:

allexport Equivalent to **−a**.

errexit Equivalent to **−e**.

ignoreeof Prevent an interactive shell from exiting on end-of-file. This setting prevents accidental logouts when <control>-D is entered. A user shall explicitly *exit* to leave the interactive shell.

monitor	Equivalent to **–m**. This option is supported if the system supports the User Portability Utilities option.
noclobber	Equivalent to **–C** (uppercase C).
noglob	Equivalent to **–f**.
noexec	Equivalent to **–n**.
nolog	Prevent the entry of function definitions into the command history; see **Command History List** (on page 3052).
notify	Equivalent to **–b**.
nounset	Equivalent to **–u**.
verbose	Equivalent to **–v**.
vi	Allow shell command line editing using the built-in *vi* editor. Enabling *vi* mode shall disable any other command line editing mode provided as an implementation extension. It need not be possible to set *vi* mode on for certain block-mode terminals.
xtrace	Equivalent to **–x**.

–u The shell shall write a message to standard error when it tries to expand a variable that is not set and immediately exit. An interactive shell shall not exit.

–v The shell shall write its input to standard error as it is read.

–x The shell shall write to standard error a trace for each command after it expands the command and before it executes it. It is unspecified whether the command that turns tracing off is traced.

The default for all these options shall be off (unset) unless the shell was invoked with them on; see *sh*.

The remaining arguments shall be assigned in order to the positional parameters. The special parameter '#' shall be set to reflect the number of positional parameters. All positional parameters shall be unset before any new values are assigned.

The special argument "––" immediately following the *set* command name can be used to delimit the arguments if the first argument begins with '+' or '–', or to prevent inadvertent listing of all shell variables when there are no arguments. The command *set*–– without *argument* shall unset all positional parameters and set the special parameter '#' to zero.

APPLICATION USAGE

None.

EXAMPLES

Write out all variables and their values:

```
set
```

Set $1, $2, and $3 and set "$#" to 3:

```
set c a b
```

Turn on the –**x** and –**v** options:

```
set –xv
```

Unset all positional parameters:

```
set ––
```

Set $1 to the value of –**x**, even if **x** begins with '–' or '+':

```
set –– "$x"
```

Set the positional parameters to the expansion of **x**, even if **x** expands with a leading '–' or '+':

```
set –– $x
```

RATIONALE

The *set* –– form is listed specifically in the SYNOPSIS even though this usage is implied by the Utility Syntax Guidelines. The explanation of this feature removes any ambiguity about whether the *set* –– form might be misinterpreted as being equivalent to *set* without any options or arguments. The functionality of this form has been adopted from the KornShell. In System V, *set* –– only unsets parameters if there is at least one argument; the only way to unset all parameters is to use *shift*. Using the KornShell version should not affect System V scripts because there should be no reason to issue it without arguments deliberately; if it were issued as, for example:

```
set –– "$@"
```

and there were in fact no arguments resulting from `"$@"`, unsetting the parameters would have no result.

The *set* + form in early proposals was omitted as being an unnecessary duplication of *set* alone and not widespread historical practice.

The *noclobber* option was changed to allow *set* −**C** as well as the *set* −**o** *noclobber* option. The single-letter version was added so that the historical `"$−"` paradigm would not be broken; see Section 2.5.2 (on page 2235).

The −**h** flag is related to command name hashing and is only required on XSI-conformant systems.

The following *set* flags were omitted intentionally with the following rationale:

−**k** The −**k** flag was originally added by the author of the Bourne shell to make it easier for users of pre-release versions of the shell. In early versions of the Bourne shell the construct *set name*=*value*, had to be used to assign values to shell variables. The problem with −**k** is that the behavior affects parsing, virtually precluding writing any compilers. To explain the behavior of −**k**, it is necessary to describe the parsing algorithm, which is implementation-defined. For example:

```
set −k; echo name=value
```

and:

```
set x−−k
echo name=value
```

behave differently. The interaction with functions is even more complex. What is more, the −**k** flag is never needed, since the command line could have been reordered.

−**t** The −**t** flag is hard to specify and almost never used. The only known use could be done with here-documents. Moreover, the behavior with *ksh* and *sh* differs. The reference page says that it exits after reading and executing one command. What is one command? If the input is *date*;*date*, *sh* executes both *date* commands while *ksh* does only the first.

Consideration was given to rewriting *set* to simplify its confusing syntax. A specific suggestion was that the *unset* utility should be used to unset options instead of using the non-*getopt*( )-able +*option* syntax. However, the conclusion was reached that the historical practice of using +*option* was satisfactory and that there was no compelling reason to modify such widespread historical practice.

The −**o** option was adopted from the KornShell to address user needs. In addition to its generally friendly interface, −**o** is needed to provide the *vi* command line editing mode, for which historical practice yields no single-letter option name. (Although it might have been possible to invent such a letter, it was recognized that other editing modes would be developed and −**o** provides ample name space for describing such extensions.)

Historical implementations are inconsistent in the format used for −**o** option status reporting. The **+o** format without an option-argument was added to allow portable access to the options that can be saved and then later restored using, for instance, a dot script.

Historically, *sh* did trace the command *set* **+x**, but *ksh* did not.

The *ignoreeof* setting prevents accidental logouts when the end-of-file character (typically <control>-D) is entered. A user shall explicitly *exit* to leave the interactive shell.

The *set* −**m** option was added to apply only to the UPE because it applies primarily to interactive use, not shell script applications.

The ability to do asynchronous notification became available in the 1988 version of the KornShell. To have it occur, the user had to issue the command:

```
trap "jobs –n" CLD
```

The C shell provides two different levels of an asynchronous notification capability. The environment variable *notify* is analogous to what is done in *set* –**b** or *set* –**o** *notify*. When set, it notifies the user immediately of background job completions. When unset, this capability is turned off.

The other notification ability comes through the built-in utility *notify*. The syntax is:

```
notify [%job ... ]
```

By issuing *notify* with no operands, it causes the C shell to notify the user asynchronously when the state of the current job changes. If given operands, *notify* asynchronously informs the user of changes in the states of the specified jobs.

To add asynchronous notification to the POSIX shell, neither the KornShell extensions to *trap*, nor the C shell *notify* environment variable seemed appropriate (*notify* is not a proper POSIX environment variable name).

The *set* –**b** option was selected as a compromise.

The *notify* built-in was considered to have more functionality than was required for simple asynchronous notification.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.14 (on page 2266)

CHANGE HISTORY

Issue 6

The obsolescent *set* command name followed by `'–'` has been removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The *nolog* option is added to *set* –**o**.

NAME

shift — shift positional parameters

SYNOPSIS

```
shift [n]
```

DESCRIPTION

The positional parameters shall be shifted. Positional parameter 1 shall be assigned the value of parameter (1+*n*), parameter 2 shall be assigned the value of parameter (2+*n*), and so on. The parameters represented by the numbers `"$#"` down to `"$#−n+1"` shall be unset, and the parameter `'#'` is updated to reflect the new number of positional parameters.

The value *n* shall be an unsigned decimal integer less than or equal to the value of the special parameter `'#'`. If *n* is not given, it shall be assumed to be 1. If *n* is 0, the positional and special parameters are not changed.

NAME

times — write process times

SYNOPSIS

`times`

DESCRIPTION

Write the accumulated user and system times for the shell and for all of its child processes, in the following POSIX locale format:

```
"%dm%fs %dm%fs\n%dm%fs %dm%fs\n", <shell user minutes>,
    <shell user seconds>, <shell system minutes>,
    <shell system seconds>, <children user minutes>,
    <children user seconds>, <children system minutes>,
    <children system seconds>
```

The four pairs of times shall correspond to the members of the **<sys/times.h>** **tms** structure (defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers) as returned by *times*( ): *tms_utime*, *tms_stime*, *tms_cutime*, and *tms_cstime*, respectively. |

NAME

trap — trap signals

SYNOPSIS

```
trap [action condition ...]
```

DESCRIPTION

If *action* is '−', the shell shall reset each *condition* to the default value. If *action* is null (""), the shell shall ignore each specified *condition* if it arises. Otherwise, the argument *action* shall be read and executed by the shell when one of the corresponding conditions arises. The action of *trap* shall override a previous action (either default action or one explicitly set). The value of "$?" after the *trap* action completes shall be the value it had before *trap* was invoked.

The condition can be EXIT, 0 (equivalent to EXIT), or a signal specified using a symbolic name, without the SIG prefix, as listed in the tables of signal names in the **<signal.h>** header defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers; for example, HUP, INT, QUIT, TERM. Implementations may permit lowercase signal names or names with the SIG prefix as an extension. Setting a trap for SIGKILL or SIGSTOP produces undefined results.

The environment in which the shell executes a *trap* on EXIT shall be identical to the environment immediately after the last command executed before the *trap* on EXIT was taken.

Each time *trap* is invoked, the *action* argument shall be processed in a manner equivalent to:

```
eval "$action"
```

Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although no error need be reported when attempting to do so. An interactive shell may reset or catch signals ignored on entry. Traps shall remain in place for a given shell until explicitly changed with another *trap* command.

When a subshell is entered, traps that are not being ignored are set to the default actions. This does not imply that the *trap* command cannot be used within the subshell to set new traps.

The *trap* command with no arguments shall write to standard output a list of commands associated with each condition. The format shall be:

```
"trap -- %s %s ...\n", <action>, <condition> ...
```

The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same trapping results. For example:

```
save_traps=$(trap)
...
eval "$save_traps"
```

XSI XSI-conformant systems also allow numeric signal numbers for the conditions corresponding to the following signal names:

	Signal Number	Signal Name
XSI	1	SIGHUP
XSI	2	SIGINT
XSI	3	SIGQUIT
XSI	6	SIGABRT
XSI	9	SIGKILL
XSI	14	SIGALRM
XSI	15	SIGTERM

The *trap* special built-in shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If the trap name or number is invalid, a non-zero exit status shall be returned; otherwise, zero shall be returned. For both interactive and non-interactive shells, invalid signal names or numbers shall not be considered a syntax error and do not cause the shell to abort.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

Write out a list of all traps and actions:

```
trap
```

Set a trap so the *logout* utility in the directory referred to by the *HOME* environment variable executes when the shell terminates:

```
trap '$HOME/logout' EXIT
```

or:

```
trap '$HOME/logout' 0
```

Unset traps on INT, QUIT, TERM, and EXIT:

```
trap - INT QUIT TERM EXIT
```

RATIONALE

Implementations may permit lowercase signal names as an extension. Implementations may also accept the names with the SIG prefix; no known historical shell does so. The *trap* and *kill* utilities in this volume of IEEE Std 1003.1-200x are now consistent in their omission of the SIG prefix for signal names. Some *kill* implementations do not allow the prefix, and *kill* −**l** lists the signals without prefixes.

Trapping SIGKILL or SIGSTOP is syntactically accepted by some historical implementations, but it has no effect. Portable POSIX applications cannot attempt to trap these signals.

The output format is not historical practice. Since the output of historical *trap* commands is not portable (because numeric signal values are not portable) and had to change to become so, an opportunity was taken to format the output in a way that a shell script could use to save and then later reuse a trap if it wanted.

The KornShell uses an **ERR** trap that is triggered whenever *set* −**e** would cause an exit. This is allowable as an extension, but was not mandated, as other shells have not used it.

The text about the environment for the EXIT trap invalidates the behavior of some historical versions of interactive shells which, for example, close the standard input before executing a trap on 0. For example, in some historical interactive shell sessions the following trap on 0 would always print `"--"`:

```
trap 'read foo; echo "-$foo-"' 0
```

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.14 (on page 2266)

CHANGE HISTORY

Issue 6

XSI-conforming implementations provide the mapping of signal names to numbers given above (previously this had been marked obsolescent). Other implementations need not provide this optional mapping.

NAME

unset — unset values and attributes of variables and functions

SYNOPSIS

```
unset [−fv] name ...
```

DESCRIPTION

Each variable or function specified by *name* shall be unset.

If **−v** is specified, *name* refers to a variable name and the shell shall unset it and remove it from the environment. Read-only variables cannot be unset.

If **−f** is specified, *name* refers to a function and the shell shall unset the function definition.

If neither **−f** nor **−v** is specified, *name* refers to a variable; if a variable by that name does not exist, it is unspecified whether a function by that name, if any, shall be unset.

Unsetting a variable or function that was not previously set shall not be considered an error and does not cause the shell to abort.

The *unset* special built-in shall support the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

Note that:

```
VARIABLE=
```

is not equivalent to an *unset* of **VARIABLE**; in the example, **VARIABLE** is set to `""`. Also, the variables that can be *unset* should not be misinterpreted to include the special parameters (see Section 2.5.2 (on page 2235)).

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

0 All *name* operands were successfully unset.

>0 At least one *name* could not be unset.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

Unset *VISUAL* variable:

```
unset −v VISUAL
```

Unset the functions **foo** and **bar**:

```
unset −f foo bar
```

RATIONALE

Consideration was given to omitting the **−f** option in favor of an *unfunction* utility, but the standard developers decided to retain historical practice.

The **−v** option was introduced because System V historically used one name space for both variables and functions. When *unset* is used without options, System V historically unset either a function or a variable, and there was no confusion about which one was intended. A portable POSIX application can use *unset* without an option to unset a variable, but not a function; the **−f** option must be used.

Chapter 3

Batch Environment Services

BE This chapter describes the services and utilities that shall be implemented on all systems that claim conformance to the Batch Environment option. This functionality is dependent on support of this option (and the rest of this section is not further shaded for this option).

3.1 General Concepts

3.1.1 Batch Client-Server Interaction

Batch jobs are created and managed by batch servers. A batch client interacts with a batch server to access batch services on behalf of the user. In order to use batch services, a user must have access to a batch client.

A batch server is a computational entity, such as a daemon process, that provides batch services. Batch servers route, queue, modify, and execute batch jobs on behalf of batch clients.

The batch utilities described in this volume of IEEE Std 1003.1-200x (and listed in Table 3-1) are clients of batch services; they allow users to perform actions on the job such as creating, modifying, and deleting batch jobs from a shell command line. Although these batch utilities may be said to accomplish certain services, they actually obtain services on behalf of a user by means of requests to batch servers.

Table 3-1 Batch Utilities

qmove
qmsg
qrerun
qrls
qselect
qsig
qstat
qsub

Client-server interaction takes place by means of the batch requests defined in this chapter. Because direct access to batch jobs and queues is limited to batch servers, clients and servers of different implementations can interoperate, since dependencies on private structures for batch jobs and queues are limited to batch servers. Also, batch servers may be clients of other batch servers.

3.1.2 Batch Queues

Two types of batch queue are described: *routing queues* and *execution queues*. When a batch job is placed in a routing queue, it is a candidate for routing. A batch job is removed from routing queues under the following conditions:

- The batch job has been routed to another queue.
- The batch job has been deleted from the batch queue.
- The batch job has been aborted.

When a batch job is placed in an execution queue, it is a candidate for execution.

A batch job is removed from an execution queue under the following conditions:

- The batch job has been executed and exited.

- The batch job has been aborted.
- The batch job has been deleted from the batch queue.
- The batch job has been moved to another queue.

Access to a batch queue is limited to the batch server that manages the batch queue. Clients never access a batch queue or a batch job directly, either to read or write information; all client access to batch queues or jobs takes place through batch servers.

3.1.3 Batch Job Creation

When a batch server creates a batch job on behalf of a client, it shall assign a batch job identifier to the job. A batch job identifier consists of both a sequence number that is unique among the sequence numbers issued by that server and the name of the server. Since the batch server name is unique within a name space, the job identifier is likewise unique within the name space.

The batch server that creates a batch job shall return the batch server-assigned job identifier to the client that requested the job creation. If the batch server routes or moves the job to another server, it sends the job identifier with the job. Once assigned, the job identifier of a batch job shall never change.

3.1.4 Batch Job Tracking

Since a batch job may be moved after creation, the batch server name component of the job identifier need not indicate the location of the job. An implementation may provide a batch job tracking mechanism, in which case the user generally does not need to know the location of the job. However, an implementation need not provide a batch job tracking mechanism, in which case the user must find routed jobs by probing the possible destinations.

3.1.5 Batch Job Routing

To route a batch job, a batch server either moves the job to some other queue that is managed by the batch server, or requests that some other batch server accept the job.

Each routing queue has one or more queues to which it can route batch jobs. The batch server administrator creates routing queues.

A batch server may route a batch job from a routing queue to another routing queue. Batch servers shall prevent or otherwise handle cases of circular routing paths. As a deferred service, a batch server routes jobs from the routing queues that it manages. The algorithm by which a batch server selects a batch queue to which to route a batch job is implementation-defined.

A batch job need not be eligible for routing to all the batch queues fed by the routing queue from which it is routed. A batch server that has been asked to accept the job may reject the request if the job requires resources that are unavailable to that batch server, or if the client is not authorized to access the batch server.

Batch servers may route high-priority jobs before low-priority jobs, but, on other than overloaded systems, the effect may be imperceptible to the user. If all the batch servers fed by a routing queue reject requests to accept the job for reasons that are permanent, the batch server that manages the job shall abort the job. If all or some rejections are temporary, the batch server should try to route the job again at some later point.

The reasons for rejecting a batch job are implementation-defined. The reasons for which the routing should be retried later and the reasons for which the job should be aborted are also implementation-defined.

3.1.6 Batch Job Execution

To execute a batch job is to create a session leader (a process) that runs the shell program indicated by the *Shell_Path* attribute of the job. The script shall be passed to the program as its standard input. An implementation may pass the script to the program by other implementation-defined means. At the time a batch job begins execution, it is defined to enter the RUNNING state. The primary program that is executed by a batch job is typically, though not necessarily, a shell program.

A batch server shall execute eligible jobs as a deferred service—no client request is necessary once the batch job is created and eligible. However, the attributes of a batch job, such as the job hold type, may render the job ineligible. A batch server shall scan the execution queues that it manages for jobs that are eligible for execution. The algorithm by which the batch server selects eligible jobs for execution is implementation-defined.

As part of creating the process for the batch job, the batch server shall open the standard output and standard error streams of the session.

The attributes of a batch job may indicate that the batch server executing the job shall send mail to a list of users at the time it begins execution of the job.

3.1.7 Batch Job Exit

When the session leader of an executing job terminates, the job exits. As part of exiting a batch job, the batch server that manages the job shall remove the job from the batch queue in which it resides. The server shall transfer output files of the job to a location described by the attributes of the job.

The attributes of a batch job may indicate that the batch server managing the job shall send mail to a list of users at the time the job exits.

3.1.8 Batch Job Abort

A batch server shall abort jobs for which a required deferred service cannot be performed. The attributes of a batch job may indicate that the batch server that aborts the job shall send mail to a list of users at the time it aborts the job.

3.1.9 Batch Authorization

Clients, such as the batch environment utilities (marked BE), access batch services by means of requests to one or more batch servers. To acquire the services of any given batch server, the user identifier under which the client runs must be authorized to use that batch server.

The user with an associated user name that creates a batch job shall own the job and can perform actions such as read, modify, delete, and move.

A user identifier of the same value at a different host need not be the same user. For example, user name *smith* at host **alpha** may or may not represent the same person as user name *smith* at host **beta**. Likewise, the same person may have access to different user names on different hosts.

An implementation may optionally provide an authorization mechanism that permits one user name to access jobs under another user name.

A process on a client host may be authorized to run processes under multiple user names at a batch server host. Where appropriate, the utilities defined in this volume of IEEE Std 1003.1-200x provide a means for a user to choose from among such user names when creating or modifying a batch job.

3.1.10 Batch Administration

The processing of a batch job by a batch server is affected by the attributes of the job. The processing of a batch job may also be affected by the attributes of the batch queue in which the job resides and by the status of the batch server that manages the job. See also the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.43, Batch Administrator and the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.58, Batch Operator.

3.1.11 Batch Notification

Whereas batch servers are persistent entities, clients are often transient. For example, the *qsub* utility creates a batch job and exits. For this reason, batch servers notify users of batch job events by sending mail to the user that owns the job, or to other designated users.

3.2 Batch Services

The presence of Batch Environment option services is indicated by the configuration variable POSIX2_PBS. A conforming batch server provides services as defined in this section.

A batch server shall provide batch services in two ways:

1. The batch server provides a service at the request of a client.
2. The batch server provides a deferred service as a result of a change in conditions monitored by the batch server.

If a batch server cannot complete a request, it shall reject the request. If a batch server cannot complete a deferred service for a batch job, the batch server shall abort the batch job. Table 3-2 (on page 2307) is a summary of environment variables that shall be supported by an implementation of the batch server and utilities.

Table 3-2 Environment Variable Summary

Variable	Description
PBS_DPREFIX	Defines the directive prefix (see *qsub*)
PBS_ENVIRONMENT	Batch Job is batch or interactive (see Section 3.2.2.1 (on page 2308))
PBS_JOBID	The *job_identifier* attribute of job (see Section 3.2.3.8 (on page 2320))
PBS_JOBNAME	The *job_name* attribute of job (see Section 3.2.3.8 (on page 2320))
PBS_O_HOME	Defines the *HOME* of the batch client (see *qsub*)
PBS_O_HOST	Defines the host name of the batch client (see *qsub*)
PBS_O_LANG	Defines the *LANG* of the batch client (see *qsub*)
PBS_O_LOGNAME	Defines the *LOGNAME* of the batch client (see *qsub*)
PBS_O_MAIL	Defines the *MAIL* of the batch client (see *qsub*)
PBS_O_PATH	Defines the *PATH* of the batch client (see *qsub*)
PBS_O_QUEUE	Defines the submit queue of the batch client (see *qsub*)
PBS_O_SHELL	Defines the *SHELL* of the batch client (see *qsub*)
PBS_O_TZ	Defines the *TZ* of the batch client (see *qsub*)
PBS_O_WORKDIR	Defines the working directory of the batch client (see *qsub*)
PBS_QUEUE	Defines the initial execution queue (see Section 3.2.2.1 (on page 2308))

3.2.1 Batch Job States

A batch job shall always be in one of the following states: QUEUED, RUNNING, HELD, WAITING, EXITING, or TRANSITING. The state of a batch job determines the types of requests that the batch server that manages the batch job can accept for the batch job. A batch server shall change the state of a batch job either in response to service requests from clients or as a result of deferred services, such as job execution or job routing.

A batch job that is in the QUEUED state resides in a queue but is still pending either execution or routing, depending on the queue type.

A batch server that queues a batch job in a routing queue shall put the batch job in the QUEUED state. A batch server that puts a batch job in an execution queue, but has not yet executed the batch job, shall put the batch job in the QUEUED state. A batch job that resides in an execution queue and is executing is defined to be in the RUNNING state. While a batch job is in the RUNNING state, a session leader is associated with the batch job.

A batch job that resides in an execution queue, but is ineligible to run because of a hold attribute, is defined to be in the HELD state.

A batch job that is not held, but must wait until a future date and time before executing, is defined to be in the WAITING state.

When the session leader associated with a running job exits, the batch job shall be placed in the EXITING state.

A batch job for which the session leader has terminated is defined to be in the EXITING state, and the batch server that manages such a batch job cannot accept job modification requests that affect the batch job. While a batch job is in the EXITING state, the batch server that manages the batch job is staging output files and notifying clients of job completion. Once a batch job has exited, it no longer exists as an object managed by a batch server.

A batch job that is being moved from a routing queue to another queue is defined to be in the TRANSITING state.

When a batch job in a routing queue has been selected to be moved to a new destination, then the batch job shal be in either the QUEUED state or the TRANSITING state, depending on the batch server implementation.

Batch jobs with either a *Execution_Time* attribute value set in the future or a *Hold_Types* attribute of value not equal to NO_HOLD, or both, may be routed or held in the routing queue. The treatment of jobs with the *Execution_Time* or *Hold_Types* attributes in a routing queue is implementation-defined.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has a *Hold_Types* attribute value of other than NO_HOLD, then the job should be in the HELD state.

Note: The effect of a hold upon a batch job in a routing queue is implementation-defined. The implementation should use the state that matches whether the batch job can route with a hold or not.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has:

- A *Hold_Types* attribute value of NO_HOLD
- An *Execution_Time* attribute in the past

then the batch job shall be in the QUEUED state.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has:

- A *Hold_Types* attribute value of NO_HOLD
- An *Execution_Time* attribute in the future

then the batch job may be in the WAITING state.

Note: The effect of a future execution time upon a batch job in a routing queue is implementation-defined. The implementation should use the state that matches whether the batch job can route with a hold or not.

Table 3-3 (on page 2309) describes the next state of a batch job, given the current state of the batch job and the type of request. Table 3-4 (on page 2310) describes the response of a batch server to a request, given the current state of the batch job and the type of request.

3.2.2 Deferred Batch Services

This section describes the deferred services performed by batch servers: job execution, job routing, job exit, job abort, and the rerunning of jobs after a restart.

3.2.2.1 Batch Job Execution

To execute a batch job is to create a session leader (a process) that runs the shell program indicated by the *Shell_Path_List* attribute of the batch job. The script is passed to the program as its standard input. An implementation may pass the script to the program by other implementation-defined means. At the time a batch job begins execution, it is defined to enter the RUNNING state.

Table 3-3 Next State Table

Request Type	**Current State**						
	X	**Q**	**R**	**H**	**W**	**E**	**T**
Queue Batch Job Request	Q	e	e	e	e	e	e
Modify Batch Job Request	e	Q	R	H	W	e	T
Delete Batch Job Request	e	X	E	X	X	E	X
Batch Job Message Request	e	Q	R	H	W	E	T
Rerun Batch Job Request	e	e	Q	e	e	e	e

Locate Batch Job Request	e	Q	R	H	W	E	T

Legend

X	Nonexistent
Q	QUEUED
R	RUNNING
H	HELD
W	WAITING
E	EXITING
T	TRANSITING
e	Error

A batch server that has an execution queue containing jobs is said to own the queue and manage the batch jobs in that queue. A batch server that has been started shall execute the batch jobs in the execution queues owned by the batch server. The batch server shall schedule for execution those jobs in the execution queues that are in the QUEUED state. The algorithm for scheduling jobs is implementation-defined.

A batch server that executes a batch job shall create, in the environment of the session leader of the batch job, an environment variable named *PBS_ENVIRONMENT*, the value of which is the string PBS_BATCH encoded in the portable character set.

A batch server that executes a batch job shall create, in the environment of the session leader of the batch job, an environment variable named *PBS_QUEUE*, the value of which is the name of the execution queue of the batch job encoded in the portable character set.

To rerun a batch job is to requeue a batch job that is currently executing and then kill the session leader of the executing job by sending a SIGKILL prior to completion; see Section 3.2.3.11 (on page 2322). A batch server that reruns a batch job shall append the standard output and standard error files of the batch job to the corresponding files of the previous execution, if they exist, with appropriate annotation. If either file does not exist, that file shall be created as in normal execution.

Table 3-4 Results / Output Table

Request Type	Current State						
	X	**Q**	**R**	**H**	**W**	**E**	**T**
Queue Batch Job Request	O	e	e	e	e	e	e
Modify Batch Job Request	e	O	e	O	O	e	e

Server Shutdown Request	O	O	e	O	O	e	e
Locate Batch Job Request	e	O	O	O	O	O	O

Legend

O	OK
e	Error message

The execution of a batch job by a batch server shall be controlled by job, queue, and server attributes, as defined in this section.

Account_Name Attribute

Batch accounting is an optional feature of batch servers. If a batch server implements accounting, the statements in this section apply and the configuration variable POSIX2_PBS_ACCOUNTING shall be set to 1.

A batch server that executes a batch job shall charge the account named in the *Account_Name* attribute of the batch job for resources consumed by the batch job.

If the *Account_Name* attribute of the batch job is absent from the batch job attribute list or is altered while the batch job is in execution, the batch server action is implementation-defined.

Checkpoint Attribute

Batch checkpointing is an optional feature of batch servers. If a batch server implements checkpointing, the statements in this section apply and the configuration variable POSIX2_PBS_CHECKPOINT shall be set to 1.

There are two attributes associated with the checkpointing feature: *Checkpoint* and *Minimum_Cpu_Interval*. *Checkpoint* is a batch job attribute, while *Minimum_Cpu_Interval* is a queue attribute. An implementation that does not support checkpointing shall support the *Checkpoint* job attribute to the extent that the batch server shall maintain and pass this attribute to other servers.

The behavior of a batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_UNSPECIFIED is implementation-defined. A batch server that executes a batch job for which the value of the *Checkpoint* attribute is NO_CHECKPOINT shall not checkpoint the batch job.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_AT_SHUTDOWN shall checkpoint the batch job only when the batch server accepts a request to shut down during the time when the batch job is in the RUNNING state.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_AT_MIN_CPU_INTERVAL shall checkpoint the batch job at the interval specified by the *Minimum_Cpu_Interval* attribute of the queue for which the batch job has been selected. The *Minimum_Cpu_Interval* attribute shall be specified in units of CPU minutes.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is an unsigned integer shall checkpoint the batch job at an interval that is the value of either the *Checkpoint* attribute, or the *Minimum_Cpu_Interval* attribute of the queue for which the batch job has been selected, whichever is greater. Both intervals shall be in units of CPU minutes. When the *Minimum_Cpu_Interval* attribute is greater than the *Checkpoint* attribute, the batch job shall write a warning message to the standard error stream of the batch job.

Error_Path Attribute

The *Error_Path* attribute of a running job cannot be changed by a *Modify Batch Job Request*. When the *Join_Path* attribute of the batch job is set to the value FALSE and the *Keep_Files* attribute of the batch job does not contain the value KEEP_STD_ERROR, a batch server that executes a batch job shall perform one of the following actions:

- Set the standard error stream of the session leader of the batch job to the path described by the value of the *Error_Path* attribute of the batch job.
- Buffer the standard error of the session leader of the batch job until completion of the batch job, and when the batch job exits return the contents to the destination described by the value of the *Error_Path* attribute of the batch job.

Applications shall not rely on having access to the standard error of a batch job prior to the completion of the batch job.

When the *Error_Path* attribute does not specify a host name, then the batch server shall retain the standard error of the batch job on the host of execution.

When the *Error_Path* attribute does specify a host name and the *Keep_Files* attribute does not contain the value KEEP_STD_ERROR, then the final destination of the standard error of the batch job shall be on the host whose host name is specified.

If the path indicated by the value of the *Error_Path* attribute of the batch job is a relative path, the batch server shall expand the path relative to the home directory of the user on the host to which the file is being returned.

When the batch server buffers the standard error of the batch job and the file cannot be opened for write upon completion of the batch job, then the server shall place the standard error in an implementation-defined location and notify the user of the location via mail. It shall be possible for the user to process this mail using the *mailx* utility.

If a batch server that does not buffer the standard error cannot open the standard error path of the batch job for write access, then the batch server shall abort the batch job.

Execution_Time Attribute

A batch server shall not execute a batch job before the time represented by the value of the *Execution_Time* attribute of the batch job. The *Execution_Time* attribute is defined in seconds since the Epoch.

Hold_Types Attribute

A batch server shall support the following hold types:

`s`	Can be set or released by a user with at least a privilege level of batch administrator (SYSTEM).
`o`	Can be set or released by a user with at least a privilege level of batch operator (OPERATOR).
`u`	Can be set or released by the user with at least a privilege level of user, where the user is defined in the *Job_Owner* attribute (USER).
`n`	Indicates that none of the *Hold_Types* attributes are set (NO_HOLD).

An implementation may define other hold types. Any additional hold types, how they are specified, their internal representation, their behavior, and how they affect the behavior of other utilities are implementation-defined.

The value of the *Hold_Types* attribute shall be the union of the valid hold types (`'s'`, `'o'`, `'u'`, and any implementation-defined hold types), or `'n'`.

A batch server shall not execute a batch job if the *Hold_Types* attribute of the batch job has a value other than NO_HOLD. If the *Hold_Types* attribute of the batch job has a value other than NO_HOLD, the batch job shall be in the HELD state.

Job_Owner Attribute

The *Job_Owner* attribute consists of a pair of user name and host name values of the form:

```
username@hostname
```

A batch server that accepts a *Queue Batch Job Request* shall set the *Job_Owner* attribute to a string that is the *username@hostname* of the user who submitted the job.

Join_Path Attribute

A batch server that executes a batch job for which the value of the *Join_Path* attribute is TRUE shall ignore the value of the *Error_Path* attribute and merge the standard error of the batch job with the standard output of the batch job.

Keep_Files Attribute

A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes the value KEEP_STD_OUTPUT shall retain the standard output of the batch job on the host where execution occurs. The standard output shall be retained in the home directory of the user under whose user ID the batch job is executed and the filename shall be the default filename for the standard output as defined under the **−o** option of the *qsub* utility. The *Output_Path* attribute is not modified.

A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes the value KEEP_STD_ERROR shall retain the standard error of the batch job on the host where execution occurs. The standard error shall be retained in the home directory of the user under whose user ID the batch job is executed and the filename shall be the default filename for standard error as defined under the **–e** option of the *qsub* utility. The *Error_Path* attribute is not modified.

A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes values other than KEEP_STD_OUTPUT and KEEP_STD_ERROR shall retain these other files on the host where execution occurs. These files (with implementation-defined names) shall be retained in the home directory of the user under whose user identifier the batch job is executed.

Mail_Points and Mail_Users Attributes

A batch server that executes a batch job for which one of the values of the *Mail_Points* attribute is the value MAIL_AT_BEGINNING shall send a mail message to each user account listed in the *Mail_Users* attribute of the batch job.

The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides, and the *Job_Owner* attribute.

Output_Path Attribute

The *Output_Path* attribute of a running job cannot be changed by a *Modify Batch Job Request*. When the *Keep_Files* attribute of the batch job does not contain the value KEEP_STD_OUTPUT, a batch server that executes a batch job shall either:

- Set the standard output stream of the session leader of the batch job to the destination described by the value of the *Output_Path* attribute of the batch job.

  or:

- Buffer the standard output of the session leader of the batch job until completion of the batch job, and when the batch job exits return the contents to the destination described by the value of the *Output_Path* attribute of the batch job.

When the *Output_Path* attribute does not specify a host name, then the batch server shall retain the standard output of the batch job on the host of execution.

When the *Keep_Files* attribute does not contain the value KEEP_STD_OUTPUT and the *Output_Path* attribute does specify a host name, then the final destination of the standard output of the batch job shall be on the host specified.

If the path specified in the *Output_Path* attribute of the batch job is a relative path, the batch server shall expand the path relative to the home directory of the user on the host to which the file is being returned.

Whether or not the batch server buffers the standard output of the batch job until completion of the batch job is implementation-defined. Applications shall not rely on having access to the standard output of a batch job prior to the completion of the batch job.

When the batch server does buffer the standard output of the batch job and the file cannot be opened for write upon completion of the batch job, then the batch server shall place the standard output in an implementation-defined location and notify the user of the location via mail. It shall be possible for the user to process this mail using the *mailx* utility.

If a batch server that does not buffer the standard output cannot open the standard output path of the batch job for write access, then the batch server shall abort the batch job.

Priority Attribute

A batch server implementation may choose to preferentially execute a batch job based on the *Priority* attribute. The interpretation of the batch job *Priority* attribute by a batch server is implementation-defined. If an implementation uses the *Priority* attribute, it shall interpret larger values of the *Priority* attribute to mean the batch job shall be preferentially selected for execution.

Rerunable Attribute

A batch job that began execution but did not complete, because the batch server either shut down or terminated abnormally, shall be requeued if the *Rerunable* attribute of the batch job has the value TRUE.

If a batch job, which was requeued after beginning execution but prior to completion, has a valid checkpoint file and the batch server supports checkpointing, then the batch job shall be restarted from the last valid checkpoint.

If the batch job cannot be restarted from a checkpoint, then when a batch job has a *Rerunable* attribute value of TRUE and was requeued after beginning execution but prior to completion, the batch server shall place the batch job into execution at the beginning of the job.

When a batch job has a *Rerunable* attribute value other than TRUE and was requeued after beginning execution but prior to completion, and the batch job cannot be restarted from a checkpoint, then the batch server shall abort the batch job.

Resource_List Attribute

A batch server that executes a batch job shall establish the resource limits of the session leader of the batch job according to the values of the *Resource_List* attribute of the batch job. Resource limits shall be enforced by an implementation-defined method.

Shell_Path_List Attribute

The *Shell_Path_List* job attribute consists of a list of pairs of pathname and host name values. The host name component can be omitted, in which case the pathname serves as the default pathname when a batch server cannot find the name of the host on which it is running in the list.

A batch server that executes a batch job shall select, from the value of the *Shell_Path_List* attribute of the batch job, a pathname where the shell to execute the batch job shall be found. The batch server shall select the pathname, in order of preference, according to the following methods:

- Select the pathname that contains the name of the host on which the batch server is running.
- Select the pathname for which the host name has been omitted.
- Select the pathname for the login shell of the user under which the batch job is to execute.

If the shell path value selected is an invalid pathname, the batch server shall abort the batch job.

If the value of the selected pathname from the *Shell_Path_List* attribute of the batch job represents a partial path, the batch server shall expand the path relative to a path that is implementation-defined.

The batch server that executes the batch job shall execute the program that was selected from the *Shell_Path_List* attribute of the batch job. The batch server shall pass the path to the script of the batch job as the first argument to the shell program.

User_List Attribute

The *User_List* job attribute consists of a list of pairs of user name and host name values. The host name component can be omitted, in which case the user name serves as a default when a batch server cannot find the name of the host on which it is running in the list.

A batch server that executes a batch job shall select, from the value of the *User_List* attribute of the batch job, a user name under which to create the session leader. The server shall select the user name, in order of preference, according to the following methods:

- Select the user name of a value that contains the name of the host on which the batch server executes.
- Select the user name of a value for which the host name has been omitted.
- Select the user name from the *Job_Owner* attribute of the batch job.

Variable_List Attribute

A batch server that executes a batch job shall create, in the environment of the session leader of the batch job, each environment variable listed in the *Variable_List* attribute of the batch job, and set the value of each such environment variable to that of the corresponding variable in the variable list.

3.2.2.2 Batch Job Routing

To route a batch job is to select a queue from a list and move the batch job to that queue.

A batch server that has routing queues, which have been started, shall route the jobs in the routing queues owned by the batch server. A batch server may delay the routing of a batch job. The algorithm for selecting a batch job and the queue to which it will be routed is implementation-defined.

When a routing queue has multiple possible destinations specified, then the precedence of the destinations is implementation-defined.

A batch server that routes a batch job to a queue at another server shall move the batch job into the target queue with a *Queue Batch Job Request*.

If the target server rejects the *Queue Batch Job Request*, the routing server shall retry routing the batch job or abort the batch job. A batch server that retries failed routings shall provide a means for the batch administrator to specify the number of retries and the minimum period of time between retries. The means by which an administrator specifies the number of retries and the delay between retries is implementation-defined. When the number of retries specified by the batch administrator has been exhausted, the batch server shall abort the batch job and perform the functions of *Batch Job Exit*; see Section 3.2.2.3.

3.2.2.3 Batch Job Exit

For each job in the EXITING state, the batch server that exited the batch job shall perform the following deferred services in the order specified:

1. If buffering standard error, move that file into the location specified by the *Error_Path* attribute of the batch job.
2. If buffering standard output, move that file into the location specified by the *Output_Path* attribute of the batch job.
3. If the *Mail_Points* attribute of the batch job includes MAIL_AT_EXIT, send mail to the users listed in the *Mail_Users* attribute of the batch job. The mail message shall contain at least

the batch job identifier, queue, and server at which the batch job currently resides, and the *Job_Owner* attribute.

4. Remove the batch job from the queue.

If a batch server that buffers the standard error output cannot return the standard error file to the standard error path at the time the batch job exits, the batch server shall do one of the following:

- Mail the standard error file to the batch job owner.
- Save the standard error file and mail the location and name of the file where the standard error is stored to the batch job owner.
- Save the standard error file and notify the user by other implementation-defined means.

If a batch server that buffers the standard output cannot return the standard output file to the standard output path at the time the batch job exits, the batch server shall do one of the following:

- Mail the standard output file to the batch job owner.
- Save the standard output file and mail the location and name of the file where the standard output is stored to the batch job owner.
- Save the standard output file and notify the user by other implementation-defined means.

At the conclusion of job exit processing, the batch job is no longer managed by a batch server.

3.2.2.4 *Batch Server Restart*

A batch server that has been either shutdown or terminated abnormally, and has returned to operation, is said to have *restarted*.

Upon restarting, a batch server shall requeue those jobs managed by the batch server that were in the RUNNING state at the time the batch server shut down and for which the *Rerunable* attribute of the batch job has the value TRUE.

Queues are defined to be non-volatile. A batch server shall store the content of queues that it controls in such a way that server and system shutdowns do not erase the content of the queues.

3.2.2.5 *Batch Job Abort*

A batch server that cannot perform a deferred service for a batch job shall abort the batch job.

A batch server that aborts a batch job shall perform the following services:

- Delete the batch job from the queue in which it resides.
- If the *Mail_Points* attribute of the batch job includes the value MAIL_AT_ABORT, send mail to the users listed in the value of the *Mail_Users* attribute of the job. The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides, the *Job_Owner* attribute, and the reason for the abort.
- If the batch job was in the RUNNING state, terminate the session leader of the executing job by sending the session leader a SIGKILL, place the batch job in the EXITING state, and perform the actions of *Batch Job Exit*.

3.2.3 Requested Batch Services

This section describes the services provided by batch servers in response to requests from clients. Table 3-5 summarizes the current set of batch service requests and for each gives its type (deferred or not) and whether it is an optional function.

Table 3-5 Batch Services Summary

Batch Service	**Deferred**	**Optional**
Batch Job Execution	Yes	No
Batch Job Routing	Yes	No
Batch Job Exit	Yes	No
Batch Server Restart	Yes	No
Batch Job Abort	Yes	No
Delete Batch Job Request	No	No
Hold Batch Job Request	No	No
Batch Job Message Request	No	Yes
Batch Job Status Request	No	No
Locate Batch Job Request	No	Yes
Modify Batch Job Request	No	No
Move Batch Job Request	No	No
Queue Batch Job Request	No	No
Batch Queue Status Request	No	No
Release Batch Job Request	No	No
Rerun Batch Job Request	No	No
Select Batch Jobs Request	No	No
Server Shutdown Request	No	No
Server Status Request	No	No
Signal Batch Job Request	No	No
Track Batch Job Request	No	Yes

If a request is rejected because the batch client is not authorized to perform the action, the batch server shall return the same status as when the batch job does not exist.

3.2.3.1 Delete Batch Job Request

A batch job is defined to have been deleted when it has been removed from the queue in which it resides and not instantiated in another queue. A client requests that the server that manages a batch job delete the batch job. Such a request is called a *Delete Batch Job Request*.

A batch server shall reject a *Delete Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to delete the designated job.
- The designated job is not managed by the batch server.
- The designated job is in a state inconsistent with the delete request.

A batch server may reject a *Delete Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server requested to delete a batch job shall delete the batch job if the batch job exists and is not in the EXITING state.

A batch server that deletes a batch job in the RUNNING state shall send a SIGKILL signal to the session leader of the batch job. It is implementation-defined whether additional signals are sent to the session leader of the job prior to sending the SIGKILL signal.

A batch server that deletes a batch job in the RUNNING state shall place the batch job in the EXITING state after it has killed the session leader of the batch job and shall perform the actions of *Batch Job Exit*.

3.2.3.2 *Hold Batch Job Request*

A batch client can request that the batch server add one or more holds to a batch job. Such a request is called a *Hold Batch Job Request*.

A batch server shall reject a *Hold Batch Job Request* if any of the following statements are true:

- The batch server does not support one or more of the requested holds to be added to the batch job.
- The user of the batch client is not authorized to add one or more of the requested holds to the batch job.
- The batch server does not manage the specified job.
- The designated job is in the EXITING state.

A batch server may reject a *Hold Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Hold Batch Job Request* for a batch job in the RUNNING state shall place a hold on the batch job. The effects, if any, the hold will have on a batch job in the RUNNING state are implementation-defined.

A batch server that accepts a *Hold Batch Job Request* shall add each type of hold listed in the *Hold Batch Job Request*, that is not already present, to the value of the *Hold_Types* attribute of the batch job.

3.2.3.3 *Batch Job Message Request*

Batch Job Message Request is an optional feature of batch servers. If an implementation supports *Batch Job Message Request*, the statements in this section apply and the configuration variable POSIX2_PBS_MESSAGE shall be set to 1.

A batch client can request that a batch server write a message into certain output files of a batch job. Such a request is called a *Batch Job Message Request*.

A batch server shall reject a *Batch Job Message Request* if any of the following statements are true:

- The batch server does not support sending messages to jobs.
- The user of the batch client is not authorized to post a message to the designated job.
- The designated job does not exist on the batch server.
- The designated job is not in the RUNNING state.

A batch server may reject a *Batch Job Message Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Batch Job Message Request* shall write the message sent by the batch client into the files indicated by the batch client.

3.2.3.4 Batch Job Status Request

A batch client can request that a batch server respond with the status and attributes of a batch job. Such a request is called a *Batch Job Status Request*.

A batch server shall reject a *Batch Job Status Request* if any of the following statements are true:

- The user of the batch client is not authorized to query the status of the designated job.
- The designated job is not managed by the batch server.

A batch server may reject a *Batch Job Status Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Batch Job Status Request* shall return a *Batch Job Status Message* to the batch client.

A batch server may return other information in response to a *Batch Job Status Request*.

3.2.3.5 Locate Batch Job Request

Locate Batch Job Request is an optional feature of batch servers. If an implementation supports *Locate Batch Job Request*, the statements in this section apply and the configuration variable POSIX2_PBS_LOCATE shall be set to 1.

A batch client can ask a batch server to respond with the location of a batch job that was created by the batch server. Such a request is called a *Locate Batch Job Request*.

A batch server that accepts a *Locate Batch Job Request* shall return a *Batch Job Location Message* to the batch client.

A batch server may reject a *Locate Batch Job Request* for a batch job that was not created by that server.

A batch server may reject a *Locate Batch Job Request* for a batch job that is no longer managed by that server; that is, for a batch job that is not in a queue owned by that server.

A batch server may reject a *Locate Batch Job Request* for other implementation-defined reasons.

3.2.3.6 Modify Batch Job Request

Batch clients modify (alter) the attributes of a batch job by making a request to the server that manages the batch job. Such a request is called a *Modify Batch Job Request*.

A batch server shall reject a *Modify Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to make the requested modification to the batch job.
- The designated job is not managed by the batch server.
- The requested modification is inconsistent with the state of the batch job.
- An unrecognized resource is requested for a batch job in an execution queue.

A batch server may reject a *Modify Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Modify Batch Job Request* shall modify all the specified attributes of the batch job. A batch server that rejects a *Modify Batch Job Request* shall modify none of the attributes of the batch job.

If the servicing by a batch server of an otherwise valid request would result in no change, then the batch server shall indicate successful completion of the request.

3.2.3.7 Move Batch Job Request

A batch client can request that a batch server move a batch job to another destination. Such a request is called a *Move Batch Job Request*.

A batch server shall reject a *Move Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to remove the designated job from the queue in which the batch job resides.
- The user of the batch client is not authorized to move the designated job to the destination.
- The designated job is not managed by the batch server.
- The designated job is in the EXITING state.
- The destination is inaccessible.

A batch server can reject a *Move Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Move Batch Job Request* shall perform the following services:

- Queue the designated job at the destination.
- Remove the designated job from the queue in which the batch job resides.

If the destination resides on another batch server, the batch server shall queue the batch job at the destination by sending a *Queue Batch Job Request* to the other server. If the *Queue Batch Job Request* fails, the batch server shall reject the *Move Batch Job Request*. If the *Queue Batch Job Request* succeeds, the batch server shall remove the batch job from its queue.

The batch server shall not modify any attributes of the batch job.

3.2.3.8 Queue Batch Job Request

A batch queue is controlled by one and only one batch server. A batch server is said to own the queues that it controls. Batch clients make requests of batch servers to have jobs queued. Such a request is called a *Queue Batch Job Request*.

A batch server requested to queue a batch job for which the queue is not specified shall select an implementation-defined queue for the batch job. Such a queue is called the *default queue* of the batch server. The implementation shall provide the means for a batch administrator to specify the default queue. The queue, whether specified or defaulted, is called the *target queue.*

A batch server shall reject a *Queue Batch Job Request* if any of the following statements are true:

- The client is not authorized to create a batch job in the target queue.
- The request specifies a queue that does not exist on the batch server.
- The target queue is an execution queue and the batch server cannot satisfy a resource requirement of the batch job.
- The target queue is an execution queue and an unrecognized resource is requested.
- The target queue is an execution queue, the batch server does not support checkpointing, and the value of the *Checkpoint* attribute of the batch job is not NO_CHECKPOINT.

- The job requires access to a user identifier that the batch client is not authorized to access.

A batch server may reject a *Queue Batch Job Request* for other implementation-defined reasons.

A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_O_QUEUE value is missing from the value of the *Variable_List* attribute of the batch job shall add that variable to the list and set the value to the name of the target queue. Once set, no server shall change the value of PBS_O_QUEUE, even if the batch job is moved to another queue.

A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_JOBID value is missing from the value of the *Variable_List* attribute shall add that variable to the list and set the value to the batch job identifier assigned by the server in the format:

```
sequence_number.server
```

A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_JOBNAME value is missing from the value of the *Variable_List* attribute of the batch job shall add that variable to the list and set the value to the *Job_Name* attribute of the batch job.

3.2.3.9 Batch Queue Status Request

A batch client can request that a batch server respond with the status and attributes of a queue. Such a request is called a *Batch Queue Status Request*.

A batch server shall reject a *Batch Queue Status Request* if any of the following statements are true:

- The user of the batch client is not authorized to query the status of the designated queue.
- The designated queue does not exist on the batch server.

A batch server may reject a *Batch Queue Status Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Batch Queue Status Request* shall return a *Batch Queue Status Reply* to the batch client.

3.2.3.10 Release Batch Job Request

A batch client can request that server remove one or more holds from a batch job. Such a request is called a *Release Batch Job Request*.

A batch server shall reject a *Release Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to remove one or more of the requested holds from the batch job.
- The batch server does not manage the specified job.

A batch server may reject a *Release Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Release Batch Job Request* shall remove each type of hold listed in the *Release Batch Job Request*, that is present, from the value of the *Hold_Types* attribute of the batch job.

3.2.3.11 *Rerun Batch Job Request*

To rerun a batch job is to kill the session leader of the batch job and leave the batch job eligible for re-execution. A batch client can request that a batch server rerun a batch job. Such a request is called *Rerun Batch Job Request*.

A batch server shall reject a *Rerun Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to rerun the designated job.
- The *Rerunable* attribute of the designated job has the value FALSE.
- The designated job is not in the RUNNING state.
- The batch server does not manage the designated job.

A batch server may reject a *Rerun Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that rejects a *Rerun Batch Job Request* shall in no way modify the execution of the batch job.

A batch server that accepts a request to rerun a batch job shall perform the following services:

- Requeue the batch job in the execution queue in which it was executing.
- Send a SIGKILL signal to the process group of the session leader of the batch job.

An implementation may indicate to the batch job owner that the batch job has been rerun. Whether and how the batch job owner is notified that a batch job is rerun is implementation-defined.

A batch server that reruns a batch job may send other implementation-defined signals to the session leader of the batch job prior to sending the SIGKILL signal.

A batch server may preferentially select a rerun job for execution. Whether rerun jobs shall be selected for execution before other jobs is implementation-defined.

3.2.3.12 *Select Batch Jobs Request*

A batch client can request from a batch server a list of jobs managed by that server that match a list of selection criteria. Such a request is called a *Select Batch Jobs Request*. All the batch jobs managed by the batch server that receives the request are candidates for selection.

A batch server that accepts a *Select Batch Jobs Request* shall return a list of zero or more job identifiers that correspond to jobs that meet the selection criteria.

If the batch client is not authorized to query the status of a batch job, the batch server shall not select the batch job.

3.2.3.13 *Server Shutdown Request*

A batch server is defined to have shut down when it does not respond to requests from clients and does not perform deferred services for jobs. A batch client can request that a batch server shut down. Such a request is called a *Server Shutdown Request*.

A batch server shall reject a *Server Shutdown Request* from a client that is not authorized to shut down the batch server. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server may reject a *Server Shutdown Request* for other implementation-defined reasons. The reasons for which a *Server Shutdown Request* may be rejected are implementation-defined.

At server shutdown, a batch server shall do, in order of preference, one of the following:

- If checkpointing is implemented and the batch job is checkpointable, then checkpoint the batch job and requeue it.
- If the batch job is rerunable, then requeue the batch job to be rerun (restarted from the beginning).
- Abort the batch job.

3.2.3.14 *Server Status Request*

A batch client can request that a batch server respond with the status and attributes of the batch server. Such a request is called a *Server Status Request*.

A batch server shall reject a *Server Status Request* if the following statement is true:

- The user of the batch client is not authorized to query the status of the designated server.

A batch server may reject a *Server Status Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Server Status Request* shall return a *Server Status Reply* to the batch client.

3.2.3.15 *Signal Batch Job Request*

A batch client can request that a batch server signal the session leader of a batch job. Such a request is called a *Signal Batch Job Request*.

A batch server shall reject a *Signal Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to signal the batch job.
- The job is not in the RUNNING state.
- The batch server does not manage the designated job.
- The requested signal is not supported by the implementation.

A batch server may reject a *Signal Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a request to signal a batch job shall send the signal requested by the batch client to the process group of the session leader of the batch job.

3.2.3.16 *Track Batch Job Request*

Track Batch Job Request is an optional feature of batch servers. If an implementation supports *Track Batch Job Request*, the statements in this section apply and the configuration variable POSIX2_PBS_TRACK shall be set to 1.

Track Batch Job Request provides a method for tracking the current location of a batch job. Clients may use the tracking information to determine the batch server that should receive a batch server request.

If *Track Batch Job Request* is supported by a batch server, then when the batch server queues a batch job as a result of a *Queue Batch Job Request*, and the batch server is not the batch server that created the batch job, the batch server shall send a *Track Batch Job Request* to the batch server that created the job.

If *Track Batch Job Request* is supported by a batch server, then the *Track Batch Job Request* may also be sent to other servers as a backup to the primary server. The method by which backup servers are specified is implementation-defined.

If *Track Batch Job Request* is supported by a batch server that receives a *Track Batch Job Request*, then the batch server shall record the current location of the batch job as contained in the request.

3.3 Common Behavior for Batch Environment Utilities

3.3.1 Batch Job Identifier

A utility shall recognize *job_identifier*s of the format:

```
[sequence_number][.server_name][@server]
```

where:

sequence_number	An integer that, when combined with *server_name*, provides a batch job identifier that is unique within the batch system.
server_name	The name of the batch server to which the batch job was originally submitted.
server	The name of the batch server that is currently managing the batch job.

If the application omits the batch *server_name* portion of a batch job identifier, a utility shall use the name of a default batch server.

If the application omits the batch *server* portion of a batch job identifier, a utility shall use:

- The batch server indicated by *server_name*, if present.
- The name of the default batch server.
- The name of the batch server that is currently managing the batch job.

If only *@server* is specified, then the status of all jobs owned by the user on the requested server is listed.

The means by which a utility determines the default batch server is implementation-defined.

If the application presents the batch *server* portion of a batch job identifier to a utility, the utility shall send the request to the specified server.

A strictly conforming application shall use the syntax described for the job identifier. Whenever a batch job identifier is specified whose syntax is not recognized by an implementation, then a message for each error that occurs shall be written to standard error and the utility shall exit with an exit status greater than zero.

When a batch job identifier is supplied as an argument to a batch utility and the *server_name* portion of the batch job identifier is omitted, then the utility shall use the name of the default batch server.

When a batch job identifier is supplied as an argument to a batch utility and the batch *server* portion of the batch job identifier is omitted, then the utility shall use either:

- The name of the default batch server

  or:

- The name of the batch server that is currently managing the batch job

When a batch job identifier is supplied as an argument to a batch utility and the batch *server* portion of the batch job identifier is specified, then the utility shall send the required *Batch Server Request* to the specified server.

3.3.2 Destination

The utility shall recognize a *destination* of the format:

```
[queue][@server]
```

where:

queue	The name of a valid execution or routing queue at the batch server denoted by *@server*, defined as a string of up to 15 alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set) where the first character is alphabetic.
server	The name of a batch server, defined as a string of alphanumeric characters in the portable character set.

If the application omits the batch *server* portion of a destination, then the utility shall use either:

- The name of the default batch server

  or:

- The name of the batch server that is currently managing the batch job

The means by which a utility determines the default batch server is implementation-defined.

If the application omits the *queue* portion of a destination, then the utility shall use the name of the default queue at the batch server chosen. The means by which a batch server determines its default queue is implementation-defined. If a destination is specified in the *queue@server* form, then the utility shall use the specified queue at the specified server.

A strictly conforming application shall use the syntax described for a destination. Whenever a destination is specified whose syntax is not recognized by an implementation, then a message shall be written to standard error and the utility shall exit with an exit status greater than zero.

3.3.3 Multiple Keyword-Value Pairs

For each option that can have multiple keyword-value pair arguments, the following rules shall apply. Examples of options that can have list-oriented option-arguments are −**u** *value@keyword* and −**l** *keyword=value*.

1. If a batch utility is presented with a list-oriented option-argument for which a keyword has a corresponding value that begins with a single or double quote, then the utility shall stop interpreting the input stream for delimiters until a second single or double quote, respectively, is encountered. This feature allows some flexibility for a comma (`','`) or equals sign (`'='`) to be part of the value string for a particular keyword; for example:

   ```
   keywd1='val1,val2',keywd2="val3,val4"
   ```

   Note: This may require the user to escape the quotes as in the following command:

```
foo −xkeywd1=\'val1,val2\',keywd2=\"val3,val4\"
```

2. If a batch server is presented with a list-oriented attribute that has a keyword that was encountered earlier in the list, then the later entry for that keyword shall replace the earlier entry.

3. If a batch server is presented with a list-oriented attribute that has a keyword without any corresponding value of the form *keyword*= or @*keyword* and the same keyword was encountered earlier in the list, then the prior entry for that keyword shall be ignored by the batch server.

4. If a batch utility is expecting a list-oriented option-argument entry of the form *keyword*=*value*, but is presented with an entry of the form *keyword* without any corresponding *value*, then the entry shall be treated as though a default value of NULL was assigned (that is, *keyword*=NULL) for entry parsing purposes. The utility shall include only the keyword, not the NULL value, in the associated job attribute.

5. If a batch utility is expecting a list-oriented option-argument entry of the form *value*@*keyword*, but is presented with an entry of the form *value* without any corresponding *keyword*, then the entry shall be treated as though a keyword of NULL was assigned (that is, *value*@NULL) for entry parsing purposes. The utility shall include only the value, not the NULL keyword, in the associated job attribute.

6. A batch server shall accept a list-oriented attribute that has multiple occurrences of the same keyword, interpreting the keywords, in order, with the last value encountered taking precedence over prior instances of the same keyword. This rule allows, but does not require, a batch utility to preprocess the attribute to remove duplicate keywords.

7. If a batch utility is presented with multiple list-oriented option-arguments on the command line or in script directives, or both, for a single option, then the utility shall concatenate, in order, any command line keyword and value pairs to the end of any directive keyword and value pairs separated by a single comma to produce a single string that is an equivalent, valid option-argument. The resulting string shall be assigned to the associated attribute of the batch job (after optionally removing duplicate entries as described in item 6.

Chapter 4

Utilities

This chapter contains the definitions of the utilities, as follows:

- Mandatory utilities that are present on every conformant system
- Optional utilities that are present only on systems supporting the associated option; see Section 1.8.1 (on page 2210) for information on the options in this volume of IEEE Std 1003.1-200x

NAME

admin — create and administer SCCS files (**DEVELOPMENT**)

SYNOPSIS

XSI

```
admin -i[name][-n][-a login][-d flag][-e login][-f flag][-m mrlist]
    [-r rel][-t[name][-y[comment]] newfile
```

```
admin -n[-a login][-d flag][-e login][-f flag][-m mrlist][-t[name]]
    [-y[comment]] newfile ...
```

```
admin [-a login][-d flag][-m mrlist][-r rel][-t[name]] file ...
```

```
admin -h file ...
```

```
admin -z file ...
```

DESCRIPTION

The *admin* utility shall create new SCCS files or change parameters of existing ones. If a named file does not exist, it shall be created, and its parameters shall be initialized according to the specified options. Parameters not initialized by an option shall be assigned a default value. If a named file does exist, parameters corresponding to specified options shall be changed, and other parameters shall be left as is.

All SCCS filenames supplied by the application shall be of the form s.*filename*. New SCCS files shall be given read-only permission mode. Write permission in the parent directory is required to create a file. All writing done by *admin* shall be to a temporary *x-file*, named x.*filename* (see *get*) created with read-only mode if *admin* is creating a new SCCS file, or created with the same mode as that of the SCCS file if the file already exists. After successful execution of *admin*, the SCCS file shall be removed (if it exists), and the *x-file* shall be renamed with the name of the SCCS file. This ensures that changes are made to the SCCS file only if no errors occur.

The *admin* utility shall also use a transient lock file (named z.*filename*), which is used to prevent simultaneous updates to the SCCS file; see *get* (on page 2675).

OPTIONS

The *admin* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the **–i**, **–t**, and **–y** options have optional option-arguments. These optional option-arguments shall not be presented as separate arguments. The following options are supported:

–n Create a new SCCS file. When **–n** is used without **–i**, the SCCS file shall be created with control information but without any file data.

–i[*name***]** Specify the *name* of a file from which the text for a new SCCS file shall be taken. The text constitutes the first delta of the file (see the **–r** option for delta numbering scheme). If the **–i** option is used, but the *name* option-argument is omitted, the text shall be obtained by reading the standard input. If this option is omitted, the SCCS file shall be created with control information but without any file data. The **–i** option implies the **–n** option.

–r *SID* Specify the SID of the initial delta to be inserted. This SID shall be a trunk SID; that is, the branch and sequence numbers shall be zero or missing. The level number is optional, and defaults to 1.

–t[*name***]** Specify the *name* of a file from which descriptive text for the SCCS file shall be taken. In the case of existing SCCS files (neither **–i** nor **–n** is specified):

- A **−t** option without a *name* option-argument shall cause the removal of descriptive text (if any) currently in the SCCS file.
- A **−t** option with a *name* option-argument shall cause the text (if any) in the named file to replace the descriptive text (if any) currently in the SCCS file.

−f *flag* Specify a *flag*, and, possibly, a value for the *flag*, to be placed in the SCCS file. Several **−f** options may be supplied on a single *admin* command line. Implementations shall recognize the following flags and associated values:

b Allow use of the **−b** option on a *get* command to create branch deltas.

c*ceil* Specify the highest release (that is, ceiling), a number less than or equal to 9 999, which may be retrieved by a *get* command for editing. The default value for an unspecified **c** flag shall be 9 999.

f*floor* Specify the lowest release (that is, floor), a number greater than 0 but less than 9 999, which may be retrieved by a *get* command for editing. The default value for an unspecified **f** flag shall be 1.

d*SID* Specify the default delta number (SID) to be used by a *get* command.

i*str* Treat the ‘‘No ID keywords’’ message issued by *get* or *delta* as a fatal error. In the absence of this flag, the message is only a warning. The message is issued if no SCCS identification keywords (see *get* (on page 2675)) are found in the text retrieved or stored in the SCCS file. If a value is supplied, the application shall ensure that the keywords exactly match the given string; however, the string shall contain a keyword, and no embedded <newline>s.

j Allow concurrent *get* commands for editing on the same SID of an SCCS file. This allows multiple concurrent updates to the same version of the SCCS file.

l*list* Specify a *list* of releases to which deltas can no longer be made (that is, *get* **−e** against one of these locked releases fails). Conforming applications shall use the following syntax to specify a *list*. Implementations may accept additional forms as an extension:

```
<list> ::= a | <range-list>
<range-list> ::= <range> | <range-list>, <range>
<range> ::= <SID>
```

The character *a* in the *list* shall be equivalent to specifying all releases for the named SCCS file. The non-terminal <*SID*> in range shall be the delta number of an existing delta associated with the SCCS file.

n Cause *delta* to create a null delta in each of those releases (if any) being skipped when a delta is made in a new release (for example, in making delta 5.1 after delta 2.7, releases 3 and 4 are skipped). These null deltas shall serve as anchor points so that branch deltas may later be created from them. The absence of this flag shall cause skipped releases to be nonexistent in the SCCS file, preventing branch deltas from being created from them in the future. During the initial creation of an SCCS file, the **n** flag may be ignored; that is, if the **−r** option is used to set the release number of the initial SID to a value greater than 1, null deltas need not be created for the ‘‘skipped’’ releases.

q*text* Substitute user-definable *text* for all occurrences of the %**Q**% keyword in the SCCS file text retrieved by *get*.

m*mod* Specify the module name of the SCCS file substituted for all occurrences of the %**M**% keyword in the SCCS file text retrieved by *get*. If the **m** flag is not specified, the value assigned shall be the name of the SCCS file with the leading `'.'` removed.

t*type* Specify the *type* of module in the SCCS file substituted for all occurrences of the %**Y**% keyword in the SCCS file text retrieved by *get*.

v*pgm* Cause *delta* to prompt for modification request (MR) numbers as the reason for creating a delta. The optional value specifies the name of an MR number validation program. (If this flag is set when creating an SCCS file, the application shall ensure that the **m** option is also used even if its value is null.)

−**d** *flag* Remove (delete) the specified *flag* from an SCCS file. Several −**d** options may be supplied on a single *admin* command. See the −**f** option for allowable *flag* names. (The **l***list* flag gives a *list* of releases to be unlocked. See the −**f** option for further description of the **l** flag and the syntax of a *list*.)

−**a** *login* Specify a *login* name, or numerical group ID, to be added to the list of users who may make deltas (changes) to the SCCS file. A group ID shall be equivalent to specifying all *login* names common to that group ID. Several −**a** options may be used on a single *admin* command line. As many *login*s, or numerical group IDs, as desired may be on the list simultaneously. If the list of users is empty, then anyone may add deltas. If *login* or group ID is preceded by a `'!'`, the users so specified shall be denied permission to make deltas.

−**e** *login* Specify a *login* name, or numerical group ID, to be erased from the list of users allowed to make deltas (changes) to the SCCS file. Specifying a group ID is equivalent to specifying all *login* names common to that group ID. Several −**e** options may be used on a single *admin* command line.

−**y**[*comment*] Insert the *comment* text into the SCCS file as a comment for the initial delta in a manner identical to that of *delta*. In the POSIX locale, omission of the −**y** option shall result in a default comment line being inserted in the form:

```
"date and time created %s %s by %s", <date>, <time>, <login>
```

where <*date*> is expressed in the format of the *date* utility's `%y/%m/%d` conversion specification, <*time*> in the format of the *date* utility's `%T` conversion specification format, and <*login*> is the login name of the user creating the file.

−**m** *mrlist* Insert the list of modification request (MR) numbers into the SCCS file as the reason for creating the initial delta in a manner identical to *delta*. The application shall ensure that the **v** flag is set and the MR numbers are validated if the **v** flag has a value (the name of an MR number validation program). A diagnostic message shall be written if the **v** flag is not set or MR validation fails.

−**h** Check the structure of the SCCS file and compare the newly computed checksum (the sum of all the characters in the SCCS file except those in the first line) with the checksum that is stored in the first line of the SCCS file. If the newly computed checksum does not match the checksum in the SCCS file, a diagnostic message shall be written.

−z	Recompute the SCCS file checksum and store it in the first line of the SCCS file (see the **−h** option above). Note that use of this option on a truly corrupted file may prevent future detection of the corruption.

OPERANDS

The following operands shall be supported:

file	A pathname of an existing SCCS file or a directory. If *file* is a directory, the *admin* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored.
newfile	A pathname of an SCCS file to be created.

If exactly one *file* or *newfile* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only if the **−i** is specified without an option-argument or if a *file* or *newfile* operand is specified as `'−'`. If the first character of any standard input line is <SOH> in the POSIX locale, the results are unspecified.

INPUT FILES

The existing SCCS files shall be text files of an unspecified format.

The application shall ensure that the file named by the **−i** option's *name* option-argument shall be a text file; if the first character of any line in this file is <SOH> in the POSIX locale, the results are unspecified. If this file contains more than 99 999 lines, the number of lines recorded in the header for this file shall be 99 999 for this delta.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *admin*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and the contents of the default **−y** comment.
NLSPATH	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

Any SCCS files created shall be text files of an unspecified format. During processing of a *file*, a locking *z-file*, as described in *get* (on page 2675), may be created and deleted.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

It is recommended that directories containing SCCS files be writable by the owner only, and that SCCS files themselves be read-only. The mode of the directories should allow only the owner to modify SCCS files contained in the directories. The mode of the SCCS files prevents any modification at all except by SCCS commands.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The normative text is reworded to emphasize the term ‘‘shall’’ for implementation requirements.

The grammar is updated.

The Open Group Base Resolution bwg 2001-007 is applied, adding new text to the INPUT FILES section warning that the maximum lines recorded in the file is 99 999.

NAME

alias — define or display aliases

SYNOPSIS

UP
```
alias [alias-name[=string] ...]
```

DESCRIPTION

The *alias* utility shall create or redefine alias definitions or write the values of existing alias definitions to standard output. An alias definition provides a string value that shall replace a command name when it is encountered; see Section 2.3.1 (on page 2234).

An alias definition shall affect the current shell execution environment and the execution environments of the subshells of the current shell. When used as specified by this volume of IEEE Std 1003.1-200x, the alias definition shall not affect the parent process of the current shell nor any utility environment invoked by the shell; see Section 2.12 (on page 2263).

OPTIONS

None.

OPERANDS

The following operands shall be supported:

alias-name	Write the alias definition to standard output.
alias-name=string	Assign the value of *string* to the alias *alias-name*.

If no operands are given, all alias definitions shall be written to standard output.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *alias*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The format for displaying aliases (when no operands or only *name* operands are specified) shall be:

```
"%s=%s\n", name, value
```

The *value* string shall be written with appropriate quoting so that it is suitable for reinput to the shell. See the description of shell quoting in Section 2.2 (on page 2232).

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	One of the *name* operands specified did not have an alias definition, or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. Change *ls* to give a columnated, more annotated output:

```
alias ls="ls −CF"
```

2. Create a simple "redo" command to repeat previous entries in the command history file:

```
alias r='fc −s'
```

3. Use 1K units for *du*:

```
alias du=du\ −k
```

4. Set up *nohup* so that it can deal with an argument that is itself an alias name:

```
alias nohup="nohup "
```

RATIONALE

The *alias* description is based on historical KornShell implementations. Known differences exist between that and the C shell. The KornShell version was adopted to be consistent with all the other KornShell features in this volume of IEEE Std 1003.1-200x, such as command line editing.

Since *alias* affects the current shell execution environment, it is generally provided as a shell regular built-in.

Historical versions of the KornShell have allowed aliases to be exported to scripts that are invoked by the same shell. This is triggered by the *alias* −**x** flag; it is allowed by this volume of IEEE Std 1003.1-200x only when an explicit extension such as −**x** is used. The standard developers considered that aliases were of use primarily to interactive users and that they should normally not affect shell scripts called by those users; functions are available to such scripts.

Historical versions of the KornShell had not written aliases in a quoted manner suitable for reentry to the shell, but this volume of IEEE Std 1003.1-200x has made this a requirement for all similar output. Therefore, consistency with this volume of IEEE Std 1003.1-200x was chosen over this detail of historical practice.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

NAME

ar — create and maintain library archives

SYNOPSIS

```
SD    ar -d[-v] archive file ...

XSI   ar -m[-abiv][posname] archive file ...

XSI   ar -p[-v][-s]archive [file ...]
XSI   ar -q[-cv] archive file ...

XSI   ar -r[-cuv][-abi][posname]archive file ...
XSI   ar -t[-v][-s]archive [file ...]
XSI   ar -x[-v][-sCT]archive [file ...]
```

DESCRIPTION

The *ar* utility can be used to create and maintain groups of files combined into an archive. Once an archive has been created, new files can be added, and existing files in an archive can be extracted, deleted, or replaced. When an archive consists entirely of valid object files, the implementation shall format the archive so that it is usable as a library for link editing (see *c99* and *fort77*). When some of the archived files are not valid object files, the suitability of the archive for library use is undefined. XSI If an archive consists entirely of printable files, the entire archive shall be printable.

When *ar* creates an archive, it creates administrative information indicating whether a symbol table is present in the archive. When there is at least one object file that *ar* recognizes as such in the archive, an archive symbol table shall be created in the archive and maintained by *ar*; it is used by the link editor to search the archive. Whenever the *ar* utility is used to create or update the contents of such an archive, the symbol table shall be rebuilt. The **–s** option shall force the symbol table to be rebuilt.

All *file* operands can be pathnames. However, files within archives shall be named by a filename, which is the last component of the pathname used when the file was entered into the archive. The comparison of *file* operands to the names of files in archives shall be performed by comparing the last component of the operand to the name of the file in the archive.

It is unspecified whether multiple files in the archive may be identically named. In the case of such files, however, each *file* XSI and *posname* operand shall match only the first file in the archive having a name that is the same as the last component of the operand.

OPTIONS

The *ar* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

XSI	**–a**	Position new files in the archive after the file named by the *posname* operand.
XSI	**–b**	Position new files in the archive before the file named by the *posname* operand.
	–c	Suppress the diagnostic message that is written to standard error by default when the archive *archive* is created.
XSI	**–C**	Prevent extracted files from replacing like-named files in the file system. This option is useful when **–T** is also used, to prevent truncated filenames from

replacing files with the same prefix.

−d Delete one or more *file*s from *archive*.

XSI **−i** Position new files in the archive before the file in the archive named by the *posname* operand (equivalent to **−b**).

XSI **−m** Move the named files in the archive. The **−a**, **−b**, or **−i** options with the *posname* operand indicate the position; otherwise, move the names files in the archive to the end of the archive.

−p Write the contents of the *file*s in the archive named by *file* operands from *archive* to the standard output. If no *file* operands are specified, the contents of all files in the archive shall be written in the order of the archive.

XSI **−q** Append the named files to the end of the archive. In this case *ar* does not check whether the added files are already in the archive. This is useful to bypass the searching otherwise done when creating a large archive piece by piece.

−r Replace or add *file*s to *archive*. If the archive named by *archive* does not exist, a new archive shall be created and a diagnostic message shall be written to standard error (unless the **−c** option is specified). If no *file*s are specified and the *archive* exists, the results are undefined. Files that replace existing files in the archive shall not change the order of the archive. Files that do not replace existing files in the archive shall be appended to the archive unless a **−a**, **−b**, or **−i** option specifies another position.

XSI **−s** Force the regeneration of the archive symbol table even if *ar* is not invoked with an option that modifies the archive contents. This option is useful to restore the archive symbol table after it has been stripped; see *strip*.

−t Write a table of contents of *archive* to the standard output. The files specified by the *file* operands shall be included in the written list. If no *file* operands are specified, all files in *archive* shall be included in the order of the archive.

XSI **−T** Allow filename truncation of extracted files whose archive names are longer than the file system can support. By default, extracting a file with a name that is too long shall be an error; a diagnostic message shall be written and the file shall not be extracted.

−u Update older files in the archive. When used with the **−r** option, files in the archive shall be replaced only if the corresponding *file* has a modification time that is at least as new as the modification time of the file in the archive.

−v Give verbose output. When used with the option characters **−d**, **−r**, or **−x**, write a detailed file-by-file description of the archive creation and maintenance activity, as described in the STDOUT section.

When used with **−p**, write the name of the file in the archive to the standard output before writing the file in the archive itself to the standard output, as described in the STDOUT section.

When used with **−t**, include a long listing of information about the files in the archive, as described in the STDOUT section.

−x Extract the files in the archive named by the *file* operands from *archive*. The contents of the archive shall not be changed. If no *file* operands are given, all files in the archive shall be extracted. The modification time of each file extracted shall be set to the time the file is extracted from the archive.

OPERANDS

The following operands shall be supported:

archive	A pathname of the archive.
file	A pathname. Only the last component shall be used when comparing against the names of files in the archive. If two or more *file* operands have the same last pathname component (basename), the results are unspecified. The implementation's archive format shall not truncate valid filenames of files added to or replaced in the archive.
XSI *posname*	The name of a file in the archive, used for relative positioning; see options −**m** and −**r**.

STDIN

Not used.

INPUT FILES

The archive named by *archive* shall be a file in the format created by *ar* −**r**.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ar*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_TIME	Determine the format and content for date and time strings written by *ar* −**tv**.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES.*
TMPDIR	Determine the pathname that overrides the default directory for temporary files, if any.
TZ	Determine the timezone used to calculate date and time strings written by *ar* −**tv**. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the −**d** option is used with the −**v** option, the standard output format shall be:

```
"d − %s\n", <file>
```

where *file* is the operand specified on the command line.

If the −**p** option is used with the −**v** option, *ar* shall precede the contents of each file with:

```
"\n<%s>\n\n", <file>
```

where *file* is the operand specified on the command line, if *file* operands were specified, and the name of the file in the archive if they were not.

If the **−r** option is used with the **−v** option:

- If *file* is already in the archive, the standard output format shall be:

  ```
  "r − %s\n", <file>
  ```

  where <*file*> is the operand specified on the command line.

- If *file* is not already in the archive, the standard output format shall be:

  ```
  "a − %s\n", <file>
  ```

  where <*file*> is the operand specified on the command line.

If the **−t** option is used, *ar* shall write the names of the files in the archive to the standard output in the format:

```
"%s\n", <file>
```

where *file* is the operand specified on the command line, if *file* operands were specified, or the name of the file in the archive if they were not.

If the **−t** option is used with the **−v** option, the standard output format shall be:

```
"%s %u/%u %u %s %d %d:%d %d %s\n", <member mode>, <user ID>,
    <group ID>, <number of bytes in member>,
    <abbreviated month>, <day-of-month>, <hour>,
    <minute>, <year>, <file>
```

where:

<*file*>	Shall be the operand specified on the command line, if *file* operands were specified, or the name of the file in the archive if they were not.
<*member mode*>	Shall be formatted the same as the <*file mode*> string defined in the STDOUT section of *ls*, except that the first character, the <*entry type*>, is not used; the string represents the file mode of the file in the archive at the time it was added to or replaced in the archive.

The following represent the last-modification time of a file when it was most recently added to or replaced in the archive:

<*abbreviated month*>	Equivalent to the format of the `%b` conversion specification format in *date*.
<*day-of-month*>	Equivalent to the format of the `%e` conversion specification format in *date*.
<*hour*>	Equivalent to the format of the `%H` conversion specification format in *date*.
<*minute*>	Equivalent to the format of the `%M` conversion specification format in *date*.
<*year*>	Equivalent to the format of the `%Y` conversion specification format in *date*.

When *LC_TIME* does not specify the POSIX locale, a different format and order of presentation of these fields relative to each other may be used in a format appropriate in the specified locale.

If the −**x** option is used with the −**v** option, the standard output format shall be:

```
"x − %s\n", <file>
```

where *file* is the operand specified on the command line, if *file* operands were specified, or the name of the file in the archive if they were not.

STDERR

The standard error shall be used only for diagnostic messages. The diagnostic message about creating a new archive when −**c** is not specified shall not modify the exit status.

OUTPUT FILES

Archives are files with unspecified formats.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	Successful completion.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The archive format is not described. It is recognized that there are several known *ar* formats, which are not compatible. The *ar* utility is included, however, to allow creation of archives that are intended for use only on one machine. The archive is specified as a file, and it can be moved as a file. This does allow an archive to be moved from one machine to another machine that uses the same implementation of *ar*.

Utilities such as *pax* (and its forebears *tar* and *cpio*) also provide portable ‘‘archives’’. This is a not a duplication; the *ar* utility is included to provide an interface primarily for *make* and the compilers, based on a historical model.

In historical implementations, the −**q** option (available on XSI-conforming systems) is known to execute quickly because *ar* does not check on whether the added members are already in the archive. This is useful to bypass the searching otherwise done when creating a large archive piece-by-piece. These remarks may but need not remain true for a brand new implementation of this utility; hence, these remarks have been moved into the RATIONALE.

BSD implementations historically required applications to provide the −**s** option whenever the archive was supposed to contain a symbol table. As in this volume of IEEE Std 1003.1-200x, System V historically creates or updates an archive symbol table whenever an object file is removed from, added to, or updated in the archive.

The OPERANDS section requires what might seem to be true without specifying it: the archive cannot truncate the filenames below {NAME_MAX}. Some historical implementations do so, however, causing unexpected results for the application. Therefore, this volume of IEEE Std 1003.1-200x makes the requirement explicit to avoid misunderstandings.

According to the System V documentation, the options −**dmpqrtx** are not required to begin with a hyphen (`'−'`). This volume of IEEE Std 1003.1-200x requires that a conforming application use the leading hyphen.

The archive format used by the 4.4 BSD implementation is documented in this RATIONALE as an example:

> A file created by *ar* begins with the ''magic'' string `"!<arch>\n"`. The rest of the archive is made up of objects, each of which is composed of a header for a file, a possible filename, and the file contents. The header is portable between machine architectures, and, if the file contents are printable, the archive is itself printable.
>
> The header is made up of six ASCII fields, followed by a two-character trailer. The fields are the object name (16 characters), the file last modification time (12 characters), the user and group IDs (each 6 characters), the file mode (8 characters), and the file size (10 characters). All numeric fields are in decimal, except for the file mode, which is in octal.
>
> The modification time is the file *st_mtime* field. The user and group IDs are the file *st_uid* and *st_gid* fields. The file mode is the file *st_mode* field. The file size is the file *st_size* field. The two-byte trailer is the string `"<newline>"`.
>
> Only the name field has any provision for overflow. If any filename is more than 16 characters in length or contains an embedded space, the string `"#1/"` followed by the ASCII length of the name is written in the name field. The file size (stored in the archive header) is incremented by the length of the name. The name is then written immediately following the archive header.
>
> Any unused characters in any of these fields are written as <space>s. If any fields are their particular maximum number of characters in length, there is no separation between the fields.
>
> Objects in the archive are always an even number of bytes long; files that are an odd number of bytes long are padded with a <newline>, although the size in the header does not reflect this.

The *ar* utility description requires that (when all its members are valid object files) *ar* produce an object code library, which the linkage editor can use to extract object modules. If the linkage editor needs a symbol table to permit random access to the archive, *ar* must provide it; however, *ar* does not require a symbol table.

The BSD −**o** option was omitted. It is a rare conforming application that uses *ar* to extract object code from a library with concern for its modification time, since this can only be of importance to *make*. Hence, since this functionality is not deemed important for applications portability, the modification time of the extracted files is set to the current time.

There is at least one known implementation (for a small computer) that can accommodate only object files for that system, disallowing mixed object and other files. The ability to handle any type of file is not only historical practice for most implementations, but is also a reasonable expectation.

Consideration was given to changing the output format of *ar* −**tv** to the same format as the output of *ls* −**l**. This would have made parsing the output of *ar* the same as that of *ls*. This was rejected in part because the current *ar* format is commonly used and changes would break historical usage. Second, *ar* gives the user ID and group ID in numeric format separated by a slash. Changing this to be the user name and group name would not be correct if the archive were moved to a machine that contained a different user database. Since *ar* cannot know whether the archive was generated on the same machine, it cannot tell what to report.

The text on the **–ur** option combination is historical practice—since one filename can easily represent two different files (for example, **/a/foo** and **/b/foo**), it is reasonable to replace the file in the archive even when the modification time in the archive is identical to that in the file system.

FUTURE DIRECTIONS

None.

SEE ALSO

c99, *pax*, *strip* the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers, **<unistd.h>** description of {POSIX_NO_TRUNC}

CHANGE HISTORY

First released in Issue 2.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the Software Development Utilities option.

The STDOUT description is changed for the **–v** option to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

IEEE PASC Interpretation 1003.2 #198 is applied, changing the description to consistently use ‘‘file’’ to refer to a file in the file system hierarchy, ‘‘archive’’ to refer to the archive being operated upon by the *ar* utility, and ‘‘file in the archive’’ to refer to a copy of a file that is contained in the archive.

NAME

asa — interpret carriage-control characters

SYNOPSIS

FR `asa [ file ... ]`

DESCRIPTION

The *asa* utility shall write its input files to standard output, mapping carriage-control characters from the text files to line-printer control sequences in an implementation-defined manner.

The first character of every line shall be removed from the input, and the following actions are performed:

If the character removed is:

<space>	The rest of the line is output without change.
0	A <newline> is output, then the rest of the input line.
1	One or more implementation-defined characters that causes an advance to the next page shall be output, followed by the rest of the input line.
+	The <newline> of the previous line shall be replaced with one or more implementation-defined characters that causes printing to return to column position 1, followed by the rest of the input line. If the `'+'` is the first character in the input, it shall be equivalent to <space>. |

The action of the *asa* utility is unspecified upon encountering any character other than those listed above as the first character in a line.

OPTIONS

None.

OPERANDS

file	A pathname of a text file used for input. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified; see the INPUT FILES section. |

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *asa*:

LANG	Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL	If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be the text from the input file modified as described in the DESCRIPTION section.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0	All input files were output successfully.
>0	An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. The following command:

   ```
   asa file
   ```

   permits the viewing of *file* (created by a program using FORTRAN-style carriage control characters) on a terminal.

2. The following command:

   ```
   a.out | asa | lp
   ```

   formats the FORTRAN output of **a.out** and directs it to the printer.

RATIONALE

The *asa* utility is needed to map ‘‘standard’’ FORTRAN 77 output into a form acceptable to contemporary printers. Usually, *asa* is used to pipe data to the *lp* utility; see *lp*.

This utility is generally used only by FORTRAN programs. The standard developers decided to retain *asa* to avoid breaking the historical large base of FORTRAN applications that put carriage-control characters in their output files. There is no requirement that a system have a FORTRAN compiler in order to run applications that need *asa*.

Historical implementations have used an ASCII <form-feed> in response to a 1 and an ASCII <carriage-return> in response to a `'+'`. It is suggested that implementations treat characters other than 0, 1, and `'+'` as <space> in the absence of any compelling reason to do otherwise. However, the action is listed here as ‘‘unspecified’’, permitting an implementation to provide extensions to access fast multiple-line slewing and channel seeking in a non-portable manner.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the FORTRAN Runtime Utilities option.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

at — execute commands at a later time

SYNOPSIS

UP

```
at [−m][−f file][−q queuename] −t time_arg

at [−m][−f file][−q queuename] timespec ...

at −r at_job_id ...

at −l −q queuename

at −l [at_job_id ...]
```

DESCRIPTION

The *at* utility shall read commands from standard input and group them together as an *at-job*, to be executed at a later time.

The at-job shall be executed in a separate invocation of the shell, running in a separate process group with no controlling terminal, except that the environment variables, current working directory, file creation mask, and other implementation-defined execution-time attributes in effect when the *at* utility is executed shall be retained and used when the at-job is executed.

When the at-job is submitted, the *at_job_id* and scheduled time shall be written to standard error. The *at_job_id* is an identifier that shall be a string consisting solely of alphanumeric characters and the period character. The *at_job_id* shall be assigned by the system when the job is scheduled such that it uniquely identifies a particular job.

User notification and the processing of the job's standard output and standard error are described under the −**m** option.

XSI Users shall be permitted to use *at* if their name appears in the file **/usr/lib/cron/at.allow**. If that file does not exist, the file **/usr/lib/cron/at.deny** shall be checked to determine whether the user shall be denied access to *at*. If neither file exists, only a process with the appropriate privileges shall be allowed to submit a job. If only **at.deny** exists and is empty, global usage shall be permitted. The **at.allow** and **at.deny** files shall consist of one user name per line.

OPTIONS

The *at* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−**f** *file* Specify the pathname of a file to be used as the source of the at-job, instead of standard input.

−**l** (The letter ell.) Report all jobs scheduled for the invoking user if no *at_job_id* operands are specified. If *at_job_id*s are specified, report only information for these jobs. The output shall be written to standard output.

−**m** Send mail to the invoking user after the at-job has run, announcing its completion. Standard output and standard error produced by the at-job shall be mailed to the user as well, unless redirected elsewhere. Mail shall be sent even if the job produces no output.

If −**m** is not used, the job's standard output and standard error shall be provided to the user by means of mail, unless they are redirected elsewhere; if there is no such output to provide, the implementation need not notify the user of the job's completion.

−q *queuename*	Specify in which queue to schedule a job for submission. When used with the **−l** option, limit the search to that particular queue. By default, at-jobs shall be scheduled in queue *a*. In contrast, queue *b* shall be reserved for batch jobs; see *batch*. The meanings of all other *queuename*s are implementation-defined. If **−q** is specified along with either of the **−t** *time_arg* or *timespec* arguments, the results are unspecified.
−r	Remove the jobs with the specified *at_job_id* operands that were previously scheduled by the *at* utility.
−t *time_arg*	Submit the job to be run at the time specified by the *time* option-argument, which the application shall ensure has the format as specified by the *touch* **−t** *time* utility.

OPERANDS

The following operands shall be supported:

at_job_id The name reported by a previous invocation of the *at* utility at the time the job was scheduled.

timespec Submit the job to be run at the date and time specified. All of the *timespec* operands are interpreted as if they were separated by <space>s and concatenated, and shall be parsed as described in the grammar at the end of this section. The date and time shall be interpreted as being in the timezone of the user (as determined by the *TZ* variable), unless a timezone name appears as part of *time*, below.

In the POSIX locale, the following describes the three parts of the time specification string. All of the values from the *LC_TIME* categories in the POSIX locale shall be recognized in a case-insensitive manner.

time The time can be specified as one, two, or four digits. One-digit and two-digit numbers shall be taken to be hours; four-digit numbers to be hours and minutes. The time can alternatively be specified as two numbers separated by a colon, meaning *hour*:*minute*. An AM/PM indication (one of the values from the **am_pm** keywords in the *LC_TIME* locale category) can follow the time; otherwise, a 24-hour clock time shall be understood. A timezone name can also follow to further qualify the time. The acceptable timezone names are implementation-defined, except that they shall be case-insensitive and the string **utc** is supported to indicate the time is in Coordinated Universal Time. In the POSIX locale, the *time* field can also be one of the following tokens:

midnight	Indicates the time 12:00 am (00:00).
noon	Indicates the time 12:00 pm.
now	Indicates the current day and time. Invoking *at* <**now**> shall submit an at-job for potentially immediate execution (that is, subject only to unspecified scheduling delays).

date An optional *date* can be specified as either a month name (one of the values from the **mon** or **abmon** keywords in the *LC_TIME* locale category) followed by a day number (and possibly year number preceded by a comma), or a day of the week (one of the values from the **day** or **abday** keywords in the *LC_TIME* locale category). In the POSIX locale, two special days shall be recognized:

today	Indicates the current day.
tomorrow	Indicates the day following the current day.

If no *date* is given, **today** shall be assumed if the given time is greater than the current time, and **tomorrow** shall be assumed if it is less. If the given month is less than the current month (and no year is given), next year shall be assumed.

increment The optional *increment* shall be a number preceded by a plus sign ('+') and suffixed by one of the following: **minutes**, **hours**, **days**, **weeks**, **months**, or **years**. (The singular forms shall be also accepted.) The keyword **next** shall be equivalent to an increment number of +1. For example, the following are equivalent commands:

```
at 2pm + 1 week
at 2pm next week
```

The following grammar describes the precise format of *timespec* in the POSIX locale. The general conventions for this style of grammar are described in Section 1.10 (on page 2220). This formal syntax shall take precedence over the preceding text syntax description. The longest possible token or delimiter shall be recognized at a given point. When used in a *timespec*, white space shall also delimit tokens.

```
%token hr24clock_hr_min
%token hr24clock_hour
/*
  A hr24clock_hr_min is a one, two, or four-digit number. A one-digit
  or two-digit number constitutes a hr24clock_hour. A hr24clock_hour
  may be any of the single digits [0,9], or may be double digits, ranging
  from [00,23]. If a hr24clock_hr_min is a four digit number, the
  first two digits shall be a valid hr24clock_hour, while the last two
  represent the number of minutes, from [00,59].
*/

%token wallclock_hr_min
%token wallclock_hour
/*
  A wallclock_hr_min is a one, two-digit, or four-digit number.
  A one-digit or two-digit number constitutes a wallclock_hour.
  A wallclock_hour may be any of the single digits [1,9], or may
  be double digits, ranging from [01,12]. If a wallclock_hr_min
  is a four-digit number, the first two digits shall be a valid
  wallclock_hour, while the last two represent the number of
  minutes, from [00,59].
*/

%token minute
/*
  A minute is a one or two-digit number whose values can be [0,9]
  or [00,59].
*/

%token day_number
/*
  A day_number is a number in the range appropriate for the particular
  month and year specified by month_name and year_number, respectively.
```

```
      If no year_number is given, the current year is assumed if the given
      date and time are later this year. If no year_number is given and
      the date and time have already occurred this year and the month is
      not the current month, next year is the assumed year.
    */

    %token year_number
    /*
      A year_number is a four-digit number representing the year A.D., in
      which the at_job is to be run.
    */

    %token inc_number
    /*
      The inc_number is the number of times the succeeding increment
      period is to be added to the specified date and time.
    */

                    | "week" | "weeks"
                    | "month" | "months"
                    | "year" | "years"
                    ;
```

STDIN

The standard input shall be a text file consisting of commands acceptable to the shell command language described in Chapter 2 (on page 2231). The standard input shall only be used if no **–f** *file* option is specified.

INPUT FILES

See the STDIN section.

XSI The text files **/usr/lib/cron/at.allow** and **/usr/lib/cron/at.deny** shall contain zero or more user names, one per line, of users who are, respectively, authorized or denied access to the *at* and *batch* utilities.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *at*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of

	diagnostic messages written to standard error and informative messages written to standard output.
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
LC_TIME	Determine the format and contents for date and time strings written and accepted by *at*.
SHELL	Determine a name of a command interpreter to be used to invoke the at-job. If the variable is unset or null, *sh* shall be used. If it is set to a value other than a name for *sh*, the implementation shall do one of the following: use that shell; use *sh*; use the login shell from the user database; or any of the preceding accompanied by a warning diagnostic about which was chosen.
TZ	Determine the timezone. The job shall be submitted for execution at the time specified by *timespec* or **–t** *time* relative to the timezone specified by the *TZ* variable. If *timespec* specifies a timezone, it shall override *TZ*. If *timespec* does not specify a timezone and *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When standard input is a terminal, prompts of unspecified format for each line of the user input described in the STDIN section may be written to standard output.

In the POSIX locale, the following shall be written to the standard output for each job when jobs are listed in response to the **–l** option:

```
"%s\t%s\n", at_job_id, <date>
```

where *date* shall be equivalent in format to the output of:

```
date +"%a %b %e %T %Y"
```

The date and time written shall be adjusted so that they appear in the timezone of the user (as determined by the *TZ* variable).

STDERR

In the POSIX locale, the following shall be written to standard error when a job has been successfully submitted:

```
"job %s at %s\n", at_job_id, <date>
```

where *date* has the same format as is described in the STDOUT section. Neither this, nor warning messages concerning the selection of the command interpreter, shall be considered a diagnostic that changes the exit status.

Diagnostic messages, if any, shall be written to standard error.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The *at* utility successfully submitted, removed, or listed a job or jobs.

>0 An error occurred.

CONSEQUENCES OF ERRORS

The job shall not be scheduled, removed, or listed.

APPLICATION USAGE

The format of the *at* command line shown here is guaranteed only for the POSIX locale. Other cultures may be supported with substantially different interfaces, although implementations are encouraged to provide comparable levels of functionality.

Since the commands run in a separate shell invocation, running in a separate process group with no controlling terminal, open file descriptors, traps, and priority inherited from the invoking environment are lost.

Some implementations do not allow substitution of different shells using *SHELL*. System V systems, for example, have used the login shell value for the user in **/etc/passwd**. To select reliably another command interpreter, the user must include it as part of the script, such as:

```
$ at 1800
myshell myscript
job ... at ...
$
```

EXAMPLES

1. This sequence can be used at a terminal:

```
at −m 0730 tomorrow
sort < file >outfile
EOT
```

2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

```
at now + 1 hour <<!
diff file1 file2 2>&1 >outfile | mailx mygroup
!
```

3. To have a job reschedule itself, *at* can be invoked from within the at-job. For example, this daily processing script named **my.daily** runs every day (although *crontab* is a more appropriate vehicle for such work):

```
# my.daily runs every day
daily processing
at now tomorrow < my.daily
```

4. The spacing of the three portions of the POSIX locale *timespec* is quite flexible as long as there are no ambiguities. Examples of various times and operand presentation include:

```
at 0815am Jan 24
at 8 :15amjan24
at now "+ 1day"
at 5 pm FRIday
at ’17
    utc+
    30minutes’
```

RATIONALE

The *at* utility reads from standard input the commands to be executed at a later time. It may be useful to redirect standard output and standard error within the specified commands.

The **–t** *time* option was added as a new capability to support an internationalized way of specifying a time for execution of the submitted job.

Early proposals added a ''jobname'' concept as a way of giving submitted jobs names that are meaningful to the user submitting them. The historical, system-specified *at_job_id* gives no indication of what the job is. Upon further reflection, it was decided that the benefit of this was not worth the change in historical interface. The *at* functionality is useful in simple environments, but in large or complex situations, the functionality provided by the Batch Services option is more suitable.

The **–q** option historically has been an undocumented option, used mainly by the *batch* utility.

The System V **–m** option was added to provide a method for informing users that an at-job had completed. Otherwise, users are only informed when output to standard error or standard output are not redirected.

The behavior of *at* <*now*> was changed in an early proposal from being unspecified to submitting a job for potentially immediate execution. Historical BSD *at* implementations support this. Historical System V implementations give an error in that case, but a change to the System V versions should have no backwards compatibility ramifications.

On BSD-based systems, a **–u** *user* option has allowed those with appropriate privileges to access the work of other users. Since this is primarily a system administration feature and is not universally implemented, it has been omitted. Similarly, a specification for the output format for user with appropriate privileges viewing the queues of other users has been omitted.

The **–f** *file* option from System V is used instead of the BSD method of using the last operand as the pathname. The BSD method is ambiguous—does:

```
at 1200 friday
```

mean the same thing if there is a file named **friday** in the current directory?

The *at_job_id* is composed of a limited character set in historical practice, and it is mandated here to invalidate systems that might try using characters that require shell quoting or that could not be easily parsed by shell scripts.

The *at* utility varies between System V and BSD systems in the way timezones are used. On System V systems, the *TZ* variable affects the at-job submission times and the times displayed for the user. On BSD systems, *TZ* is not taken into account. The BSD behavior is easily achieved with the current specification. If the user wishes to have the timezone default to that of the system, they merely need to issue the *at* command immediately following an unsetting or null assignment to *TZ*. For example:

```
TZ= at noon ...
```

gives the desired BSD result.

While the *yacc*-like grammar specified in the OPERANDS section is lexically unambiguous with respect to the digit strings, a lexical analyzer would probably be written to look for and return digit strings in those cases. The parser could then check whether the digit string returned is a valid *day_number*, *year_number*, and so on, based on the context.

FUTURE DIRECTIONS

None.

batch, *crontab*

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- If −**m** is not used, the job's standard output and standard error are provided to the user by mail.

The effects of using the −**q** and −**t** options as defined in the IEEE P1003.2b draft standard are specified.

The normative text is reworded to avoid use of the term ''must'' for application requirements.

NAME

awk — pattern scanning and processing language

SYNOPSIS

```
awk [−F ERE][−v assignment] ... program [argument ...]

awk [−F ERE] −f progfile ... [−v assignment] ...[argument ...]
```

DESCRIPTION

The *awk* utility shall execute programs written in the *awk* programming language, which is specialized for textual data manipulation. An *awk* program is a sequence of patterns and corresponding actions. When input is read that matches a pattern, the action associated with that pattern is carried out.

Input shall be interpreted as a sequence of records. By default, a record is a line, less its terminating <newline>, but this can be changed by using the **RS** built-in variable. Each record of input shall be matched in turn against each pattern in the program. For each pattern matched, the associated action shall be executed.

The *awk* utility shall interpret each input record as a sequence of fields where, by default, a field is a string of non-<blank>s. This default white-space field delimiter can be changed by using the **FS** built-in variable or the **−F** *ERE*. The *awk* utility shall denote the first field in a record $1, the second $2, and so on. The symbol $0 shall refer to the entire record; setting any other field causes the re-evaluation of $0. Assigning to $0 shall reset the values of all other fields and the **NF** built-in variable.

OPTIONS

The *awk* utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

−F *ERE* Define the input field separator to be the extended regular expression *ERE*, before any input is read; see **Regular Expressions** (on page 2363).

−f *progfile* Specify the pathname of the file *progfile* containing an *awk* program. If multiple instances of this option are specified, the concatenation of the files specified as *progfile* in the order specified shall be the *awk* program. The *awk* program can alternatively be specified in the command line as a single argument.

−v *assignment*

The application shall ensure that the *assignment* argument is in the same form as an *assignment* operand. The specified variable assignment shall occur prior to executing the *awk* program, including the actions associated with **BEGIN** patterns (if any). Multiple occurrences of this option can be specified.

OPERANDS

The following operands shall be supported:

program If no **−f** option is specified, the first operand to *awk* shall be the text of the *awk* program. The application shall supply the *program* operand as a single argument to *awk*. If the text does not end in a <newline>, *awk* shall interpret the text as if it did.

argument Either of the following two types of *argument* can be intermixed:

file A pathname of a file that contains the input to be read, which is matched against the set of patterns in the program. If no *file* operands are specified, or if a *file* operand is `'−'`, the standard input shall be used.

assignment An operand that begins with an underscore or alphabetic character from the portable character set (see the table in the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set), followed by a sequence of underscores, digits, and alphabetics from the portable character set, followed by the `'='` character, shall specify a variable assignment rather than a pathname. The characters before the `'='` represent the name of an *awk* variable; if that name is an *awk* reserved word (see **Grammar** (on page 2372)) the behavior is undefined. The characters following the equal sign shall be interpreted as if they appeared in the *awk* program preceded and followed by a double-quote (`'"'`) character, as a **STRING** token (see **Grammar** (on page 2372)), except that if the last character is an unescaped backslash, it shall be interpreted as a literal backslash rather than as the first character of the sequence `"\""`. The variable shall be assigned the value of that **STRING** token and, if appropriate, shall be considered a *numeric string* (see **Expressions in awk** (on page 2358)), the variable shall also be assigned its numeric value. Each such variable assignment shall occur just prior to the processing of the following *file*, if any. Thus, an assignment before the first *file* argument shall be executed after the **BEGIN** actions (if any), while an assignment after the last *file* argument shall occur before the **END** actions (if any). If there are no *file* arguments, assignments shall be executed before processing the standard input.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'−'`; see the INPUT FILES section. If the *awk* program contains no actions and no patterns, but is otherwise a valid *awk* program, standard input and any *file* operands shall not be read and *awk* shall exit with a return status of zero.

INPUT FILES

Input files to the *awk* program from any of the following sources shall be text files:

- Any *file* operands or their equivalents, achieved by modifying the *awk* variables **ARGV** and **ARGC**
- Standard input in the absence of any *file* operands
- Arguments to the **getline** function

Whether the variable **RS** is set to a value other than a <newline> or not, for these files, implementations shall support records terminated with the specified separator up to {LINE_MAX} bytes and may support longer records.

If −**f** *progfile* is specified, the application shall ensure that the files named by each of the *progfile* option-arguments are text files containing an *awk* program.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *awk*:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE	Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions and in comparisons of string values.
LC_CTYPE	Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, the identification of characters as letters, and the mapping of uppercase and lowercase characters for the **toupper** and **tolower** functions.
LC_MESSAGES	Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_NUMERIC	Determine the radix character used when interpreting numeric input, performing conversions between numeric and string values, and formatting numeric output. Regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing *awk* programs (including assignments in command line arguments).
XSI *NLSPATH*	Determine the location of message catalogs for the processing of *LC_MESSAGES*.
PATH	Determine the search path when looking for commands executed by *system*(*expr*), or input and output pipes; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

In addition, all environment variables shall be visible via the *awk* variable **ENVIRON**.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The nature of the output files depends on the *awk* program.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The nature of the output files depends on the *awk* program.

EXTENDED DESCRIPTION

Overall Program Structure

An *awk* program is composed of pairs of the form:

```
pattern { action }
```

Either the pattern or the action (including the enclosing brace characters) can be omitted.

A missing pattern shall match any record of input, and a missing action shall be equivalent to:

```
{ print }
```

Execution of the *awk* program shall start by first executing the actions associated with all **BEGIN** patterns in the order they occur in the program. Then each *file* operand (or standard input if no files were specified) shall be processed in turn by reading data from the file until a record separator is seen (<newline> by default). Before the first reference to a field in the record is evaluated, the record shall be split into fields, according to the rules in **Regular Expressions** (on page 2363), using the value of **FS** that was current at the time the record was read. Each pattern in the program then shall be evaluated in the order of occurrence, and the action associated with each pattern that matches the current record executed. The action for a matching pattern shall be executed before evaluating subsequent patterns. Finally, the actions associated with all **END** patterns shall be executed in the order they occur in the program.

Expressions in awk

Expressions describe computations used in *patterns* and *actions*. In the following table, valid expression operations are given in groups from highest precedence first to lowest precedence last, with equal-precedence operators grouped between horizontal lines. In expression evaluation, where the grammar is formally ambiguous, higher precedence operators shall be evaluated before lower precedence operators. In this table *expr*, *expr1*, *expr2*, and *expr3* represent any expression, while lvalue represents any entity that can be assigned to (that is, on the left side of an assignment operator). The precise syntax of expressions is given in **Grammar** (on page 2372).

Table 4-1 Expressions in Decreasing Precedence in *awk*

Syntax	Name	Type of Result	Associativity
`( expr )`	Grouping	Type of *expr*	N/A
`$expr`	Field reference	String	N/A
`++ lvalue`	Pre-increment	Numeric	N/A
`-- lvalue`	Pre-decrement	Numeric	N/A
`lvalue ++`	Post-increment	Numeric	N/A
`lvalue --`	Post-decrement	Numeric	N/A
`expr ^ expr`	Exponentiation	Numeric	Right
`! expr`	Logical not	Numeric	N/A
`+ expr`	Unary plus	Numeric	N/A
`- expr`	Unary minus	Numeric	N/A
`expr * expr`	Multiplication	Numeric	Left
`expr / expr`	Division	Numeric	Left
`expr % expr`	Modulus	Numeric	Left
`expr + expr`	Addition	Numeric	Left
`expr - expr`	Subtraction	Numeric	Left
`expr expr`	String concatenation	String	Left
`expr < expr`	Less than	Numeric	None
`expr <= expr`	Less than or equal to	Numeric	None
`expr != expr`	Not equal to	Numeric	None
`expr == expr`	Equal to	Numeric	None
`expr > expr`	Greater than	Numeric	None
`expr >= expr`	Greater than or equal to	Numeric	None
`expr ~ expr`	ERE match	Numeric	None
`expr !~ expr`	ERE non-match	Numeric	None

Syntax	**Name**	**Type of Result**	**Associativity**
`expr in array`	Array membership	Numeric	Left
`( index ) in array`	Multi-dimension array membership	Numeric	Left
`expr && expr`	Logical AND	Numeric	Left
`expr || expr`	Logical OR	Numeric	Left
`expr1 ? expr2 : expr3`	Conditional expression	Type of selected `expr2` or `expr3`	Right
`lvalue ^= expr`	Exponentiation assignment	Numeric	Right
`lvalue %= expr`	Modulus assignment	Numeric	Right
`lvalue *= expr`	Multiplication assignment	Numeric	Right
`lvalue /= expr`	Division assignment	Numeric	Right
`lvalue += expr`	Addition assignment	Numeric	Right
`lvalue −= expr`	Subtraction assignment	Numeric	Right
`lvalue = expr`	Assignment	Type of *expr*	Right

Each expression shall have either a string value, a numeric value, or both. Except as stated for specific contexts, the value of an expression shall be implicitly converted to the type needed for the context in which it is used. A string value shall be converted to a numeric value by the equivalent of the following calls to functions defined by the ISO C standard:

```
setlocale(LC_NUMERIC, "");
numeric_value = atof(string_value);
```

A numeric value that is exactly equal to the value of an integer (see Section 1.7.2 (on page 2207)) shall be converted to a string by the equivalent of a call to the **sprintf** function (see **String Functions** (on page 2369)) with the string `"%d"` as the *fmt* argument and the numeric value being converted as the first and only *expr* argument. Any other numeric value shall be converted to a string by the equivalent of a call to the **sprintf** function with the value of the variable **CONVFMT** as the *fmt* argument and the numeric value being converted as the first and only *expr* argument. The result of the conversion is unspecified if the value of **CONVFMT** is not a floating-point format specification. This volume of IEEE Std 1003.1-200x specifies no explicit conversions between numbers and strings. An application can force an expression to be treated as a number by adding zero to it, or can force it to be treated as a string by concatenating the null string (`""`) to it.

A string value shall be considered a *numeric string* if it comes from one of the following:

1. Field variables
2. Input from the *getline*( ) function
3. **FILENAME**
4. **ARGV** array elements
5. **ENVIRON** array elements
6. Array elements created by the *split*( ) function
7. A command line variable assignment
8. Variable assignment from another numeric string variable

and after all the following conversions have been applied, the resulting string would lexically be recognized as a **NUMBER** token as described by the lexical conventions in **Grammar** (on page

2372):

- All leading and trailing <blank>s are discarded
- If the first non-<blank> is `'+'` or `'-'`, it is discarded
- Changing each occurrence of the decimal point character from the current locale to a period

If a `'−'` character is ignored in the preceding description, the numeric value of the *numeric string* shall be the negation of the numeric value of the recognized **NUMBER** token. Otherwise, the numeric value of the *numeric string* shall be the numeric value of the recognized **NUMBER** token. Whether or not a string is a *numeric string* shall be relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero shall be treated as false and any other value shall be treated as true. Otherwise, a string value of the null string shall be treated as false and any other value shall be treated as true. A Boolean context shall be one of the following:

- The first subexpression of a conditional expression
- An expression operated on by logical NOT, logical AND, or logical OR
- The second expression of a **for** statement
- The expression of an **if** statement
- The expression of the **while** clause in either a **while** or **do**. . .**while** statement
- An expression used as a pattern (as in Overall Program Structure)

All arithmetic shall follow the semantics of floating-point arithmetic as specified by the ISO C standard (see Section 1.7.2 (on page 2207)).

The value of the expression:

```
expr1 ^ expr2
```

shall be equivalent to the value returned by the ISO C standard function call:

```
pow(expr1, expr2)
```

The expression:

```
lvalue ^= expr
```

shall be equivalent to the ISO C standard expression:

```
lvalue = pow(lvalue, expr)
```

except that lvalue shall be evaluated only once. The value of the expression:

```
expr1 % expr2
```

shall be equivalent to the value returned by the ISO C standard function call:

```
fmod(expr1, expr2)
```

The expression:

```
lvalue %= expr
```

shall be equivalent to the ISO C standard expression:

```
lvalue = fmod(lvalue, expr)
```

except that lvalue shall be evaluated only once.

Variables and fields shall be set by the assignment statement:

```
lvalue = expression
```

and the type of *expression* shall determine the resulting variable type. The assignment includes the arithmetic assignments ("+=", "-=", "*=", "/=", "%=", "^=", "++", "--") all of which shall produce a numeric result. The left-hand side of an assignment and the target of increment and decrement operators can be one of a variable, an array with index, or a field selector.

The *awk* language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They shall initially be empty, and their sizes shall change dynamically. The subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an lvalue and thus as an expression, as described in the grammar; see **Grammar** (on page 2372). Unsubscripted array names can be used in only the following contexts:

- A parameter in a function definition or function call
- The **NAME** token following any use of the keyword **in** as specified in the grammar (see **Grammar** (on page 2372)); if the name used in this context is not an array name, the behavior is undefined

A valid array *index* shall consist of one or more comma-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because *awk* arrays are really one-dimensional, such a comma-separated list shall be converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the **SUBSEP** variable. Thus, the following two index operations shall be equivalent:

```
var[expr1, expr2, ... exprn]

var[expr1 SUBSEP expr2 SUBSEP ... SUBSEP exprn]
```

The application shall ensure that a multi-dimensioned *index* used with the **in** operator is parenthesized. The **in** operator, which tests for the existence of a particular array element, shall not cause that element to exist. Any other reference to a nonexistent array element shall automatically create it.

Comparisons (with the '<', "<=", "!=", "==", '>', and ">=" operators) shall be made numerically if both operands are numeric, if one is numeric and the other has a string value that is a numeric string, or if one is numeric and the other has the uninitialized value. Otherwise, operands shall be converted to strings as required and a string comparison shall be made using the locale-specific collation sequence. The value of the comparison expression shall be 1 if the relation is true, or 0 if the relation is false.

Variables and Special Variables

Variables can be used in an *awk* program by referencing them. With the exception of function parameters (see **User-Defined Functions** (on page 2371)), they are not explicitly declared. Function parameter names shall be local to the function; all other variable names shall be global. The same name shall not be used as both a function parameter name and as the name of a function or a special *awk* variable. The same name shall not be used both as a variable name with global scope and as the name of a function. The same name shall not be used within the same scope both as a scalar variable and as an array. Uninitialized variables, including scalar variables, array elements, and field variables, shall have an uninitialized value. An uninitialized value shall have both a numeric value of zero and a string value of the empty string. Evaluation of variables with an uninitialized value, to either string or numeric, shall be determined by the context in which they are used.

Field variables shall be designated by a `'$'` followed by a number or numerical expression. The effect of the field number *expression* evaluating to anything other than a non-negative integer is unspecified; uninitialized variables or string values need not be converted to numeric values in this context. New field variables can be created by assigning a value to them. References to nonexistent fields (that is, fields after $**NF**), shall evaluate to the uninitialized value. Such references shall not create new fields. However, assigning to a nonexistent field (for example, $(**NF**+2)=5) shall increase the value of **NF**; create any intervening fields with the uninitialized value; and cause the value of $0 to be recomputed, with the fields being separated by the value of **OFS**. Each field variable shall have a string value or an uninitialized value when created. Field variables shall have the uninitialized value when created from $0 using **FS** and the variable does not contain any characters. If appropriate, the field variable shall be considered a numeric string (see **Expressions in awk** (on page 2358)).

Implementations shall support the following other special variables that are set by *awk*:

ARGC The number of elements in the **ARGV** array.

ARGV An array of command line arguments, excluding options and the *program* argument, numbered from zero to **ARGC**–1.

The arguments in **ARGV** can be modified or added to; **ARGC** can be altered. As each input file ends, *awk* shall treat the next non-null element of **ARGV**, up to the current value of **ARGC**–1, inclusive, as the name of the next input file. Thus, setting an element of **ARGV** to null means that it shall not be treated as an input file. The name `'–'` indicates the standard input. If an argument matches the format of an *assignment* operand, this argument shall be treated as an assignment rather than a *file* argument.

CONVFMT The **printf** format for converting numbers to strings (except for output statements, where **OFMT** is used); `"%.6g"` by default.

ENVIRON An array representing the value of the environment, as described in the *exec* functions defined in the System Interfaces volume of IEEE Std 1003.1-200x. The indices of the array shall be strings consisting of the names of the environment variables, and the value of each array element shall be a string consisting of the value of that variable. If appropriate, the environment variable shall be considered a *numeric string* (see **Expressions in awk** (on page 2358)), the array element shall also have its numeric value.

In all cases where the behavior of *awk* is affected by environment variables (including the environment of any commands that *awk* executes via the **system** function or via pipeline redirections with the **print** statement, the **printf** statement, or the **getline** function), the environment used shall be the environment at the time *awk* began executing; it is implementation-defined whether any modification of **ENVIRON** affects this environment.

FILENAME A pathname of the current input file. Inside a **BEGIN** action the value is undefined. Inside an **END** action the value shall be the name of the last input file processed.

FNR The ordinal number of the current record in the current file. Inside a **BEGIN** action the value shall be zero. Inside an **END** action the value shall be the number of the last record processed in the last file processed.

FS	Input field separator regular expression; a <space> by default.
NF	The number of fields in the current record. Inside a **BEGIN** action, the use of **NF** is undefined unless a **getline** function without a *var* argument is executed previously. Inside an **END** action, **NF** shall retain the value it had for the last record read, unless a subsequent, redirected, **getline** function without a *var* argument is performed prior to entering the **END** action.
NR	The ordinal number of the current record from the start of input. Inside a **BEGIN** action the value shall be zero. Inside an **END** action the value shall be the number of the last record processed.
OFMT	The **printf** format for converting numbers to strings in output statements (see **Output Statements** (on page 2367)); `"%.6g"` by default. The result of the conversion is unspecified if the value of **OFMT** is not a floating-point format specification.
OFS	The **print** statement output field separation; <space> by default.
ORS	The **print** statement output record separator; a <newline> by default.
RLENGTH	The length of the string matched by the **match** function.
RS	The first character of the string value of **RS** shall be the input record separator; a <newline> by default. If **RS** contains more than one character, the results are unspecified. If **RS** is null, then records are separated by sequences consisting of a <newline> plus one or more blank lines, leading or trailing blank lines shall not result in empty records at the beginning or end of the input, and a <newline> shall always be a field separator, no matter what the value of **FS** is.
RSTART	The starting position of the string matched by the **match** function, numbering from 1. This shall always be equivalent to the return value of the **match** function.
SUBSEP	The subscript separator string for multi-dimensional arrays; the default value is implementation-defined.

Regular Expressions

The *awk* utility shall make use of the extended regular expression notation (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4, Extended Regular Expressions) except that it shall allow the use of C-language conventions for escaping special characters within the EREs, as specified in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation (`′\\′`, `′\a′`, `′\b′`, `′\f′`, `′\n′`, `′\r′`, `′\t′`, `′\v′`) and the following table; these escape sequences shall be recognized both inside and outside bracket expressions. Note that records need not be separated by <newline>s and string constants can contain <newline>s, so even the `"\n"` sequence is valid in *awk* EREs. Using a slash character within an ERE requires the escaping shown in the following table.

Table 4-2 Escape Sequences in *awk*

Escape Sequence	Description	Meaning
`\"`	Backslash quotation-mark	Quotation-mark character
`\/`	Backslash slash	Slash character
`\ddd`	A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the one, two, or three-digit octal integer. If the size of a byte on the system is greater than nine bits, the valid escape sequence used to represent a byte is implementation-defined. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading `'\'` for each byte.
`\c`	A backslash character followed by any character not described in this table or in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`)	Undefined

A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, `'~'` and `"!~"`. These operators shall interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the `'~'` expression shall evaluate to a value of 1, and the `"!~"` expression shall evaluate to a value of 0. (The regular expression matching operation is as defined by the term matched in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.1, Regular Expression Definitions, where a match occurs on any part of the string unless the regular expression is limited with the circumflex or dollar sign special characters.) If the regular expression does not match the string, the `'~'` expression shall evaluate to a value of 0, and the `"!~"` expression shall evaluate to a value of 1. If the right-hand operand is any expression other than the lexical token **ERE**, the string value of the expression shall be interpreted as an extended regular expression, including the escape conventions described above. Note that these same escape conventions shall also be applied in determining the value of a string literal (the lexical token **STRING**), and thus shall be applied a second time when a string literal is used in this context.

When an **ERE** token appears as an expression in any context other than as the right-hand of the `'~'` or `"!~"` operator or as one of the built-in function arguments described below, the value of the resulting expression shall be the equivalent of:

```
$0 ~ /ere/
```

The *ere* argument to the **gsub**, **match**, **sub** functions, and the *fs* argument to the **split** function (see **String Functions** (on page 2369)) shall be interpreted as extended regular expressions. These can be either **ERE** tokens or arbitrary expressions, and shall be interpreted in the same manner as the right-hand side of the `'~'` or `"!~"` operator.

An extended regular expression can be used to separate fields by using the **–F** *ERE* option or by assigning a string containing the expression to the built-in variable **FS**. The default value of the **FS** variable shall be a single <space>. The following describes **FS** behavior:

1. If **FS** is a null string, the behavior is unspecified.
2. If **FS** is a single character:
    a. If **FS** is <space>, skip leading and trailing <blank>s; fields shall be delimited by sets of one or more <blank>s.
    b. Otherwise, if **FS** is any other character *c*, fields shall be delimited by each single occurrence of *c*.
3. Otherwise, the string value of **FS** shall be considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression shall delimit fields.

Except for the `'~'` and `"!~"` operators, and in the **gsub**, **match**, **split**, and **sub** built-in functions, ERE matching shall be based on input records; that is, record separator characters (the first character of the value of the variable **RS**, <newline> by default) cannot be embedded in the expression, and no expression shall match the record separator character. If the record separator is not <newline>, <newline>s embedded in the expression can be matched. For the `'~'` and `"!~"` operators, and in those four built-in functions, ERE matching shall be based on text strings; that is, any character (including <newline> and the record separator) can be embedded in the pattern, and an appropriate pattern shall match any character. However, in all *awk* ERE matching, the use of one or more NUL characters in the pattern, input record, or text string produces undefined results.

Patterns

A *pattern* is any valid *expression*, a range specified by two expressions separated by comma, or one of the two special patterns **BEGIN** or **END**.

Special Patterns

The *awk* utility shall recognize two special patterns, **BEGIN** and **END**. Each **BEGIN** pattern shall be matched once and its associated action executed before the first record of input is read (except possibly by use of the **getline** function—see **Input/Output and General Functions** (on page 2370)—in a prior **BEGIN** action) and before command line assignment is done. Each **END** pattern shall be matched once and its associated action executed after the last record of input has been read. These two patterns shall have associated actions.

BEGIN and **END** shall not combine with other patterns. Multiple **BEGIN** and **END** patterns shall be allowed. The actions associated with the **BEGIN** patterns shall be executed in the order specified in the program, as are the **END** actions. An **END** pattern can precede a **BEGIN** pattern in a program.

If an *awk* program consists of only actions with the pattern **BEGIN**, and the **BEGIN** action contains no **getline** function, *awk* shall exit without reading its input when the last statement in the last **BEGIN** action is executed. If an *awk* program consists of only actions with the pattern **END** or only actions with the patterns **BEGIN** and **END**, the input shall be read before the statements in the **END** actions are executed.

Expression Patterns

An expression pattern shall be evaluated as if it were an expression in a Boolean context. If the result is true, the pattern shall be considered to match, and the associated action (if any) shall be executed. If the result is false, the action shall not be executed.

Pattern Ranges

A pattern range consists of two expressions separated by a comma; in this case, the action shall be performed for all records between a match of the first expression and the following match of the second expression, inclusive. At this point, the pattern range can be repeated starting at input records subsequent to the end of the matched range.

Actions

An action is a sequence of statements as shown in the grammar in **Grammar** (on page 2372). Any single statement can be replaced by a statement list enclosed in braces. The application shall ensure that statements in a statement list are separated by <newline>s or semicolons. Statements in a statement list shall be executed sequentially in the order that they appear.

The *expression* acting as the conditional in an **if** statement shall be evaluated and if it is non-zero or non-null, the following *statement* shall be executed; otherwise, if **else** is present, the statement following the **else** shall be executed.

The **if**, **while**, **do**...**while**, **for**, **break**, and **continue** statements are based on the ISO C standard (see Section 1.7.2 (on page 2207)), except that the Boolean expressions shall be treated as described in **Expressions in awk** (on page 2358), and except in the case of:

```
for (variable in array)
```

which shall iterate, assigning each *index* of *array* to *variable* in an unspecified order. The results of adding new elements to *array* within such a **for** loop are undefined. If a **break** or **continue** statement occurs outside of a loop, the behavior is undefined.

The **delete** statement shall remove an individual array element. Thus, the following code deletes an entire array:

```
for (index in array)
    delete array[index]
```

The **next** statement shall cause all further processing of the current input record to be abandoned. The behavior is undefined if a **next** statement appears or is invoked in a **BEGIN** or **END** action.

The **exit** statement shall invoke all **END** actions in the order in which they occur in the program source and then terminate the program without reading further input. An **exit** statement inside an **END** action shall terminate the program without further execution of **END** actions. If an expression is specified in an **exit** statement, its numeric value shall be the exit status of *awk*, unless subsequent errors are encountered or a subsequent **exit** statement with an expression is executed.

Output Statements

Both **print** and **printf** statements shall write to standard output by default. The output shall be written to the location specified by *output_redirection* if one is supplied, as follows:

```
> expression
>> expression
| expression
```

In all cases, the *expression* shall be evaluated to produce a string that is used as a pathname into which to write (for `'>'` or `">>"`) or as a command to be executed (for `'|'`). Using the first two forms, if the file of that name is not currently open, it shall be opened, creating it if necessary and using the first form, truncating the file. The output then shall be appended to the file. As long as the file remains open, subsequent calls in which *expression* evaluates to the same string value shall simply append output to the file. The file remains open until the **close** function (see **Input/Output and General Functions** (on page 2370)) is called with an expression that evaluates to the same string value.

The third form shall write output onto a stream piped to the input of a command. The stream shall be created if no stream is currently open with the value of *expression* as its command name. The stream created shall be equivalent to one created by a call to the *popen*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x with the value of *expression* as the *command* argument and a value of *w* as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value shall write output to the existing stream. The stream shall remain open until the **close** function (see **Input/Output and General Functions** (on page 2370)) is called with an expression that evaluates to the same string value. At that time, the stream shall be closed as if by a call to the *pclose*( ) function defined in the System Interfaces volume of IEEE Std 1003.1-200x.

As described in detail by the grammar in **Grammar** (on page 2372), these output statements shall take a comma-separated list of *expression*s referred to in the grammar by the non-terminal symbols **expr_list**, **print_expr_list**, or **print_expr_list_opt**. This list is referred to here as the *expression list*, and each member is referred to as an *expression argument*.

The **print** statement shall write the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable **OFS** above), and terminated by the output record separator (see variable **ORS** above). All expression arguments shall be taken as strings, being converted if necessary; this conversion shall be as described in **Expressions in awk** (on page 2358), with the exception that the **printf** format in **OFMT** shall be used instead of the value in **CONVFMT**. An empty expression list shall stand for the whole input record ($0).

The **printf** statement shall produce output based on a notation similar to the File Format Notation used to describe file formats in this volume of IEEE Std 1003.1-200x (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation). Output shall be produced as specified with the first expression argument as the string *format* and subsequent expression arguments as the strings *arg1* to *argn*, inclusive, with the following exceptions:

1. The *format* shall be an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The <space> in the *format* string, in any context other than a *flag* of a conversion specification, shall be treated as an ordinary character that is copied to the output.

2. If the character set contains a `'Δ'` character and that character appears in the *format* string, it shall be treated as an ordinary character that is copied to the output.

3. The *escape sequences* beginning with a backslash character shall be treated as sequences of ordinary characters that are copied to the output. Note that these same sequences shall be interpreted lexically by *awk* when they appear in literal strings, but they shall not be treated specially by the **printf** statement.
4. A *field width* or *precision* can be specified as the `'*'` character instead of a digit string. In this case the next argument from the expression list shall be fetched and its numeric value taken as the field width or precision.
5. The implementation shall not precede or follow output from the *d* or *u* conversion specifications with <blank>s not specified by the *format* string.
6. The implementation shall not precede output from the *o* conversion specification with leading zeros not specified by the *format* string.
7. For the *c* conversion specification: if the argument has a numeric value, the character whose encoding is that value shall be output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value shall be output; if the string does not contain any characters, the behavior is undefined.
8. For each conversion specification that consumes an argument, the next expression argument shall be evaluated. With the exception of the *c* conversion, the value shall be converted (according to the rules specified in **Expressions in awk** (on page 2358)) to the appropriate type for the conversion specification.
9. If there are insufficient expression arguments to satisfy all the conversion specifications in the *format* string, the behavior is undefined.
10. If any character sequence in the *format* string begins with a `'%'` character, but does not form a valid conversion specification, the behavior is unspecified.

Both **print** and **printf** can output at least {LINE_MAX} bytes.

Functions

The *awk* language has a variety of built-in functions: arithmetic, string, input/output, and general.

Arithmetic Functions

The arithmetic functions, except for **int**, shall be based on the ISO C standard (see Section 1.7.2 (on page 2207)). The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar (see **Grammar** (on page 2372)) permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the `"[]"` brackets), such use is undefined.

atan2(*y*,*x*)	Return arctangent of y/x in radians in the range $[-\pi,\pi]$.
cos(*x*)	Return cosine of *x*, where *x* is in radians.
sin(*x*)	Return sine of *x*, where *x* is in radians.
exp(*x*)	Return the exponential function of *x*.
log(*x*)	Return the natural logarithm of *x*.
sqrt(*x*)	Return the square root of *x*.

int(*x*)	Return the argument truncated to an integer. Truncation shall be toward 0 when $x > 0$.
rand( )	Return a random number *n*, such that $0 \le n < 1$.
srand(**[***expr***]**)	Set the seed value for *rand* to *expr* or use the time of day if *expr* is omitted. The previous seed value shall be returned.

String Functions

The string functions in the following list shall be supported. Although the grammar (see **Grammar** (on page 2372)) permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the "[ ]" brackets), such use is undefined.

gsub(*ere*, *repl***[**, *in***]**)	Behave like **sub** (see below), except that it shall replace all occurrences of the regular expression (like the *ed* utility global substitute) in $0 or in the *in* argument, when specified.
index(*s*, *t*)	Return the position, in characters, numbering from 1, in string *s* where string *t* first occurs, or zero if it does not occur at all.
length[(**[***s***]**)**]**	Return the length, in characters, of its argument taken as a string, or of the whole record, $0, if there is no argument.
match(*s*, *ere*)	Return the position, in characters, numbering from 1, in string *s* where the extended regular expression *ere* occurs, or zero if it does not occur at all. RSTART shall be set to the starting position (which is the same as the returned value), zero if no match is found; RLENGTH shall be set to the length of the matched string, –1 if no match is found.
split(*s*, *a***[**, *fs* **]**)	Split the string *s* into array elements *a*[1], *a*[2], . . ., *a*[*n*], and return *n*. All elements of the array shall be deleted before the split is performed. The separation shall be done with the ERE *fs* or with the field separator **FS** if *fs* is not given. Each array element shall have a string value when created and, if appropriate, the array element shall be considered a numeric string (see **Expressions in awk** (on page 2358)). The effect of a null string as the value of *fs* is unspecified.
sprintf(*fmt*, *expr*, *expr*, . . .)	Format the expressions according to the **printf** format given by *fmt* and return the resulting string.
